AGE: 11

While the Babylonians, Greeks, and Romans were able to do remarkably sophisticated calculations, mathematical development was limited until introduction of a true zero. In this article, we will explain why zero was such an important development. We try to answer the question: where did zero come from and how old is the concept of zero? There is strong evidence that zero is an Eastern development that came to the West from India or a civilization with roots in India, such as Cambodia. This would mean that zero is not a Greek or Western invention, as scholars had long thought. Mathematics is a wonderful mystery—many questions remain about how and why zero developed in the East and how it likely traveled to Europe.

ZERO, A HARD-WORKING HERO!

Imagine for a minute what your life would be like without that little circle we use to represent zero!

¹ Ifrah [1] is a good introduction to the full history of numbers from “prehistory to the computer”!

BASE 60 (SEXAGESIMAL) SYSTEM

An ancient number system that uses sixty as its base. This system was used by the ancient Sumerians in the third millennium BCE, was passed down to the ancient Babylonians, and is still used today for measuring time, angles, and geographic coordinates.

BASE 10 (DECIMAL) SYSTEM

Our current number system is a base-10 system, which has 10 digits and uses place value and a decimal point to separate whole numbers from decimal fractions.

² <http://www.amathsdictionaryforkids.com/qr/b/base10system.html>.

While we take zero for granted, it is a relatively recent invention. The Babylonians and Romans did not have a way to represent zero with a distinct symbol; nor did the Greeks, who did not think “nothing” was a number. The Mayans living in Central America used the idea of zero [1]¹ in their calendar system, but because they were isolated from other people, their zero did not travel beyond their own civilization. To find the source of zero, we must look elsewhere.

Let us look at numerals used in ancient Babylon, where there was a sophisticated mathematical system over 5,000 years ago. This system was developed and refined from even older systems of writing numbers and making calculations! We know a lot about the Babylonian system, because they wrote on clay tablets that have survived. The Babylonians were good mathematicians and astronomers who used a complicated **base 60 system**, rather than our **base 10 system**². In modern mathematics, we still use base 60 for certain functions. For example, think of how we keep time: 60 s in a minute, 60 min in an hour. The Babylonians, like us, used positions (like our base 10 ones, tens, hundreds, thousands) to represent numbers. But using the base 60 system meant that calculations and keeping track of places was exceedingly complicated. In the base 60 system, positions become sixes, sixties, six hundreds, six thousands. Imagine that you are trying to keep track of positions with no symbol for zero to mark the space. That little symbol for zero is very helpful. The Babylonians eventually began to mark the empty column with a space, but just think how easy it must have been to miss a space in columns of numbers. With their complicated system, the Babylonians had to rely on context to understand the meaning of a number. As an example of using context, if someone tells you that something costs four-fifty, you could assume \$4.50, if you were thinking about ordering an ice cream, rather than \$450, which might seem logical if you were buying an airline ticket.

The Greeks knew of zero as a concept but did not think of it as a number with the same usefulness in mathematics as the numbers 1–9. According to Aristotle, it was not possible to divide by 0 and get a meaningful result, so the Greek system was based on 9 numbers—no zero.

The Romans did not use numerals for calculations, so they did not have the need for a zero to hold a place or keep a column empty. The Roman numeral system was used for trade and they did not need to represent zero with a special symbol. They used a counting board for computations and their numerals were used only for writing down the results. This does not mean they did not understand nothingness. They had a word to mean nothing but no symbol.

PLACEHOLDER

A number with no value on its own, used in decimals and number lines to show the value of other numbers.

WHOLE NUMBERS

Non-decimal or non-fraction numbers, such as 1, 2, 3 onwards.

BASE 2 (BINARY) SYSTEM

A system in which information can be expressed by combinations of the digits 0 and 1.

MIDDLE AGES

The time period in European history from the fall of the Roman Empire in the West (around 1100) to the fall of Constantinople (1453).

SUPER ZERO!

Why do we care about zero? Zero can be used as a **placeholder**, with no value on its own, or as a mathematical number. For example, when we name a year, such as 2019, each numeral has its own well-defined place. We call the zero a placeholder, as it tells us that there are zero 100s. We can represent our system, in base 10, with columns as seen below:

1000s	100s	10s	1s
2	0	1	9

That 0 keeps the 1s on either side “in place” so we know their value. Take that placeholder away, and it is no longer clear what number we mean.

Zero can be more than a placeholder. Zero also marks the dividing point between positive numbers and negative numbers. If we count backwards with **whole numbers**, we reach zero. Similarly, if we count forward with negative numbers, we also arrive at 0.

⇐ −10 −9 −8 −7 −6 −5 −4 −3 −2 −1 0 1 2 3 4 5 6 7 8 9 10 ⇒

As long as you only want to count and measure, you can do it without zero. But with no zero, advanced mathematics would be impossible: no algebra, no calculus. And we would not have computers, because computers use a binary, or **base 2 system**, meaning that information is recorded and read as a series of 0s and 1s.

WHO INVENTED ZERO?

Arabs in the **Middle Ages**—centuries after the greatest age of Greek mathematics—were both remarkable mathematicians and important transmitters of ancient knowledge, including mathematics. Muhammad ibn Musa al-Khwarizmi was a famous Persian mathematician, astronomer, and geographer who contributed much to our modern understanding of mathematics, especially in the areas of algebra and trigonometry. His name—Al-Khwarizmi—eventually became Algorithmi when translated into Latin. From that Latinized version of his name, we got the word algorithm, which means the set of rules we follow when we do calculations. In the early ninth century CE, Al-Khwarizmi was head astronomer and librarian in the famous House of Wisdom in Baghdad, where he studied scientific and mathematical manuscripts, including those of the ancient Greeks and Hindus.

In *Al'Khwarizmi on the Hindu Art of Reckoning*, he describes a Hindu, or Indian, number system, based on 10 numerals: 1–9, and 0. He gives credit for this zero, saying that he had discovered it when he

translated the mathematical works of the seventh century CE Indian scholar Brahmagupta. This useful system was soon adopted by the Arab world.

ZERO TRAVELS A LONG ROAD TO EUROPE

Europeans in the Middle Ages were still conducting business using Roman numerals. But trade routes did more than move silks and spices from the East to the West—they also moved knowledge. Fibonacci, the son of an Italian merchant, often traveled for his father's business. In North Africa he discovered that Arab traders were using an accounting system based on 10 numbers, 1–9 + 0. He quickly understood that this system could improve bookkeeping and accounting in Europe. In 1202, he published a book called *Liber Abaci*, which spread the idea of this new number system that had a zero “to keep the rows.” The book talked about the system's practical applications: how to convert one currency to another, calculations of profits and losses, and other important business needs [2].

THE SEARCH MOVES TO INDIA AND CAMBODIA

Georges Coëdès was in his early 20s when he visited the Near East Collection at the Louvre, the famous museum in Paris near where he lived. He was intrigued an ancient Babylonian inscription in a display. This early experience led him to study ancient languages and to spend his life uncovering ancient mysteries contained in inscriptions from Southeast Asia.

Coëdès had an intriguing theory. He believed that numerals had originated in civilizations throughout Asia that shared a common culture based in the religions of Buddhism or Hinduism. Other scholars at the time assumed that numbers had to have come from Greece or Arabia, but Coëdès felt that this belief failed to value the intellectual developments of the East. At this point, Coëdès had no proof for his theory. Then, in the course of his work, he came across an untranslated inscription found on a stone that he called K-127, from an ancient temple at Sambor on Mekong in Cambodia. Translating the writing, he was stunned to discover that it contained the elusive zero that he had hoped to find! (Figures 1, 2).

The inscription describes a merchant's transactions and includes a date with a zero—a placeholding zero—represented as a small dot! Whoever carved the inscription conveniently added the date: 605 of the çaka era. Converting the çaka date to our own calendar system was not difficult. Coëdès knew that the first king of the çaka era began his rule in the year 78, so by adding 78 to the 605 on the stone he knew that the inscription had been made in the year 683 CE. Coëdès had his proof, which he

Figure 1

published in a 1931 scientific paper [3]. This proved that zero had originated in the East, because this zero found in Cambodia was carved before the work of Arab mathematicians. This early finding proved that our written digits and the zero had an Eastern, Asian origin [4].

ANOTHER TWIST TO OUR NUMBER THEORY

About 40 years before Coëdès translated K-127, a manuscript written on birch bark, called the Bakhshali Manuscript, was found in Bakhshali, in what is now Pakistan. This text contained an ancient zero represented by a small circle. The age of this zero was not known, but some experts believed it was very old. Unlike K-127, this manuscript did not conveniently include a date in the text, so it was hard to determine when it was written. Also, scholars believed that parts of the manuscript had been written at different times.

Today, the Bakhshali is in the Bodleian Library of Oxford University. In 2017 [5], the Bodleian permitted a small piece of the bark material to be removed for **radiocarbon dating**. Results indicated that the portion containing the zero dates from the third or fourth century. If this is correct, the Bakhshali manuscript is older than K-127, and older than any inscription containing zero yet discovered. Some experts are not convinced. Their argument is that the section removed for testing did not contain any writing—and because the pages are believed to have been written at different times, this presents a problem. Scientists are hoping the Bodleian Library will conduct further tests on other parts of the manuscript. Many questions remain—how accurate is the method of dating used on the manuscript? Will other, older zeros be discovered? And finally, how did the idea of zero move from India to Cambodia and Indonesia and then spread to the rest of the world? What we do know is that the zero we use today was born in Southern Asia! We hope

RADIOCARBON DATING

A scientific method used to determine the age of an object based on a radioactive isotope of carbon.

Figure 2

Stone rubbing of K-127 made by the National Museum of Cambodia in 2015. K-127, ancient inscription found in Cambodia with one of oldest known zeros.

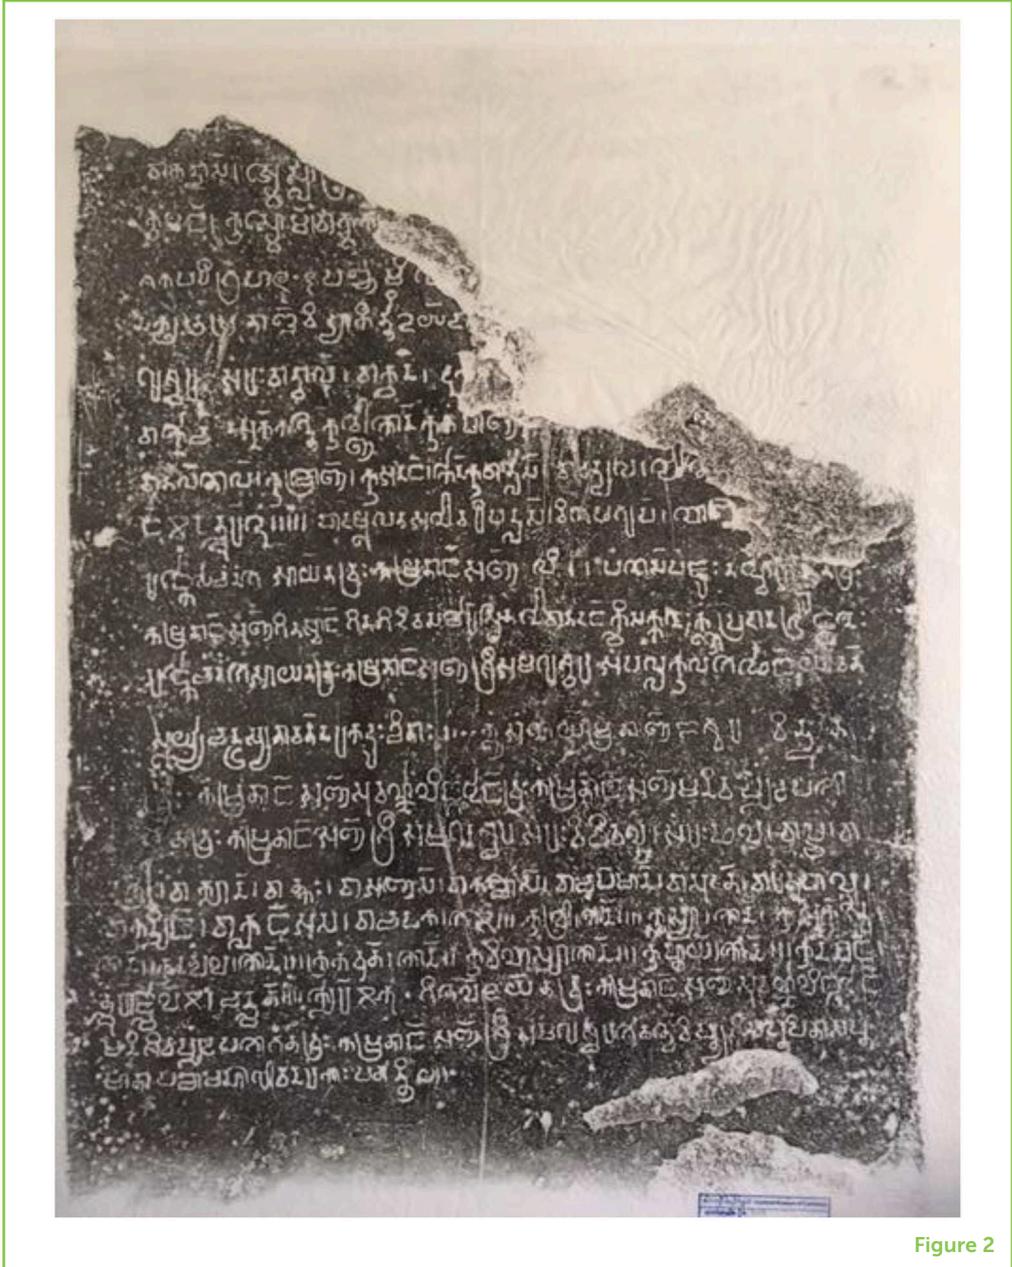

Figure 2

future historians of mathematics will fill in more pieces of this intriguing puzzle.

END OF STORY?

So why did an Indians civilization invent zero? While the Greeks believed zero was nothing, nothingness was very important in certain religions of the East, including Buddhism and Hinduism. Perhaps Indian religion and philosophy hold a clue. In any event, mathematics—and the numbers—have many questions just waiting for you to explore.

YOUNG REVIEWERS

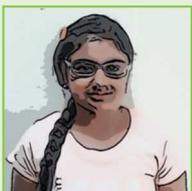

MAREN, AGE: 10

I am a student who loves to learn, read, and write. I play piano and violin. I like science and math at school, and to read books, and watch movies at home.

RYKA, AGE: 11

I am Ryka. I am 11 years old and I really love Computer Science and Math. When I grow up, I want to create lots of computer games and own a gaming company. I love reviewing for the journal as the articles are so cool! I wonder how does one write them? I also want to write lots of articles, but I am scared. What if people do not like my articles? Oh well, I guess I will give it a try.

AUTHORS

MIRIAM R. ACZEL

I am a President's Ph.D. Scholar at Imperial College London. My research looks at how drilling for shale gas (natural gas trapped inside shale rock) affects both human health and the environment. I am also the co-Founder and co-Director of the Amir D. Aczel Foundation for Research and Education in Science and Mathematics, which works to encourage young students in Cambodia to study science and math. I am passionate about science writing and currently serve as Director of Communications for Leaders in Energy, an environmental non-profit in Washington DC. I was born on Earth Day, so naturally I love being outside and look for any excuse to spend time with animals of all shapes and sizes! *miriam.aczel14@imperial.ac.uk

DEBRA ACZEL

Debra was an advisor of first year students at Massachusetts Institute of Technology (MIT) for 25 years, including in a program in which students had to propose solutions to the world's most challenging problems: how can we make sure the whole world has enough to eat? What do we do about climate change? To "test" their solutions, each year Debra took students to talk to people in communities that would be affected by their proposals: India to see how a small village feeds its community, South Africa to learn about access to water. She co-directs the Amir D. Aczel Foundation for Research and Education in Science and Mathematics, a non-profit working to support math education in Cambodia.

MARINA VILLE

Marina Ville is a French mathematician who spent 10 years in Israel and another 10 in Boston; she is now back in Paris and working at the University of Tours, France. She is a geometer and researches all kinds of shapes, including soap films or knots. Marina loves sharing ideas with colleagues and also sitting by herself in a café with a tricky problem: sometimes she does the same computation twenty times and the twenty-first time, she suddenly sees her ways out of the maze.
