## About Frontiers

Frontiers is more than just an open-access publisher of scholarly articles: it is a pioneering approach to the world of academia, radically improving the way scholarly research is managed. The grand vision of Frontiers is a world where all people have an equal opportunity to seek, share and generate knowledge. Frontiers provides immediate and permanent online open access to all its publications, but this alone is not enough to realize our grand goals.

## Frontiers Journal Series

The Frontiers Journal Series is a multi-tier and interdisciplinary set of open-access, online journals, promising a paradigm shift from the current review, selection and dissemination processes in academic publishing. All Frontiers journals are driven by researchers for researchers; therefore, they constitute a service to the scholarly community. At the same time, the Frontiers Journal Series operates on a revolutionary invention, the tiered publishing system, initially addressing specific communities of scholars, and gradually climbing up to broader public understanding, thus serving the interests of the lay society, too.

## Dedication to Quality

Each Frontiers article is a landmark of the highest quality, thanks to genuinely collaborative interactions between authors and review editors, who include some of the world's best academicians. Research must be certified by peers before entering a stream of knowledge that may eventually reach the public - and shape society; therefore, Frontiers only applies the most rigorous and unbiased reviews.

Frontiers revolutionizes research publishing by freely delivering the most outstanding research, evaluated with no bias from both the academic and social point of view. By applying the most advanced information technologies, Frontiers is catapulting scholarly publishing into a new generation.

## What are Frontiers Research Topics?

Frontiers Research Topics are very popular trademarks of the Frontiers Journals Series: they are collections of at least ten articles, all centered on a particular subject. With their unique mix of varied contributions from Original Research to Review Articles, Frontiers Research Topics unify the most influential researchers, the latest key findings and historical advances in a hot research area! Find out more on how to host your own Frontiers Research Topic or contribute to one as an author by contacting the Frontiers Editorial Office: [frontiersin.org/about/contact](https://frontiersin.org/about/contact)

# INTEGRATIVE PHARMACOLOGY-BASED RESEARCH ON TRADITIONAL MEDICINE: METHODOLOGIES, MEDICAL AND PHARMACOLOGICAL APPLICATIONS, 2nd Edition

Topic Editors:

**Hai Yu Xu**, Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences, China

**Chang-xiao Liu**, Tianjin Institute of Pharmaceutical Research, China

**Yanqiong Zhang**, Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences, China

**Yan Xu**, Cleveland State University, United States

**Takashi Sato**, Tokyo University of Pharmacy and Life Sciences, Japan

**Publisher's note:** This is a 2nd edition due to an article retraction.

**Citation:** Xu, H. Y., Liu, C.-x., Zhang, Y., Xu, Y., Sato, T., eds. (2023). Integrative Pharmacology-Based Research on Traditional Medicine: Methodologies, Medical and Pharmacological Applications, 2nd Edition. Lausanne: Frontiers Media SA. doi: 10.3389/978-2-8325-3551-6

# Table of Contents

- 10** *An Integrative Pharmacology-Based Analysis of Refined Qingkailing Injection Against Cerebral Ischemic Stroke: A Novel Combination of Baicalin, Geniposide, Cholic Acid, and Hyodeoxycholic Acid*  
Chongyang Ma, Xueqian Wang, Tian Xu, Shuang Zhang, Shuling Liu, Changming Zhai, Zisong Wang, Jie Mu, Changxiang Li, Fafeng Cheng and Qingguo Wang
- 24** *Screening for Susceptibility-Related Factors and Biomarkers of Xianling Gubao Capsule-Induced Liver Injury*  
Chun-yu Li, Ming Niu, Ya-lei Liu, Jin-fa Tang, Wei Chen, Geng Qian, Ming-yu Zhang, Ya-fei Shi, Jun-zhi Lin, Xing-jie Li, Rui-sheng Li, Xiao-he Xiao, Guo-hui Li and Jia-bo Wang
- 37** *Pharmacological Activity, Pharmacokinetics, and Toxicity of Timosaponin AIII, a Natural Product Isolated From Anemarrhena asphodeloides Bunge: A Review*  
Yan Lin, Wai-Rong Zhao, Wen-Ting Shi, Jing Zhang, Kai-Yu Zhang, Qian Ding, Xin-Lin Chen, Jing-Yi Tang and Zhong-Yan Zhou
- 53** *Treating Different Diseases With the Same Method—A Traditional Chinese Medicine Concept Analyzed for Its Biological Basis*  
Xing Zhai, Xi Wang, Li Wang, Linlin Xiu, Weilu Wang and Xiaohan Pang
- 69** *Traditional Asian Herbs in Skin Whitening: The Current Development and Limitations*  
Yibo Hu, Hongliang Zeng, Jinhua Huang, Ling Jiang, Jing Chen and Qinghai Zeng
- 79** *Inhibitory Effect of Cudratrixanthone U on RANKL-Induced Osteoclast Differentiation and Function in Macrophages and BMM Cells*  
Eun-Nam Kim, Jaeyoung Kwon, Hyun-Su Lee, Sooyeon Lee, Dongho Lee and Gil-Saeng Jeong
- 93** *Antioxidant Phytoconstituents From Onosma bracteata Wall. (Boraginaceae) Ameliorate the CCl<sub>4</sub> Induced Hepatic Damage: In Vivo Study in Male Wistar Rats*  
Ajay Kumar, Varinder Kaur, Kritika Pandit, Hardeep Singh Tuli, Katrin Sak, Subheet Kumar Jain and Satwinderjeet Kaur
- 111** *Unsupervised Learning and Multipartite Network Models: A Promising Approach for Understanding Traditional Medicine*  
Mohieddin Jafari, Yinyin Wang, Ali Amiryousefi and Jing Tang
- 121** *Jian-Pi-Bu-Xue-Formula Alleviates Cyclophosphamide-Induced Myelosuppression via Up-Regulating NRF2/HO1/NQO1 Signaling*  
Qiuju Huang, Lizhi Feng, Hang Li, Liang Zheng, Xiaoxiao Qi, Ying Wang, Qian Feng, Zhongqiu Liu, Xiaohong Liu and Linlin Lu
- 136** *Huoxue Huatan Decoction Ameliorates Myocardial Ischemia/Reperfusion Injury in Hyperlipidemic Rats via PGC-1 $\alpha$ –PPAR $\alpha$  and PGC-1 $\alpha$ –NRF1–mtTFA Pathways*  
Fei Lin, Yu-Qing Tan, Xuan-Hui He, Li-Li Guo, Ben-Jun Wei, Jun-Ping Li, Zhong Chen, Heng-Wen Chen and Jie Wang

- 153 ***Traditional Chinese Medicine in Treating Influenza: From Basic Science to Clinical Applications***  
Yibai Xiong, Na Xiao Li, Naifang Duan, Bin Liu, Hui Zhu, Chi Zhang, Li Li, Cheng Lu and Luqi Huang
- 162 ***Veratilla baillonii Franch Could Alleviate Lipid Accumulation in LO2 Cells by Regulating Oxidative, Inflammatory, and Lipid Metabolic Signaling Pathways***  
Xian-ju Huang, Cai-jing He, Shuai Liang, Jing Wang, Jun Li, Guang-zhong Yang and Zhang Zhao
- 176 ***Gastrointestinal Motility, Muscle Relaxation, Antipyretic and Acute Toxicity Screening of Amyrin Type Triterpenoid (Daturaolone) Isolated From Datura metel Linnaeus (Angel's Trumpet) Fruits***  
Saud Bawazeer, Abdur Rauf and Sami Bawazeer
- 184 ***Tripterygium Ingredients for Pathogenicity Cells in Rheumatoid Arthritis***  
Yujun Tang, Qiuping Liu, Yuxiang Feng, Yi Zhang, Zhenghao Xu, Chengping Wen and Yun Zhang
- 200 ***Onion Bulb Extract Downregulates EGFR/ERK1/2/AKT Signaling Pathway and Synergizes With Steroids to Inhibit Allergic Inflammation***  
Ahmed Z. El-Hashim, Maitham A. Khajah, Khaled Y. Orabi, Sowmya Balakrishnan, Hanan G. Sary and Ala A. Abdelali
- 218 ***An Integrative Serum Pharmacology-Based Approach to Study the Anti-Tumor Activity of B. paniculatum Aqueous Bulb Extract on the Human Hepatocellular Carcinoma Cell Line BEL-7404***  
Xuesong Feng, Guangyuan Ma, Hailong Shi, Yuewen Wang and Xu Chao
- 230 ***The Interventional Effects of Tubson-2 Decoction on Ovariectomized Rats as Determined by a Combination of Network Pharmacology and Metabolomics***  
Fan Yang, Xin Dong, Feixiang Ma, Feng Xu, Jie Liu, Jingkun Lu, Chunyan Li, Ren Bu and Peifeng Xue
- 243 ***Regulation of GABA<sub>A</sub> and 5-HT Receptors Involved in Anxiolytic Mechanisms of Jujube Seed: A System Biology Study Assisted by UPLC-Q-TOF/MS and RT-qPCR Method***  
Liang Chen, Xue Zhang, Chun Hu, Yi Zhang, Lu Zhang, Juntao Kan, Bo Li and Jun Du
- 259 ***Integrating Pharmacology and Gut Microbiota Analysis to Explore the Mechanism of Citri Reticulatae Pericarpium Against Reserpine-Induced Spleen Deficiency in Rats***  
Yuying Zheng, Xuan Zeng, Pan Chen, Tingting Chen, Wei Peng and Weiwei Su
- 277 ***A Novel Strategy for Decoding and Validating the Combination Principles of Huanglian Jiedu Decoction From Multi-Scale Perspective***  
Ke-Xin Wang, Yao Gao, Wen-Xia Gong, Xiao-Feng Ye, Liu-Yi Fan, Chun Wang, Xue-Fei Gao, Li Gao, Guan-Hua Du, Xue-Mei Qin, Ai-Ping Lu and Dao-Gang Guan
- 295 ***Hydroxysafflor Yellow A: A Systematical Review on Botanical Resources, Physicochemical Properties, Drug Delivery System, Pharmacokinetics, and Pharmacological Effects***  
Feng Zhao, Ping Wang, Yuanyuan Jiao, Xiaoxiao Zhang, Daquan Chen and Haiyu Xu

- 316 ***Bufei Jianpi Formula Improves Mitochondrial Function and Suppresses Mitophagy in Skeletal Muscle via the Adenosine Monophosphate-Activated Protein Kinase Pathway in Chronic Obstructive Pulmonary Disease***  
Jing Mao, Ya Li, Suxiang Feng, Xuefang Liu, Yange Tian, Qingqing Bian, Junzi Li, Yuanyuan Hu, Lanxi Zhang, Huige Ji and Suyun Li
- 333 ***Quality Markers for Astragali Radix and Its Products Based on Process Analysis***  
Yuntao Dai, Dongbo Wang, Manjia Zhao, Lihua Yan, Chao Zhu, Pengyue Li, Xuemei Qin, Rob Verpoorte and Shilin Chen
- 343 ***Network Pharmacology Reveals the Mechanism of Activity of Tongqiao Huoxue Decoction Extract Against Middle Cerebral Artery Occlusion-Induced Cerebral Ischemia-Reperfusion Injury***  
Si-peng Wu, Ning Wang and Li Zhao
- 356 ***An Integrated Strategy for Effective-Component Discovery of Astragali Radix in the Treatment of Lung Cancer***  
Bing Yang, Nan Yang, Yaping Chen, Maomao Zhu, Yuanpei Lian, Zhiwei Xiong, Bei Wang, Liang Feng and Xiaobin Jia
- 375 ***Clinical Practice Guideline for Tripterygium Glycosides/Tripterygium wilfordii Tablets in the Treatment of Rheumatoid Arthritis***  
Na Lin, Yan-Qiong Zhang, Quan Jiang, Wei Liu, Jian Liu, Qing-Chun Huang, Kuan-Yu Wu, Sheng-Hao Tu, Zu-Shan Zhou, Wei-Heng Chen, Xiao-Xia Li, Ying Ding, Yong-Fei Fang, Jian-Ping Liu, Zhen-Bin Li, Dong-Yi He, Yao-Long Chen, Yu-Qian Lou, Qing-Wen Tao, Qing-Wen Wang, Ying-Hui Jin, Xing Liao, Tai-Xian Li and Xiao-Yue Wang
- 382 ***Effects of Guanxinshutong Capsules as Complementary Treatment in Patients With Chronic Heart Failure: Study Protocol for a Randomized Controlled Trial***  
Yu Wang, Jiaping Xu, Jiehong Yang, Ling Zhang, Yuanjiang Pan, Liping Dou, Peng Zhou, Yizhou Xu, Chang Li, Yu He, Huifen Zhou, Li Yu, Jingwen Chen, Shuwei Huang, Wei Fu and Haitong Wan
- 392 ***Network Patterns of Herbal Combinations in Traditional Chinese Clinical Prescriptions***  
Ning Wang, Ninglin Du, Yonghong Peng, Kuo Yang, Zixin Shu, Kai Chang, Di Wu, Jian Yu, Caiyan Jia, Yana Zhou, Xiaodong Li, Baoyan Liu, Zhuye Gao, Runshun Zhang and Xuezhong Zhou
- 404 ***The Traditional Chinese Medicine Fuyou Formula Alleviates Precocious Puberty by Inhibiting GPR54/GnRH in the Hypothalamus***  
Guo-liang Bai, Kai-li Hu, Yi Huan, Xing Wang, Lei Lei, Meng Zhang, Chun-yan Guo, Hong-sheng Chang, Li-bo Zhao, Jing Liu, Zhu-fang Shen, Xiao-ling Wang and Xin Ni
- 416 ***Paeonol Protects Against Myocardial Ischemia/Reperfusion-Induced Injury by Mediating Apoptosis and Autophagy Crosstalk***  
Chin-Feng Tsai, Hsing-Hui Su, Ke-Min Chen, Jiuan-Miaw Liao, Yi-Ting Yao, Yi-Hung Chen, Meilin Wang, Ya-Chun Chu, Yi-Hsin Wang and Shiang-Suo Huang

- 427 Integrating Network Pharmacology and Experimental Validation to Investigate the Effects and Mechanism of Astragalus Flavonoids Against Hepatic Fibrosis**  
Lin An, Yuefang Lin, Leyan Li, Muyan Kong, Yanmei Lou, Jinjun Wu and Zhongqiu Liu
- 444 The Efficacy and Mechanism of Chinese Herbal Medicines in Lowering Serum Uric Acid Levels: A Systematic Review**  
Liqian Chen, Zhengmao Luo, Ming Wang, Jingru Cheng, Fei Li, Hanqi Lu, Qiuxing He, Yanting You, Xinghong Zhou, Hiu Yee Kwan, Xiaoshan Zhao and Lin Zhou
- 468 Epigallocatechin Gallate During Dietary Restriction — Potential Mechanisms of Enhanced Liver Injury**  
Zhuo Shi, Jing-xiao Zhu, Yu-ming Guo, Ming Niu, Le Zhang, Can Tu, Ying Huang, Peng-yan Li, Xu Zhao, Zi-teng Zhang, Zhao-fang Bai, Guang-qin Zhang, Yang Lu, Xiao-he Xiao and Jia-bo Wang
- 481 An Integrative Pharmacology-Based Approach for Evaluating the Potential Effects of Purslane Seed in Diabetes Mellitus Treatment Using UHPLC-LTQ-Orbitrap and TCMIP V2.0**  
Jinli Hou, Xiang Zhou, Ping Wang, Chunhui Zhao, Yuewen Qin, Feng Liu, Liping Yu and Haiyu Xu
- 499 Chemical Characteristics of Platycodon grandiflorum and its Mechanism in Lung Cancer Treatment**  
Yaling Deng, Xianwen Ye, Yufan Chen, Hongmin Ren, Lanting Xia, Ying Liu, Minmin Liu, Haiping Liu, Huangang Zhang, Kairui Wang, Jinlian Zhang and Zhongwei Zhang
- 515 Review of the Efficacy and Mechanisms of Traditional Chinese Medicines as a Therapeutic Option for Ionizing Radiation Induced Damage**  
Xiaomeng Zhang, Xiaoying Chen, Lei Wang, Changhao He, Zhongyu Shi, Qian Fu, Wenhui Xu, Shujing Zhang and Sumin Hu
- 533 An Integrative Pharmacology-Based Pattern to Uncover the Pharmacological Mechanism of Ginsenoside H Dripping Pills in the Treatment of Depression**  
Libin Zhao, Rui Guo, Ningning Cao, Yingxian Lin, Wenjing Yang, Shuai Pei, Xiaowei Ma, Yu Zhang, Yingpeng Li, Zhaohui Song, Wuxun Du, Xuefeng Xiao and Changxiao Liu
- 551 Deciphering the Pharmacological Mechanisms of Guizhi-Fuling Capsule on Primary Dysmenorrhea Through Network Pharmacology**  
Siqin Zhang, Xinxing Lai, Xin Wang, Gang Liu, Zhenzhong Wang, Liang Cao, Xinzhuang Zhang, Wei Xiao and Shao Li
- 565 The Protective Effects of Shengmai Formula Against Myocardial Injury Induced by Ultrafine Particulate Matter Exposure and Myocardial Ischemia are Mediated by the PI3K/AKT/p38 MAPK/Nrf2 Pathway**  
Lina Chen, Yuan Guo, Shuiqing Qu, Kai Li, Ting Yang, Yuanmin Yang, Zhongyuan Zheng, Hui Liu, Xi Wang, Shuoqiu Deng, Yu Zhang, Xiaoxin Zhu and Yujie Li

- 582** *Inhibition of TLR4/MAPKs Pathway Contributes to the Protection of Salvianolic Acid A Against Lipotoxicity-Induced Myocardial Damage in Cardiomyocytes and Obese Mice*  
Zhen Yang, Yanli Chen, Zhaoyuan Yan, Tian Tian Xu, Xiangyao Wu, Aiwen Pi, Qingsheng Liu, Hui Chai, Songtao Li and Xiaobing Dou
- 592** *Palmul-Tang, a Korean Medicine, Promotes Bone Formation via BMP-2 Pathway in Osteoporosis*  
La Yoon Choi, Mi Hye Kim, Yeon Kyung Nam, Ju Hee Kim, Hea-Young Cho and Woong Mo Yang
- 601** *An Integrative Pharmacology-Based Strategy to Uncover the Mechanism of Xiong-Pi-Fang in Treating Coronary Heart Disease With Depression*  
Lihong Zhang, Yu Zhang, Mingdan Zhu, Limin Pei, Fangjun Deng, JinHong Chen, Shaoqiang Zhang, Zidong Cong, Wuxun Du and Xuefeng Xiao
- 618** *The Treatment of Rhodiola Mimics Exercise to Resist High-Fat Diet-Induced Muscle Dysfunction via Sirtuin1-Dependent Mechanisms*  
Baiyang You, Yaoshan Dun, Siqian Fu, Dake Qi, Wenliang Zhang, Yuan Liu, Ling Qiu, Murong Xie and Suixin Liu
- 629** *Galectin-3 Mediated Inflammatory Response Contributes to Neurological Recovery by QiShenYiQi in Subacute Stroke Model*  
Yule Wang, Shuang He, Xinyan Liu, Zhixiong Li, Lin Zhu, Guangxu Xiao, Xiaoli Du, Hongxia Du, Wen Zhang, Yiqian Zhang, John Orgah, Yuxin Feng, Boli Zhang and Yan Zhu
- 645** *An Effective Workflow for Differentiating the Same Genus Herbs of Chrysanthemum morifolium Flower and Chrysanthemum Indicum Flower*  
Jiao He, Qian Zhang, Cuiying Ma, Gabriel I. Giancaspro, Kaishun Bi and Qing Li
- 656** *Yi-Qi-Jian-Pi Formula Suppresses RIPK1/RIPK3-Complex-Dependent Necroptosis of Hepatocytes Through ROS Signaling and Attenuates Liver Injury in Vivo and in Vitro*  
Feixia Wang, Li Tang, Baoyu Liang, Chun Jin, Liyuan Gao, Yujia Li, Zhanghao Li, Jiangjuan Shao, Zili Zhang, Shanzhong Tan, Feng Zhang and Shizhong Zheng
- 672** *Network Pharmacology-Based Strategy for Elucidating the Molecular Basis Forthe Pharmacologic Effects of Licorice (Glycyrrhiza spp.)*  
Jia Chen, Lin-Fu Li, Xiao-Ru Hu, Feng Wei and Shuangcheng Ma
- 687** *Qing-Yi Decoction in the Treatment of Acute Pancreatitis: An Integrated Approach Based on Chemical Profile, Network Pharmacology, Molecular Docking and Experimental Evaluation*  
Tian-Fu Wei, Liang Zhao, Peng Huang, Feng-Lin Hu, Ju-Ying Jiao, Kai-Lai Xiang, Zhi-Zhou Wang, Jia-Lin Qu and Dong Shang
- 700** *Evaluation of the Efficacy and Safety of Chinese Herbal Injection Combined With Trimetazidine for Viral Myocarditis: A Network Meta-Analysis*  
Kerui Wu, Dingwei Deng, Binghui Yu, Ziyun Han, Lanlin Huang, Yaxing He, Xia Yan and Dawei Wang
- 713** *Gegen Qinlian Decoction Ameliorates Hyperuricemia-Induced Renal Tubular Injury via Blocking the Inflammatory Signaling Pathway*  
Xiao-Jun Wang, Yi-Ding Qi, Hao-Chen Guan, Hua-Gang Lin, Pei-Qing He, Kang-Wei Guan, Lei Fu, Mao-Qing Ye, Jing Xiao and Tao Wu

Stroke is the second leading cause of death after heart disease globally and cerebral ischemic stroke accounts for approximately 70% of all incident stroke cases. We selected four main compounds from a patent Chinese medicine, Qingkailing (QKL) injection, including baicalin from *Scutellaria baicalensis* Georgi (Huang Qin), geniposide from *Gardenia jasminoides* J. Ellis (Zhizi), and cholic acid and hyodeoxycholic acid from *Bovis Calculus* (Niu Huang) with a ratio of 4.4:0.4:3:2.6 m/m, to develop a more efficacious and safer modern Chinese medicine injection against ischemic stroke, refined QKL (RQKL). In this study, we investigated multiple targets, levels, and pathways of RQKL by using an integrative pharmacology combining experimental validation approach. In silica study showed that RQKL may regulate PI3K-Akt, estrogen, neurotrophin, HIF-1, MAPK, Hippo, FoxO, TGF-beta, NOD-like receptor, apoptosis, NF-kappa B, Wnt, chemokine, TNF, Toll-like receptor signaling pathways against ischemic stroke. The experimental results showed that RQKL improved neurological function and prevented infarct volume and blood-brain-barrier damage. RQKL inhibited microgliosis and astrogliosis, and protected neurons from ischemic/reperfusion injury. RQKL also inhibited cell apoptosis and affecting the ratio of the anti-apoptosis protein B-cell lymphoma-2 (Bcl2) and pro-apoptosis protein Bcl2-associated X protein (Bax). Western blot analysis showed that RQKL activated AKT/PI3K signaling pathway and antibody array showed RQKL inhibited inflammatory response and decreased proinflammatory factor Tnf, Il6, and Il1b, and chemokines Ccl2, Cxcl2, and Cxcl3, and increased anti-inflammatory cytokine Il10. In conclusion, RQKL protected tissue against ischemic stroke through multiple-target, multiple signals, and modulating

multiple cell-types in brain. This study not only promoted our understanding of the role of RQKL against ischemic stroke, but also provided a pattern for the study of Chinese medicine combining pharmaceutical Informatics and system biology methods.

**Keywords:** network pharmacology, ischemic stroke, combination of drug, Chinese medicine, protein-protein interaction (PPI) network, topological analysis, Qingkailing, modern Chinese medicine

## INTRODUCTION

Stroke is the second leading cause of death after heart disease globally and is associated with the highest disability-adjusted life-years lost of any disease in China (Wu et al., 2019). Approximately 795,000 new stroke cases are reported in the US yearly and 4.3 times this number was recently surveyed by the nationwide community-based study, NESS-China (Wang W. et al., 2017). Cerebral ischemic stroke accounts for approximately 70% of all incident stroke cases. Since the 1990s, intravenous alteplase has been considered the only evidence-based therapeutic agent for improving the prognosis of patients with cerebral ischemic stroke and accepted as standard of care all around the world (Powers et al., 2019). However, its short therapeutic window and high risk of hemorrhagic complications have hampered its widespread adoption in China. Therefore, exploring novel therapeutic strategies to treat ischemic stroke is an urgent need.

Qingkailing (QKL) injection, is a patent traditional Chinese medicine formulation approved by the China Food and Drug Administration to treat ischemic stroke for over 30 years. We previously study screened a novel modern drug combination (refined Qingkailing, RQKL) consisting of four compounds, baicalin (CAS number 21967-41-9) from *Scutellaria baicalensis* Georgi (Huang Qin), geniposide (CAS number 24512-63-8) from *Gardenia jasminoides* J. Ellis (Zhizi), and cholic acid (CAS number 81-25-4) and hyodeoxycholic acid (CAS number 83-49-8) from *Bovis Calculus* (Niu Huang) with a ratio of 4.4:0.4:3:2.6 m/m. Our previous study showed that RQKL protected the brain against ischemia-reperfusion (I/R) injury *in vivo* and *in vitro* (Cheng et al., 2012; Cheng et al., 2018). However, the underlying mechanisms and core signaling pathways mediating the multi-linked and multi-targeted effects of RQKL against ischemic stroke are still unknown.

Generally, natural bioactive compounds exert therapeutic effects through multiple targets and pathways that cannot be accurately detected solely using conventional pharmacological approaches.

Integrative pharmacology could enhance the comprehension and facilitate the prediction of potential targets, pathways, and consequences, which might provide clues for designing subsequent research studies. In this work, we used an integrative pharmacology approach with the goal of understanding the systemic, organ-related, and molecular effects of RQKL. This approach combined the prediction of multiple drug targets, visualization of compound-target network and target-cell-type network, topological analysis of protein-protein interaction (PPI) networks and gene ontology (GO), and KEGG pathway analysis of core targets. Importantly,

our experimental results largely validated the mechanism of action of RQKL, as predicted by the integrative pharmacology analysis (Figure 1).

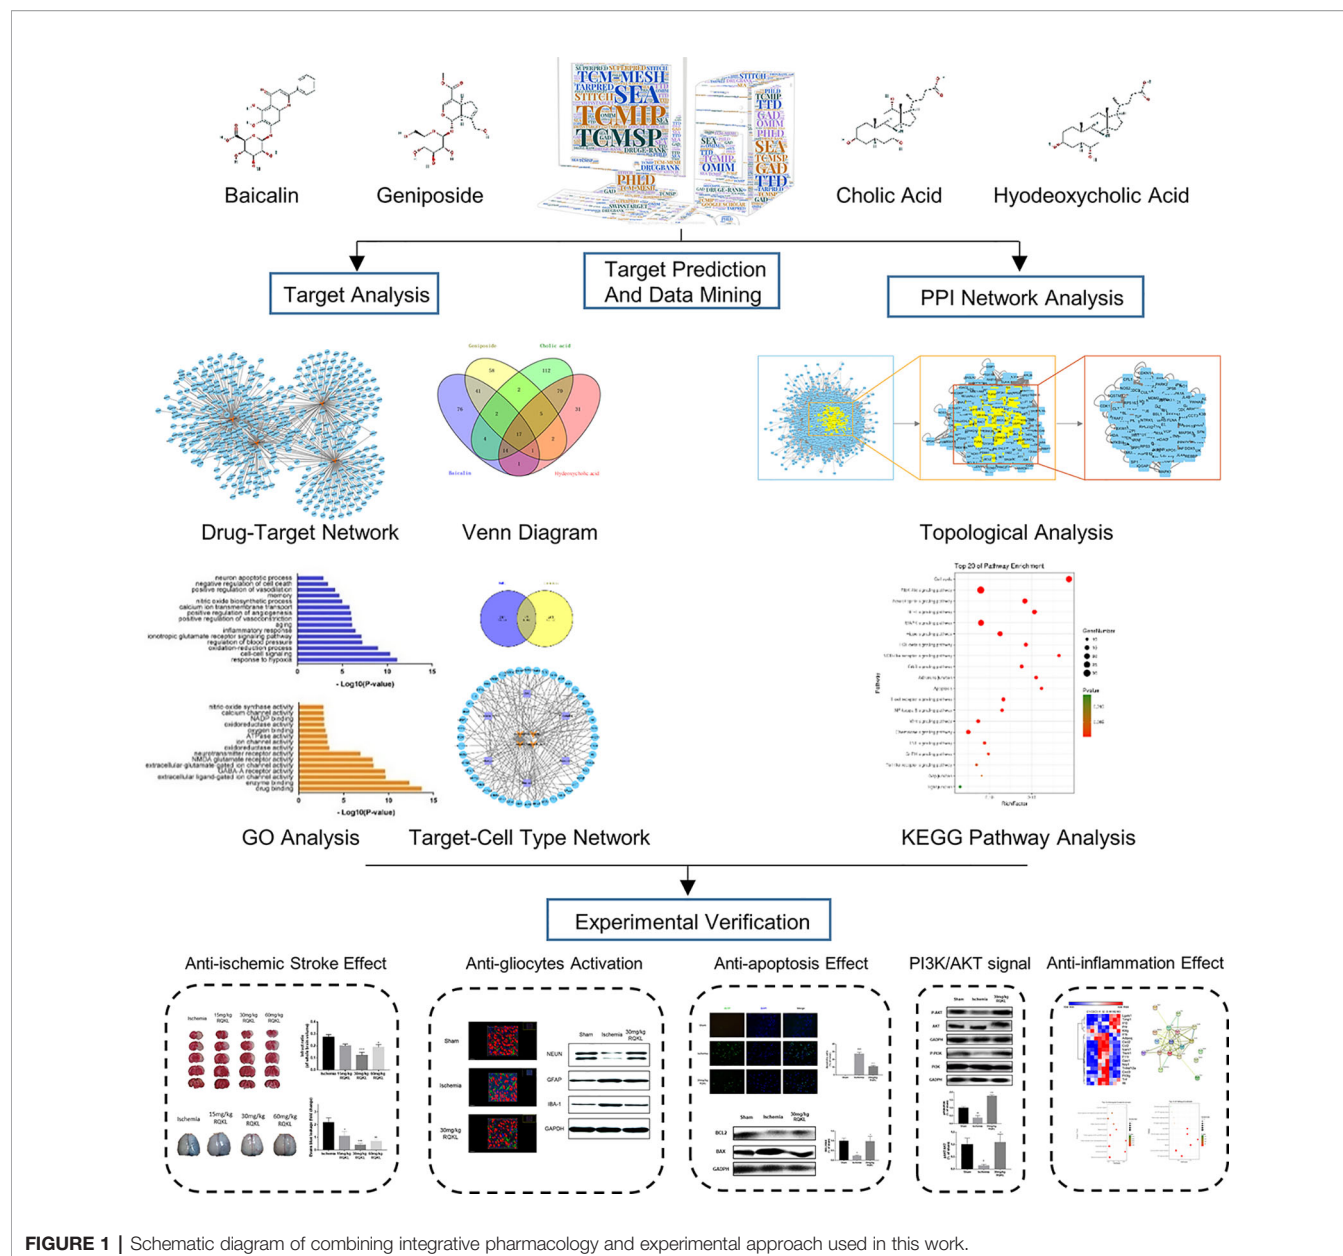

## MATERIALS AND METHODS

### Materials and Reagents

The RQKL used in this study was a mixture of baicalin, geniposide, cholic acid, and hyodeoxycholic acid (4.4:0.4:3:2.6). Baicalin (CAS number 21967-41-9), geniposide (CAS number 24512-63-8), and cholic acid (CAS number 81-25-4), and hyodeoxycholic acid (CAS number 83-49-8) were purchased from Shanghai Aladdin Biochemical Technology Co., Ltd. (Shanghai China). Protease inhibitor, radioimmunoprecipitation assay (RIPA) lysis buffer, and enhanced chemiluminescence (ECL) reagent were obtained from Applygen Technologies Inc. (Beijing China). The antibodies against B-cell lymphoma-2 (Bcl2, 12789-1-AP) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH, 10494-1-AP) were obtained from Proteintech Group, Inc (Rosemont, USA). The antibodies against BCL2-associated X protein (BAX, #2772), serine-threonine protein kinase (AKT, #9272), phosphorylated-AKT (pAKT, #9271), phosphatidylinositol-4,5-Bisphosphate 3-kinase (PI3K, #4249), and phosphorylated-PI3K (pPI3K, #4228) were obtained from Cell Signaling Technology (Boston, USA). The antibodies against glial fibrillary acidic protein (GFAP, ab7260) was obtained from Abcam (Cambridge, USA). The antibodies against GFAP labeled Alexa Fluor 488 (MAB3402X) and neuronal nuclei antigen (NEUN, MAB37) were purchased from Millipore (Darmstadt, Germany) and the antibody against ionized calcium binding adaptor molecule-1 (IBA1, 019-19741) was purchased from WAKO CHEMICAL, CO., LTD. (Japan). Terminal deoxynucleotidyl transferase (TdT)-mediated deoxyuridine triphosphate (dUTP) nick-end labeling (TUNEL) apoptosis detection kit was purchased from Roche Applied Science (Mannheim, Germany). Rat cytokine array antibody arrays (GSR-CAA-67) were purchased from RayBiotech Life (California, USA).

### Construction of the Compound-Target and Disease-Target Databases

To identify the corresponding targets of the four active ingredients of RQKL, several approaches combined with a chemometric method, information integration, and data-mining were implemented. First, the biological targets of the active ingredients were obtained from SEA (<http://sea.bkslab.org/>) (Keiser et al., 2007), STITCH (<http://stitch.embl.de/>) (Szkarczyk et al., 2016), DrugE-Rank ([Frontiers in Pharmacology | www.frontiersin.org](http://datamining-iip.</a></p>
</div>
<div data-bbox=)

fudan.edu.cn/service/DrugE-Rank) (Yuan et al., 2016), PhlD (<http://phid.ditad.org/>) (Hu et al., 2014), SuperPred (<http://prediction.charite.de/index.php?site=home>) (Nickel et al., 2014), SwissTarget (<http://www.swisstargetprediction.ch/>) (Gfeller et al., 2014), and TarPred (<http://www.dddc.ac.cn/tarpred>) (Liu et al., 2015). All active compounds were also sent to TCMIP (<http://www.tcmip.cn/TCMIP/index.php/Home/Index/index.html>) (Xu et al., 2019) TCM-Mesh (<http://mesh.tcm.microbiinformatics.org/>) (Zhang et al., 2017), TCMSP (<http://tcmsp.com/tcm-sp.php>) (Ru et al., 2014), and Google Scholar to mine compound-target interactions. Please see detailed information in **Supplementary Table S1**.

Known therapeutic targets for ischemic stroke were collected from the DrugBank (<http://www.drugbank.ca/>) (Wishart et al.,

2018), Online Mendelian Inheritance in Man (OMIM) (<http://www.omim.org>) (Hamosh et al., 2005), Genetic Association (GAD, <http://geneticassociationdb.nih.gov/>) (Becker et al., 2004), and Therapeutic Target Database (TTD, <https://db.idrblab.org/ttd/>) (Yang et al., 2016) databases. After deleting the redundant information, 321 known therapeutic targets for the treatment of ischemic stroke were included in this study. Please see detailed information in **Supplementary Table S2**.

### Screening of Target Related Cell-Type

AlzData (<http://www.alzdata.org/>) database contains gene expression data of different cell-types from human brain single cell RNA-seq (GSE67835) and was used to recognize target related cell-type in the present study (Xu et al., 2018). In

briefly, after overlapping compound-target and disease-target databases, we input the obtained targets into AlzData database to investigate each target related cell-types.

## Network Construction

Two kinds of networks in this study were established using Cytoscape (version 3.2.1) software (Shannon et al., 2003): compound-target network and target-cell-type network. Compound-target network was composed of compounds and their potential targets, which was built to reveal the compound-target interactions. Target-cell-type network was built based on the potential targets and their related cell-types.

## Protein-Protein Interaction Network Construction

PPI data were imported from six currently available PPI databases, including the Biological General Repository for Interaction Datasets (BioGRID), Biomolecular Interaction Network Database (BIND), Molecular INTeraction Database (MINT), Human Protein Reference Database (HPRD), and Database of Interacting Proteins (DIP), which were searched using BisoGenet, a Cytoscape plugin (Martin et al., 2010). An interactive network for the candidate drug targets and known ischemic stroke-related targets of RQKL was constructed based on their interaction data and was visualized using the Cytoscape software.

## Definition of Topological Feature Set for the Network

As previously mentioned the topological properties of every node in the interaction network were analyzed by calculating six measures: “betweenness centrality (BC),” “degree centrality (DC),” “eigenvector centrality (EC),” “closeness centrality (CC),” “network centrality (NC),” and “local average connectivity (LAC)” using CytoNCA (Wang X. et al., 2017). The definitions and computation equations of these six parameters represent the topological importance of a node in the network. More important nodes receive higher quantitative values within the network than less important nodes did (Tang et al., 2015).

## Gene Oncology Enrichment and Pathway Analysis

Further, we performed GO analysis of the 438 non-repetitive putative targets of RQKL using the Database for Annotation, Visualization, and Integrated Discovery (DAVID) to gain insights into their involvement in two different categories namely, biological processes (BP) and molecular function (MF) (Sherman and Lempicki, 2009). Tissue enrichment analysis was performed using FunRich software (<http://www.funrich.org>) (Pathan et al., 2015). Then, we performed Kyoto Encyclopedia of Genes and Genomes (KEGG) signaling pathway enrichment analysis of the 189 candidate targets of RQKL after the topological analysis. A  $P < 0.05$  was considered significant, and the enriched GO terms were identified using the hypergeometric test. A Bubble Chart was plotted using the OmicShare tools, a free online platform for data analysis ([www.omicshare.com/tools](http://www.omicshare.com/tools)).

## Animals

Adult male Sprague-Dawley rats (220–230 g), provided by Vital River Laboratory Animal Technology (number SCXK 2016-0006, Beijing, China), were housed in the laboratory animal room and maintained at  $25 \pm 1^\circ\text{C}$  with  $65 \pm 5\%$  humidity on a 12-h light/dark cycle (lights on from 07:30 to 19:30) for at least 1 week before the experiments. Animals were provided food and water *ad libitum*. The animal experimental design and protocols used in this study were approved by the Ethics Review Committee for Animal Experimentation of Beijing University of Chinese Medicine (BUCM-4-2017090116-3016).

## Transient Middle Cerebral Artery Occlusion

All animals were fasted overnight but allowed free access to water and were then randomly assigned to five groups: low-, medium-, and high-dose RQKL treatment; ischemic, and control groups. The transient middle cerebral artery (tMCA) occlusion (tMCAO) model was established as described previously to induce focal cerebral I/R injury (Zheng et al., 2014). The right MCA was occluded using a poly-L-lysine-coated nylon suture, which was inserted from the external carotid artery into the common carotid artery, and after a 90-min occlusion, the MCA-suture was carefully removed for reperfusion. The body temperature of the rats was maintained at  $37^\circ\text{C}$ . The sham group was subjected to the same procedure except for the nylon thread insertion. Rats in the low-, medium, and high-dose RQKL groups were administered intraperitoneal injections of RQKL dissolved in saline water at doses of 15, 30, and 60 mg/kg, respectively, and those in the ischemic group were administered physiological saline at the same volume. The first injection was performed immediately after model establishment, followed by administration after 4 h, and once every 12 h after that. At 24 h after reperfusion, 10 rats in each group were euthanized, and the brains were rapidly excised for histomorphological assay or protein detection.

## Neurological Assessment

The neurological deficit score of each rat was measured 24 h after tMCAO induction in a blinded fashion according to a well-established five-point neurological scale (Longa et al., 1989): 0 = no apparent deficits, 1 = failure to fully extend the right forepaw, 2 = circling to the right, 3 = falling or leaning over to the right, 4 = no spontaneous walking and a depressed level of consciousness, and 5 = death.

## Infarct Volume Assessment

Following neurological function evaluation, the rats were euthanized, and the brains were harvested for triphenyltetrazolium chloride (TTC) staining. The percentage infarct volume relative to the entire brain represented the degree of cerebral infarction. Serial coronal sections (2 mm thick) were prepared and soaked in 2% TTC phosphate buffer at  $37^\circ\text{C}$  for 10 min in the dark. Normal brain tissues were stained red while infarct tissues were not stained (white). The sections were soaked in 4%

paraformaldehyde (PFA) phosphate buffer for 30 min, arranged in order and scanned (Tsinghua Unisplendour A688, Xi'an, China). Areas of red and white staining were measured using a computer color multimedia image analysis system (Image-Pro Plus 6.0, Media Cybernetics, WY, USA). The percentage of the infarction was calculated using the following equation: infarct volume (%) = infarct volume/total volume of slice  $\times$  100.

### Blood-Brain-Barrier Permeability

The blood-brain barrier (BBB) permeability was determined using Evans blue (EB) extravasation 24 h after tMCAO. In brief, EB dye (2%, 4 ml/kg) was injected over a 2-min period into the left femoral vein at a dose of 2 ml/kg and allowed to circulate for 1 h. Rats were anesthetized and perfused transcardially using saline to remove the intravascular EB dye. After decapitated, the entire brain of each animal was removed, homogenized in physiological phosphate-buffered saline (PBS), trichloroacetic acid was added to precipitate the protein, and then the tissue homogenates were cooled and centrifuged. The EB absorbance of the resulting supernatant was measured at 620 nm using a spectrophotometer.

### Nissl Staining

Coronal brain sections from four equidistant brain levels, 1 mm apart, were stained with cresyl violet according to a standard protocol. For Nissl staining, air-dried sections were fixed in 4% PFA solution for 15 min; immersed in 100, 95, 85, and 70% ethanol, followed by double distilled water for 3 min each; stained for 15 min with filtered cresyl violet solution [Sigma, 0.2% (w/v)]; and then briefly rinsed in double distilled water. Finally, the sections were dehydrated again in 70, 95, and 100% ethanol for 1 min each; placed in xylene for another 10 min; and then coverslipped. Nissl staining was performed to examine the neuronal injury, and necrotic neurons (red triangles) showed the absence of Nissl's bodies in the cytoplasm, a shrunken intercellular space, and deep staining. The following four scores were used to evaluate necrotic neurons in the infarct area: 0, normal; 1, damaged neurons were < 25%; 2, damaged neurons were 25–50%; 3, damaged neurons were 50–75%; and 4, damaged neurons were > 75% (Sun et al., 2009).

### Terminal Deoxynucleotidyl Transferase-Mediated Deoxyuridine Triphosphate Nick-End Labeling Staining

Ischemic stroke-induced DNA fragmentation was quantified in frozen sections using the TdT-mediated dUTP nick-end labeling (TUNEL) assay according to the manufacturer's instructions. Briefly, air-dried sections were fixed with methanol-free 4% PFA at room temperature for 15 min and washed twice with PBS. The sections were immersed in equilibration buffer for 10 min, which was then replaced by a mixture of 1  $\mu$ l TdT enzyme, 5  $\mu$ l nucleotide mix, and 45  $\mu$ l equilibration buffer. The sections were then kept at 37°C for 90 min, and then SSC (2 $\times$ ) was added for 15 min at room temperature to terminate the TdT enzyme reaction.

### Confocal Microscopy and Morphology Analysis

Brains were cut into coronal sections (40  $\mu$ m) on a cryostat, placed in 1 ml of anti-freeze solution (40% PBS, 30% ethylene-glycol, 30%, glycerol, v/v) and stored at  $-20^{\circ}\text{C}$  until immunohistochemistry. Triple immunostaining was performed on coronal slices with the free-floating method as previously described (Lana et al., 2014). The following primary antibodies were used: a mouse monoclonal anti-neuronal nuclei (NeuN, 1:200; Millipore, Billerica, MA) for neurons; a rabbit polyclonal anti-glial fibrillary acidic protein (GFAP, 1:1,000; DakoCytomation, Glostrup, Denmark) for astrocytes; a rabbit polyclonal anti-IBA1 (1:300, WAKO Pure Chem. Ind., Osaka, Japan) for microglia. Slices were observed under a ZEISS LSM 5 confocal laser scanning microscope. Confocal scans were taken at 0.5  $\mu$ m z-steps keeping pinhole, contrast, and brightness constant. Semi-automated image analysis was performed using Bitplane IMARIS 7.4 3D image analysis software (Oxford Instruments, Concord, MA) and the 3-D reconstructed images of microglia and astrocyte were using surface function based on previously described (Radford et al., 2015).

### Western Blotting

The cortical tissue in the penumbra was collected for western blot analysis. The protein was extracted using RIPA lysis buffer containing protease inhibitor, and the concentration was measured using a bicinchoninic acid (BCA) protein assay kit (#CW0014, CWBio, China). Protein samples (50  $\mu$ g) were separated on sodium dodecyl sulfate (SDS)-polyacrylamide gels and transferred onto a polyvinylidene fluoride membrane (Millipore Corporation, Billerica, MA, USA). The membrane was blocked with 5% nonfat dry milk in Tris-buffered saline containing 0.05% Tween-20 (TBST) buffer and then incubated with primary antibodies against BCL2, BAX, pAKT, AKT, pPI3K, PI3K, NEUN, GFAP, IBA-1, and GAPDH overnight at 4°C. Subsequently, the membranes were incubated for 1 h at room temperature with secondary antibodies coupled to horseradish peroxidase (1: 10,000). The antigen-antibody complexes were then exposed to the ECL reagent and visualized using a c600 western blot imaging system (Azure Biosystems, Dublin, CA, USA). The protein levels of pro-inflammatory mediators were expressed as relative integrated intensity and were normalized to that of GAPDH.

### Cytokine Antibody Microarray

Rat cytokine array antibody arrays were used to analyze cytokine expression profiles in brain samples according to the manufacturer's instructions. A digital imaging system (InnoScan 300 Microarray Scanner, Innopsys) was used to detect chemiluminescent signals which were analyzed using ImageJ software (NIH). Measured cytokines included the following: ADIPOQ, AGER, CCL11, CCL2, CCL27, CCL3, CCL5, CD48, CD80, CD86, CDH3, CNTF, CSF2, CX3CL1, CXCL1, CXCL2, CXCL3, CXCL5, DCN, EPHA5, EPO, F11R, FGFBP1, FLT3LG, GAS1, GFRA1, HAVCR1, HGF, ICAM1,

IFNG, IGDCC4, IL10, IL13, IL17F, IL1A, IL1B, IL1RL2, IL1RN, IL2, IL22, IL2RA, IL3, IL4, IL6, IL6ST, IL7, INHBA, KITLG, LGALS1, LGALS3, NGF, NOTCH1, NOTCH2, NRP1, NRP2, PDGFA, PPBP, PRL, PRLR, SELL, TIMP1, TIMP2, TNF, TNFRSF9, TNFSF12, TNFSF9, TREM1, VEGFA.

## Statistical Analysis

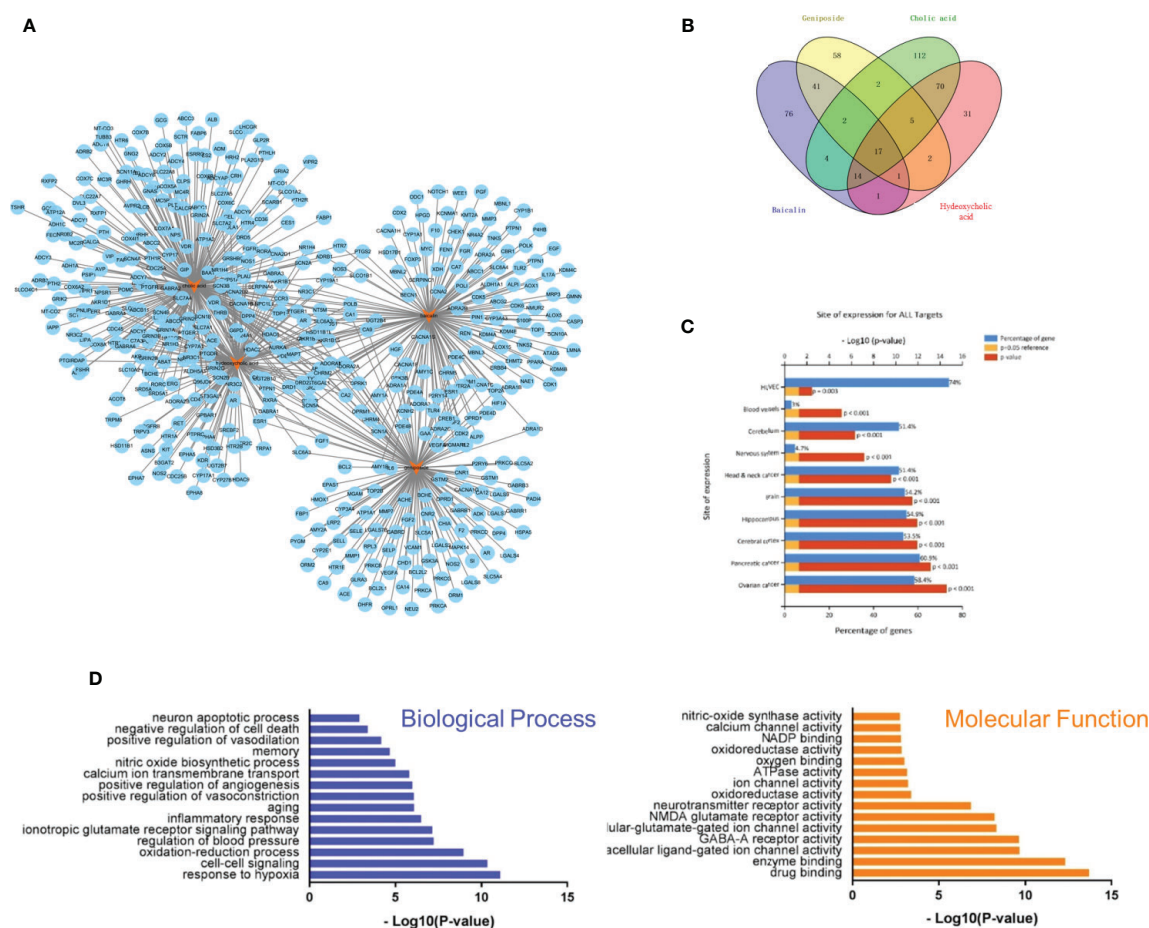

Statistical analysis was performed using the GraphPad Prism 5 software. Normally distributed data and homogeneous variances were expressed as means  $\pm$  standard error of the mean (SEM). These data were analyzed by one-way analysis of variance (ANOVA) followed by a *post hoc* Bonferroni multiple comparison test or Dunnett's test. Nonnormally distributed data were expressed as the median. Kruskal-Wallis test was used for the within-group differences comparison, and the Wilcoxon rank test was used to compare two groups. A  $P < 0.05$  was considered significant.

## RESULTS

### Network Pharmacological Analysis of Refined Qingkailing

#### Construction and Analysis of Compound-Target Network of Refined Qingkailing

RQKL is composed of baicalin, geniposide, cholic acid, and hyodeoxycholic acid, which have all been identified to be crucial bioactive natural compounds of a famous patent Chinese medicine, QKL injection. In this work, we explored the therapeutic targets of RQKL predicted using multiple online databases as previously described. Then, a network of potential targets of the compounds in RQKL was constructed using Cytoscape software as shown in **Figure 2A**, and 652 compound-target interactions were generated between the four compounds and 438 non-repetitive targets: 156, 129, 226, and 141 for baicalin, geniposide, cholic acid, and hyodeoxycholic acid, respectively. As shown in **Figure 2B**,

**FIGURE 2 |** Compound-target interaction network and preliminary gene ontology (GO) analysis of drug targets. **(A)** Compound-target network of refined Qingkailing (RQKL). **(B)** Preliminary screening targets of four compounds in RQKL. **(C)** Tissue enrichment analysis of drug target **(D)** GO analysis of drug targets classified into two categories, biological process (BP), and molecular function (MF).

we found that 16 differential genes were overlapping among all the targets of each compound, indicating a synergistic effect of RQKL compounds on these targets, such as the dopamine receptor D2 (DRD2) and estrogen receptor 1 (ESR1), adenosine A1 receptor (ADORA1), and retinoid X receptor alpha (RXRA).

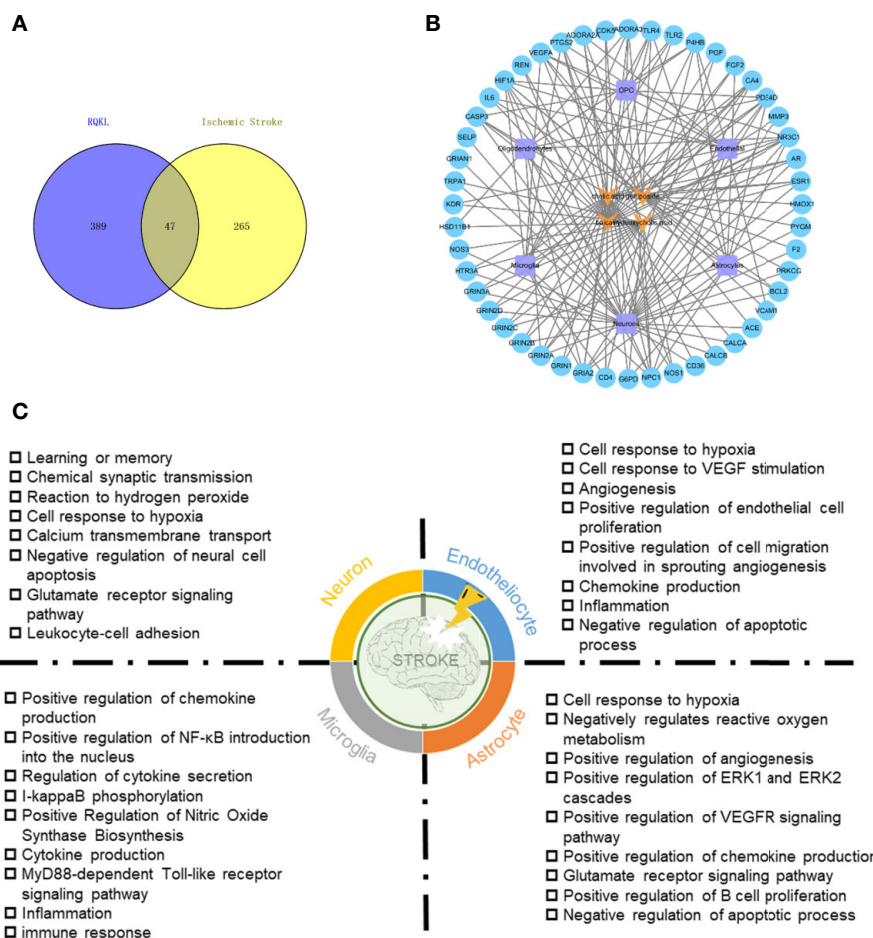

### Tissue and Gene Ontology Enrichment of Refined Qingkailing Targets

Tissue enrichment using the FunRich software (<http://www.funrich.org>) showed in **Figure 2C**, indicated that all targets of the four compounds were located in the cerebral cortex, hippocampus, and blood vessels, especially human umbilical vein endothelial cells (HUVEC), indicating a therapeutic effect on brain disease. GO analysis of the putative RQKL targets described based on BP and MF terms were constructed using the DAVID database. In total, 597 BPs and 183 MFs that were enriched for this dataset were identified, which consisted

of 449 BPs and 145 MFs with  $P < 0.05$ . **Figure 2D** illustrates an overview of the GO analysis with 15 remarkably enriched terms in the BP and MF categories. We noticed that some BPs and MFs might be associated with the pathogenesis of ischemic stroke such as response to hypoxia, inflammatory response, negative regulation of cell death, and calcium channel activity, indicating the potential mechanisms of action of RQKL in ischemic stroke.

### Construction and Analysis of Compound-Target-Cell Type Network of Refined Qingkailing Against Ischemic Stroke

To evaluate targets of RQKL against ischemic stroke, we collected 321 ischemic stroke-related targets from four existing databases, namely the DrugBank, Online Mendelian Inheritance in Man, Genetic Association, and Therapeutic Target database. A Venn diagram was shown in **Figure 3A** and 47 targets were found overlapped between compound

**FIGURE 3 |** Ischemic stroke-related targets of refined Qingkailing (RQKL) regulated multiple cell type via multiple biological processes. **(A)** Venn diagram of compound targets of RQKL and ischemic stroke-related targets. **(B)** The compound-target-cell-type network of RQKL anti-ischemic stroke effect. The yellow refers to the compounds of RQKL. The purple represents six cell-types in brain and the blue represents intersectant targets of RQKL and ischemic stroke. **(C)** Biological process enrichment analysis of targets related to different cell-types in brain.

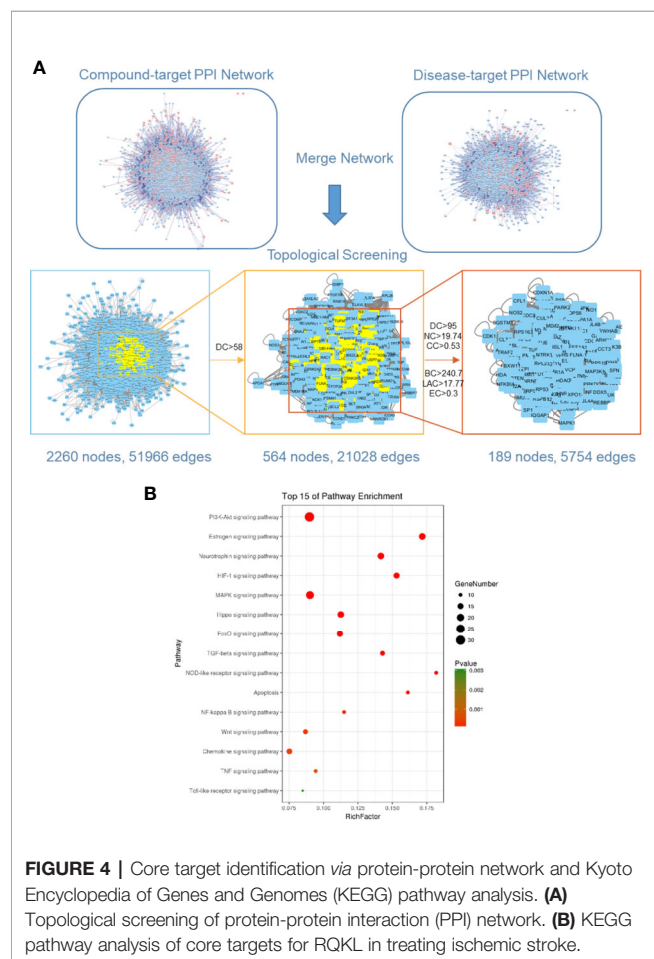

targets and ischemic stroke targets. AlzData online database was used to understand the relationship between these 47 targets and cell types in brain. A compound-target-cell type network was constructed in **Figure 3B**, and we found 31 targets were related to neurons, 14 targets were related to astrocytes, 13 targets were related to endothelial cells, and 11 targets were related to microglia, indicating an effect of RQKL on these cells. BP enrichment showed in **Figure 3C** indicated different effects of RQKL on different cell type. In neuron, RQKL may involve in learning or memory, chemical synaptic transmission, response to hydrogen peroxide, cellular response to hypoxia, calcium transmembrane transport, negative regulation of neural cell apoptosis, and glutamate receptor signaling pathway. In astrocyte, cell response to hypoxia, negatively regulates reactive oxygen metabolism, positive regulation of angiogenesis, positive regulation of ERK1 and ERK2 cascades, positive regulation of VEGFR signaling pathway, positive regulation of chemokine production, glutamate receptor signaling pathway, positive regulation of B cell proliferation, and negative regulation of apoptotic process. In endotheliocyte, cell response to hypoxia, cell response to VEGF stimulation, angiogenesis, positive regulation of endothelial cell proliferation, positive

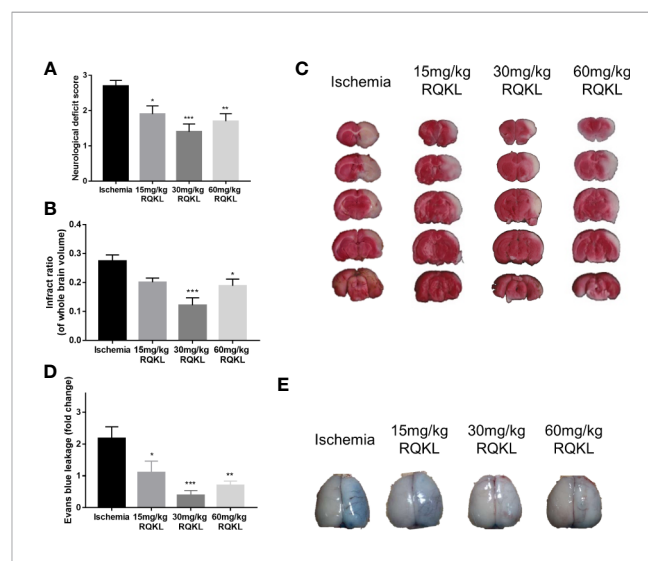

regulation of cell migration involved in sprouting angiogenesis, chemokine production, inflammation, and negative regulation of apoptotic process. In microglia, RQKL may involve in some inflammation process, including positive regulation of chemokine production, positive regulation of NF- $\kappa$ B introduction into the nucleus, regulation of cytokine secretion, I-kappaB phosphorylation, positive regulation of nitric oxide synthase biosynthesis, cytokine production, MyD88-dependent Toll-like receptor signaling pathway, inflammation, and immune response.

## Identification of Core Anti-Ischemic Stroke Targets *via* Protein-Protein Interaction Network

Ischemic stroke-related targets are interconnected, and the PPI network has been shown to organize all protein-coding genes into a large network, which provides a better understanding of the role of various proteins in complex diseases such as ischemic stroke [29, 30]. Therefore, a compound-related target network (6,605 nodes and 158,668 edges) and a known ischemic stroke-related target network (2,861 nodes and 57,981 edges) were constructed using the PPI data. Further, we intersected both networks, consisting of 2,260 nodes and 51,966 edges. We identified nodes with degrees that were more than twice the median degree (58) of all nodes as significant targets as previously described. Thus, we constructed a network of significant targets for RQKL against ischemic stroke that had 564 nodes and 21,028 edges. Further, we calculated the topological features of each hub namely, “degree centrality (DC),” “betweenness centrality (BC),” “closeness centrality

**FIGURE 4 |** Core target identification *via* protein-protein network and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis. **(A)** Topological screening of protein-protein interaction (PPI) network. **(B)** KEGG pathway analysis of core targets for RQKL in treating ischemic stroke.

**FIGURE 5 |** Effects of different doses of refined Qingkailing (RQKL) on ischemia/reperfusion injury. **(A)** Effects RQKL on neurological deficits score **(B)** Quantitative analysis of cerebral infarct areas. **(C)** Representative pictures of brain sections stained with 2% TTC. **(D)** Evans blue (EB) leakage analysis to evaluate prevention of blood-brain barrier (BBB) damage by RQKL. **(E)** Representative pictures of EB leakage. Data points indicate means  $\pm$  SEM. Vs. ischemia group: \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ . At least three independent experiments were performed for each group.

(CC), “eigenvector centrality (EC),” “network centrality (NC),” and “local average connectivity (LAC).” The median values of “DC,” “BC,” “CC,” “EC,” “NC,” and “LAC” were 95, 240.7, 0.53, 0.3, 19.74, and 17.77, respectively. A flowchart of the core target screening is presented in **Figure 4A**. Detailed topological features of the core PPI and 189 core targets are shown in **Supplementary Table S3**.

## Kyoto Encyclopedia of Genes and Genomes Enrichment Analysis of Core Targets for Refined Qingkailing Against Ischemic Stroke

To further clarify the possible roles of the 189 core targets, we performed an enrichment analysis of their KEGG pathways. Specifically, we obtained signaling pathways related to PI3K-Akt, estrogen, neurotrophin, HIF-1, MAPK, Hippo, FoxO, TGF-beta, NOD-like receptor, apoptosis, NF-kappa B, Wnt, chemokine, TNF, Toll-like receptor, shown in **Figure 4B**. Based on the p-values, the PI3K-Akt signaling pathway was the most probable candidate for RQKL function targeting ischemic stroke.

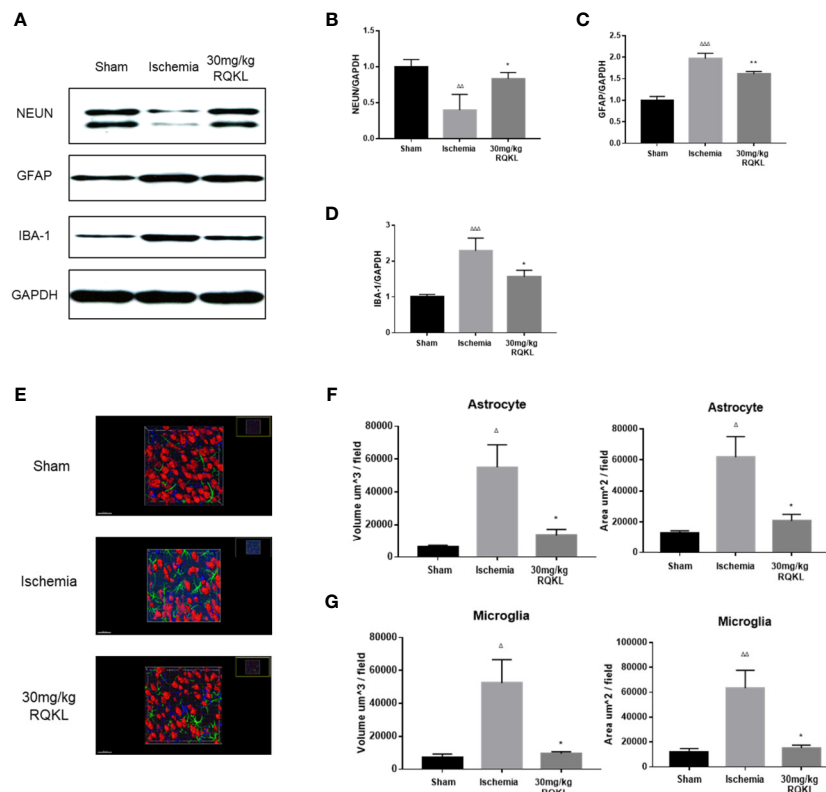

## Experimental Validation

### Refined Qingkailing Treatment Attenuated Ischemia-Reperfusion Injury

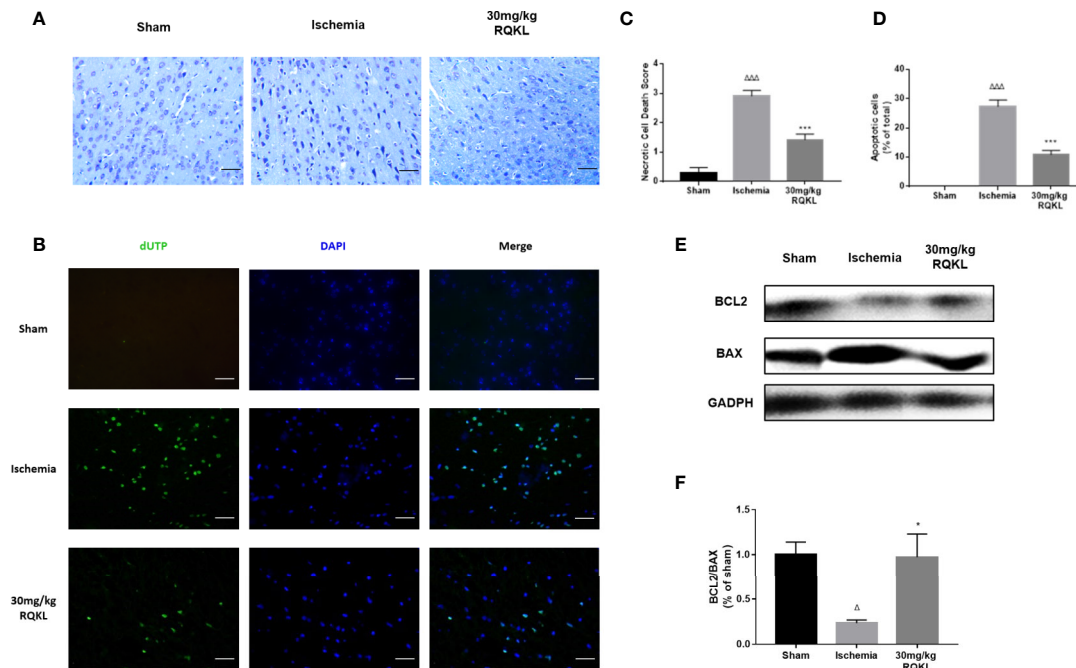

To determine whether RQKL treatment improved neurological function after ischemic stroke, neurological deficit scoring was carried out. As shown in **Figure 5A**, obvious neurological deficits were observed in the ischemic group. Furthermore, while 15 mg/kg RQKL reduced the neurological deficits without a significant difference, treatment with 30 and 60 mg/kg remarkably decreased the neurological deficit score.

The infarct volume rate was assessed using TTC staining, and normal tissues were stained red, whereas the infarction area was unstained (white, **Figure 5C**). As shown in **Figure 5B**, after the 24 h tMCAO, the infarct ratio of the 30 and the 60 mg/kg groups declined obviously compared with that of the ischemic group. No significant neuroprotective effect was observed at the lowest dose.

After determining that RQKL inhibits cell death after I/R, we further investigated whether it affects the BBB integrity. In **Figures 5D, E**, the quantitative data showed that RQKL significantly decreased Evans blue extravasation leakage in the ipsilateral cortex, indicating that RQKL reduced the BBB permeability

**FIGURE 6 |** Anti-gliocyte response effect of refined Qingkailing (RQKL) on ischemia/reperfusion injury. **(A)** Representative pictures of expression of NEUN, GFAP, and IBA-1. **(B)** Quantitative analysis of NEUN expression. **(C)** Quantitative analysis of GFAP expression. **(D)** Quantitative analysis of IBA-1 expression. **(E)** Representative pictures of 3D reconstruction of astrocytes, microglia and neuron nuclei. Green represented astrocytes labeled by GFAP. Blue represented microglia labeled by IBA-1. Red represented neuron nuclei labeled by NEUN. **(F)** Volume and surface area of astrocytes. **(G)** Volume and surface area of microglia. Data points indicate means ± SEM. Vs. Sham group:  $\Delta p < 0.05$ ,  $\Delta\Delta p < 0.01$ ,  $\Delta\Delta\Delta p < 0.001$ , vs. ischemia group:  $*p < 0.05$ ,  $**p < 0.01$ . At least three independent experiments were performed for each group.

**FIGURE 7 |** Anti-apoptosis effect of refined Qingkailing (RQKL) on ischemia/reperfusion injury. **(A)** Representative pictures of Nissl staining and **(B)** representative images of cell apoptosis stained by terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling TUNEL method. **(C)** Relevant quantitative analysis based on pathological four-score scale and **(D)** rate of apoptotic cells in each group. **(E)** Western blot analysis of B-cell lymphoma 2 (BCL2) and BCL2-associated X protein (BAX). **(F)** Quantitative analysis of BCL2:BAX expression ratio. Data points indicate means $\pm$ SEM. Vs. Sham group:  $\Delta p < 0.05$ ,  $\Delta\Delta p < 0.001$ , vs. ischemia group:  $p < 0.05$ ,  $***p < 0.001$ . At least three independent experiments were performed for each group.

after ischemic stroke. Dose of 30 mg/kg RQKL was chosen for further biological experiment because of its optimal effect.

### Refined Qingkailing Treatment Decreased Glia Activation After Ischemic Stroke

To evaluate RQKL on neuron, astrocyte, and microglia, we evaluated expression level of protein marker of neuron, astrocyte, and microglia *via* western blot. As shown in **Figures 6A–D**, RQKL increased the expression level of NEUN compared to ischemia group, indicating a neuroprotective effect of RQKL against ischemic stroke. And RQKL decreased expression level of GFAP and IBA-1 compared to ischemia group, indicating RQKL inhibited activation of astrocyte and microglia. Next we discussed RQKL on morphology of astrocyte and microglia. After 3D reconstructing astrocyte and microglia *via* software, the volume and surface area were calculated automatically. As shown in **Figures 6E–G**, ischemic stroke significantly increased the volume and surface area of astrocyte and microglia, and RQKL significantly decreased above index compared to ischemia group. These data suggested RQKL decreased glia activation after ischemic stroke.

### Refined Qingkailing Treatment Inhibited Cell Apoptosis Induced by Ischemic Stroke

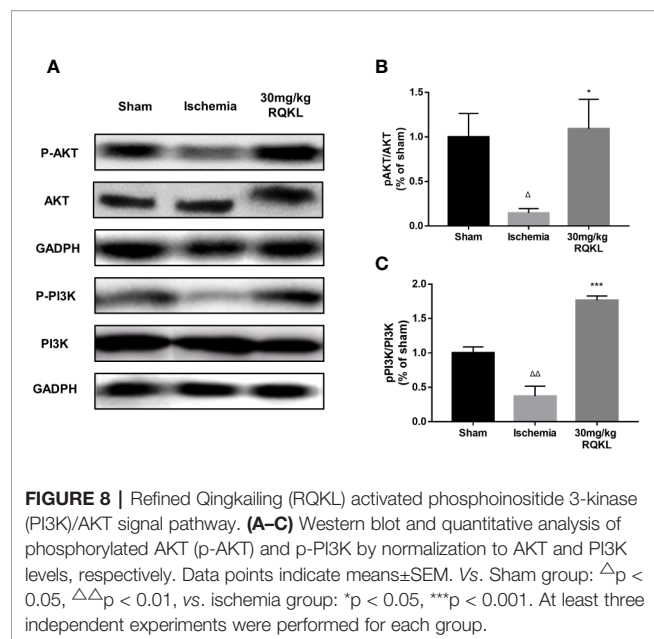

Integrative pharmacology showed RQKL neuroprotective effect involved in cell apoptosis signal. In the present work, Nissl staining of the cerebral cortex (**Figures 7A, C**) was used to

assess the cellular protective effect of treatment with the medium-dose RQKL (30 mg/kg). The results showed that RQKL significantly decreased the necrotic cell death score based on a published four-point scale evaluating necrotic neurons in the infarct area. The TUNEL staining (**Figures 7B, D**) showed no apparent positively stained cells in the cerebral cortices of the sham group, whereas numerous apoptotic cells with positively stained nuclei were observed in the ischemic group, which also showed shrinkage of the nuclei or chromatin margination. RQKL treatment induced the percentage of apoptotic cells compared to ischemia group.

Moreover, the analysis of alterations in apoptosis-related proteins showed that RQKL dramatically increased the Bcl-2/Bax ratio in ischemic animals (**Figures 7E, F**). Thus, the overall effect of RQKL in ischemic stroke was likely mediated by both the elevation of anti-apoptotic signaling and suppression of cellular death progress.

### Refined Qingkailing Treatment Activated PI3K/AKT Signaling Pathways

Previous integrative pharmacology analysis showed that the PI3K/Akt signaling pathway is the main signaling pathway mediating the biological effects of RQKL on ischemic stroke. Therefore, we designed a western blot experiment to detect the activation of this signaling pathway. As shown in **Figures 8A–C**, the results of the western blotting showed that the expression

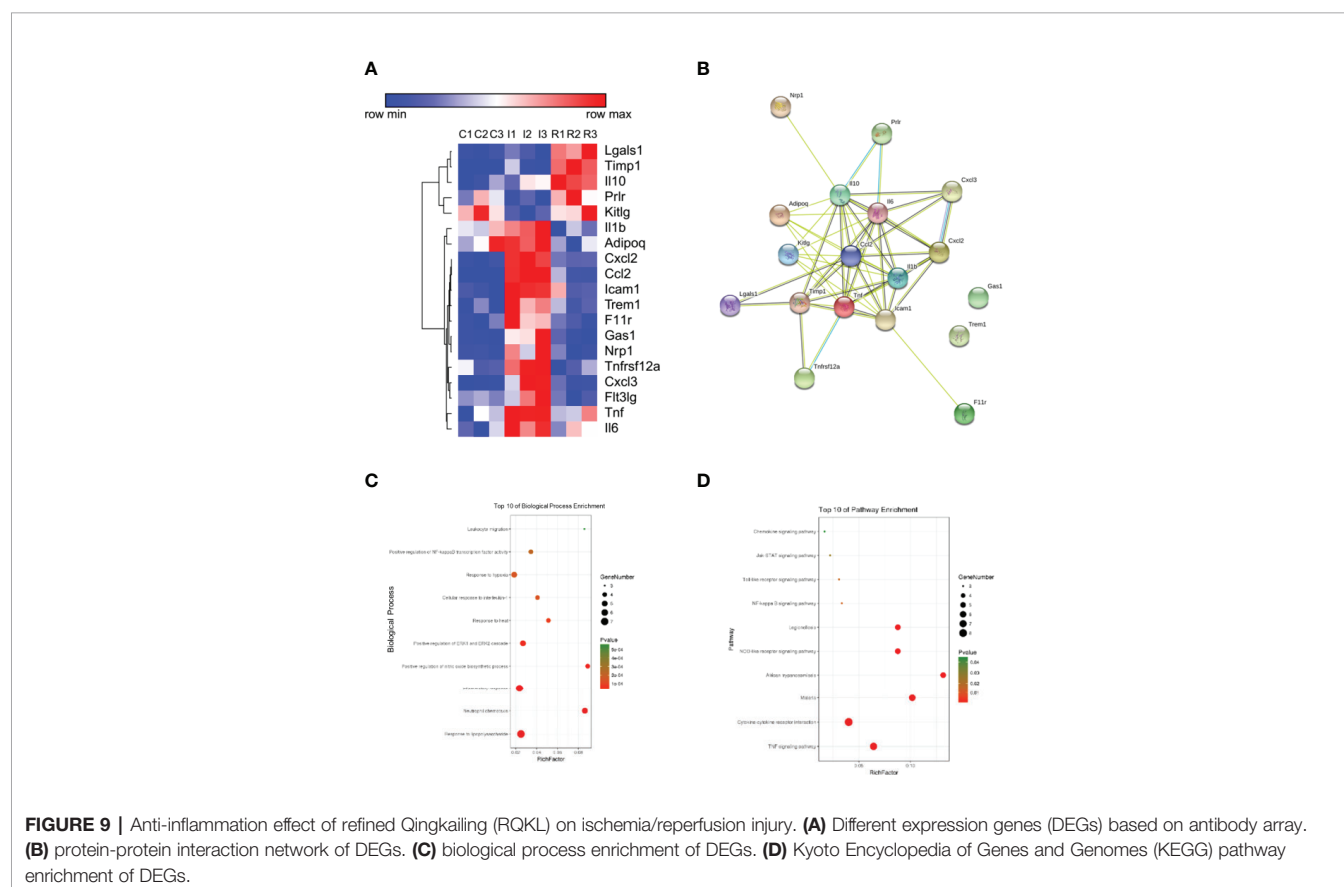

levels of p-AKT/AKT ratio and p-PI3K/PI3K ratio in the ischemic group were significantly decreased 24 h after ischemic stroke. Moreover, RQKL significantly increased the level of the two, indicating RQKL activated PI3K/Akt signaling suppressed by ischemic stroke.

## Refined Qingkailing Treatment Reduced Inflammatory Response

To evaluate RQKL on inflammatory response, an antibody microarray containing 67 cytokines and chemokines was used. As shown in **Figures 9A–D**, 19 proteins were identified as different expression proteins of RQKL treatment compared to ischemia group. A PPI network was constructed, and BP and KEGG enrichment analysis was illustrated in bubble plots. Some BP and KEGG signals mentioned in integrative pharmacology part were obtained, including inflammatory response, response to hypoxia, TNF signaling pathway, NOD-like receptor signaling pathway, NF-kappa B signaling pathway, Toll-like receptor signaling pathway.

## DISCUSSION

QKL injection is a famous traditional Chinese medicine formulation that has been widely used in China for more than 30 years. However, some adverse drug reactions and events have been reported, which has limited the clinical use of QKL injection since 2001 (Hao et al., 2010). Therefore, the development of a considerably safer and more efficacious QKL injection is urgently required. Therefore, we refined QKL into a novel medicine, RQKL, also targeted at treating acute ischemic stroke, one of the indications of QKL. RQKL is composed of only four main components of QKL and has the advantage of quality stabilization and clinical safety. In

this study, we evaluated the neuroprotective effect of RQKL in a tMCAO rat model. We observed not only the effect of RQKL in improving neurological deficits and decreasing infarct ratio but also on the BBB permeability following BBB injury in a dose-independent manner. And our unpublished *in vitro* data showed that RQKL protected neurons from ischemia/reperfusion injury with a dosage-independent manner, which was consistent with this study. And we also tested the efficacy of ingredients in RQKL against ischemia/reperfusion injury, only geniposide was found to have dose-dependent manner.

Most natural compounds are known to affect more than one gene or protein and have the potential to potentially affect the entire biological process without severe side effects or excessive inhibition of certain single signaling pathway. Unfortunately, traditional methods have failed to reveal the obscure mechanisms of multi-target medicines in the systemic analysis. Recently, integrative pharmacology has provided an efficient approach for determining the underlying molecular mechanisms of multi-target medicine. We applied an integrative pharmacology approach that included target prediction, PPI analysis, GO enrichment analysis, network analysis, and experimental verification to decipher the mechanisms of the combination of four bioactive components derived from QKL injection (RQKL) for the therapy of ischemic stroke.

In this work, we built a network of 652 compound-target interactions generated between the four compounds and 438 non-repetitive targets, and numerous targets located in the cerebral cortex, hippocampus, and blood vessels, indicating a pharmacological efficacy of RQKL in treating cerebral vascular disease. GO analysis showed the multi-effects of RQKL including response to hypoxia, as well as negative regulation of cell death and inflammatory responses. Based on single cell RNA-seq data, we found RQKL could influence different cell-type, including neuron, astrocyte and microglia. Experimental data suggested an increased level of NEUN in penumbra of cortex, indicating a neuroprotective effect of RQKL treatment. According to previous studies, after ischemic stroke, astrocytes was activated into hypertrophic morphology with extended processes and swollen cell bodies and microglia was activated into hypertrophic morphology with thickened and retracted processes (Tian et al., 2019; Zhang et al., 2019). In the present study, we used 3D reconstruction software to reveal the morphology of astrocyte and microglia. We found RQKL treatment altered hypertrophic morphology of astrocyte and microglia in ischemic stroke model, indicating RQKL inhibited glia cells activation. Crucially, it is not clear whether the structural alteration of glia cells, is the cause or the consequence of protection of neurons in ischemic stroke. Further studies should focus on potential molecular mechanisms on modulating microgliosis and astrogliosis of RQKL.

After merging the PPI network of ischemic stroke- and RQKL-related targets, 189 candidate targets of RQKL treatment were characterized based on topological features. Enrichment analysis of their KEGG pathways highlighted the PI3K/Akt signaling pathway as the most probable candidate mediating the effects of RQKL on ischemic stroke. According to previous studies, suppression of PI3k/Akt signaling has been associated with the

neuronal death induced by cerebral I/R. Therefore, enhanced Akt activity contributes to the anti-apoptotic and neuroprotective effects on the ischemic brain (Sun et al., 2018). Experiments showed that RQKL treatment activated PI3K/Akt signaling pathway and inhibited apoptosis progress. There are number literature reports of the cellular protective effect of compounds in RQKL *via* PI3K/Akt signal. Baicalin was reported to alleviate the neuronal apoptosis induced by ketamine toxicity (Zuo et al., 2016) and protect neonatal brains against hypoxic-ischemic injury *via* activation of PI3K/Akt signaling pathway (Zhou et al., 2017). A recent study showed that baicalin might directly bind to the pleckstrin homology domain of AKT and activate the phosphorylation of AKT on Ser473 site (Yang et al., 2019). Geniposide was reported to protect against hypoxic-ischemia-induced brain injury through the activation of PI3K/Akt signaling pathway (Liu et al., 2019). And the anti-apoptotic effects of geniposide mediated *via* the PI3K/AKT signaling pathway were also reported in H9c2 cells in response to the H/R injury (Jiang et al., 2016; Huang et al., 2017). Furthermore, numerous kinds of bile acids have been reported to activate the PI3k/Akt signaling pathway and attenuate certain kinds of brain injury (Hanafi et al., 2016; Sun et al., 2017). Activation of TGR5, a receptor of cholic acid and hyodeoxycholic acid, phosphorylate AKT at Ser473 and activate PI3K/Akt signal (Li et al., 2020). Consistent with the observation of these studies, our data showed that RQKL promoted the phosphorylation of PI3K/AKT and upregulated the ratio of the anti-apoptotic protein Bcl2 and pro-apoptotic protein Bax, which was confirmed by the downstream phosphorylation of Akt (Huang et al., 2015; Chen et al., 2017).

Our data confirmed some inflammation related signal was regulated by RQKL treatment, including TNF signaling pathway, NOD-like receptor signaling pathway, NF-kappa B signaling pathway, and Toll-like receptor signaling pathway. Ischemic stroke leads to the release of danger-associated molecular patterns (DAMPs) from dying neurons and other damaged cells. These molecules trigger the activation of resident microglia and astrocytes and leads to secretion of chemokines and cytokines, formation of an inflammatory environment, and damage amplification (Xiong et al., 2019). Modulating these inflammatory signals is a promising area of therapeutics research against ischemic stroke.

## CONCLUSION

In conclusion, in this study, we combined a method of Big data discovery with biological validation to study the mechanism of the actions of RQKL against ischemic stroke at the systemic level. We confirmed the neuroprotective effect of RQKL against cerebral I/R injury, which was associated with its attenuation of brain damage, cell apoptosis and activation of glia cells, modulation of the PI3K/Akt pathway, TNF signaling pathway, NOD-like receptor signaling pathway, NF-kappa B signaling pathway, and Toll-like receptor signaling pathway. Whether other pathways or mechanisms predicted in this network pharmacological approach participate in the beneficial effects of RQKL needs to be further investigated.

However, this study has some limitations that are worth mentioning. First, the reliability of the drug- and disease-related targets and protein-protein interaction database was of great importance in analyzing the underlying mechanisms of the effects of RQKL against ischemic stroke. The accuracy of GO and pathway analyses depends on *a priori* biological knowledge. Secondly, different data mining machines lead to different results. Therefore, biological verification is necessary to evaluate the reliability of bioinformatic analysis *in silico*. Lastly, more specific evidence should be considered in determining the exact effect of these drugs on this signaling pathway. Furthermore, quantitative analysis of the synergistic effect of the four compounds should be investigated in the future.

## DATA AVAILABILITY STATEMENT

All datasets generated for this study are included in the article/**Supplementary Material**.

## ETHICS STATEMENT

The animal study was reviewed and approved. The animal experimental design and protocols used in this study were approved by the Ethics Review Committee for Animal Experimentation of Beijing University of Chinese Medicine (BUCM-4-2017090116-3016).

Although increasing reports from the literature on herbal-related hepatotoxicity, the identification of susceptibility-related factors and biomarkers remains challenging due to idiosyncratic drug-induced liver injury (IDILI). As a well-known Chinese medicine prescription, Xianling Gubao Capsule (XLGB) has attracted great attention due to reports of potential liver toxicity. But the mechanism behind it is difficult to determine. In this paper, we found that XLGB-induced liver injury belongs to IDILI through the analysis of clinical liver injury cases. In toxicological experiment assessment, co-exposure to XLGB and non-toxic dose of lipopolysaccharide (LPS) could cause evident liver injury as manifested by significantly increased plasma alanine aminotransferase activity and obvious liver histological damage. However, it failed to induce observable liver injury in normal rats, suggesting that mild immune stress may be a susceptibility factor for XLGB-induced idiosyncratic liver injury. Furthermore, plasma cytokines were determined and 15 cytokines (such as IL-1 $\beta$ , IFN- $\gamma$ , and MIP-2 $\alpha$  etc) were acquired by receiver operating characteristic (ROC) curves analysis. The expression of these 15 cytokines in LPS group was significantly up-regulated in contrast to the normal group. Meanwhile, the metabolomics profile showed that mild immune stress caused metabolic reprogramming, including sphingolipid metabolism, phenylalanine metabolism, and glycerophospholipid metabolism. 8 potential biomarkers (such as sphinganine, glycerophosphoethanolamine, and phenylalanine etc.) were identified by correlation analysis. Therefore, these results suggested that intracellular metabolism and immune changes induced by mild immune stress may be important susceptibility mechanisms for XLGB IDILI.

**Keywords:** Xianling Gubao capsule, idiosyncratic drug-induced liver injury, susceptibility-related factors, metabolomics, biomarkers

## INTRODUCTION

Recently, with a deep belief that traditional Chinese medicines (TCM) are safe because they are “natural,” TCM and related products are applied more and more widely in the world, especially in the fields of tonics, health products, and food (Luo et al., 2019). However, TCM-related hepatotoxicity issues have also become increasingly prominent, causing widespread concern among researchers and drug regulatory authorities. Xianling Gubao (XLGB) is extensively applied to treat osteoporosis, osteoarthritis, menopausal syndrome, aseptic bone necrosis and bone fracture for about 20 years, and has definite therapeutic effect (Cheng et al., 2013). However, many cases of liver injury associated with XLGB have emerged in recent years. The China Food and Drug Administration (CFDA) has also warned of the risk of liver damage from XLGB in 2016.

The formulation of XLGB consists of six herbs: *Epimedium folium* (*Epimedium brevicornu* Maxim., *Epimedium koreanum* Nakai, *Epimedium pubescens* Maxim., *Epimedium sagittatum* (Siebold & Zucc.) Maxim., or *Epimedium wushanense* T.S.Ying), *Psoraleae fructus* (*Cullen corylifolium* (L.) Medik.), *Dipsaci radix* (*Dipsacus asperoides* C.Y.Cheng & T.M.Ai or *Dipsacus inermis* Wall.), *Salvia miltiorrhiza radix et rhizoma* (*Salvia miltiorrhiza* Bunge), *Anemarrhenae rhizoma* (*Anemarrhena asphodeloides* Bunge), and *Rehmanniae radix preparata* (*Rehmannia glutinosa* (Gaertn.) DC.) (Guan et al., 2011). No toxic herbs were found in the routine recipe. Moreover, no obvious adverse effects or toxicity developed in ovariectomized rats administrated XLGB at dosages 1000 mg/kg for 26 weeks (Cheng et al., 2013) or 1200 mg/kg/day for 12 months and up to 1800 mg/kg/day for 26 weeks (equivalent to six times the daily-recommended dose) (Wu et al., 2017). The safety and effectiveness of XLGB in treating osteoporosis has been proven in a randomized, multicenter, double-blind, placebo-controlled clinical trial (Li et al., 2018). Currently, in spite of predictable liver toxicity is often found in preclinical and clinical testing for drugs, it is extremely difficult to recognize or assess Chinese herbs-related to hepatotoxicity, especially idiosyncratic liver injury. Therefore, the underlying mechanisms of XLGB-induced liver injury remain unknown. Our previous research has indicated that mild inflammation might be one of the factors related to susceptibility of Chinese herbs (He shou wu in Chinese)-induced liver injury (Li et al., 2016; Li et al., 2017). Simultaneous exposure to small doses of LPS can serve on a susceptibility-related determinant of many chemicals to intoxication, such as trovafloxacin and monocrotaline (Yee et al., 2003; Poulsen et al., 2014). A critical need exists to predict IDILI of Chinese herbs and understand the mechanisms behind it. Here, we investigated the objectivity of XLGB-induced liver injury by analyzing clinical liver injury cases and simultaneously evaluated XLGB susceptibility on previously established animal models of mild immune stress. As a follow-up, we employed a metabolomics strategy in order to explore the susceptibility related biomarkers of XLGB-induced liver toxicity from the perspective of metabolic reprogramming. The immune cytokines and differentially expressed biomarkers associated with

the susceptibility factors of XLGB-induced liver injury were identified.

## MATERIALS AND METHODS

### Chemicals and Reagents

Xianling Gubao Capsule (batch number 1601046) was produced by Guizhou Tongjitang Pharmaceutical Co., Ltd (Guizhou, China). Epimedin A, Epimedin B; Epimedin C, icariin, psoralen, angelicin, icaricidin II and anhydroicaritin were from Chengdu Pufei De Biotechnology Co., Ltd. (Chengdu, China). Sodium pentobarbital (cat 57-33-0) and LPS [derived from *Escherichia coli*, 055:B5 (lot 086M4159V)] were supplied by Sigma Chemical Company. Methanol and formic acid are both HPLC grade, purchased from Fisher Chemicals (Pittsburg, PA, USA); Acetonitrile is also HPLC grade, obtained from Merck (Darmstadt, Germany); Water was purified by a Millipore's ultrapure water system (Millipore, Bedford, MA, USA). Luminex multiplex cytokine analysis kits was from R&D Systems (MN, United States). Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) detection kits were acquired from Jiancheng Biological Technology, Co., Ltd (Nanjing, China).

### Data Sources of Adverse Drug Reactions Cases

A total of 55,388 cases of drug-induced liver injury were collected from the National Adverse Drug Reaction (ADR) Monitoring Database (2012–2016), of which 63 cases of XLGB-related liver injury were found and included in the study. All cases were evaluated and included using the integrated evidence chain-based identification of traditional Chinese medicine in the “Guideline for diagnosis and treatment of herb-induced liver injury” issued by the China Association of Chinese Medicine and “Technical guidelines for clinical evaluation of liver injury induced by traditional Chinese medicine” issued by National Medical Products Administration (Wang et al., 2014; Wang et al., 2016; Zhu et al., 2016b). Retrospective analysis was performed for statistical analysis in this study.

### Animals and Treatment Protocol

Male, Sprague-Dawley Rats weighing 180 to 250 g (Laboratory Animal Center of the Academy of Military Medical Sciences, License No. SYXK 2007- 004, Beijing, China) were used for this research. Rats were given continual access to water and food *ad libitum*. Animals were maintained in a 12 h light/dark cycle for one week of acclimatization. They received humane care according to the Guiding Principles for the Care and Use of Laboratory Animals of China and Institutional Animal Care, and procedures were approved by the Use Committee of 302 hospital of PLA. The powder of Xianling Gubao Capsule was suspended in 0.5% sodium carboxymethyl cellulose solution.

Evaluation of idiosyncratic liver injury was according to literature and our previously reported rat model and adjusted appropriately (Luyendyk et al., 2006; Li et al., 2015). Doses of LPS

and XLGB were selected from our preliminary range-finding studies. Briefly, the animals were given normal saline or 2.8 mg/kg LPS by tail vein injection. Two hours later, 1.62 g/kg Xianling Gubao Capsule or an equivalent volume of normal saline was administered intragastrically. Rats were anesthetized (sodium pentobarbital, 50 mg/kg, ip) after six hours later. Blood was gathered from the inferior vena cava using a syringe filled with 0.38% sodium citrate. Plasma was collected after centrifugation (3,000 rpm, 10 min) and stored at 20°C until use. The left lateral liver lobe (3–4 mm) were removed and performed histopathological examination after fixing in 10% neutral buffered formalin for at least 72 h (He et al., 2018).

## Assessment of Hepatic Injury and Analysis of Cytokines in Plasma

Hepatic parenchymal cell damage is assessed by an increase in ALT and AST activity in plasma, which is determined in accordance with the procedures of the microplate assay kit. Formalin-fixed liver lobes were embedded in paraffin, cut at a 4 µm, and stained with hematoxylin and eosin. Resulting slides were coded, and evaluated by light microscopy. Plasma cytokine/chemokine profiles, including IL-18A, MIP-2, MIP-2α, Rantes, MCP-3, MCP-1, IP-10, IL-6, VEGF-α, GRO-α, IL-4, IFN-γ, IL-2, IL-13, TNF-α, IL-1β, GM-CSF, IL-5, IL-11, IL-12p70, and Eotaxin were determined according to the manufacturer's instructions of the Cytokine array of Luminex Assays Kit.

## Sample Handling of Metabolomics Study

The plasma samples were thawed at room temperature, and 600 µl of methanol was added to the 200 µl sample for extraction. The mixture were vortexed for 1 min and centrifuged (10,000 rpm, 10 min) at 4°C. Then, the supernatants were collected and filtered through a 0.22-µm syringe filter.

## Chromatography and Mass Spectrometry Conditions

The metabolic profiling analysis was performed on a Waters I-Class UPLC system (Waters Corporation, Milford, USA). The sample sequence is random, and all samples were separated on a reverse phase HSS T3 C18 column (100 mm × 2.1 mm, 1.8 µm particle size). The column temperature was maintained at 40 °C. To ensure the stability and repeatability of the system, 10 µl of each sample was combined for quality control (QC), which was inserted and analyzed in every 10 samples. The mobile phase used 0.1% formic acid in water as solvent A and 0.1% formic acid in acetonitrile as solvent B. The flow rate was 0.3 mL/min. The gradient program was as follows: 0 to 1 min, 5 to 5% B, 1 to 9 min, 5 to 40% B, 9 to 19 min, 40 to 90% B, 19 to 21 min, 90 to 100% B, 21 to 25 min, 100 to 100% B. The sample inject volume was 4 µl. During the whole experiment, all the samples were held at 4°C.

For mass spectrometry analysis, Waters Xevo G2-XS QTOF/MS with positive and negative electrospray ionization sources (ESI) was used (Waters Corporation, Manchester, UK). The data collection was controlled by the UNIFI informatics platform (Waters Corporation, Manchester, UK), and the data range was

50–1200 Da. Capillary voltages were at 2.5 and 2.2 kV in positive and negative modes, respectively. For positive mode and negative mode, the cone voltage was 40 V. The applied source temperature was 130°C. The desolvation gas flow was set to 800 L/h, and the desolvation temperature was 350°C. The high collision energy scan was set at a ramp energy scan from 10 to 55 eV, and the low collision energy scan was set at 4 eV. The scan time for each function was 0.20 s. Leucine enkephalin (100 pg/µl) was applied as the lock mass, generating reference ions in negative mode of 554.2610 and positive mode of m/z 556.2771, and introducing reference ions at 10 µl/min at by a lockspray for accurate mass acquisition.

## Multivariate Pattern Recognition Analysis and Identification of Biomarkers

UNIFI informatics platform was used to pre-process all data. Normalize the intensity of each ion in relation to the total number of ions to generate a data matrix consisting of normalized peak area, m/z value, and retention time (Wang et al., 2012). Then the data was introduced into (Umetrics, Umea, Sweden) software for principal component analysis (PCA) and orthogonal partial least squares-discriminant analysis (OPLS-DA) (Zhang et al., 2016; Huang et al., 2018). To screen variables that have a significant contribution to distinguishing potential biomarkers between the two groups (LPS vs Normal group or XLGB vs Normal group), only variables with  $|p(\text{corr})| \geq 0.5$  and VIP values  $> 1$  were chose and applied for further data analysis in the OPLS-DA model. Meanwhile, significant variables with p values  $< 0.05$  and folder changes  $> 2$  or  $< 0.5$  were considered potential biomarkers. Biochemical databases, HMDB (<http://www.hmdb.ca/>) and METLIN (<http://metlin.scripps.edu/>) were used to identify potential biomarkers. Metabolic pathway analysis was performed by the KEGG ([www.genome.jp/kegg/](http://www.genome.jp/kegg/)) pathway database, which was carried out using MetaboAnalyst 3.0 (<http://www.metaboanalyst.ca/>) in line with the pathway library of *Rattus norvegicus* (rat) (Wang et al., 2012).

## Correlation Analysis

Pearson's correlation coefficient is a statistical measure of the strength of the linear relationship between paired data (Han et al., 2018; Li et al., 2019). To quantify the association between two consecutive variables, correlation analysis, a common statistical method, was applied to analyze the relevance between concentrations of cytokines and the peak area values from the UPLC-Q-TOF/MS in this study. Then, Pearson's correlation coefficient was obtained and further used to explore important related metabolites.

## Statistical Analysis

One-way analysis of variance (ANOVA, Student's t-test) was used to assess the significant difference of potential biomarkers between groups (SPSS version 15.0; IBM: Chicago, IL, USA, 2006).  $P < 0.05$  was considered statistically significant, and  $P < 0.01$  was considered highly significant.

## RESULTS

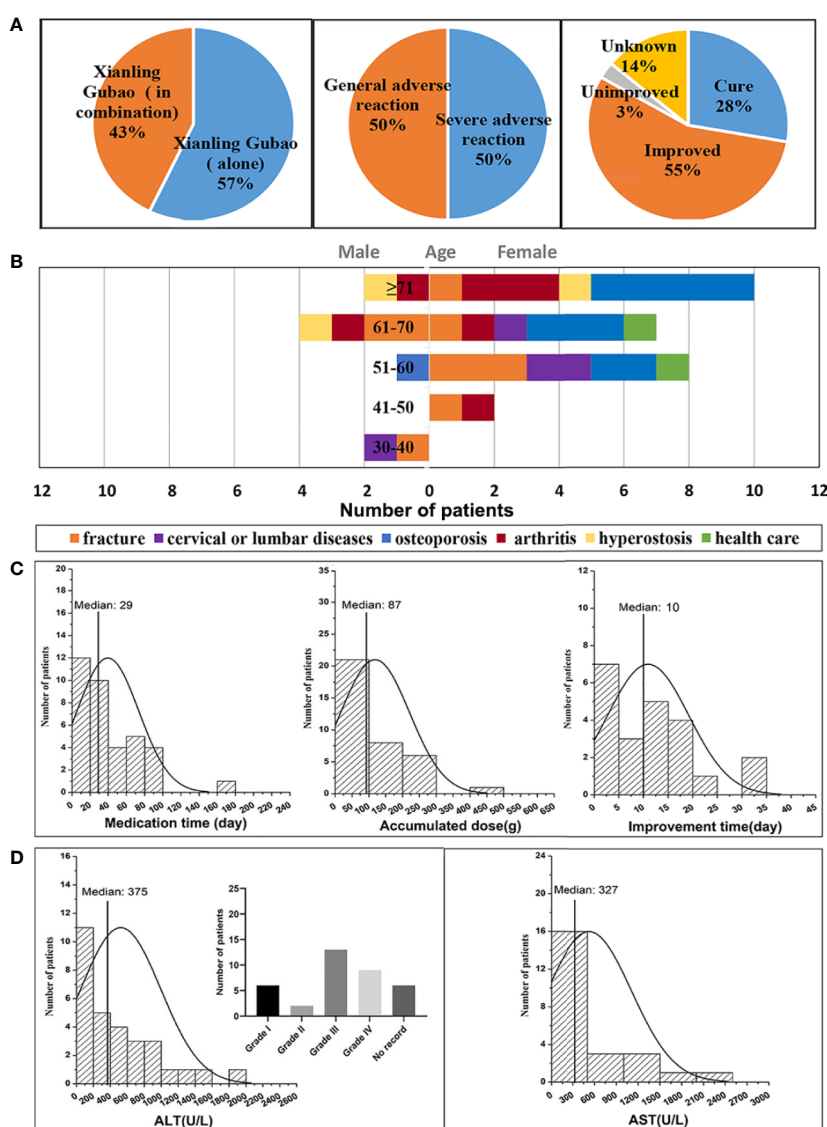

### Chemical Compositions Determination of XLGB

The chemical compositions of XLGB were determined by HPLC method. The representative HPLC chromatograms of mixed standards and XLGB were shown in **Supplementary Figures 1A, B**. The results showed that there was a roughly separation within different chromatographic peaks of XLGB. Eight major components in XLGB including Epimedin A, Epimedin B, Epimedin C, icariin, psoralen, angelicin, icarisid II and anhydroicaritin were determined and quantified, and the relative proportion of these compounds in the preparation is

0.058%, 0.015%, 0.012%, 0.373%, 0.155%, 0.056%, 0.058% and 4.937%, respectively.

### Clinical Features of XLGB-Induced Liver Injury

As shown in **Figure 1A**, of the 63 cases of XLGB-induced liver injury, 36 cases were treated with XLGB alone, and 27 cases were used in combination with diclofenac sodium, omeprazole, and cisapride. Since diclofenac sodium itself is prone to liver damage, in order to reveal the objective authenticity of XLGB-induced liver injury, it is necessary to rule out the effects of other combination drugs, and only 36 cases of XLGB alone are included in the next study. Serious adverse reactions occurred

**FIGURE 1 |** Analysis of clinical features of XLGB-induced liver injury **(A)** the incidence of XLGB-induced liver injury, drug compatibility, degree of adverse drug reaction, prognosis; **(B)** gender, age, and the purpose of medications; **(C)** Medication time, accumulated dose and improvement time; **(D)** biochemical indicators (ALT and AST).

in 50% of cases, and the general adverse reactions were the same. After treatment, most patients had a good prognosis, 55% of cases improved, 3% did not improve, the cure rate was 28%, and 14% of cases were unknown (**Figure 1A**).

The age distribution characteristics of liver injury cases indicated that the median age of onset was 64 years (range, 20–91 years), the ratio of males to females was 1:3.5, and the percentage is 6% in the 30–40 year-olds, 6% in the 41–50 year-olds, 25% in the 51–60 year-olds, 30% in the 5–60 year-olds, 33% in the more than 71 years old. Thus, the XLGB-induced liver injury was more common in women, and the peak age of which occurred at more than 71 years of age (**Figure 1B**). The purpose of XLGB medication included osteoporosis (30.6%), fracture (25%), arthritis (19.4%), cervical lumbar spondylosis (11.1%), hyperostosis (8.3%), and health care (5.6%), which were all in the scope of the instructions except health care (**Figure 1B**). As depicted in **Figure 1C**, the median duration of administration was 29 days. Obvious dose-to-toxic relationship was not observed between the duration of administration and the cumulative dosage. The median time of improvement after treatment drug or discontinuation was 10 days. Clinical

biochemical indicators can be found in **Figure 1D**, the median of the ALT and AST levels were 10 and 9 times greater than the upper limit of the normal range (**Figure 1D**). Moreover, the higher ratio of grade 3/4 liver enzyme elevation were observed in 22/36(ALT) of patients in accordance with National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) (Ahn et al., 2017).

## Liver Functional and Histologic Changes of XLGB

As shown in **Figures 2A, B**, compared with normal group, plasma ALT, and AST activities were not increased significantly by XLGB treatment alone ( $P > 0.05$ ). Likewise, LPS administration did not cause increase in ALT and AST activities ( $P > 0.05$ ). However, as marked by increased ALT and AST activities in plasma, liver injury from XLGB and LPS coexposure occurred in contrast with LPS group.

The results of histopathology displayed that no significant lesions were observed in the saline (control) and XLGB treatment groups. LPS-treated group showed evidence of mild leukocyte infiltration in portal area but no evident hepatocytes

**FIGURE 2 | (A, B)** Influence of co-treatment with LPS (2.8 mg/kg, i.v.) and XLGB (1.62 g/kg, i.g.) on plasma ALT and AST activities. **(C)** Representative microphotographs of liver sections isolated from rats. The arrows indicate multifocal midzonal necrosis of hepatocytes caused by co-treatment XLGB (1.62 g/kg, i.g.) and LPS (2.8 mg/kg, i.v.). HE staining ( $\times 200$ ).  $n = 10$ ,  $x \pm s$ .  $^{**}P < 0.01$  vs normal group or vs LPS group.

injury. However, When combined with LPS and XLGB, the severity of histologic changes was pronounced, such as multifocal midzonal necrosis of hepatocytes and many inflammatory cell infiltration (**Figure 2C**). These data suggested that the LPS-induced inflammation activation presumably plays a crucial part in the pathogenesis of XLGB IDILI.

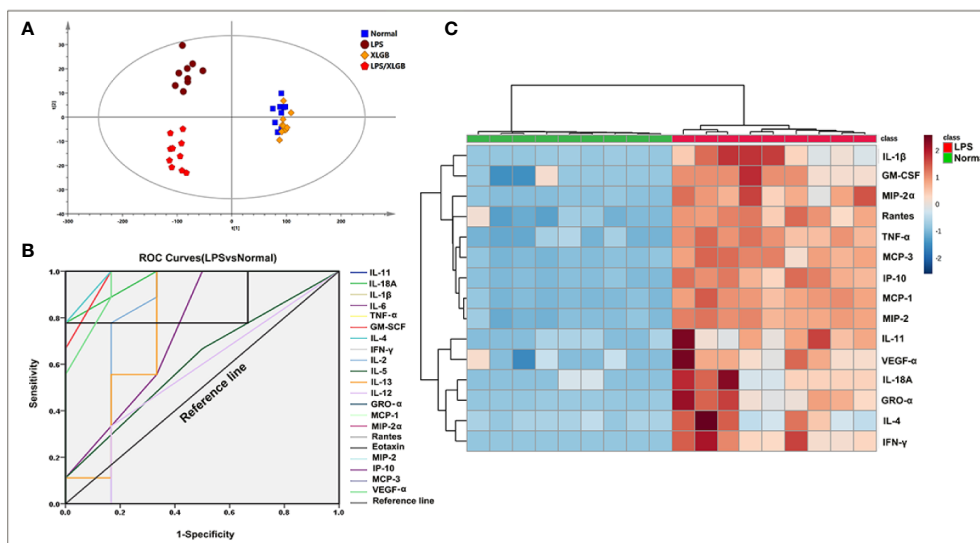

### Screening for Susceptibility-Related Cytokines of XLGB-Induced Liver Injury

To observe possible cytokine/chemokine profiles in the normal, LPS, XLGB, and LPS/XLGB groups, the PCA analysis was performed to visualize cytokines/chemokines differences between the above four groups (**Figure 3A**). The results indicated that the LPS group and LPS/XLGB group were able to significantly distinguished from the normal group and XLGB group. The susceptibility of XLGB-induced liver injury was therefore evident from the cytokine expression profiles. Next, The susceptibility-related cytokines of XLGB-induced liver injury were screened by a Receiver Operating Characteristic (ROC) Curve analysis (**Figure 3B**). Finally, MCP-1, IL-11, Rantes, IL-1 $\beta$ , IFN- $\gamma$ , GRO- $\alpha$ , MIP-2 $\alpha$ , IP-10, MCP-3, IL-4, MIP-2, GM-CSF, IL-18A, VEGF- $\alpha$ , and TNF- $\alpha$  were seen as potential factors (AUC > 0.9) (**Figure 3C**). Meanwhile, we performed cluster analysis of plasma-derived samples and cytokines and represented the result as a heat map. The results showed that there was a clear separation between the above two groups in line with cytokine expression profiles. The sample tree was divided into two clusters: cluster1: the normal group with relatively low (cold spots) cytokine expression; cluster 2: the LPS group with relatively high (hot spots) cytokine expression (**Figure 3C**).

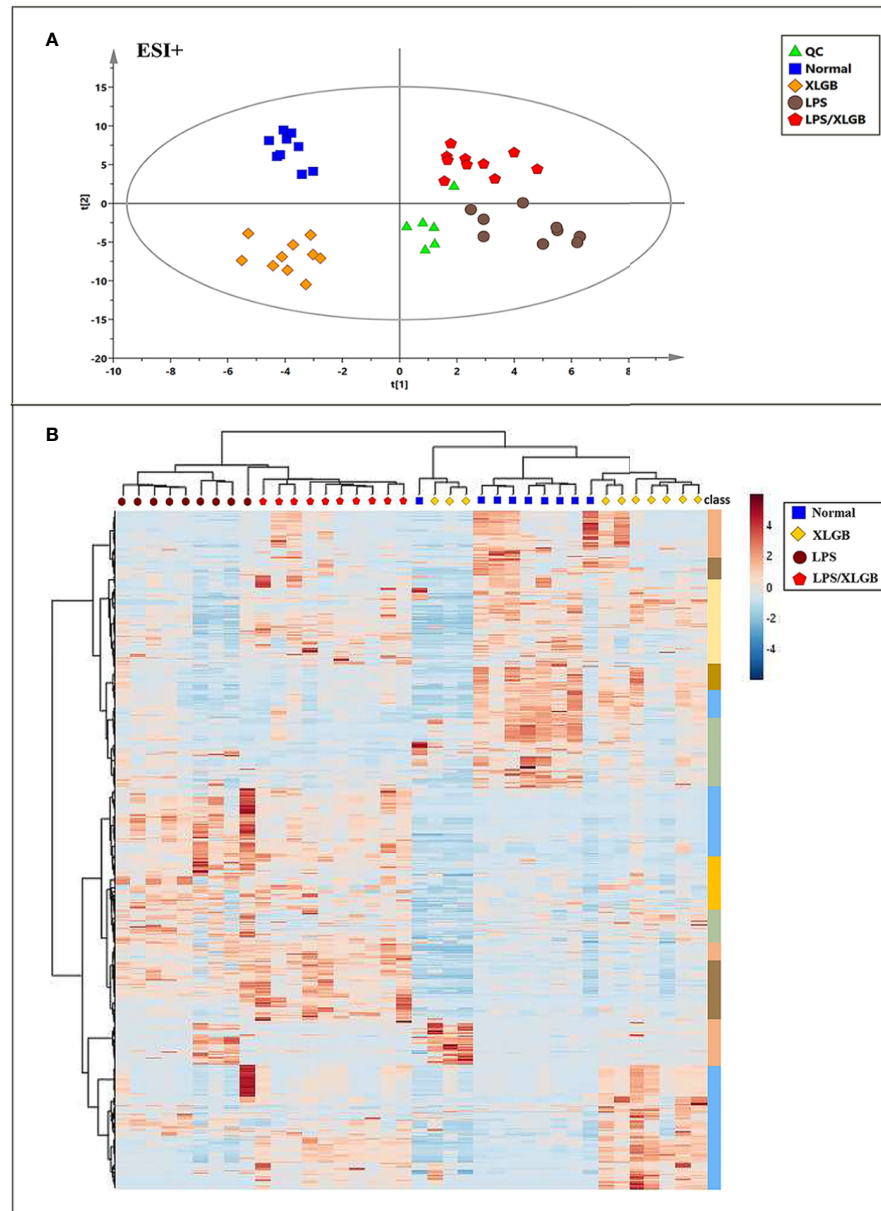

### Metabolomic Analysis of Plasma

The unsupervised PCA and supervised method OPLS-DA were performed in positive and negative ion modes. **Figure 4A** showed the score plots of PCA analysis in ESI+ mode. QC samples were chosen to assess the stability and accuracy of metabolomics methods because they contain a wide range of m/z values and chemical polarities. The RSD % results showed that the within-run precision, between-run precision and stability of m/z values, retention times, and peak areas were within the error range, respectively, which verified the feasibility of the method. In addition, QC samples clustered closely in PCA score plots indicating that the LC/MS system was stable throughout the experiment. Plasma samples from normal, LPS, XLGB, and XLGB/LPS groups could be divided into different blocks by PCA, which indicated that metabolic profiles vary greatly between the four groups. In addition, there was a clear separation between the normal group and the LPS group from PCA1, indicating that the metabolic environment was significantly affected by different physiological states. Similar results in ESI- were displayed in **Supplementary Figure 2A**. Moreover, as shown in **Figure 4B** and **Supplementary Figure 2D**, the four groups (normal, LPS, XLGB, and LPS/XLGB groups) in both ESI+ and ESI-modes could also be obviously distinguished by the clustering heatmaps based on these metabolites.

To further investigate the potential metabolites of the susceptibility-related XLGB-induced liver injury, OPLS-DA was applied to classify or discriminate analysis. As displayed in **Figure 5A**, and XLGB and normal groups can be clearly separated (in ESI+ mode) and showed a good predictive ability with a R<sup>2</sup><sub>Y</sub> (cum) of 0.981, R<sup>2</sup><sub>X</sub> (cum) of 0.764, and Q<sup>2</sup> (cum) of 0.523. Meanwhile, the LPS group could also be obviously

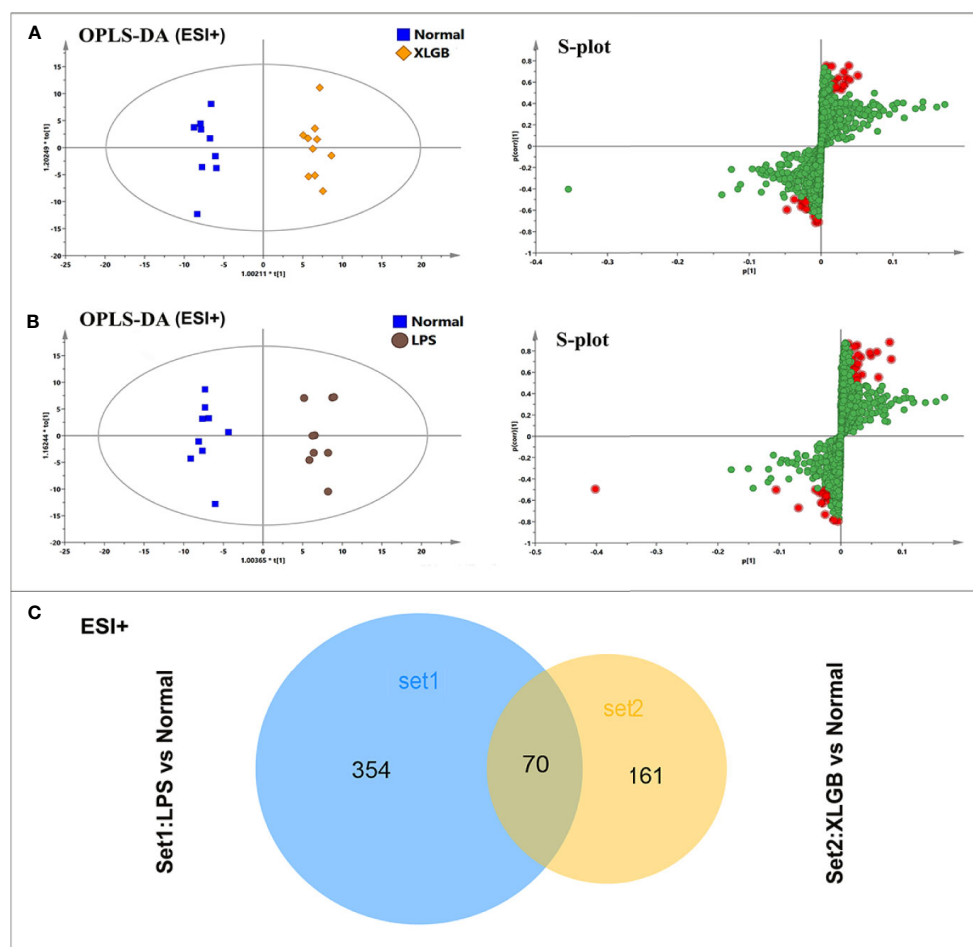

**FIGURE 3 |** Screening for susceptibility-related cytokines of XLGB-Induced liver injury. **(A)** principal component analysis (PCA) of plasma cytokines; **(B)** receiver operating characteristic (ROC) curves of susceptibility-related to cytokines (LPS group vs normal group); **(C)** cluster analysis of susceptibility-related to cytokines (ROC > 9); the heat map colours represent concentration of cytokines relative to the minimum and maximum of all values in this analysis.

**FIGURE 4 |** Metabolomic Profile Analysis of XLGB-induced liver injury. **(A)** PCA score plots of different groups in positive ESI mode; **(B)** cluster analysis of the 654 significantly changed ions among the normal, LPS, XLGB, and LPS/XLGB groups. The colors from blue to red indicate the relative contents of metabolites.

detached from normal group. The  $R^2Y$  (cum),  $R^2X$  (cum), and  $Q^2$  (cum) were 0.969, 0.73, and 0.576, respectively, indicating that the OPLS-DA model was reliable. The S-plots for LPS vs normal and XLGB vs normal are shown in **Figures 5A, B**. Data analysis of ESI- mode was also performed and described in **Supplementary Figures 3A, B**. Then, the variables with a  $|p(\text{corr})| \geq 0.5$ , VIP value  $> 1$ ,  $P < 0.05$  and fold change (FC)  $> 2$  or  $< 0.5$  were selected as the potential biomarkers for further analysis. Next, area-proportional 3-Venn diagrams have been used to analyze differences and similarities between differential

metabolites in two different groups. The results depicted that there were 424 (LPS vs normal) and 231 (XLGB vs normal) differential ions in two independent comparisons of the ESI+ mode (**Figure 5C**), while the above comparisons were 403 and 188 in the ESI- mode, respectively (**Supplementary Figure 3C**). Therefore, the results showed that 126 differential variables were affected by the synergistic effect of LPS and XLGB, not just the individual effects of XLGB or LPS, so they could be used as potential biomarkers related to susceptibility to XLGB IDILI.

**FIGURE 5 |** Analysis of potential biomarkers associated with susceptibility to XLGB-induced liver injury. OPLS-DA analysis of the data generated from the XLGB vs normal (A), LPS vs normal (B) in the ESI+ mode. S-score plots constructed from the supervised OPLS analysis, the axes that are plotted in the S-plot from the predictive component are  $p_1$  vs  $p(\text{corr})_1$ , representing the magnitude and reliability respectively. Metabolite ions with VIP value  $>1$  were marked with a red square. (C) The shared and unique numbers of metabolites were also visualized in Venn diagram from LPS vs normal and XLGB vs normal.

## Identification Potential Biomarkers and Enrichment Pathway

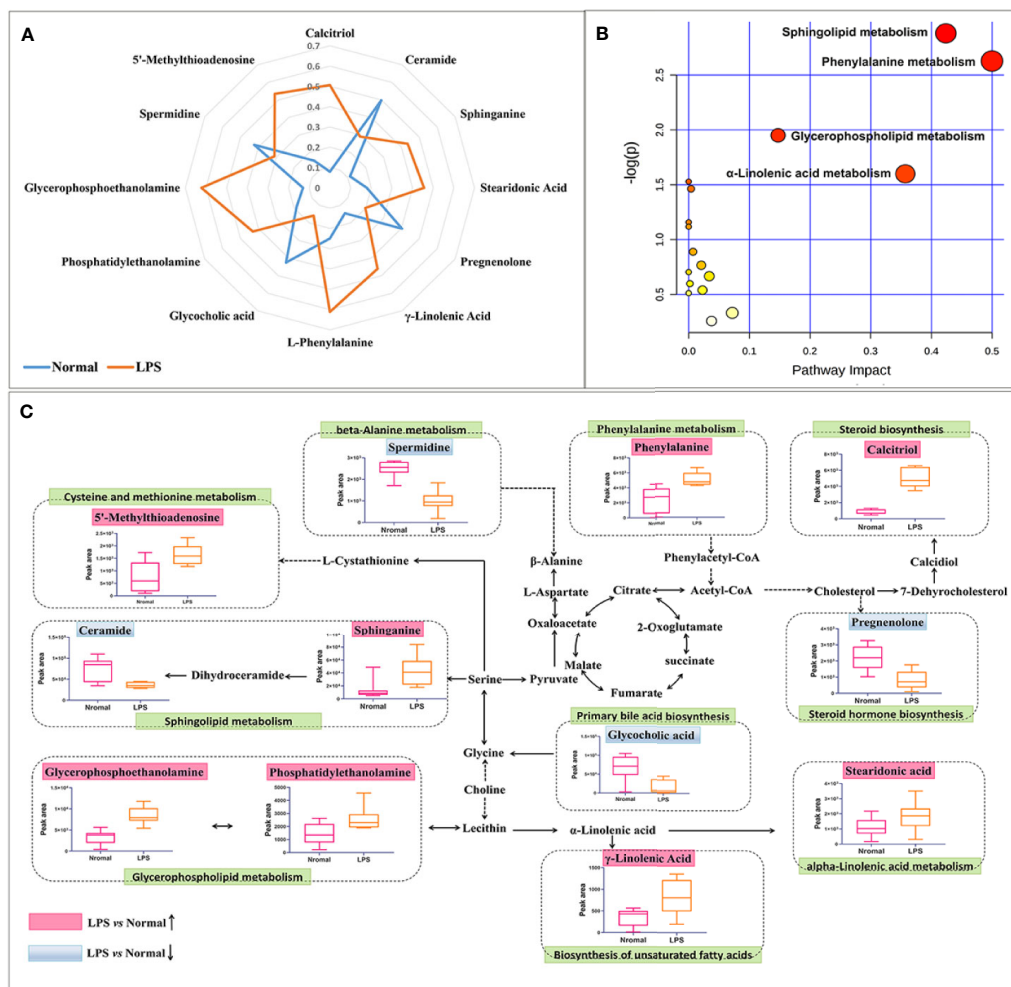

The acquired metabolites were combined and tentatively identified with the accurate mass charge ratio. Finally, 77 variables were considered candidates for potential biomarkers and then imported into MetaboAnalyst 3.0 and enriched in the KEGG pathway to further explore the metabolic pathways. Of these, 12 significant metabolites were obtained, including calcitriol, pregnenolone, spermidine, ceramide, sphinganine, glycerophosphoethanolamine, phenylalanine, phosphatidylethanolamine, stearidonic acid,  $\gamma$ -linolenic acid, glycocholic acid, 5'-methylthioadenosine (Supplementary Table 1). In order to more intuitively compare the metabolite differences between the LPS group and the normal group, a spider diagram of the differential metabolites was constructed based on their relative abundance (Figure 6A). The results showed that except for pregnenolone, spermidine, ceramide, and glycocholic acid, the expression of differential metabolites in the LPS group was notably higher than that in the normal group. A

schematic diagram of disturbed metabolic pathways was displayed in Figure 4B. Meanwhile, a complex network was constructed based on enriched metabolic pathways and the identified differential metabolites, which contributed to contrast the differences between the LPS group and the normal group in metabolic profiles (Figure 6C).

## Correlation Analysis of Susceptibility-Related Cytokines and Biomarkers

To further screen for susceptibility-related metabolites of XLGB-Induced liver Injury, correlation analysis was used to evaluate metabolite-cytokine relationships between area values of 12 metabolites and concentrations of 15 cytokines. From the results depicted in Figure 7, the correlation coefficients demonstrated that five metabolites, sphinganine, 5'-methylthioadenosine, calcitriol, phenylalanine, and glycerophosphoethanolamine were significantly positively correlated, while pregnenolone, spermidine, ceramide, and glycocholic acid were negatively correlated. Besides, there was no

**FIGURE 6 |** Overall metabolic profile. **(A)** spider plot of 12 metabolites of which the change in relative abundance best differentiated between the LPS group and normal group. Blue line represents normal group, orange line represents LPS group. **(B)** Schematic diagram of the disturbed metabolic pathways. **(C)** Network map of metabolic pathways and metabolites. The notations are as follows: (↑) in red, metabolite higher in the LPS-treated group than in the normal group; (↓) in blue, metabolite lower in the LPS-treated group than in the normal group. The related metabolic pathways are cycled in a green box.

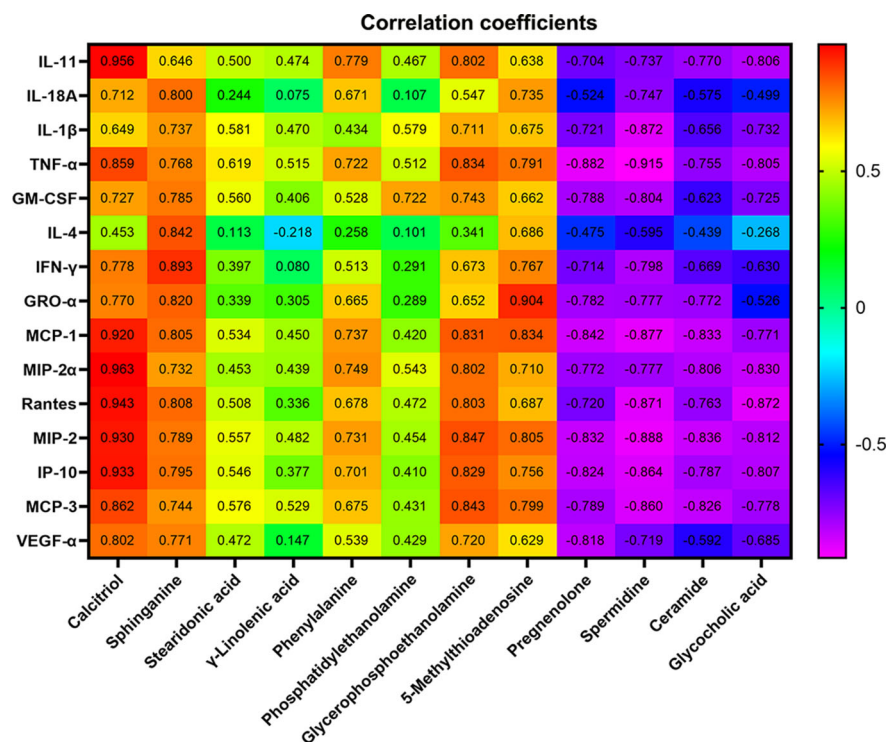

correlation between  $\gamma$ -linolenic acid and 15 cytokines ( $P > 0.05$ ). Compared with the normal group, the content of the five positively related metabolites increased significantly, while the content of the other four negatively related metabolites decreased. These data suggest that the change trend of the content is consistent with the positive and negative correlation of cytokines. In addition, sphinganine and 5'-methylthioadenosine were significantly correlated with 15 cytokines. Stearidonic acid and calcitriol were not correlated with 15 cytokines except for TNF- $\alpha$ . Specially, TNF- $\alpha$  was related to 9 metabolites except for phosphatidylethanolamine and  $\gamma$ -linolenic acid.

## DISCUSSION

IDILI is one type of drug-related adverse reaction, which is relatively rare but may be severe or even fatal in some cases

(Andrade et al., 2019). IDILI is determined by the interaction of environmental and host factors with the drug. As the significant individual differences and susceptibility of the liver to adverse drug reactions, it is still a formidable challenge to predict IDILI (Utrecht, 2019). Despite many cases of TCM-induced hepatotoxicity have been reported, preclinical studies have not revealed and predicted their hepatotoxicity in normal experimental animals. Therefore, it is speculated that the hepatotoxicity of TCM may belong to IDILI. Our study demonstrated that the ratio of XLGB-induced liver injury in all DILI cases was very low, only 0.06% (36 in 55388), and not dose- or time-dependent by virtue of the retrospective statistics of DILI cases in the National Adverse Drug Reaction (ADR) Monitoring Database (2012–2016). Moreover, all patients took the drugs according to the instructions, and there was no overdose. Thus, XLGB-induced liver injury might be IDILI.

**FIGURE 7 |** Pearson correlation coefficient of 12 metabolites and concentrations of 15 cytokines.  $P > 0.05$  or  $P > 0.01$  (the correlation coefficient  $> 0.6$ ).

Currently, combined treatment of rats with endotoxin (LPS) and a model drug related to drug idiosyncrasy inpatients, led to severe hepatotoxicity in toxicological experiment assessment (Ramm et al., 2015). This model has been applied to assess IDILI of some drugs, including trovafloxacin, pyrrolizidine alkaloids, ranitidine, nefazodone, nimesulide, clarithromycin, and telithromycin successfully (Tukov et al., 2007; Guo et al., 2013; Hammad et al., 2013). In our previous work, *Polygoni multiflora radix* (*Reynoutria multiflora* (Thunb.) Moldenke), *Epimedium folium* (*Epimedium brevicornu* Maxim.), and *Psoraleae fructus* (*Cullen corylifolium* (L.) Medik.) could induce acute liver injury in the LPS rats, suggesting that this model could evaluate the susceptibility of the liver to hepatotoxic chemicals from TCM (Li et al., 2015). In this study, we found that a single administration of XLGB or LPS did not develop a significant liver injury phenotype, but co-administration of XLGB with LPS to rats resulted in an increase in the plasma ALT and AST levels and the severity of histologic changes. Additionally, LPS led to a slight infiltration of inflammatory cells in portal area and upregulation of cytokines such as IL-11, GRO-α, IL-1β, MCP-3, IFN-γ, MCP-1, Rantes, MIP-2, IL-4, GM-CSF, IP-10, MIP-2α, IL-18A, VEGF-α, and TNF-α. Given the effect of cytokines in regulating inflammatory responses, changes in cytokine expression modes may be as potential biomarkers for DILI (Lavery et al., 2010). During the exploration of the LPS/Trovafloxacin model, neutrophil recruitment and activation, and increased cytokines such as IL-18, IFN-γ, and PAI-1 played an important role in the

pathogenesis of liver damage (Shaw et al., 2009). LPS alone led to an obvious increase in the levels of IL-1, IL-6, TNF-α, CINC-1, which were remarkably amplified by co-administration with diclofenac and closely related to the observed liver injury (Ramm et al., 2015). Inflammatory stress has the potential to interact with co-exposure drug treatment and might be a susceptibility factor participated in the mechanism of IDILI (Shaw et al., 2010). As far as XLGB is concerned, a lot of patients have inflammatory-related diseases, including osteoarthritis and rheumatoid arthritis. This result is consistent with diclofenac, which is well known to induce IDILI (Kishida et al., 2012). In addition, our previous epidemiological investigations have shown that many patients with immune or inflammation-related diseases such as osteoarthritis, psoriasis, and systemic lupus are prone to cause liver injury after taking *Polygoni multiflora radix* (*Reynoutria multiflora* (Thunb.) Moldenke) (Zhu et al., 2016a). Accordingly, inflammatory mediators evoked by concurrent LPS exposure should alter liver homeostasis to provide the cells more susceptible to toxic chemicals in XLGB.

Inflammation is not only a physiological response to harmful stimuli but also an important factor to the pathogenesis of various metabolic disorders (Kim et al., 2017). As shown in **Figure 6B**, 12 significant metabolites accountable for class discrimination were enriched into 10 metabolic pathways. Sphingolipid metabolism, phenylalanine metabolism, and glycerophospholipid metabolism are the top 3 important pathway. Emerging experimental evidence suggests that sphingolipids can be intimately involved in

inflammation (Sakamoto et al., 2019). It has been reported that LPS can increase the levels of sphinganine in serum, indicating that LPS induces the release of TNF- $\alpha$  and IL-1 $\beta$ , thereby activating a variable sphingosine kinase (Jang et al., 2007). As a second messenger molecule of sphingolipids, ceramide also acts as a systemic mediator of inflammation (Lightle et al., 2003). The production of ceramide in the liver increased the secretion of cytokines such as IL-6, TNF- $\alpha$ , and IL-1 $\beta$ , which should contribute to enhancing inflammatory responses in metabolic diseases (Schilling et al., 2013). Ceramide synthase catalyzes the N-transacylation of sphinganine to form dihydroceramides and then to ceramide in the *de novo* sphingolipid biosynthesis pathway (Tolleson et al., 1999). In the present study, the results demonstrated that sphinganine levels increased and ceramide decreased after LPS-treatment. Therefore, the concentration of sphinganine decreased in LPS group may be relevant to sphingosine accumulation. Glycerophospholipids and sphingolipids are structural units of biological membranes and act as bioactive mediators and signaling molecules in inflammation process (Dang et al., 2016). Glycerophosphoethanolamine (PE) is an important lipid marker of inflammation in glycerophospholipid metabolism. Increased concentrations of PE was detected in systemic circulation of Nonalcoholic steatohepatitis patients (Anjani et al., 2015). Inflammation is characterized by elevated plasma levels of PE and elevated proinflammatory cytokines IL-6, MCP-1, IL-8, and TNF- $\alpha$  (Ruiz et al., 2015). The results revealed that LPS dramatically altered numerous metabolic pathways that were associated with inflammatory response, immune modulation, and nutrient metabolism, which all may play a crucial part in the susceptibility of XLGB-induced liver injury.

At present, the hepatotoxic chemicals attributed to XLGB-induced liver injury are not still clarified. *Epimedium folium* (*Epimedium brevicornu* Maxim.) and *Psoraleae fructus* (*Cullen corylifolium* (L.) Medik.) could amplify inflammation cytokines such as TNF- $\alpha$ , IL-6, and IL-1 $\beta$  individually or in combination, resulting in liver injury in the LPS rat model (Gao et al., 2020). These two herbs are also contained in XLGB. Whether they are the main hepatotoxic drugs for XLGB-induced liver damage needs further study.

However, there are some limitations in this experiment. Although factors and biomarkers related to XLGB susceptibility have been explored, they still need to be validated and systematically clarified in the clinic. Additionally, the importance of mild immune stress should be validated through immunodeficiency animal models. The material basis of XLGB

IDILI and its related biological mechanisms are also required for further illumination.

## DATA AVAILABILITY STATEMENT

All datasets generated for this study are included in the article/**Supplementary Material**.

## ETHICS STATEMENT

The animal study was reviewed and approved by: All procedures on animals and their care complied with the Guiding Principles for the Care and Use of Laboratory Animals of China and Institutional Animal Care and Use Committee of 302 hospital of PLA. Fifth Medical Center of Chinese PLA General Hospital (formerly named as 302 hospital of PLA).

## AUTHOR CONTRIBUTIONS

C-yL and MN performed the experiments, analyzed the data and wrote the manuscript. Y-IL, J-ft, and WC, and collected and prepared samples. GQ, M-yZ, and Y-fS performed the analyses. J-zL, X-jL, and R-sL amended the paper. X-hX, G-hL, and J-bW designed the study and amended the paper.

## FUNDING

This research is supported by the National Key R&D Program of China (No. 2018YFC1707000), the National Natural Science Foundation of China (Nos. 81630100, 81721002, and 81503350), CAMS Innovation Fund for Medical Sciences (CIFMS) (Grant no. 2016-I2M-1-001) and Beijing Nova Program (No. Z171100001117114).

*Anemarrhena asphodeloides* Bunge is a famous Chinese Materia Medica and has been used in traditional Chinese medicine for more than two thousand years. Steroidal saponins are important active components isolated from *A. asphodeloides* Bunge. Among which, the accumulation of numerous experimental studies involved in Timosaponin AIII (Timo AIII) draws our attention in the recent decades. In this review, we searched all the scientific literatures using the key word “timosaponin AIII” in the PubMed database update to March 2020. We comprehensively summarized the pharmacological activity, pharmacokinetics, and toxicity of Timo AIII. We found that Timo AIII presents multiple-pharmacological activities, such as anti-cancer, anti-neuronal disorders, anti-inflammation, anti-coagulant, and so on. And the anti-cancer effect of Timo AIII in various cancers, especially hepatocellular cancer and breast cancer, is supposed as its most potential activity. The anti-inflammatory activity of Timo AIII is also beneficial to many diseases. Moreover, VEGFR, X-linked inhibitor of apoptosis protein (XIAP), B-cell-specific Moloney murine leukemia virus integration site 1 (BMI1), thromboxane (Tx) A2 receptor, mTOR, NF-κB, COX-2, MMPs, acetylcholinesterase (AChE), and so on are identified as the crucial pharmacological targets of Timo AIII. Furthermore, the hepatotoxicity of Timo AIII was most concerned, and the pharmacokinetics and toxicity of Timo AIII need further studies in diverse animal models. In conclusion, Timo AIII is potent as a compound or leading compound for further drug development while still needs in-depth studies.

**Keywords:** Timosaponin AIII, autophagy, apoptosis, angiogenesis, inflammation

## INTRODUCTION

Timosaponin AIII (Timo AIII, IUPAC name: (2*S*,3*R*,4*S*,5*S*,6*R*)-2-[(2*R*,3*R*,4*S*,5*R*,6*R*)-4,5-dihydroxy-6-(hydroxymethyl)-2-[(1*R*,2*S*,4*S*,5'*S*,6*R*,7*S*,8*R*,9*S*,12*S*,13*S*,16*S*,18*R*)-5',7,9,13-tetramethylspiro[5-oxapentacyclo[10.8.0.0<sup>2,9</sup>.0<sup>4,8</sup>.0<sup>13,18</sup>]icosane-6,2'-oxane]-16-yl]oxyoxan-3-yl]oxy-6-(hydroxymethyl)oxane-3,4,5-triol, CAS no: 41059-79-4) is a natural steroidal saponin with multiple-pharmacological activities, and it is primarily isolated from Chinese Materia Medica *Anemarrhena asphodeloides* Bunge (well-known as Zhimu in Chinese) (**Figure 1**) which has been used for treatment various diseases including arthralgia, hematochezia, cough, hemoptysis, and so on, in traditional Chinese medicine (Wang et al., 2014). Phytochemistry studies have identified more than 100 compounds from *A. asphodeloides* Bunge, and the main constituents are steroidal saponins, flavonoids, phenylpropanoids, alkaloids, steroids, organic acids, anthraquinones, and so on (Wang et al., 2014). The total saponins, which are rich in rhizome, could be extracted by hot water under reflux and purified by EtOAc, n-BuOH, and H<sub>2</sub>O, and the content of saponins is more than 6% (Wang et al., 2014; Yang et al., 2016; Nian et al., 2017). Timo AIII, Timosaponin BII (Timo BII) and sarsasapogenin are three main active saponins isolated from *A. asphodeloides* Bunge (**Figure 1**), and they have been identified as quality control and pharmacokinetic markers of diverse *A. asphodeloides* Bunge-contained Chinese herb formulas, such as TongGuanWan, Rhizoma Anemarrhenae-Phellodendron herb pair, guizhi-shaoyao-zhimu herb pair, zhimu-baihe herb pair, and so on (Tang et al., 2012; Wang et al., 2014; Tang et al., 2015; Yang et al., 2018). The biotransformation of Timo AIII from Timo BII could be mediated by  $\beta$ -D-glycosidase (Lu et al., 2016). Lu et al. also developed an enzyme associated five-step preparation method to produce high yield and purity Timo AIII from *A. asphodeloides* Bunge, which allowed us obtain efficient amount of Timo AIII for further study and product development (Lu et al., 2016). Although Timo AIII and Timo BII are mainly metabolized to sarsasapogenin *in vivo*, the sugar chain plays important roles in their pharmacological activities (Sy et al., 2008; Lee et al., 2010; Wang et al., 2010). The sugar chain in Timo AIII is indispensable to its pharmacological activities, and conversion of Timo BII to Timo AIII enhanced its cytotoxicity (King et al., 2009). So, Timo AIII presented most potential anti-cancer activity due to its specific sugar chain binding site. However, the hydrophobicity and low

bioavailability of Timo AIII limited its efficacy *in vivo*, and many studies also focused on derivatization or drug delivery system design based on Timo AIII (Wang et al., 2010; Hu et al., 2011; Kim et al., 2014; Lu et al., 2018).

Timo AIII affected different numerous cellular signaling pathways and presented efficacy in different cell types and various disease models both *in vitro* and *in vivo*, such as cancer, Alzheimer's disease, depression, diabetic mellitus, colitis, and so on. Timo AIII dramatically inhibited the cancer cell growth at micromole level of concentration and selectively reduced the cancer cell viability but not normal cell (King et al., 2009). Thus, Timo AIII was proposed as a potent anti-cancer agent, and its anti-cancer activity and underlying mechanisms were most investigated in the previous studies (Han et al., 2018). In this review, we comprehensively summarized the pharmacological activity, pharmacokinetics, and toxicity of Timo AIII according to the literatures in the recent decades. And this review provides an overview of the previous research related to Timo AIII, which is benefit for its further study and drug development.

## PHARMACOLOGICAL ACTIVITIES OF TIMO AIII

### Cancer Cytotoxicity

Timo AIII and Timo BII are two well-known steroidal saponins in *Anemarrhena asphodeloides* Bunge while Timo BII presented less cytotoxic effect than Timo AIII in cancer cells (King et al., 2009). Induction of tumor cell death by cytotoxicity agent is the important mechanism of current cancer chemotherapy (Wang et al., 2013). Selectively kill cancer cell, regardless of normal cell, is the basic principle in cytotoxic anti-cancer drug development. Timo AIII could cause cell death in cancer cell but not in normal cell in the certain concentration (King et al., 2009; Wang et al., 2013; Zhou et al., 2020). In addition, previous studies indicated that Timo AIII presented cytotoxicity effects in various kinds of cancer cells including breast cancer, hepatocellular cancer, cervical cancer, colon cancer, nasopharyngeal cancer, pancreatic cancer, lung cancer, renal cancer, chronic myelogenous leukemia, ovarian carcinoma, osteosarcoma, leukemia, melanoma, and so on. The detection methods and corresponding concentrations which presented cytotoxicity effect and/or IC<sub>50</sub> in cancer and normal cell lines were summarized in **Tables 1** and **2**. And the anti-cancer effects and underlying mechanisms of Timo AIII were most studied in breast cancer and hepatocellular cancer. However, only a small part of studies employed a positive control when evaluating the cytotoxicity of Timo AIII in their studies (**Tables 1** and **2**). These results also indicated that the cytotoxic effect of Timo AIII to both cancer and normal cells were not all the same in the different contexts. In addition, the dosage of Timo AIII examined in animal models including mice, rat, and zebrafish were listed in **Table 3**.

**Abbreviations:** AChE, acetylcholinesterase; AMPK, 5' AMP-activated protein kinase; BCRP, breast cancer resistance protein; BMI1, B-cell-specific Moloney murine leukemia virus integration site; CDK, cyclin-dependent kinase; COX-2, Cyclooxygenase-2; IAP, inhibitor of apoptosis protein; ISVs, intersegmental vessels; MDR1, multi-drug resistance protein 1; MMP, matrix metalloproteinase; MRP1, MDR-associated protein 1; PARP, poly-(ADP ribose) polymerase; PCA, passive cutaneous anaphylaxis; PCNA, proliferating cell nuclear antigen; PRC1, polycomb repressive complex 1; SIVs, subintestinal vessels SIVs; SMC1, structural maintenance of chromosomes protein 1; TORC1 target of rapamycin complex 1; VEGFR, vascular endothelial growth factor receptor; XIAP, X-linked inhibitor of apoptosis protein.

### Promotion of Cell Apoptosis and Cell Cycle Arrest

Induction of cell apoptosis and cell cycle arrest, which stops cancer cell proliferation and causes cell death, is the current main strategy in cancer treatment. The anti-cancer effect of Timo AIII was firstly reported ten years ago in 2008 by Sy et al. They identified that prolong treatment Timo AIII increased cytochrome c release and caspase activation in HeLa cells, and this pro-apoptosis effect of Timo AIII was mediated by over production of ROS and mitochondrial dysfunction (Sy et al., 2008). However, the anti-cancer effects of Timo AIII were most studied in breast cancer and hepatocellular cancer in the past decades. King et al. found that Timo AIII promoted breast cancer cell BT474, MDAMB231 and MCF10A apoptosis in a concentration-dependent manner, and the underlying mechanisms was co-related with target of rapamycin complex 1 (TORC1) inhibition and endoplasmic reticulum (ER) stress stimulated-apoptosis as well as the inhibition of major cell proliferation signaling transduction pathways (King et al., 2009). In the research field of hepatocellular cancer, Wang et al. found that Timo AIII enhanced the apoptosis cell population by activation of poly-ADP ribose polymerase (PARP) and caspase 3, and Z-VAD-FMK which is a cellular apoptosis inhibitor suppressed Timo AIII-induced cytotoxicity in human hepatocellular cancer cell lines including HepG2, MHCC97L, PLC/PRF/5 and Hep3B (Wang et al., 2013). And Timo AIII induced tumor cell apoptosis and increased cleavage

PARP and caspase 3 expression in xenografted tumor mice model (Wang et al., 2013). In addition, Wang et al. proved that Timo AIII reduced the expression of X-linked inhibitor of apoptosis protein (XIAP), which is one of the inhibitor of apoptosis proteins (IAP), in both hepatocellular cancer cells *in vitro* and *in vivo*, and suppression of XIAP by siRNA reduced the toxic sensitivity of Timo AIII in hepatocellular cancer cells (Wang et al., 2013). These results indicated that Timo AIII reduced the tumor growth by modulation of XIAP-mediated cellular caspase active apoptosis in hepatocellular cancer. Moreover, Kyoung et al. found that the anti-cancer effect of Timo AIII was most effective in HepG 2 liver cancer cell among MDA-MB-231 breast cancer cell, A549 no-small-cell lung cancer cell and Hep3B liver cancer cell (Nho et al., 2016). Timo AIII induced more than 90% cell apoptosis on the concentration of 15  $\mu$ M, and the IC<sub>50</sub> (24h) was 15.41  $\mu$ M in HepG2 cell. And Timo AIII-promoted cell apoptosis was associated with the decreased expression of Bcl-2, Mcl-1 and IAP family, and the increased release of cytochrome c and activities of caspase family including caspase 3, 7, 8, and 9 (Nho et al., 2016).

In addition, Timo AIII also presented efficacy in colon cancer, pancreatic cancer, lung cancer, osteosarcoma, melanoma, and leukemia. In colon cancer, human colon cancer HCT-15 cells treated various concentrations of Timo AIII for 12 or 24 h appeared different degree of G<sub>0</sub>/G<sub>1</sub> and G<sub>2</sub>/M phase cell cycle arrest, and the cell cycle regulation effect of

**TABLE 1 |** The cytotoxicity effects of Timo AIII in different cancer cell lines.

Cell line	Species	Category	Detection method	Tested concentration or IC50	Positive control	Reference
<b>BT474</b>	Human	Breast cancer	Annexin-PI staining	1–10 $\mu$ M (24 h) and IC50 < 2.5 $\mu$ M(24 h)	None	(Kang et al., 2011)
<b>MDA-MB-231</b>	Human	Breast cancer	Annexin-PI staining	1–10 $\mu$ M (24 h)	None	(Kang et al., 2011)

Timo AIII was associated with the down-regulation of cyclin A, cyclin B1, CDK2, CDK4, pRb, proliferating cell nuclear antigen (PCNA) and c-Myc (Kang et al., 2011). Moreover, Timo AIII promoted cell apoptosis by induction of DNA fragmentation, activation of caspases, induction of cleaved-PARP and reduction of Bcl-xL and Bcl-2 expression in HCT-15 cells *in vitro*. In line with this results, Timo AIII significantly decreased the tumor volume in HCT-15 cell-bearing athymic nude mice *in vivo* (Kang et al., 2011). In melanoma, Timo AIII arrested the cell cycle at G<sub>0</sub>/G<sub>1</sub> phase and enhanced the cell apoptosis by

up-regulation of cleavage-caspase 3 expression in human melanoma A375-S2 cells (Wang et al., 2017). And Timo AIII enhanced the expression of iNOS which resulted in the elevated release of NO, and Timo AIII-induced cleavage of caspase 3 was attenuated by iNOS inhibitors DTT and 1400W in A375-S2 cells. Timo AIII increased the expression of JNK and ERK, and their inhibitors enhanced Timo AIII-induced cell death but decreased cleavage-caspase 3 expression in A375-S2 cells (Wang et al., 2017). Thus, JNK and ERK seem play protective roles in the Timo AIII-induced cell death. In

dpf, day post fertilization; ICR, Institute of Cancer Research.

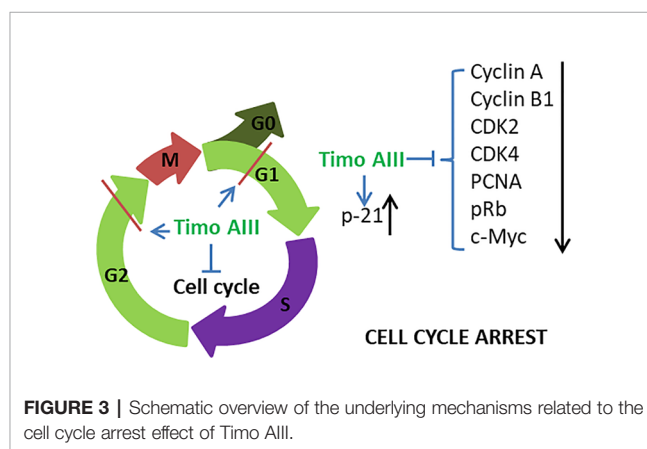

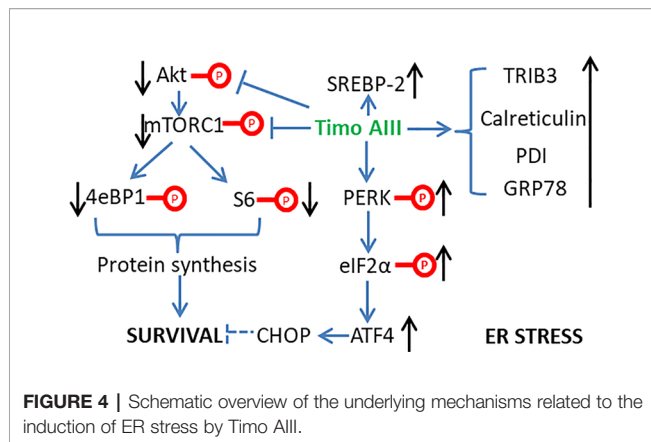

pancreatic cancer, Kim et al. demonstrated that Timo AIII increased the number of apoptotic cells which accompanied with the reduction of mRNA expression of anti-apoptosis proteins survivin, Bcl-2 and Bcl-xl, and Timo AIII elevated cell cycle distribution at sub-G1 phase which might result from the down-regulation of cell cycle regulators cyclin-D and upregulation of cyclin-dependent inhibitor p21 in human pancreatic cancer cell AsPC-1 (Kim et al., 2019b). And combination commercial available anti-cancer drug dasatinib, which is a Src inhibitor, with Timo AIII enhanced the pro-apoptosis effect by regulation of PARP and caspase 3 expressions in AsPC-1 cells (Kim et al., 2019b). Interestingly, Timo AIII enhanced the ERK/Src phosphorylation at low concentration while decreased both the amount of phosphorylated and total protein at high concentration (Kim et al., 2019b), which revealed that high concentration of Timo AIII mainly resulted in cell death. Timo AIII also inhibited the tumor growth by activation of caspase-3 which stimulated cellular apoptosis on pancreatic cancer PANC-1 cell-xenograft nude mice model (Pan et al., 2013). In osteosarcoma and lung cancer, Timo AIII significantly induced cell apoptosis by regulation of caspase 3, caspase 7 and PARP expressions in MG63 human osteosarcoma cells (Jung and Lee, 2019), and induced cell apoptosis and cell cycle arrest at G<sub>0</sub>/G<sub>1</sub> phase in human no-small-cell lung cancer cell A549 (Jung et al., 2016). Timo AIII also concentration-dependently induced cell apoptosis by upregulation of Bax and down regulation of Bcl-2 in T-cell acute lymphoblastic leukemia Jurkat cells (Wang et al., 2019).

Thus, we could conclude that the anti-cancer efficacy of Timo AIII was well studied, especially hepatocellular cancer and breast cancer, and the mainly underlying mechanism was induction of cell apoptosis (Figure 2) and cell cycle arrest (Figure 3). In addition, the XIAP might be potential pharmacological target of Timo AIII.

### Induction of ER Stress, ROS Generation, and Mitochondrial Dysfunction

Normal endoplasmic reticulum (ER) function is essential for maintaining the cellular homeostasis, and ER stress presents in cancer cells due to its nutrient limitative and hypoxic tumor micro-environment (Cubillos-Ruiz et al., 2017). However, chronic ER stress stimulated activation of cellular apoptosis pathways which could result in cancer cell death, and the anti-cancer effects of various natural products were resulted from the induction of intracellular ER stress (Kim and Kim, 2018). King et al. found that Timo AIII time-dependently enhanced the ER stress by up-regulating the protein levels of PDI, calreticulin, GRP78, ATF4, and TRIB3 and the phosphorylation levels of eIF2 $\alpha$  and PERK, which are ER stress markers (King et al., 2009). And Timo AIII also enhanced the genes expression in cholesterol biosynthesis pathways in breast cancer cell BT474, MDAMB231 and MCF10A. However, the total cholesterol levels were not changed and the cholesterol biosynthesis regulator SREBP-2 was significantly activated in Timo AIII treated cell (King et al.,

2009). Thus, the cell death induced by Timo AIII was not due to the biosynthesis of cholesterol, and the regulation of cholesterol biosynthesis by Timo AIII supported its ER stress induction activity (Figure 4).

Mitochondria regulates many cellular physical functions including energy metabolism, reactive oxidant species (ROS) generation and apoptosis, and Chiu et al. claimed that mitochondria played a central role in cancer development and suggested that mitochondria-targeted therapeutic approach was valuable in cancer (Chiu et al., 2020). Kyoung et al. found that Timo AIII dramatically induced apoptosis in HepG2 cells, which might be co-related to the translocation of Smac/Diablo and HtrA2/Omi from cytosol to mitochondria consequently triggered cell apoptosis (Nho et al., 2016). ROS could be either cause or result of mitochondria dysfunction which promotes disruption of intracellular homeostasis and cancer cell death (Kudryavtseva et al., 2016; Park et al., 2019; Zhou J. et al., 2019). Timo AIII induced intracellular ROS accumulation which could be cleared by anti-oxidant NAC and might be an important cause of cell death in triple negative breast cancer cell MDA-MB-231 (Tsai et al., 2013). Consistently, Timo AIII concentration-dependently increased the intracellular ROS and anti-oxidant enzymes including SOD and catalase in HeLa cells, which indicated that Timo AIII impaired intracellular redox homeostasis (Sy et al., 2008). In addition, Timo AIII destroyed mitochondrial membrane potential, mitochondrial permeability transition, and release of cytochrome c, and the mitochondria was the main sources of ROS-induced by Timo AIII in HeLa cells (Sy et al., 2008). So, targeting ROS production and mitochondria dysfunction might be essential mechanisms for Timo AIII-caused cancer cell death (Figure 2).

### Anti-Angiogenesis

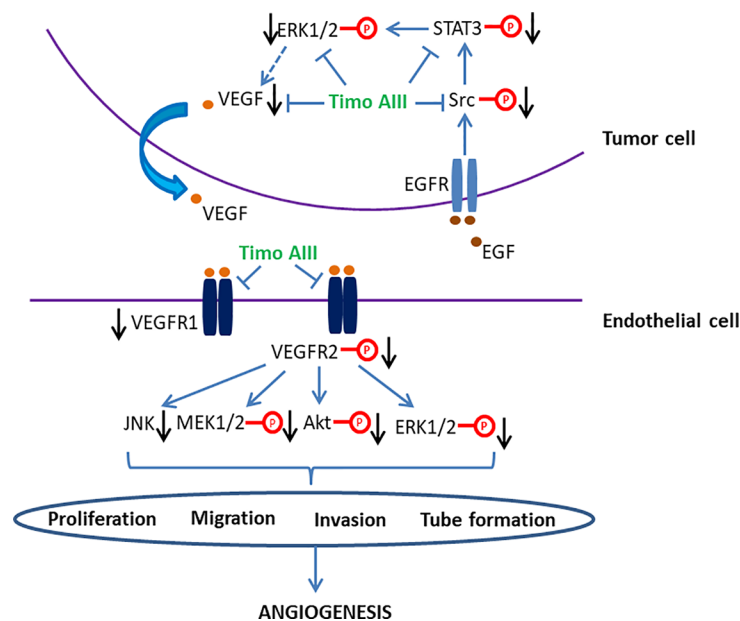

Tumor angiogenesis, which is triggered by tumor-secreted angiogenic factors, transports nutrient to tumor and promotes tumor growth and metastasis. Targeting tumor angiogenesis and vascular normalization have been a promising anti-cancer drug development strategy, and several agents have been developed (Viallard and Larrivee, 2017; Jaszi and Schmidt, 2019). The anti-tumor effect of Timo AIII on pancreatic cancer cell PANC-1 bearing nude mice model was co-related to the down-regulation

of mRNA and protein levels of the angiogenic factor VEGF (Pan et al., 2013). Timo AIII inhibited the mRNA expression of VEGF-1, and suppressed the EGF-triggered Src/STAT3/ERK signaling pathway activation in a concentration-dependent manner in pancreatic cancer cell AsPC-1 (Kim et al., 2019b). Zebrafish and vascular endothelial cell have been considered as the well-known *in vivo* and *in vitro* models for anti-angiogenesis activity evaluation with the advantages of low cost, time saving, and easy observation (Norrby, 2006; Delvecchio et al., 2011). Zhou et al. found that Timo AIII presented anti-angiogenesis effect in zebrafish *in vivo* and human umbilical vein endothelial cells (HUVECs) *in vitro* (Zhou et al., 2020). Timo AIII inhibited the intersegmental vessels (ISVs) and sub-intestinal vessels (SIVs) growth in transgenic zebrafish line Tg(Fli-1: EGFP)<sup>y1</sup> which expressed enhanced green fluorescence protein (EGFP) in vascular endothelial cells. Timo AIII also inhibited the endothelial cell proliferation, migration, invasion, and tube formation in HUVECs. And the underlying mechanism might be closely related to the down-regulation of VEGFRs and suppression of VEGF/PI3K/Akt/MAPK signaling pathway. So, the anti-tumor angiogenesis effect of Timo AIII also contributes to its anti-cancer capability, and VEGFR might be potential pharmacological target of Timo AIII (Figure 5).

### Anti-Metastasis

Most of the cancer patients die from cancer metastasis which consists of multiple physical processes and have long been associated with cancer cell migration and invasion (Guan, 2015). Matrix metalloproteinase (MMP) is the vital pharmacological target in cancer progression, which degrades extracellular matrix, affects the cancer microenvironment, and initiates cancer metastasis (Shay et al., 2015; Lyu et al., 2019). Various signaling pathways, including MAPKs, src/FAK, beta-catenin, NF-κB, STAT3, and so on are involved in the regulation of MMPs expressions (Pan et al., 2011; Merchant et al., 2017). Timo AIII significantly inhibited the proteolytic activity and mRNA expression of MMP-2/9 which are key regulators in cell migration and invasion in human no-small-cell lung cancer cells A549 and H1299, and the underlying mechanisms might be related to the suppression of ERK1/2, Src/FAK, and beta-catenin signaling pathways (Jung et al., 2016). Consistently, Timo AIII significantly decreased MMP-2/9 expression, and inhibited cell migration and invasion in human osteosarcoma cells MG63 and U2OS. The underlying mechanism was involved in suppression of Src/FAK/MAPKs signaling pathway and down-regulation of transcription factors CREB and b-catenin (Jung and Lee, 2019). In addition, Timo AIII decreased mRNA expression of MMP-9 in human pancreatic cancer cell AsPC-1 (Kim et al., 2019b) and suppressed HGF-induced MMP-9 expression in triple negative breast cancer cell MDA-MB-231 (Tsai et al., 2013).

MicroRNAs (miRNAs), which are small-noncoding RNA molecules and regulate the target genes expression, are classified as oncomiRs (tumor inducers) and tumor suppressor miRNA. And miRNA were well recognized for cancer treatment and diagnose in recent decades (Katz et al., 2015; Qadir and Faheem, 2017; Daoud et al., 2019). The expression level of cancer stem cell phenotype regulator B-cell-specific Moloney murine

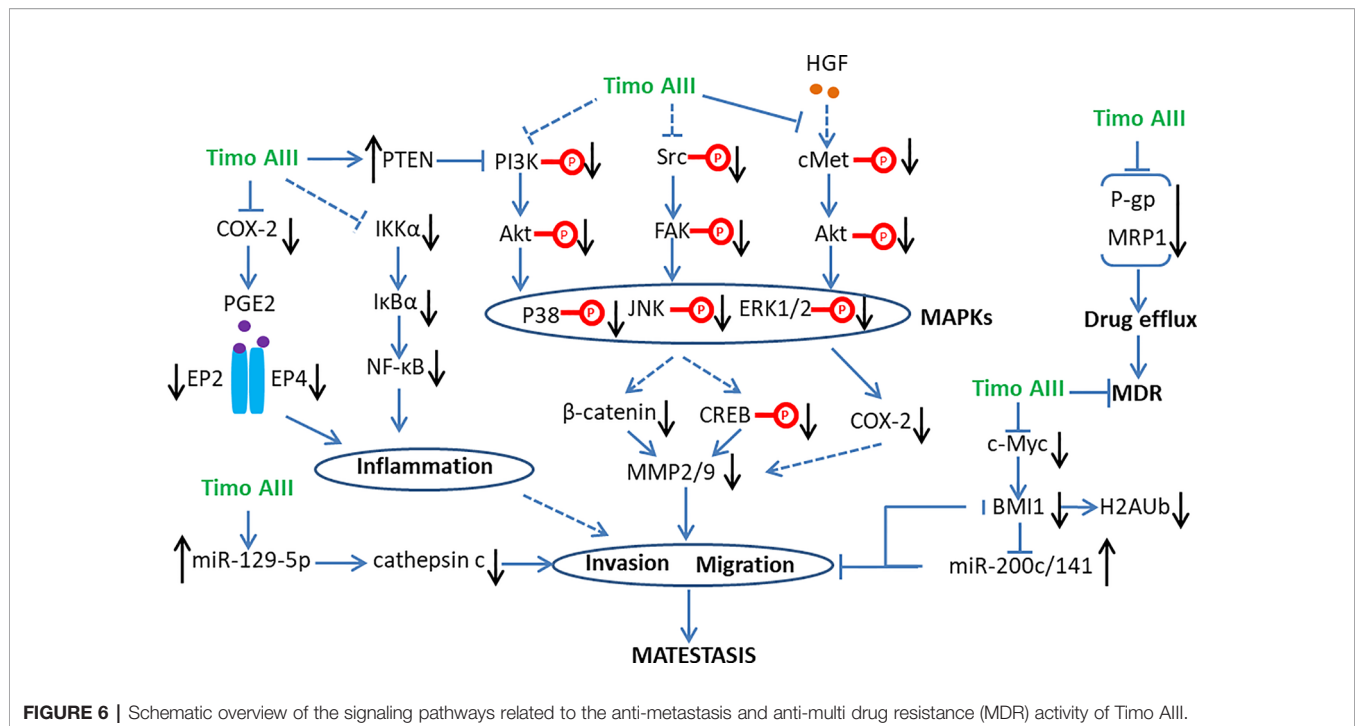

**FIGURE 5 |** Schematic overview of the signaling pathways related to the anti-angiogenesis activity of Timo AIII.

leukemia virus integration site 1 (BMI1), which is also a component of the polycomb repressive complex 1 (PRC1) and its transcription is dramatically regulated by Myc, is up-regulated in various cancers especially breast cancers (Dimiri et al., 2015; Hiraki et al., 2017). Dimiri et al. suggested that the oncogenic activity of BMI1 was also mediated by miR-200c/141 cluster-BMI1 auto-regulatory loop in cancer cells (Dimiri et al., 2016). Timo AIII concentration-dependently induced tumor cell senescence and inhibited cell oncogenic phenotypes, including migration, invasion, and colonies formation in soft-agar in both triple negative cancer cell MDA-MB-231 and non-triple negative cancer cell MCF-7 (Gergely et al., 2018). Gergely et al. proved that the inhibitory effect of Timo AIII on cell oncogenic phenotype was mediated by the up-regulation of miR-200c/141 cluster and down-regulation of BMI1, mono-ubiquitination of histone H2A at lysine 119 (H2AUb) and Myc in both MDA-MB-231 and MCF-7 cells (Gergely et al., 2018). There are also accumulated evidences which revealed the tumor suppressive role of miR-129-5p in various cancers (Liu et al., 2019; Qiu et al., 2019; Shi et al., 2019). Timo AIII inhibited cell migration and invasion among the concentration range of 2 to 6  $\mu\text{M}$  in which Timo AIII not affected the cell viability and cell cycle distribution in human renal cancer cells 786-O and A-498 (Chiang et al., 2019). And this non-toxic inhibitory effect of Timo AIII on cell migration and invasion was co-related with the down-regulation of cysteine protease cathepsin c expression, which was regulated by PI3K/Akt/miR-129-5p signaling axis (Chiang et al., 2019).

The inflammatory infiltration state of cancer microenvironment plays crucial role in cancer growth, metastasis, and resistance, which is mainly regulated by COX2/PGE2/EP and NF- $\kappa\text{B}$  signaling cascades (Hsu et al., 2017; Tong et al., 2018). The inhibition of

these processes presented potential therapeutic effect in various cancers (Yun et al., 2016; Liu et al., 2018). Timo AIII suppressed the migration capability of murine melanoma cell B16-F10 and human melanoma cell WM-115, which were induced or not induced by COX-2 stimulator 12-O-tetradecanoylphorbol-13-acetate (TPA), and it was closely associated with its concentration-dependent inhibitory effect on endogenous COX-2 expression and PGE2 production (Kim et al., 2016). Timo AIII also reduced protein levels of NF- $\kappa\text{B}$ , IKK $\alpha$ , IKK $\beta$ , and PGE2 receptors including EP2 and EP4 in B16-F10 cells (Kim et al., 2016). In line with these *in vitro* experiment results, Timo AIII significantly inhibited the metastasis of B16-F10 cells to lung with reduction of COX2 and NF- $\kappa\text{B}$  expression in mice *in vivo* (Kim et al., 2016). Many growth factors induce cancer cell proliferation, migration, and invasion, which contribute to cancer cell motility and intravasation (Guan, 2015). Hepatocyte growth factor (HGF), which promotes various cancer cell metastasis, triggered cancer cell migration and invasion *via* cMet-ERK-COX2 and MAPK signaling pathways (Siegfried et al., 2007; Kuang et al., 2017). Timo AIII concentration-dependently inhibited HGF-induced cell migration and invasion which were blocked by COX2 inhibitor NS398 and ERK inhibitor PD98059 in triple negative breast cancer cell MDA-MB-231 (Tsai et al., 2013). Timo AIII also significantly attenuated HGF-induced intracellular p-cMet and COX2 expressions as well as nuclear ERK phosphorylation and ATF2 expression in MDA-MB-231 cells (Tsai et al., 2013).

Thus, Timo AIII inhibited cancer stem cell phenotype, including cell migration and invasion, and subsequently suppressed cancer metastasis by targeting MMPs, BMI1, and cancer inflammatory infiltration (Figure 6).

### Anti-Resistance and Synergistic Anti-Cancer Effect

Multiple drug resistance (MDR) is a severe problem in current cancer therapy (Gottesman, 2002; Vasan et al., 2019). Elevating the sensitivity of therapeutic drug to resistant-cancer cell by combination with other agents might be a promising therapeutic strategy. Timo AIII concentration-dependently caused cytotoxicity, cell cycle arrest, and caspase-dependent apoptosis in PANC-1 and BxPC-3 cells, which were resistance to gemcitabine in different degree, and enhanced the sensitivity to gemcitabine in these pancreatic cancer cells (MarElia et al., 2018). The underlying mechanism of Timo AIII enhanced the sensitivity of gemcitabine on cell cycle dysfunction, and apoptosis was involved in activation of pro-apoptotic proteins in PI3K/Akt signaling cascade (MarElia et al., 2018). Timo AIII also inhibited PI3K/Akt signaling pathway on adriamycin (ADM)-resistant human chronic myelogenous leukemia cell K562 (Chen et al., 2016). And the anti-tumor effects of Timo AIII on taxol-resistance lung and ovarian cancers were co-related to the suppression of PI3K/AKT/mTOR and Ras/Raf/MEK/ERK signaling pathways (Song et al., 2019). In addition, Ginsenosides including compound K, Rb1, and Rc enhanced the cytotoxicity of Timo AIII in MG63 human osteosarcoma cells, in which Rb1 and Rc increased the population of apoptosis cell caused by Timo AIII (Jung and Lee, 2019). Thesis results indicate that Timo AIII could enhance the cancer cell apoptosis and suppressed the cell survival signaling, and ginsenoside might present synergistic effect on Timo AIII-induced cancer cell death and metastasis.

The metabolism and transport of intracellular drug to extra cell contributes to MDR, which is also called drug efflux. The

ATP-binding cassette (ABC) transporter family including multi-drug resistance protein 1 (MDR1; also known as P-glycoprotein and ABCB1), MDR-associated protein 1 (MRP1; also known as ABCC1) and breast cancer resistance protein (BCRP; also known as ABCG2) regulates the process of drug efflux, which also overexpresses in many drug-resistant cancer cells (Holohan et al., 2013). Timo AIII increased intracellular adriamycin (ADM) concentration and presented reversal effect on ADM-resistant human chronic myelogenous leukemia cell K562 in a concentration-dependent manner, and the underlying mechanisms were related to the down-regulation of P-glycoprotein (P-gp) and MRP1 (Chen et al., 2016). Moreover, Timo AIII attenuated the expression of P-gp and enhanced cell apoptosis in taxol-resistance human lung cancer cell A549/T and human ovarian cancer A2780/T *in vitro* and A549/T cell injected nude mice *in vivo* (Song et al., 2019). Thus, the inhibition of drug efflux by down-regulation of drug transporters expression was a key mechanism account for the anti-resistant capability of Timo AIII in cancer cells (Figure 6).

### Negative Regulated Cell Death by Autophagy

Autophagy characterized by the formulation of autophagic vacuoles which degrade and recycle the dysfunctional proteins and damaged organelles subsequently maintains the intracellular homeostasis (Antunes et al., 2018). Autophagy is a double-edged sword in cancer development, progression, and treatment, which could be tumor-suppressive, tumor-promoting, or neutral under different conditions (Amaravadi et al., 2016). PI3K/Akt/mTOR signaling pathway plays a key role in regulation of autophagy (Colhado Rodrigues et al.,

2019). Timo AIII notably induced cellular autophagic morphology *via* inhibition of PI3K/Akt/mTOR signaling pathway in Jurkat cells (Wang et al., 2019). Lok et al. found that Timo AIII suppressed the mTOR signaling and triggered autophagy while this process was not all the same with rapamycin-induced autophagy in HeLa cells (Lok et al., 2011). Timo AIII modulated specific transcriptional mechanisms and caused the up-regulation of cholesterol biosynthesis pathways for supporting the formation of autophagic vacuoles which capture ubiquitin proteins (Lok et al., 2011). Timo AIII-induced autophagy was co-related with elevated intracellular calcium concentration and accelerated the clearance of ubiquitin protein aggregation which induced by proteinase inhibitor MG132 (Lok et al., 2011). In addition, Timo AIII inhibited the mTORC1 and promoted selective protective autophagy in breast cancer cells (King et al., 2009). The inhibition of autophagy by chloroquine enhanced the cytotoxicity of Timo AIII in MDA-MB-231 and MCF 10A cells regardless of BT474 cell (King et al., 2009). In line with this result, Timo AIII increased the accumulation and conversion of cytosol LC3 I to autophagosome membrane located LC3 II, which revealed the autophagy induction effect in HeLa cells (Lok et al., 2011), and Timo AIII-induced apoptosis was potentiated in the presence of autophagy inhibitor 3-methyladenine (3-MA) or silenced beclin-1 gene which is a key regulator of autophagy (King et al., 2009). Moreover, Timo AIII induced autophagy in hepatocellular cancer cells both *in vitro* and *in vivo*, which mediated by AMPK $\alpha$  activation and mTOR inhibition (Wang et al., 2013). The inhibition of autophagy by Atg5 silence increased the cytotoxicity of Timo AIII in hepatocellular cancer cells, which revealed the cyto-protective role of autophagy in Timo AIII-induced hepatocellular cancer cell death (Wang et al., 2013). Timo AIII increased autophagy vacuoles, Beclin-1 and LC3 levels in human melanoma A375-S2 cells, and Timo AIII-induced apoptosis was accelerated by the autophagy inhibitor 3-MA (Wang et al., 2017). These results indicated that Timo AIII-induced autophagy might act as the role to promote

tumor cell survival *in vitro*, and mTORC1 might be the potential target of Timo AIII (Figure 7).

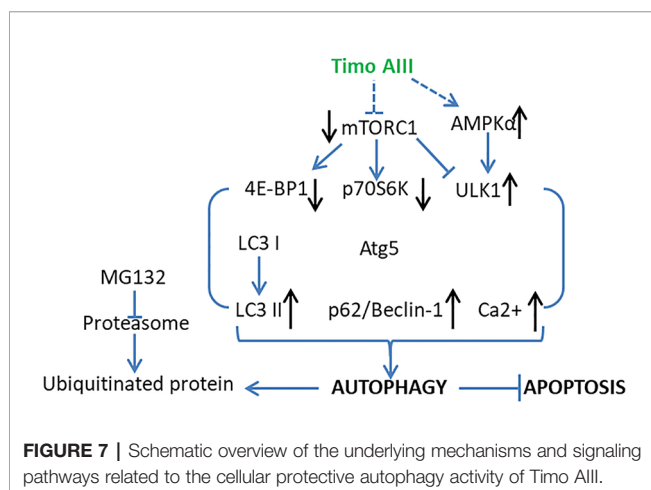

## Neuronal Disorders

### Alzheimer's Disease

Alzheimer's disease (AD), which is a progressive neurodegeneration disease and characterized by disorder of memory and cognitive functions, is the most common type of dementia with poor therapeutic efficacy until now (Oboudiyat et al., 2013). Several pathology features, including neuro-inflammation, accumulation of  $\beta$ -amyloid plaques and tau protein, and deficient cholinergic transmission were found in the brain of AD patients (Tundis et al., 2016). Acetylcholinesterase (AChE) degrades acetylcholine and lowers cholinergic activity and its selective inhibitor donepezil has been used for AD treatment in clinics (Arvanitakis et al., 2019). Lee et al. found that orally administration of Timo AIII (10, 20 and 40 mg/kg) significantly ameliorated the scopolamine-caused mice memory impairment in both passive avoidance test and Morris water maze test, and tacrine (10 mg/kg)-treated mice served as the positive control (Lee et al., 2009). Timo AIII elevated the acetylcholine level in scopolamine-treated mice brain which was correlated to its concentration dependently inhibition of the AChE activity (IC<sub>50</sub> = 35.4  $\mu$ M). In addition, the elevation levels of pro-inflammatory cytokines including TNF- $\alpha$ , IL-6 and IL-1 $\beta$  have been found in the AD brain, and microglia triggered neuro-inflammation has been considered contribution to AD progression (Webers et al., 2019). Timo AIII decreased the expression of pro-inflammatory cytokines TNF- $\alpha$  and IL-1 $\beta$  in the brain of scopolamine-treated mice, and the underlying mechanism was associated with the suppression of NF- $\kappa$ B signaling pathway activation in both microglia and neuron (Lee et al., 2009). Though the anti-AD activity of Timo AIII was demonstrated *in vivo*, whether Timo AIII could cross blood-brain barrier need to be further studied. Thus, we could conclude that Timo AIII was potentially for AD therapy due to its inhibition on AChE activity and NF- $\kappa$ B-mediated neuro-inflammation (Figure 8).

### Depression

Depression is a serious psychiatric disease and dramatically disrupted the quality of life (Smith, 2014). Although these are multiple pharmacological and physical strategies for depression treatment in clinic, various side effects accompany with the positive outcomes (Tomlinson et al., 2019). Timosaponin B-III (Timo B-III) which is also one of the main natural steroidal saponins in *A. asphodeloides* Bunge prevented from depression in a mouse postpartum depression model (Zhang et al., 2017). Timo AIII (30 mg/kg) also presented anti-depression activity according to the experiment results from open field test, tail suspension test and forced swimming test in mice, and fluoxetine-treated mice served as the positive control. However, the anti-depression effect of Timo B-III was more effective than Timo AIII (Jiang et al., 2014). Thus, further studies about the anti-depression effect of Timo B-III are more valuable than Timo AIII.

**FIGURE 8 |** Overview of the underlying mechanisms of the Alzheimer's disease protective effect of Timo AIII.

## Diabetic Mellitus

*Anemarrhena asphodeloides* Bunge is an important constitute of herb medicine formulas, like TongGuanWan, Bai-Hu-Jia-Rensheng-Tang, Rhizoma Anemarrhenae-Phellodendron herb pair and guizhi-shaoyao-*A. asphodeloides* herb pair, which have been applied for treatment of diabetic mellitus for thousands of years in China (Kimura et al., 1996; Shin et al., 2008; Tang et al., 2012; Han et al., 2015; Zhao et al., 2015). But the active constitutes of *A. asphodeloides* Bunge for diabetic mellitus treatment was not fully elucidated. The diabetic mellitus protective effect of Timo AIII was firstly investigated on streptozocin (STZ)-induced diabetic and normal mice in 1996 (Kimura et al., 1996). In diabetic mice model, Timo AIII (1 and 10 mg/kg) significantly promoted the salivary flow. And combination of  $\text{CaCl}_2$  (2 and 4 mg/kg) with Timo AIII (0.1 mg/kg) enhanced the pilocarpine-induced saliva secretion when compared with Timo AIII alone (Kimura et al., 1996). However, Nian et al. found that the glucosidase inhibitory effect of flavones, including mangiferin and isomangiferin, were more effective than steroidal saponins including Timo AIII and Timo BII, which revealed the more potent anti-diabetic mellitus effects of flavones than saponins isolated from *A. asphodeloides* Bunge (Nian et al., 2017). And Yuan et al. found Timo BII prevent from diabetic nephropathy by suppression the inflammation in alloxan-induced mice (Yuan et al., 2015). These results revealed that the anti-diabetic mechanisms were different between steroidal saponins and flavones ingredients of *A. asphodeloides* Bunge and the anti-diabetic mellitus activity of Timo AIII might be due to its anti-inflammatory property.

## Others

### Anti-Platelet and Anti-Thrombotic Activity

Platelet activation and aggregation have been considered as the main pathology of many cardiovascular diseases, such as coronary heart disease, atherosclerosis, and strokes (Yeung et al., 2018). The inhibition of thromboxane prostaglandin

(TP) receptor which blocked thromboxane (Tx) A2 pathway has been suggested as the efficient drug target for inhibition of platelet activation and aggregation (Fu et al., 2017; Kashiwagi et al., 2019). Timo AIII inhibited U46619-induced platelet aggregation by reduction of ADP secretion *in vitro* and prevented thrombus formation in mice *in vivo* (Cong et al., 2016). The thromboxane (Tx) A2 receptor activity and Gq signaling pathway were suppressed by Timo AIII, and the anti-platelet aggregation activity was enhanced by combination Timo AIII with current known antiplatelet agents including PGE1 and SQ29548. So, Timo AIII might be potential for development of cardiovascular drugs for its anti-platelet and anti-thrombotic activity targeting thromboxane (Tx) A2 receptor.

### Anti-UVB Radiation

UVB radiation was harmful to skins which resulted in cellular damage, mutation, inflammation, photoaging, and consequently, photocarcinogenesis progression (Lan, 2019). Natural herbs were precious library for discovery of UV protective agents (Li et al., 2019; Mohan and Gupta, 2019). Kim et al. found that Timo AIII, which isolated from Chinese herb *A. asphodeloides* Bunge, protected against UVB-induced cell migration and invasion in both human epidermal keratinocytes (HEKs) and dermal fibroblasts (HDF), and the underlying mechanism were involved in the inhibition of Akt/MAPK signaling pathway and down-regulation of MMP9 (Kim et al., 2019a). Timo AIII reduced UVB-induced up-regulation of COX2 and inflammatory cytokines including TNF- $\alpha$  and IL-6 expressions, which was associated with the down-regulation of pro-inflammatory factor NF- $\kappa$ B. In addition, Timo AIII reduced UVB-induced DNA damage and deposition of 8-oxo-7, 8-dihydro-2'-deoxyguanosine (8-oxo-dG), which were mediated by down regulation of cell cycle arrest-related genes PCNA and SMC1. Thus, the UVB-radiation protective effect of Timo AIII might be mainly due to its anti-inflammatory, anti-cell migration, and anti-cell invasion capabilities.

## Anti-Colitis

Timo AIII concentration-dependently inhibited in LPS- or peptidoglycan-stimulated upregulation of COX2, iNOS, and pro-inflammatory cytokines TNF- $\alpha$  and IL-6 expressions in mice peritoneal macrophages, which accompanied with suppression of MAPKs and NF- $\kappa$ B signaling pathways activation (Lim et al., 2015). Moreover, Lim et al. found that Timo AIII reduced the amount of LPS binding to TLR and restored the balance of Th17/Treg cells in mice peritoneal macrophages, and these *in vitro* experiment results were in line with the anti-inflammatory effects of Timo AIII on 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis in mice *in vivo* (Figure 9).

## Anti-Allergy

Timo AIII inhibited the passive cutaneous anaphylaxis (PCA) reaction and scratching behaviors in mice while further studies revealed that sarsasapogenin, one of the metabolites of Timo AIII, was the active metabolic compound in Timo AIII-induced anti-allergy (Lee et al., 2010). Lim et al. also found that Timo AIII inhibited the differentiation of T cell to Treg cell *in vitro* (Lim et al., 2015). Thus, Timo AIII might also be able to regulate the immune system (Figure 9).

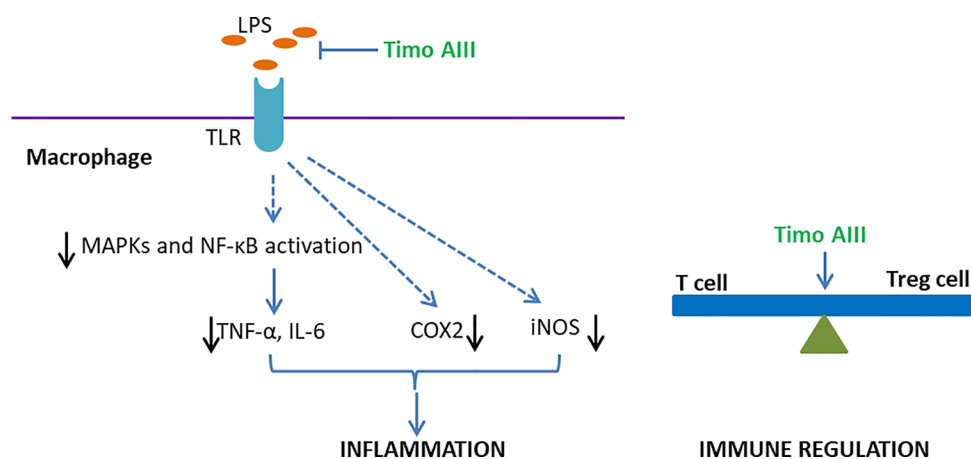

## Anti-Virus

Respiratory syncytial virus (RSV) has been identified as the most important cause of lower respiratory tract infections and results in some mortality in young children and elderly (Jorquera et al., 2016; Broor et al., 2018). Although several inhibitors targeting RSV has been found over decades, there is still no antiviral drugs or vaccines approved for the prevention or treatment of RSV infections (Heylen et al., 2017). Joung et al. isolated the Timo AIII from the BuOH fraction of *A. asphodeloides* Bunge and found that Timo AIII significantly inhibited the propagation of RSV in HEp-2 cells ( $IC_{50} = 1.0 \mu M$ ) (Joung et al., 2011). Furthermore, ribavirin-treated group served as the positive control with the  $IC_{50}$  value of  $1.15 \mu M$ , which was higher than Timo AIII. Thus,

we could conclude that Timo AIII presented potential anti-virus activity while its action mechanisms still needs further studies.

## PHARMACOKINETICS AND TOXICITY

Pharmacokinetics and toxicity studies play vital roles in the process of drug development. Several analytical methods were developed for detection of the saponins including Timo AIII and Timo BII in animal blood plasma after administration of single compound or herb formulas (Liu Y. et al., 2013; Sun et al., 2013; Feng et al., 2014). Timo AIII is one of the important active ingredients of Baihe Zhimu decoction which was used for depression treatment in traditional Chinese medicine for a long history in China (Yang et al., 2018). Yang et al. found that Timo AIII presented in the blood after oral administration of Baihe Zhimu decoction by an AB Sciex QTRAP ((R)) 5500 mass spectrometer in both normal and depression rats (Yang et al., 2018). Lee et al. detected the blood concentration of Timo AIII using LC-MS in mice, and they found that its maximum blood concentration was  $104.7 \pm 20.7 \text{ ng}/\mu\text{L}$  after oral administration of Timo AIII (50 mg/kg) for 4 to 6 h (Lee et al., 2009). And this result was consistent with efficacy results that the memory-enhancing effect of Timo AIII after orally administration for 5 h was more effective than 1 h. However, Liu et al. found that the  $C_{max}$ ,  $T_{max}$ ,  $t_{1/2}$ , and MRT (mean residence time) of Timo AIII were  $18.2 \pm 3.1 \text{ ng/mL}$ ,  $2.3 \pm 0.57 \text{ h}$ ,  $4.9 \pm 2.0 \text{ h}$ , and  $7.1 \pm 1.4 \text{ h}$  respectively after oral administration of Timo AIII (6.8 mg/kg) in health male SD rat (Liu Z. et al., 2013). Moreover, Timo AIII presented slow eliminated rate in the liver and caused hepatotoxicity which might result from its induction of intracellular ROS and down-regulation of bile acid transporters capabilities (Wu et al., 2014; Xie et al., 2018). And mangiferin, which is an active component in *A. asphodeloides* Bunge and presented anti-oxidant ability, attenuated Timo AIII-induced hepatotoxicity. The absorption, distribution, metabolism, and elimination (ADME) processes and toxicity of

**FIGURE 9 |** Overview of the underlying mechanisms of the anti-inflammation and immune regulation effects of Timo AIII.

Timo AIII still need further study in both health and disease models including mice, rat, and human.

## DISCUSSION

Timo AIII presented various pharmacological activities including anti-cancer, anti-AD, anti-diabetic mellitus, anti-colitis, anti-coagulant, and so on, while these researches were mainly conducted *in vitro*. The most effective activity of Timo AIII is anti-cancer, especially breast cancer and hepatocellular cancer, and the underlying mechanism are co-related with its anti-metastasis, anti-resistance, cytotoxicity, pro-apoptosis, and induction of cell cycle arrest, ROS, ER stress, and mitochondria dysfunction. Previous studies revealed that Timo AIII-induced autophagy might act as the role to promote tumor cell survival *in vitro*. These lack the *in vivo* evidence that explore whether inhibition of autophagy could elevate the anti-cancer effect of Timo AIII. And the autophagy induction effect of Timo AIII might contribute to other diseases, like AD and PD, in which activation of autophagy accelerates clearance of misfolding proteins. We also identified VEGFR, XIAP, BMI1, thromboxane (Tx) A2 receptor, mTOR, NF- $\kappa$ B, COX-2, MMPs, AChE, and so on are as the vital pharmacological targets of Timo AIII. Moreover, the anti-inflammatory effect of Timo AIII is also wealth for further studies, which accounts for its anti-AD, anti-metastasis, anti-metastasis, anti-UVB radiation, and anti-colitis activities. The toxicity, especially hepatotoxicity, and pharmacokinetics including ADME of Timo AIII are worth to investigate in

diverse animal models. In conclusion, Timo AIII is potent as a compound or leading compound for further drug development while still needs in-depth studies.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## AUTHOR CONTRIBUTIONS

YL and W-RZ wrote the manuscript. W-TS, JZ, K-YZ, and QD collected the related articles and summarized the figures and tables. W-TS, X-LC, J-YT, and Z-YZ designed the study and revised the manuscript.

## FUNDING

This study was supported by the National Health Commission of Shanghai (GWIV-28, ZY-(2018-2020)-FWTX-8001, XHLHGG201803) and Shanghai University of Traditional Chinese Medicine (A1-N19205010302). The authors thank Mr. Hua Chaofeng from School of Management, Jiangxi Agricultural University for drawing the features of *Anemarrhena asphodeloides* Bunge according to Compendium of Materia Medica.

**Introduction:** The fundamental theory of traditional Chinese medicine (TCM) implies that when different diseases have the same pathogen, the syndromes of these individual diseases will be the same. “Treating different diseases with the same method” is a TCM principle suggesting that when different diseases have similar pathological changes during different stages of their development, the same method of treatment can be applied. Our study aims to analyze the concept “treating different diseases with the same method” from a molecular perspective, in order to clarify its biological basis and to objectively standardize future TCM syndrome research.

**Objective:** The TCM syndromes Qi deficiency and blood stasis have similar pathogenesis in relation to coronary heart disease (CHD) and stroke. We aim to use big data technology and complex network theory to mine the genes specifically relevant to these TCM syndromes. This study aims to explore the correlation between the biological indicators of CHD and stroke from a scientific perspective.

**Methods:** Mining the relevant neuroendocrine-immune (NEI) genes by means of gene entity recognition, complex network construction, network integration, and decomposition to categorize relevant syndrome terms and establish a digital dictionary of gene specifically related to individual diseases. We analyzed the biological basis of “treating different diseases with the same method” from a molecular level using the TCMIP v2.0 platform in order to categorize the TCM syndromes most relevant to CHD and stroke.

**Results:** We found 46 genes were involved in the TCM syndromes of Qi deficiency and blood stasis of CHD and stroke. The same genes and their molecular mechanism also appeared to be in close relation to inflammatory response, apoptosis, and proliferation.

**Conclusion:** By using information extraction and complex network technology, we discovered the biological indicators of the TCM syndromes Qi deficiency and blood stasis of CHD and stroke. In the era of big data, our results can provide a new method for the researchers of TCM syndrome differentiation, as well as an effective and specific methodology for standardization of TCM.

**Keywords:** treating different diseases with the same method, traditional Chinese medicine, information extraction, complex network, TCMIP v2.0

## PREFACE

“Treating different diseases with the same treatment” is an important part of the fundamental theory of TCM, embodying the spirit of “treatment by syndrome differentiation”. A similar point of view can be seen in modern medicine where it is academically accepted that certain disease mechanisms lead to various diseases. For example, insulin resistance exists in obesity, diabetes, dyslipidemia, and other metabolic diseases. Another example is that the inflammatory response mechanism can be found in infections, atherosclerosis, glomerulosclerosis, hypertension, and ischemia-reperfusion of heart and brain. The knowledge that certain diseases have shared pathological mechanisms has a significant impact on the study of pathology both in modern medicine and TCM. From their respective perspectives both TCM and modern medicine acknowledge the importance of shared pathological mechanism of diseases. Therefore, the concept of “treating different diseases with the same method” can be seen as a focal point of the integration and unification of TCM and modern medicine (Xuezhong et al., 2004).

In the era of big data, the acknowledgment of TCM theory is closely related to informatics. The standardization and digitalization of TCM diagnosis need information and big data to improve the research. Information technology is needed to make a breakthrough in the fundamental research of TCM syndrome differentiation and biology. Getting research results published is common procedure for any scholar to have their research known and acknowledged, TCM is no exception. To this day, a large number of research documents related to TCM are stored in WOS, PubMed, and other international medicine databases. However, only a small amount of these papers and their knowledge can be found by the means of Artificial Intelligence (AI) and algorithms and has to be individually searched and found by humans. It will be of great significance for the medical society to discover the relationship between TCM syndrome differentiation and modern molecular biology. We aim to discover and compare a vast number of medical journals and texts to explore “treating different diseases with the same method” from the perspective of microbiology by using information technology (including machine learning, text mining, complex network, etc.)

To begin our research of “treating different diseases with the same method”, we chose diseases and syndromes with a high incidence rate, complex treatment and which have a major impact on the health of the general population. With the rapid

development of the Chinese national economy peoples living conditions and lifestyles have changed dramatically, ultimately resulting in a shift of the most common diseases. The incidence rate of coronary heart disease (CHD) and stroke is increasing. According to the China Health and Family Planning Statistical Yearbook, released by the national health and family planning commission, stroke and CHD have become the leading cause of death among Chinese citizens. Additionally, a WHO survey points out that the incidence rate of stroke is ranked first among diseases in China and is now trending toward younger parts of the population. How to effectively prevent and treat these two diseases has become a key point in the medical field.

Qi deficiency and blood stasis are important syndromes in the diagnosis and treatment of TCM. These two TCM syndromes are common in CHD, stroke, tumor, hypertension, cerebral infarction, and other multi-system diseases. To treat the above diseases, TCM doctors use prescriptions to invigorate Qi and activate blood. For example, *Buyang Huanwu Decoction* is a commonly used formula for the treatment of the syndromes of Qi deficiency and blood stasis, which in turn has a good effect on CHD and stroke. This principle of treating different diseases in their respective stage of development with the same method principle is the essence of “treating different diseases with the same method”. In this paper, we chose the common mechanism of CHD and stroke as our focal point to discover the biological basis of “treating different diseases with the same method”. This paper is divided into four chapters. Chapter 1, Introduction of research in China and abroad. Chapter 2, Introduction of data and methods used in this study. Chapter 3, Study results. Chapter 4, Summarization of research and suggestions for future research.

## LITERATURE REVIEW

### Information Extraction (IE) and Its Applications in the Biomedical Field

IE refers to the process of extracting, integrating and processing relevant information from existing data in order to store the specific information in a new data structure for future use and consultation (Bin, 2002). In IE, the uttermost important is to discover and extract the relationship between various entries. At present, relationship extraction generally applies to relationship extraction in dictionaries, as part of pattern matching and by means of machine learning. The dictionary based approach matches the words in the corpus with those in the professional dictionary in order to identify the words

and/or their relationships. By matching the relevant literature and gene dictionaries related to Qi deficiency and blood stasis syndromes of CHD, Zhao (Xing et al., 2015) identified the genes most relevant to these syndromes. Using relationship extractions based on dictionaries is simple and fast, but in the era of big data, the speed that information updated is even faster leading to dictionaries lacking behind the current information. Thus it can be understood that this method is not suitable for scenarios where the data of dictionaries is updated on a regular basis.

Relation extraction of pattern matching is based on the observation and analysis of entries by linguistic experts to define the specific rules and extract the correlation of biomedical entries. For example, in 2001, Ono et al. (2001) created an extraction model base on relations between protein-protein interaction (PPI) relationships by observing regular expressions, shallow syntactic patterns, and pattern matching method. Although methods based on pattern matching can extract the relationship between biomedical entities more accurately, it is difficult to identify the relationships outside of the defined set of rules. Therefore, the accuracy is often high but at the same time the recall rate is low.

Based on machine learning, the relevant features and parameters are calculated from the sample data and following used to identify and establish the new model. Machine learning can be further divided into eigenvector based methods and kernel based methods. Feature vector based method, which belongs to supervised machine learning and eigenvector based method, is a commonly used machine learning method applied in biomedical entity relationship extraction. Feature vector based method is used to change the relation of linguistic information into plane features, and following to create a high-dimensional map in vector space. This is done in order to translate information of the natural language into recognizable vector classifiers. For example, using support vector machine (SVM) models Xiao et al. (2005) extracted PPI relationship by applying a combination of lexical, syntactic, and semantic features in combination with maximum entropy classifiers. Although feature vector based relation extraction method is flexible and has good performance, the spectrum of feature selection often directly determines the extent of relation extraction. At the same time, the quantity and quality of labeled corpus usually determines the performance of extraction. The core function is used to calculate the similarity of two candidate relationship instances in potential vector space. For example, Bunescu and Mooney (2005a) proposed the idea of applying kernel function method to extract protein relations. Based on kernel function they managed to isolate PPI relationships by extracting the dependency pathways between specific proteins. The kernel based method has better performance because it has more flexibility to extract correlating information between entities. However, per definition kernel function has a direct impact on the result of relation extraction. It can be seen that there is a common problem in relation extraction methods based on machine learning. It gives rise to similar issues, whether using eigenvector or kernel function for relation extraction. Due to the

need of large quantity of labeled corpora the quality of these functions will deteriorate along with the quality of the labels.

## Use of Complex Network in Biomedical Research

The complex network theory is a method based on graph theory and complex system theory. Large-scale nodes, complex network structures, and dynamic spatiotemporal evolution of networks are the main characteristics of complex network. They coincide with the characteristics of data complexity, diversity, and the dynamic changes of informatics. Applying the theory and method of complex network to data analysis helps analysts to pinpoint what exact problems should be researched, and as a whole to improve the efficiency of their analytic tasks.

Complex network theory is not only applied to climate, politics, economy, society, military, and management, but also widely used in biomedical research. At present, the research of complex network in the biomedical field mainly focuses on the location of disease gene, disease-related sub-network recognition, network-based disease control research and drug target predictions. For example, Lim et al. (2006) used pathway information to discover pathogenic proteins. Deng et al. (2004) predicted a drug target method based on network topology. Artzy-Randrup et al. (2004) constructed the pin sub-network of Huntington's disease (HTT) and by these means discovered a new HTT pathogenic gene

Regarding TCM research, Li (Li et al., 2007) applied the information technology of text mining to prove that “disease” and “syndrome” have the possibility of a “disease syndrome combination” at the level of biological networks. Zhou et al. (Xuezhong et al., 2004) processed and integrated the database of TCM literature to find the gene related to kidney Yang deficiency and thereby provided an effective way to understand the function of this specific gene and its significance regarding the TCM syndrome. From the perspective of “interaction network function”, Li (Shao, 2007) explored and established the relevant method to apply computational system biology on TCM. He discovered through the excavation and research of the TCM syndromes of “cold and heat”, diseases, and prescriptions that the biological network of somatic angiogenesis is closely related to the TCM concept of “collateral disease”. Ding et al. (Fan et al., 2014) used network analysis method to study *Buyang Huanwu Decoction* from three aspects: chemical composition, target tissue, and related diseases to discover its potential in cancer treatment.

Since the 1970s, modern medicine has recognized the concept and interconnection of the neuro-endocrine-immune (NEI) systems. In 1973, Isaković and Janković (1973) firstly proposed the relationship between these three systems by injuring different parts off rat brains with bilateral symmetrical electrolysis and following observing their effects on lymphoid organs. The discovery and acknowledgment of NIE coincide with the overall concept advocated by TCM for thousands of years, and to a certain extent, it validates the theory of TCM, that has been developed through millennial of clinical practice. In 1990, Wang (Lan and Yusheng, 1990) firstly drew parallels between NEI network and

TCM theory. Afterward, more scholars have researched the connection between TCM theory and NEI network, such as the study of “cold and heat” syndromes (Ma et al., 2010) and the study of therapeutic mechanism of acupuncture (Ding et al., 2013). The key of “treating different diseases with the same method” is that although diseases are different, the syndromes can be the same. By using NEI network to explore the correlation between biological indicators of different diseases, we got a deeper understanding of TCM which assists to its modernization and internationalization.

Through the use of information technology in biomedical science, this TCM research has achieved good results. We still see the need for improvements. The main problems are as follows: 1) although there are many experiments of TCM using information technology, modern medicine and molecular biology most of them lack the effective combination of the mathematical modeling of precise result mining. This in turn leads to the biological significance of TCM syndromes and diseases being undiscovered. In other words, there are no clear indicators of the correlation between the perspectives of macro biology and microbiology in the research. 2) In the current research on biological networks the constructed networks are large and complex in scale. Due to the complexity of the network indicators, the results are difficult to analyze. There is no known method to compress networks and define the similarity between nodes ones the networks are compressed. We proposed to apply machine learning, information extraction and complex network technology to construct gene networks based on TCM syndromes, as well as use data mining by combining decomposition and combination throughout these networks. Our hypothesis is that by using these technologies to discover common genetic nodes through calculations, analysis and mining it will be possible to discover the genes specifically related to the syndromes of Qi deficiency and blood stasis of CHD and stroke.

Mesh (Medical Subject Headings) technology was used to mine the specific genes of NEI throughout PubMed database to construct the biological network. We also explored the mechanism of the concept “treating different diseases with the same method” from the perspective of microbiology. This has deepened the understanding

of the theoretical system of TCM syndrome differentiation, and promoted the studies of TCM syndromes.

## MATERIALS AND METHODS

This article was based on biomedical literature downloaded from <http://www.ncbi.nlm.nih.gov/entrez/query.fcgi>, including the two target syndromes. This was chosen due to vast PubMed database managed by the United States National Library of Medicine and the National Institutes of Health, providing free catalogs of biomedical papers worldwide. With the increasing internationalization of TCM research, the biomedical literature in PubMed contains a large number of articles related to Traditional Chinese medicine (A total of 148,000 articles related to Traditional Chinese medicine dated from 2010 to 2020 found by searching the keywords “Traditional Chinese medicine”, “herbal medicine”, “aspiration” and “prescriptions”). These articles are valuable to TCM scientific research and innovation, TCM technological innovation and the understanding of the current situation of TCM clinical practice in and outside of China. The free and easy access to vast biomedical literature related to TCM and modern medicine is why we chose PubMed as our data source. In order to precisely mine the genetic data of the two target syndromes, and to improve the accuracy of the data mining, the author proposed a data mining model based on the combination of “network decomposition” and “symptom combination” to mine the NEI genetic data in PubMed database (Xing et al., 2015; Liu et al., 2019). Then, the author combined the results of the two methods to draw a final conclusion. The methods of mining are described below.

### Network Decomposition

In order to reduce the complexity of network analysis, the network was divided into sub networks according to the network categories and the specific genes and their functions. Each sub network was individually analyzed and the results of each sub network were combined to find the genes related to the target syndromes. See **Figure 1**.

**FIGURE 1** | Flow chart of network decomposition method.

## Data Collection

According to the *Guidance Principle of Clinical Studies of New Drug of Traditional Chinese Medicine* (Xiao-yu, 2002), the terms of the target syndromes were selected. Then, two TCM experts weighted the rationality of these terms according to their personal clinical experiences to decisively determine the terms to be used in this paper. As the TCM terms chosen were all in Chinese and PubMed database in English, it was necessary to translate them into English. However, due to the specificity of TCM terminology many translated terms could not be searched in PubMed. Therefore, it was necessary to convert these TCM terms into corresponding modern medicine terminology. In this paper, Symmap database was used to finalize the translation of TCM terms into modern medicine terms. Symmap database (Wu et al., 2018) was developed by Chen Jian-xin, Professor of Beijing University of Chinese Medicine. Through Symmap and its classifications of internal molecular mechanism and external symptom, the database charted 1,717 TCM symptoms and allocated them to 961 modern medicine symptoms. For example, “red tongue” of TCM diagnosis is translated through Symmap database into “Glossitis” of western medicine (**Figure 2**).

The key terms were loaded into PubMed database according to the search format. We searched the Mesh subject terms and downloaded the literature summary. Following we downloaded the documents and converted them into a unified formation order to generate the corpus intended for mining.

## Gene Information Extraction

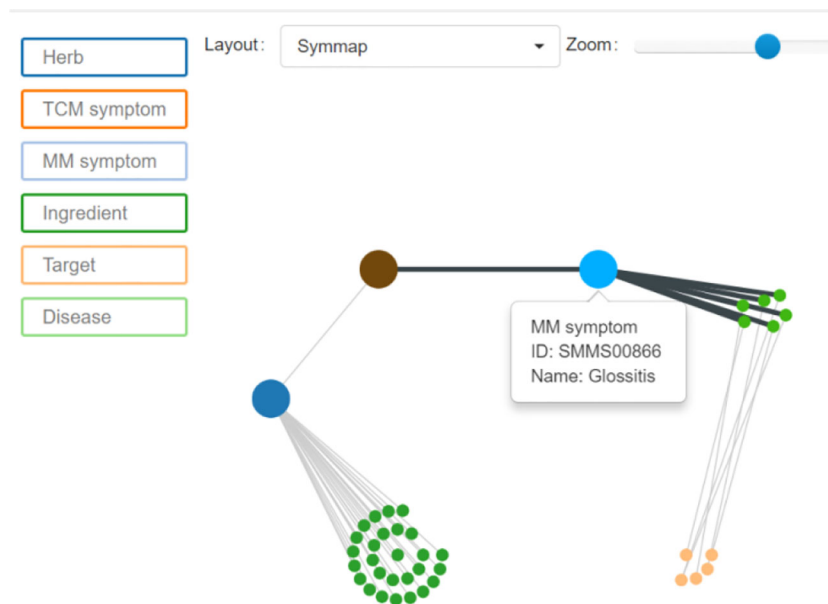

According to the basis of this paper, the entity of NEI genes that needed extraction from the literature was relatively defined and had little change. For improvements of efficiency and accuracy of entity extraction we used a dictionary matching method. The downloaded

documents were pre-processed, and following divided into independent sentences that were further segmented by using the *Jieba* word, a python segmentation package. After this process the separated words were matched with the key words of the NEI gene Dictionary. The NEI gene dictionary was downloaded from dbNEI (<http://bioinfo.au.tsinghua.edu.cn/dbNEIweb/>) A total of 1,435 NEI genes were downloaded and used for comparison (**Figure 3**).

Gene relationship extraction is used to identify the possible gene relationships in literature abstracts (In this paper it mainly refers to the gene relationships recognized in the abstracts). We found the relationships between genes and understood their potential usage through analysis and identification of the specific genes and their interrelations. We used sparse multi-instance learning algorithm (SMIL) (Wu et al., 2018) to extract gene relationships based on the summaries of previous relationship extraction algorithms. This approach can be applied to relationship extraction. By assessing whether or not a specific group of genes have interactions, and whether or not these interactions are of identical genes.

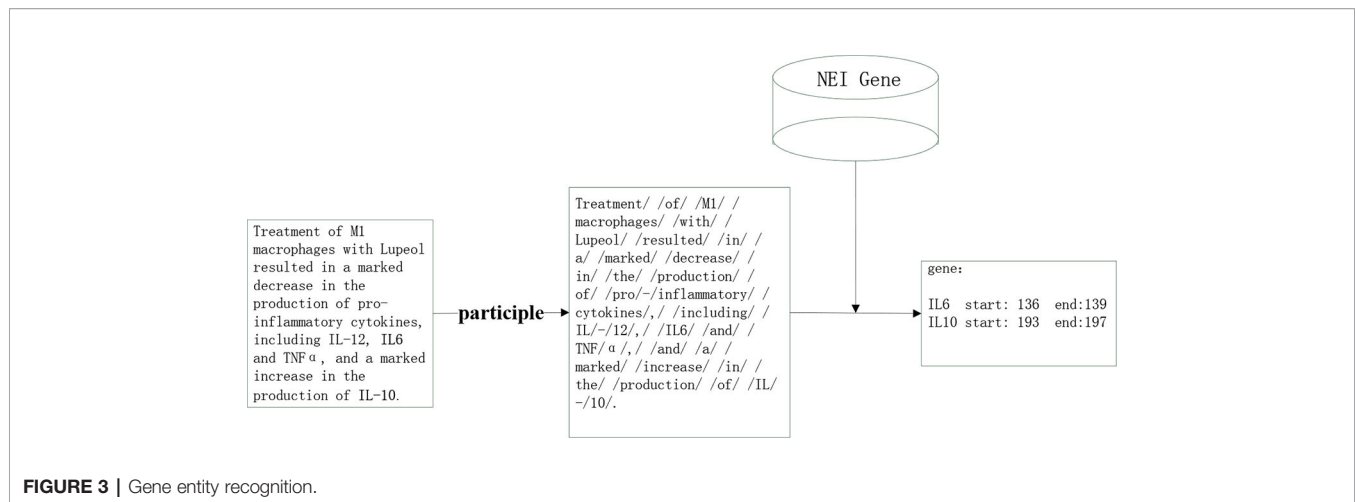

In this study, each grouping contained multiple relationships. If the relationship between two or more genes were observed, then the group was labeled positive. If no relationships between genes were observed, the package was labeled negative. E.g. A study has two genes that may be mentioned several times throughout the abstract, but generally speaking a specific relationship will only be mentioned once. Therefore, the information regarding these two specific genes will be relative sparse. We decided to use SMIL to extract the genetic relationship and avoid overlooking important information in the literature abstracts acquired from PubMed.

In addition to the data packages, “knowledge base” and “file data” are needed to extract relationships using SMIL algorithm. “File data” is a data source that contains data relations. “Knowledge

**FIGURE 2 |** Symmap query interface.

**FIGURE 3 |** Gene entity recognition.

base” has the ability to replace manual labeling of existing relationships. Therefore, the “knowledge base” must contain the exact same relationships as the relationships examined for extraction.

There are many industry databases about the relationship between genes in the field of bioinformatics. Therefore, to obtain the industry knowledge base was easy. After the comparative analysis of these specific gene databases, we finally decided to build a knowledge base from the string database. String database (<http://string-db.org/>) can analyze protein-protein interaction and includes 5,090 organisms. It not only contains the protein-protein interaction data known through validated experiments, but the database also includes predictions of unknown protein-protein interaction. We copied and pasted all NEI genes into the string database through the “multiple proteins by names/identifiers” option, selected the set species as *Homo sapiens* before beginning the search. The outcome of the protein relationship search was 823 nodes, 7,616 edges and the relationship values of each paired protein. We then downloaded the protein relationship data and used it to construct the knowledge base which contains the relationship between all NEI genes. The method of constructing the instance package is shown in algorithm 1. When two genes appear in the same paper abstract the whole text is traversed through the algorithm and the two genes added to a specific bag. If the specific gene relationship in bag exists in STRING knowledge base, the bag is flag as 1, otherwise as 0. We carried out this task until all the gene relationships in the knowledge base were mapped.

The algorithm used for word bag model generation is as follows (Lamurias et al., 2017):

```
function generate_bag (corpus,string)
begin
  bags=[]
  for abstract in corpus do
    begin
      for gene in abstract do
        begin
          bag= (genei,genej)
```

```
        if bag not in bags then
          begin
            if bag in string then
              bag.flag=1
            else
              bag.flag=0
            end
            bags.add(bag)
          end
        end
      retrain bags
    end
```

## Network Analysis

The adjacency matrix was constructed based on the gene relationship mined by SMIL method and following converted into Pajek recognized.net file. The file was imported into Pajek software to generate a visualized gene network map. We applied the method of “decomposition integration” because the complexity of the genetic network. This method was used to divide the genetic network into sub networks (community nodes), that in turn were separately analyzed. Finally, the results of each sub network were recombined to analyze the results of the whole network. Referring to the results of Yi’s research (YIDH, 2017), we calculated the community node centrality index, subnet weight index, standardized weight, and node genetic weight index. This was done according to the following formulas:

$$\text{CMI} = \text{CD} \times \text{CB} \times (1/\text{CC}) + \text{CE} \quad (\text{formula 1})$$

$$\text{SW} = \text{N} + \text{ZJW} \quad (\text{formula 2})$$

$$\text{ZSW} = (\text{SW} - \text{MIN}) / (\text{MAX} - \text{MIN}) \quad (\text{formula 3})$$

$$\text{GW} = \text{CMI} + \text{ZSW} \quad (\text{formula 4})$$

(CMI) comprehensive measurement indicator; (CD)centrality degree; (CB) betweenness centrality; (CC) closeness centrality; (CE) centrality eigenvector; (SW) subnet weight; (ZSW) standardized weight of SW; (N) number of nodes in subnet; (ZJW) The correlation between subnet function and the problem to be studied problem, which is scored by experts; (GW) gene weight.

Combination Method

Combination method is an analytic method used to combine equations and set aside variables to discover a unified value. We assumed that multiple genes would correspond to each individual symptom (key), and that multiple symptoms would in turn correspond to one TCM syndrome. We investigated the most relevant genes (Figure 4) through the research concept of “gene symptom syndrome”. The key words of target syndromes in modern medicine were regarded independently. Firstly, we discovered the genes related to the modern medicine syndrome, and following referred the data to the standard of TCM diagnosis for re-matching. As a final step we uncovered the specific gene which existed in each combination. This specific gene is the key gene and the result of these mentioned methods.

Search for Symptom Specific Gene

The search for symptom specific gene was done by the use of GenCliP software. GenCliP is a literature mining tool that can be used to form a list of genes with the use of keywords. These lists were then extracted by the software from their related literature and then manually verified. GenCliP displays specified genes and keywords mentioned in literature for manual association verification (Huang et al., 2008). We used the software to input all NEI genes in the “Upload Gene List”, and input each target syndrome and their symptom into the search box “Word Related Gene Search”. This was done to explore the NEI gene related to each specific symptom, and to define the symptom and the accompanying gene as “Abstract”. The results of these searches included two parts: “Gene” and “Hit”. “Gene” refers to the name of the searched gene, “Hit” refers to the number of documents in which the gene and the correlated searched symptom have

appeared simultaneous. This concept can also be understood as the “weight of the gene”.

Symptomatic Combination

In TCM each disease and syndrome are composed of many symptoms, and these symptoms can be further divided into primary and secondary symptoms. Under the guidance of TCM experts, we combined the individual symptoms according to the TCM diagnostic standards to better reflect the essential characteristics of the disease related to this study. The TCM experts divided the target syndromes into three parts: main syndrome, Qi deficiency syndrome and blood stasis syndrome. According to the TCM diagnosis standard, experts combined the symptoms of these three sections in different models to extract the gene information of each individual combination. We used this information to plot the intersection of the symptom combinations, and to screen out the genes existing in each combination. Finally, combining the method of Li (Li et al., 2007) and the experience of TCM experts, we discovered the core genes of each individual target syndrome. We following compared the genes of two respective target syndromes by “combination” and “decomposition” methods to extract the relevant genes.

TABLE 1 | Key words of Qi deficiency and blood stasis syndrome of coronary heart disease.

TCM symptoms	胸痛, 胸闷, 气短, 心悸, 乏力, 畏寒/肢冷, 自汗, 不寐, 舌淡紫, 偏瘫, 瘀斑, 头晕目眩
Symptoms of modern medicine	Chest pain, chest heaviness, respiratory abnormality, palpitation, lassitude, typhoid fever/monoparesis/chills, sweating, insomnia, tongue disorder, hemiplegia, ecchymoses, dizziness

TABLE 2 | Key words of Qi deficiency and blood stasis syndrome of stroke.

TCM symptoms	头晕目眩, 头痛, 易怒, 肢体麻木, 痰多, 气短, 乏力, 自汗, 便秘, 口干口渴, 舌质红, 舌质暗, 半身不遂, 口舌歪斜, 面色淡白, 瘀斑
Symptoms of modern medicine	Dizziness, headache, irritability, numbness of extremity, sputum, respiratory abnormality, lassitude, perspiration, constipation, xerostomia, glossitis, tongue disorder, hemiplegia, stroke, ecchymoses

## RESEARCH RESULTS

### Results of “Decomposition Method”

We retrieved the relationships between TCM symptoms and modern medicine symptoms based on the SymMap database. **Tables 1** and **2** show translation from Chinese of symptom keywords in English based on TCM terminology. These keywords were used for literature search in PubMed.

We used these keywords for Mesh retrieval in PubMed database. A total of 85,733 documents related to syndromes of Qi deficiency and blood stasis of CHD and 96,038 documents related to Qi deficiency and blood stasis syndromes of stroke were retrieved. We downloaded the documents (including author, title, key words, abstract, and so forth) and used them to generate the document library in XML format. A total of 84 NEI genes relevant to Qi deficiency and blood stasis syndrome of CHD and 199 NEI genes relevant to Qi deficiency and blood stasis syndrome of stroke were extracted by the mining method shown in *Gene Information Extraction*. Through the relationship recognition method shown in *Gene Information Extraction*, 109 gene pairs relevant to Qi deficiency and blood stasis syndrome of CHD and 313 gene pairs relevant to Qi deficiency and blood stasis syndrome of stroke were identified. The adjacency matrix of gene relationship was constructed and converted into a.net file recognized by Pajek software to generate a visualized gene network diagram (**Figure 5**).

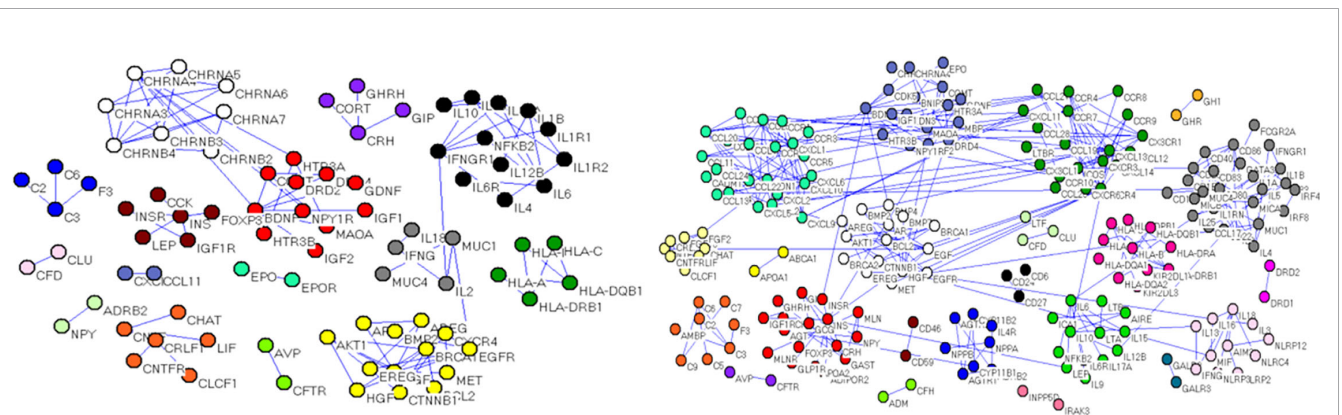

Calculations of four centrality indexes per network were made from the gene nodes, and then, according to Formula 1 the comprehensive measurement value of the centrality index was calculated. As a final step each of the two networks were individually divided into sub networks according to the community division algorithm of complex network. The results showed that the genetic network of Qi deficiency and blood stasis syndromes of CHD was divided into 14 sub networks (left of **Figure 6**). Among them, there were three large communities with more than 10 nodes, four with 5–10 nodes, and seven small communities with less than 5 nodes. A total of 21 sub networks (right of **Figure 6**) were discovered from the gene division of Qi deficiency and blood stasis syndromes of stroke. Among them, there were nine large communities with more than 10 nodes, three with 5–10 nodes, and nine small communities with less than 5 nodes. We then calculated the GW values of the target syndromes (**Tables 3** and **4**) according to formula 4.

### Results of “Combination Method”

Since TCM diseases and syndromes are composed of a variety of symptoms, and these can be divided into primary and secondary symptoms. Under the guidance of TCM experts, we clarified what symptoms are allocated to our two target syndromes, according to the criteria of TCM diagnostic, and following combined all target

symptoms. By combining these main symptoms, the results can better reflect the essential characteristics of the target diseases.

1. Results of symptoms classification of Qi deficiency and blood stasis syndromes in CHD.
  - a. Main symptoms: chest pain, chest tightness.
  - b. Symptoms of Qi deficiency: shortness of breath, fatigue, perspiration, dizziness, cold limbs, insomnia, palpitation.
  - c. Blood stasis: light purple tongue body, hemiplegia, ecchymosis.
2. Results of symptoms classification of Qi deficiency and blood stasis syndrome in stroke; stroke
  - a. Main symptoms: hemiplegia, deviated mouth and/or tongue.
  - b. Qi deficiency: shortness of breath, fatigue, perspiration, pale complexion, dizziness, thirst, phlegm, white and greasy tongue coating.
  - c. Blood stasis: ecchymosis, red tongue body, numbness, irritability, constipation.

We firstly used Genclip software to obtain the genes corresponding to each symptom and their respective keywords. This was done according to the method in *Combination Method* (see **Table 5**). Unfortunately, no genes were related to “tongue disorder”, “insomnia” and “chest heaviness” by using Genclip. These three symptoms were found in Genclip, but since our aim was to analyze the combination, rather than individual symptoms removing these three aforesaid symptoms from the symptom combination would not impact our subsequent research.

**TABLE 5 |** Number of genes discovered by keyword.

Id	Symptoms	Count
1	Dizziness	166
2	Constipation	210
3	Headache	338
4	Xerostomia	87
5	Irritability	122
6	Glossitis	19
7	Extremity Numbness	4
8	Hemiplegia	65
9	Sputums	4
10	Stroke	699
11	Respiratory Abnormality	76
12	Anemic	169
13	Lassitude	31
14	Ecchymoses	24
15	Sweating	129
16	Hemiplegia	65
17	Chest pain	225
18	Palpitation	49
19	Typhoid Fever	82
20	Chest Symptom Heaviness	0
21	Tongue Disorder	0
22	Insomnia	0

### 3. Symptom Combination Results of Qi Deficiency and Blood Stasis Syndromes in CHD

Using the formula combination of “main symptoms” + “Qi Deficiency” + “blood stasis” in Qi deficiency and blood stasis of CHD, 10 individual symptom combinations were obtained after

deleting the keywords “Chest heaviness, insomnia and tongue disorder”.

Combination 1:

Chest pain + Respiratory abnormality + Palpitation + Hemiplegia

Combination 2:

Chest pain + Respiratory abnormality + Palpitation + Ecchymoses

Combination 3:

Chest pain + Lassitude + Palpitation + Hemiplegia

Combination 4:

Chest pain + Lassitude + Palpitation + Ecchymoses

Combination 5:

Chest pain + Sweating + Palpitation + Hemiplegia

Combination 6:

Chest pain + Sweating + Palpitation + Ecchymoses

Combination 7:

Chest pain + Dizziness + Palpitation + Hemiplegia

Combination 8:

Chest pain + Dizziness + Palpitation + Ecchymoses

Combination 9:

Chest pain + Typhoid fever + Palpitation + Hemiplegia

Combination 10:

Chest pain + Typhoid fever + Palpitation + Ecchymoses

#### 4. Symptom Combination Results of Qi Deficiency and Blood Stasis Syndrome in Stroke

Using the formula combination of “main symptoms” + “Qi deficiency” + “blood stasis” in Qi deficiency and blood stasis in stroke, six different combinations of symptoms were obtained after deleting the keywords “Chest heaviness, insomnia and tongue disorder”.

Combination 1:

Hemiplegia + Stroke + Respiratory abnormality + Lassitude + Constipation + Xerostomia + Headache + Sputum + Ecchymoses + Extremity Numbness

Combination 2:

Hemiplegia + Stroke + Respiratory abnormality + Lassitude + Constipation + Xerostomia + Headache + Sputum + Glossitis + Irritability

Combination 3:

Hemiplegia + Stroke + Sweating + Constipation + Xerostomia + Headache + Sputum + Ecchymoses + Numb extremities

Combination 4:

Hemiplegia + Stroke + Sweating + Constipation + Xerostomia + Headache + Sputums + Glossitis + irritability

Combination 5:

Hemiplegia + Stroke + Anemic + Constipation + Xerostomia + Headache + Sputum + Ecchymoses + Numb extremities

Combination 6:

Hemiplegia + Stroke + Anemic + Constipation + Xerostomia + Headache + Sputum + Glossitis + Irritability

Comparing these combinations and removing any data repeated between them a total of 373 genes related to the syndrome of Qi deficiency and blood stasis of CHD and 804 genes relevant to the syndrome of Qi deficiency and blood stasis of stroke were obtained.

### Results Combination of “Decomposition” and “Combination”

According to the results of “decomposition method” and “combination method”, “decomposition method” had 84 genes related to the syndrome of Qi deficiency and blood stasis of CHD and 199 genes related to the syndrome of Qi deficiency and blood stasis of stroke, “combination method” had 373 genes related to the syndrome of Qi deficiency and blood stasis of CHD and 804 genes related to the syndrome of Qi deficiency and blood stasis of stroke. By matching the results of “decomposition method” and “combination method” a total of 84 genes related to Qi deficiency and blood stasis syndrome of CDH and 161 genes related to Qi deficiency and blood stasis syndrome of stroke were found.

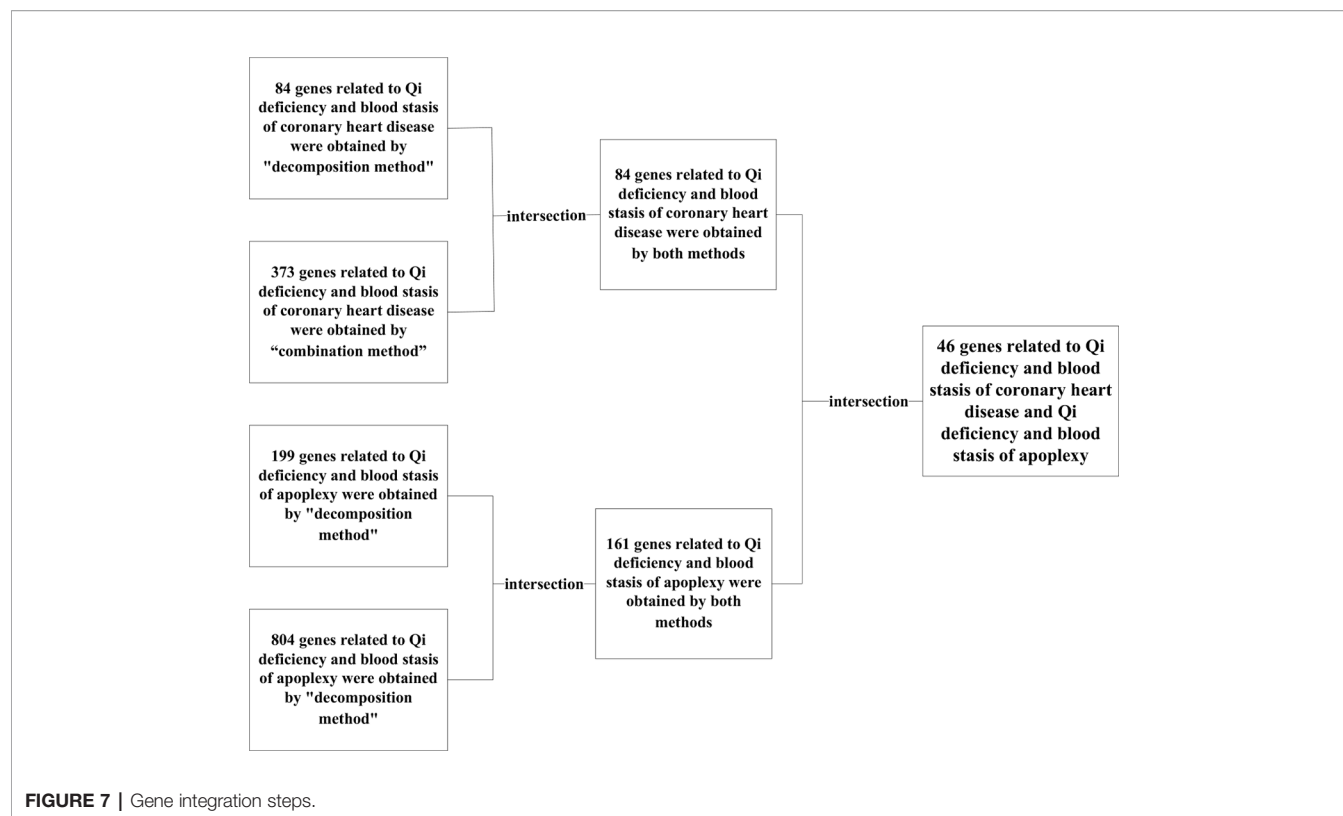

Even though Qi deficiency and blood stasis syndrome of CHD is different from that of stroke, the same treatment can be used according to TCM. Since different diseases can have the same treatment there evidently should be similar pathological changes and pathogenic mechanisms between these diseases. Therefore, we decided to investigate the common genes of these two target syndromes (see **Figure 7**) for specific similarities. After comparison, 46 genes in both diseases were identified: CXCR4, HGF, EGF, BDNF, IL10, INS, IL12B, IL13, IGF2, IGF1R, CTNNB1, IFNG, HTR3A, EGFR, HLA-B, HLA-DQB1, HLA-DRB1, IFNGR1, IGF1, CRLF1, GDNF, FOXP3, AKT1, F3, BMP2, AR, CNTF, BCL2, IL6, COMT, CHRNA4, CLCF1, CNTFR, MET, MUC1, MAOA, LEP, CCK, IL4, BRCA1, C3, IL18, IL2, IL1B, INSR, IL17A.

We further analyzed the functions and biological pathways affected by the above 46 genes. An online software (<https://www.kegg.jp/>) was used to analysis the pathways of related genes (see **Table 6**).

It can be seen from the above table that genes related to different diseases share certain common pathways. Nine shared signaling pathways (including AMPK, FoxO, ErbB, HIF-1, Jak-STAT, PI3K-Akt, Rap1, Ras, T cell receptor), 30 shared disease pathways (7 tumor related pathways, 13 infectious disease related pathways, 6 immune system disease related pathways, 4 endocrine disease pathways).

### Genes Related to Traditional Chinese Materia Medica

We searched the “TCM target database” of TCMIP v2.0 in order to further study the relevance of traditional Chinese materia medica to the target syndromes. Using the reverse search function of TCMIP v2.0 led us to the discovery of

the medical components related to the 46 genes involved in our target syndromes.

TCMIP v2.0 (Xu et al., 2019) is an intelligent data platform, which is embedded with a broad spectrum of authoritative algorithms including drugs physical and chemical properties, evaluation of drug composition, and prediction of drug targets. In addition, the system is also able to analyze functions and pathways related to drug targets and disease targets. This function allows for cross retrieval from traditional Chinese materia medica → formula → ingredients → target gene → function/pathway → disease. This cross search function can uncover the relevance of syndromes and drugs related to specific diseases, as well as rate the medicines' compatibility with target molecular groups. As shown in the **Figure 8**, a target gene was inserted into TCMIP v2.0 "TCM target database". For example, insert "AR", now the database will show the results of gene name, the specific genes corresponding to Chinese materia medica compounds and its corresponding prescription. With this search we found a total of 25 types of traditional Chinese materia medica related to the target syndromes;

Arestemona root, pinellia tuber, danshen root, common rush, adhesive rehmannia root, garden burnet root, barbary wolfberry fruit, seaweed extract, puncturevine caltrop fruit, Indian Quassia wood twing and leaf, lotus seed, pyrola herb, European verbena herb, dwarf lilyturf tuber, hogfennel root, ginseng, mulberry twig, common yam rhizome, inula root, longstamen onion bulb, inula flower, yanhusuo, Yào Wáng; Chá, poppy shell, and milkwort root.

## DISCUSSIONS

According to TCM CHD belongs to the category of chest arthralgia, palpitation, and subjective fatigue, it is located in the heart and blood vessels and mostly caused by the invasion of external evils, internal injury of emotions, improper diet, stress, and deficiency of viscera. In the development of CHD, Qi deficiency is the main factor, with inseparable bonds to phlegm and blood stasis (Houde, 2017). Yilin Gaicuo said "deficiency of vital energy(Qi) will lead to Qi not reaching the blood vessels, blood vessels without Qi will accumulate and form blood stasis", the etiology and pathogenesis of cardiovascular disease are mostly related to Qi deficiency and blood stasis (Jianqi and Yu, 2016), a vast amount of TCM literature point out that, according to TCM Qi deficiency and blood stasis are the two main pathological changes causing CHD. Stroke is located in the brain, and is according to TCM closely related to the heart, liver, spleen and kidney. Wind, fire, phlegm, blood stasis, deficiency and toxin are the main pathogenic factors of stroke (Zhe, 2010). Wang Qingren believed that the root of hemiplegia induced by stroke could be found in the deficiency of vital energy (Qi), based on this theory, he composed the *Buyang Huanwu Decoction* for the treatment of Qi deficiency and blood stasis syndromes of stroke (Zhengtai et al., 2017).

Our study shows that Qi deficiency and blood stasis of CHD and stroke includes some inflammatory factors: IL-10, FOXP3, cell apoptosis, differentiation, and proliferation. Cell apoptosis, differentiation, and proliferation: BCL-2, AKT1, CLCF1, HGF,

EGF, IGF1, CXCR4, and CTNNB1. Neurotrophic factors includes; CNTF, BDNF, and GDNF. Our results verify that the inflammatory responses, apoptosis, proliferation, and other mechanisms are shared by the two target syndromes.

Interleukin is involved in regulating the activation, proliferation, inflammatory response, and differentiation of immune cells. Interleukin-10 (IL-10) plays an important role in the pathogenesis of CHD, acute cerebral infarction, and other

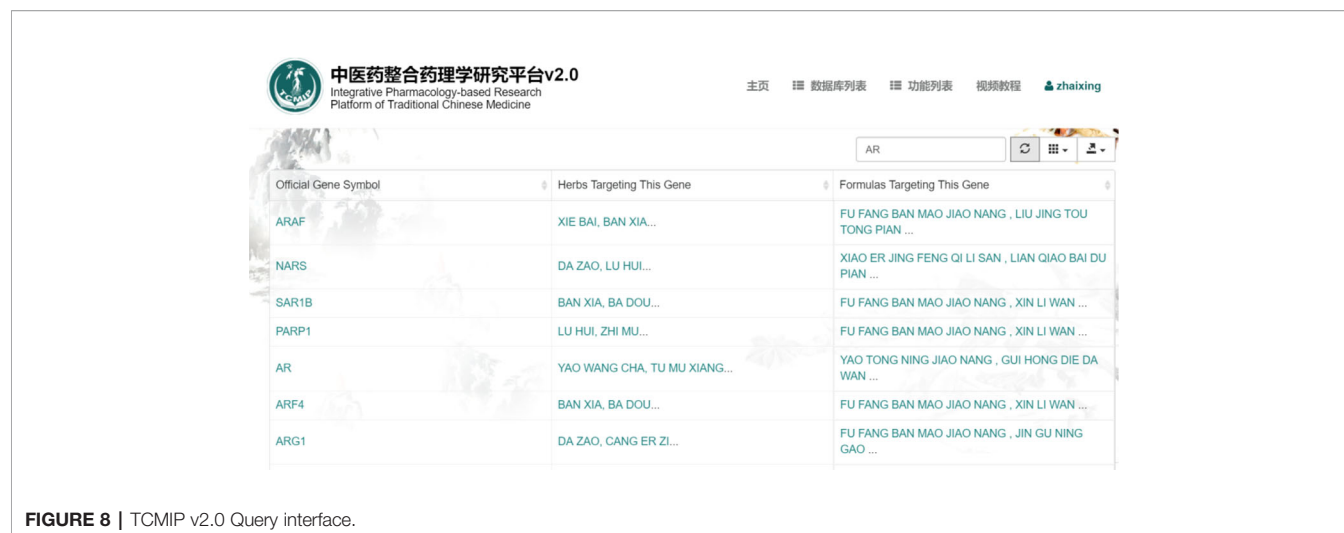

FIGURE 8 | TCMIP v2.0 Query interface.

diseases (Chao et al., 2013; Dong et al., 2015). FoxP3 regulates T-cell specific transcription factor that can secrete IL-10 as well as regulate immune functions and cause immune tolerance (Huehn et al., 2009). Other research has found that for coronary artery disease patients with low IL-10/TNF- $\alpha$  ratio has low left ventricular ejection fraction, with high incidence of cardiac related diseases within 10 years. It is therefore speculated that the imbalance of IL-10 and TNF  $\alpha$  may be relevant to the pathological development of atherosclerosis and heart failure (Dopheide et al., 2015).

The Bcl-2 gene is involved in apoptosis. Some scholars (Zhongfu et al., 2001) believe that oxygen free radicals and calcium excess can induce apoptosis during myocardial ischemia-reperfusion. Bcl-2 can inhibit apoptosis by interaction with antioxidants, inhibiting the production of oxygen free radicals, changing the cell outflow of  $\text{Ca}^{2+}$  and by regulating cGMP. Hepatocyte growth factor (HGF), insulin-like growth factor (IGF), epidermal growth factor (EGF), and other cytokines can activate PI3-Akt, Jak-STAT, and other signal pathways that are active in the facilitation of cell differentiation, angiogenesis, and apoptosis inhibition (Hosui et al., 2006). Cardiac nutrition literacy cytokine (CLCF1) is mainly involved in the Jak-STAT signaling pathway, cytokine, and chemokine mediated signaling pathway and negative regulation of apoptosis (Elsaedi et al., 2014). Chemokine receptor (CXCR4) promotes cell proliferation. It has been suggested that up regulation of CXCR4 signaling pathway may be an important mechanism in the treatment of CHD (Hristov et al., 2007). CTNNB1 is a  $\beta$ -catenin. The stable expression of  $\beta$ -catenin in cells can up-regulate the survival rate of regulatory T cells, induce the apoptosis of non-conditional T cells, accelerate cell cycles and promote cell proliferation (Ding et al., 2008).

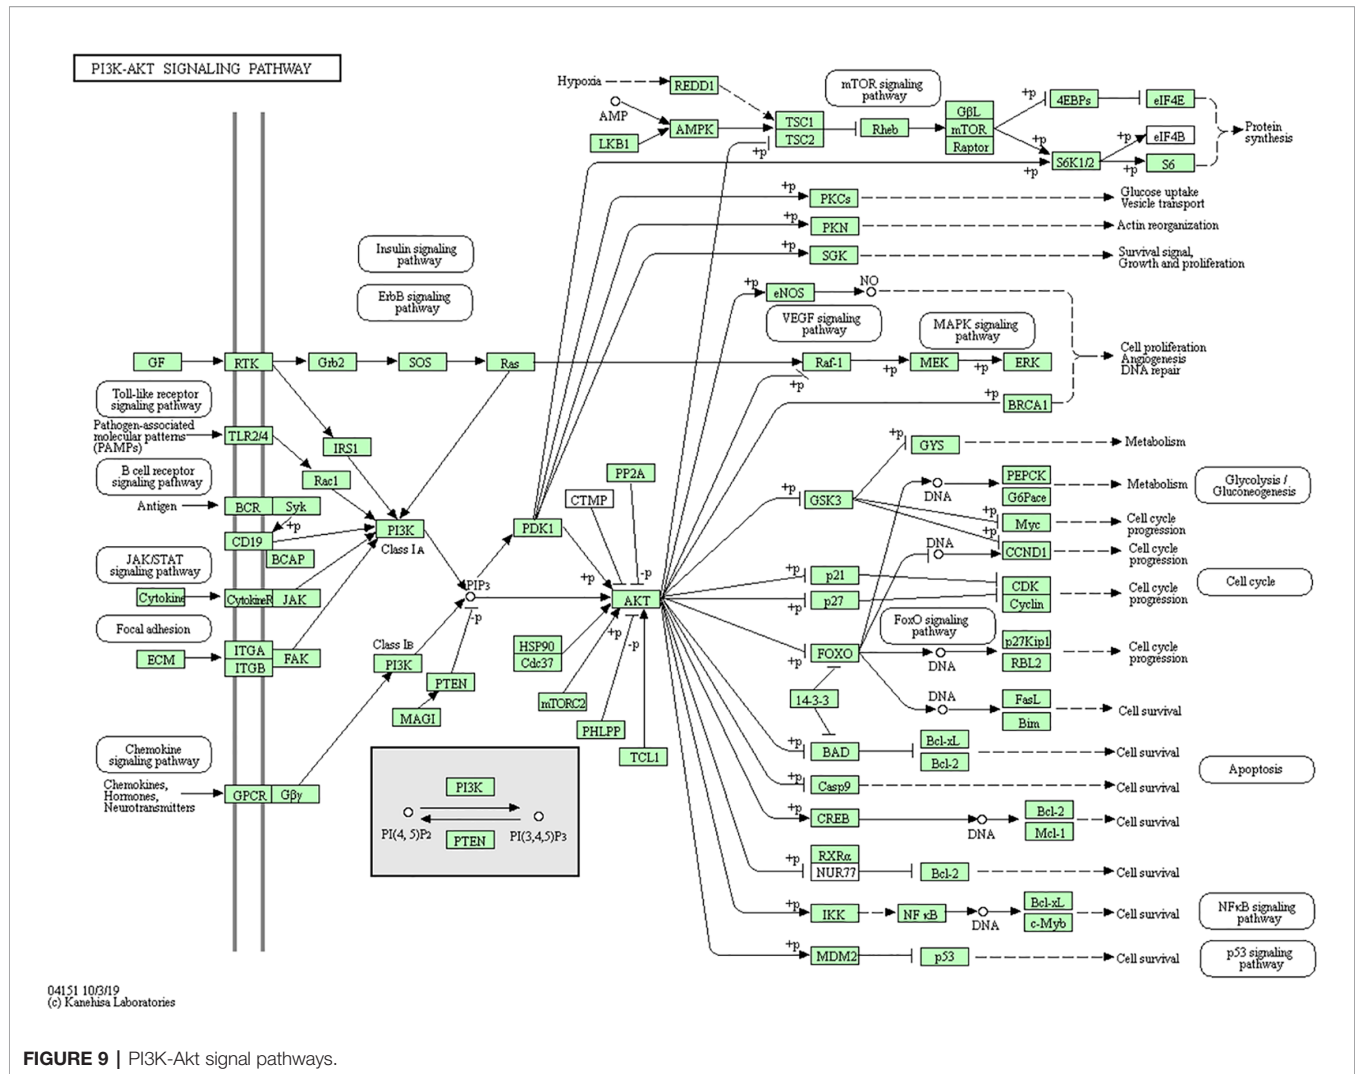

Neurotrophic factors can induce, regulate and control the survival, growth, and migration of neurons as well as establish functional connections with other cells by regenerating axons as part of nerve regeneration (Lichtman, 1987). As an important neurotrophic factor, glial cell-derived neurotrophic factor

(GDNF) can reduce the area of infarction during the acute stage of stroke (Gunther et al., 2005). The increased expression of brain-derived neurotrophic factor (BDNF) may be relevant to the recovery of neural function and plasticity after cerebral ischemia (Ergul et al., 2012).

By searching the KEGG database, we further confirmed the interrelations of the above mentioned genes and their pathways. PI3K-Akt signal path (Figure 9) involves FoxO, ErbB, Ras, and other sub modules, while FoxO, ErbB, HIF-1, and Jak-STAT also contain signals of the sub module PI3K-Akt. It is known that PI3K-Akt signaling pathway can promote endothelial regeneration, vasodilation, and platelet adhesion in cardiomyocyte, hence improve their survival rate and functionality (PAN et al., 2017). In addition, PI3K-Akt signaling pathway is also involved in cerebral infarction and other diseases (Zhang Hong and Junjian, 2011).

We found, through our analysis that the traditional Chinese herbs related to the 46 specific genes includes; Qi replenishing herbs *ginseng* and *yam*; blood activating herb *danshen* root; resuscitation herb *milkwort* root; phlegm dissolving herbs *pinellia* tuber, *hogfennel* root, and inula flower. This indicated that Qi replenishing, blood activating, resuscitation, and phlegm dissolving herbs have close connection to Qi deficiency and blood stasis syndrome. This discovery is consistent with TCM theory and clinical practice. Some scholars (Mengna et al., 2017) think that CHD is caused by Qi deficiency, Yang deficiency, blood deficiency, and Yin deficiency with Qi deficiency as the common denominator. Qi is the driving force of blood circulation. When Qi flows, blood flows. Weak Qi leads to blood not flowing smoothly that in turn leads to stagnation and pain. Qi deficiency, phlegm coagulation and blood stasis constitute the key pathogenesis of CHD and stroke. In the treatment of these diseases, emphasis should be given on Qi and blood circulation in order to tonify the body and resolve blood stasis. Modern pharmacological research validates that *ginseng* contains *ginsenoside*, *ginseng* polysaccharide, volatile oil, and other components. These chemicals can regulate the heart function, blood vessels, blood pressure, and central nervous

demonstrates the use of information technology to study the TCM term “syndrome”.

It is a new approach to use big data and complex network as a method to analysis the biological basis of the TCM concept “treating different diseases with the same method”. Follow up research will be needed to verify and validate the genes related to the two target syndromes as well as the practicality of our method. We plan to conduct more in-depth researches on the relationship between traditional Chinese materia medica—genes—syndromes—diseases by exploring their common molecular mechanism. Then, we will get a deeper biological understanding of the TCM concept “treating different diseases with the same method”.

In Asia, the market for whitening cosmetics is expanding rapidly, more and more people prefer to use natural products. Driven by natural product demand and technical advances, herbal research is also developing fast. Lots of studies reported that Asian herbal reagents can reduce melanogenesis, these findings provide evidence for the whitening application of Asian herbs. However, the current development status and challenges of herbal research need attention too. By reviewing these studies, different problems in studying herbal formulas, extracts, and active ingredients were presented. One of the most influential troubles is that the components of herbs are too complex to obtain reliable results. Thus, an understanding of the overall quality of herbal research is necessary. Further, 90 most cited Asian herbal studies on whitening were collected, which were conducted between 2017 and 2020, then statistical analysis was carried out. This work provided a comprehensive understanding of Asian herbal research in skin whitening, including the overall status and quality, as well as the focuses and limitations of these studies. By proactively confronting and analyzing these issues, it is suggested that the focus of herbal medicine research needs to shift from quantity to quality, and the new stage of development should emphasize transformation from research findings to whitening products.

**Keywords:** skin whitening, Asian herbs, traditional herbs, pigmentation, melanogenesis

## INTRODUCTION

Due to economic development and aesthetic needs, the global cosmetics market is unprecedentedly prosperous at present; likewise, the variety of cosmetics has also increased (Lee et al., 2016; Peltzer et al., 2016). Traditional herb-based natural products are putting into practical use as a new type of cosmetics, especially in skin whitening (Kanlayavattanakul and Lourith, 2018). Meanwhile, studies have screened abundant components from traditional herbs, most of them show favorable effects on pigmentation reduction. These findings have developed several hot products, such as arbutin and kojic acid (Leyden et al., 2011). In Asia, the application of traditional herbs in skin whitening has gotten more attention, two outstanding factors may contribute to this situation. One of them is local culture and aesthetic manner, generally, most Asians prefer white skin; the other factor is that Asia has a long history of using herbal medicine (Scarpa and Guerci, 1987; Gao et al., 2018).

Driven by the booming whitening market in Asia, many studies focus on the effects of traditional herbs; meanwhile, Asian consumers show strong need and trust for herbal reagents (Kanlayavattanakul and Lourith, 2018).

However, reliable herbal reagents are still in short supply. Though studies provide a basic guarantee for whitening effects and safety of many Asian herbs, there are still a lot of issues to be addressed before they transformed into products. The problems come from several aspects, for example, many natural ingredients are unstable and only show mild effects, the limitations of research methods are also a tough issue (Bent and Ko, 2004; Efferth, 2017; Espinosa-Leal and Garcia-Lara, 2019). It's not just that, we need to know the potential obstacles to the application of Asian herbs in skin whitening. Thus, this review provided a comprehensive understanding of the development status and problems of herbal research. In addition to summarizing the current findings, this work mainly focused on finding problems, which might help promote the application of traditional Asian herbs.

## THE INCREASE OF ASIAN COSMETICS MARKETS AND SKIN WHITENING DEMAND

The Asian cosmetics market is growing rapidly. Immediately behind Europe and the United States, China, Japan, India, and Korea are major consumers of cosmetics. In China, the total retail sales of cosmetics exceeded 40 billion dollars over the past three years and still maintained a high growth rate according to the National Bureau of Statistics (NBS) (China, 2018). These statistics are impressive enough, it suggests that the Asian cosmetics market is unprecedentedly prosperous. In Asia, the whitening product is an important part of cosmetics, besides, natural products have great potential in the whitening market. From the perspective of consumers, natural products are more skin-friendly, so herbal reagents are readily accepted (Kanlayavattanakul and Lourith, 2018). Meanwhile, increased skin whitening demand leads to the explosion of herbal research.

## REGULATION OF MELANOGENESIS

Skin whitening is affected by many factors, but the whitening effect of most herbs depends on regulating melanin synthesis. As an important pigment, melanin is widely distributed in mucosa, retina, and ovary (Slominski et al., 2004), but it mainly deposits in the skin and plays a role in resisting ultraviolet radiation (UVR) (Pinkert and Zeuss, 2018). Melanin is a kind of indole derivative of 3,4 di-hydroxy-phenylalanine (DOPA) produced by melanocytes. It derives from tyrosine through a series of oxidative reactions in melanosomes (Sealy et al., 1982). The first step is known as the Raper-Mason pathway, which depends on tyrosinase (TYR) (Miranda et al., 1988), the key rate-limiting enzyme. Besides, several proteins are involved in the maturation of melanosomes, such as tyrosinase-related protein 1 (TYRP1)

and dopachrome tautomerase (DCT or TYRP2) (Bertolotto et al., 1998). After that, melanosomes will be transported to nearby keratinocytes and deposit around the nucleus, where they work and eventually degrade. Proteins involved in this step are Ras-Related Protein Rab-27A (RAB27A), Myosin VA (MYO5A), Fascin Actin-Bundling Protein 1 (FSCN1) (Slominski et al., 2004), and so on. The complete process is called melanogenesis.

The regulation of melanogenesis is complex and can be divided into three aspects: melanin synthesis, transport, and degradation. Melanin synthesis is the most studied area, while transport and degradation are not well understood. First of all, the expression and activation of TYR have the most immediate impact on melanin synthesis and determines the color of human skin (Pavan and Sturm, 2019); second, oxidative stress is another vital factor in promoting melanin synthesis, though it also causes cell damage (Schalka, 2017). Moreover, Microphthalmia-associated transcription factor (MITF) is an important transcription factor that can upregulate the expression of TYR, TYRP1, and TYRP2. It's known that several signaling pathways can regulate MITF, such as the MAPKs (ERK, JNK, and p38) signaling pathway (Kim et al., 2017; Xu et al., 2018); the canonical Wnt signaling pathway, and the cAMP/PKA/CREB signaling pathway (Wang et al., 2017b; Yun et al., 2018). Besides, neighboring keratinocytes and fibroblasts have great impacts (Joly-Tonetti et al., 2018; Koike et al., 2018). It is partly due to the effects of endocrine and paracrine cytokines secreted by keratinocytes and fibroblasts, such as alpha-melanocyte-stimulating hormone ( $\alpha$ -MSH), stem cell factor (SCF) and endothelin1 (ET1) (Pei et al., 2018; Yuan and Jin, 2018). The regulating system also plays a role in hyperpigmentation diseases, such as freckles, chloasma, and sunburn (Slominski et al., 2004; Sulem et al., 2007). Most whitening cosmetics work *via* part of the regulating system. For example, ascorbic acid (AA) is a famous antioxidant, arbutin and kojic acid can inhibit tyrosinase activity (Seo et al., 2012; Qu et al., 2018). As reported, the mechanisms of other natural reagents are similar to these cosmetics, the details will be shown later.

## THE EFFECTS AND PROBLEMS OF TRADITIONAL ASIAN HERBS IN SKIN WHITENING

The application of herbs in skin whitening starts quite early in Asia. The book *Shen Nong's Herbal Classic* written in more than 2,000 years suggested that semen platycladi, the seed kernel of *Platycladus orientalis* (L.) Franco, can improve people's complexion and appearance. The book *Theory of Medicine Nature* recorded that the rhizome of *Atractylodes macrocephala* Koidz. can ameliorate dark skin (Zhen, 2006). After thousands of years' attempts in developing whitening reagents, lots of useful Asian traditional herbs have been recorded, and some of them have been studied in recent years (Xie and Yu, 1996). Generally, how traditional herbs are used can be divided into three types: formula (consisted of several herbs); extract (a mixture of several components, or a class of compounds, from the same herb), and active ingredient (a purified compound that has a definite molecular structure).

## Herbal Formulas

Herbal formulas work *via* the synergy of all components, each herb is necessary, the composition of formulas will follow a particular principle to increase efficacy and reduce side effects (Zhang, 1994). Herbal formulas account for a large proportion of herb use, but the formula-based study in whitening is rare. In Ye's study, researchers screened 50 herbal reagents (32 herbs and 18 herbal formulas) and successfully identified three useful tyrosinase inhibitors: Qian-wang-hong-bai-san, Qiong-yu-gao, and San-bai-tang (Ye et al., 2010a). The authors further revealed that Qian-wang-hong-bai-san could inhibit the p38 MAPK and PKA signaling pathway, and San-bai-tang could inhibit the p38 MAPK signaling pathway (Ye et al., 2010b; Tsang et al., 2012). This formula exists for a long time, but it is the first time to reveal the mechanisms. In addition, a Thai herbal formula AVS073 was reported to affect melanogenesis *via* suppressing the activity of tyrosinase, as well as neutralize ROS *via* increasing glutathione (GSH) biosynthesis and glutathione S-transferase (GST) activity (Panich et al., 2013). A Korean formula LASAP-C exhibited anti-melanogenic efficacy *via* inhibiting melanogenic proteins (TYR, TYRP1, and TYRP2) both in cells and zebrafish (Kim et al., 2016). Moreover, India also has a long history of using herbal formulas and an ancient medical systems: Ayurveda. Therefore, many Indian formulas have been studied in recent years. Ubtan, a traditional formula, was reported to have anti-tyrosinase and antioxidant effects (Biswas et al., 2016). (The composition of formulas showed in Table 1.)

These studies provide evidence for further research. However, some problems should be noted. First, the formulas processing, such as water decocting, is mainly based on ancient records or personal experience, but not a uniform standard. Apparently, differences in processing will affect the final composition (Bent and Ko, 2004). Moreover, the composition of formulas is incredibly complex (Yu et al., 2019), it brings uncontrollable interference to research. The inadequate knowledge of herbal formulas is a thorny issue for scientists under current conditions (Dai et al., 2019).

## Herbal Extracts

Due to the development of extraction techniques such as High Performance Liquid Chromatography (HPLC) and Ultra Performance Liquid Chromatography (UPLC), the components of herbal extracts can be identified now (Wang et al., 2017a). These techniques help separate crude herbal extracts into several classes: saccharides, glycosides, phenylpropanoids, quinones, flavonoids, terpenes, triterpenes, steroids, and alkaloids (Li et al., 2019). No doubt it is conducive to further research. Different from formulas, there are a lot of research reports on herbal extracts. For example, ginseng (*Panax ginseng* C.A.Mey.) leaves extract is found to be effective in moisturizing, anti-aging, freckle-removing, and skin whitening (Jimenez-Perez et al., 2018). *Ganoderma lucidum* polysaccharides can reduce melanogenesis by inhibiting cAMP/PKA and ROS/MAPK signaling pathways, as well as inhibiting paracrine effects

(Hu et al., 2019; Jiang et al., 2019). Goji berry (*Lycium chinense* Mill.) root extract can result in depigmentation *via* suppressing oxidation, MAPK and PKA signaling pathways (Huang et al., 2014). *Gastrodia elata* Blume and *Foeniculum vulgare* Mill. fruits extracts can resist  $\alpha$ -MSH or UV-induced melanogenesis (Nam and Lee, 2016; Shim et al., 2017). Essential oils from the leaves of *Pogostemon plectrantoides* Desf. were tyrosinase inhibitors (Suganya et al., 2015). What is more, a clinical study reported that polypodium leucotomos extract treatment is safe and effective for melasma patients (Goh et al., 2018).

As we all know, growing conditions (soil, water, climate), growth time, and harvest time have great impacts on herbs in cultivation (Yuan et al., 2016; Olennikov et al., 2017; Zhang et al., 2017). These factors will subsequently influence the components of herbal extracts, so do their effects (Bent and Ko, 2004). Furthermore, different extraction methods yield different ingredients (Lin et al., 2019). For instance, Wang et al. compared the effects of water and ethanol extracts of *Cuscuta chinensis* Lam. seeds in B16F10 cells and zebrafish; it is impressive that water extract inhibited tyrosinase activity, but ethanol extract worked oppositely (Wang et al., 2014). What is more, many ingredients widely exist in herbs, thus different herbal extracts may have similar components (Yuan et al., 2012; Wu et al., 2018), while the content of special ingredients tends to be lower (Ho et al., 2013; Tian et al., 2019). For these reasons, it is hard to guarantee the reliability of experimental results.

## Active Ingredients

With the renovation of extraction techniques, such as Enzyme-Assisted Extraction (EAE), Supercritical-Fluid Extraction (SFE), and Microwave-Assisted Extraction (MAE) (Bilal and Iqbal, 2020), a large number of active ingredients have been purified and identified, some of them show good performance in anti-tumor, anti-inflammatory, antioxidation, and skin whitening (Gao et al., 2019; Zeng et al., 2019b). Many famous herbs have been well studied, such as licorice (*Glycyrrhiza uralensis* Fisch. ex DC.), ginseng, and aloe (*Aloe vera* (L.) Burm.f.). Chen et al. confirmed that glabridin (extracted from licorice) reversibly inhibits tyrosinase in a non-competitive manner (Chen et al., 2016). Besides, floralginsenoside A (extracted from ginseng) showed anti-melanogenesis effects in cells and zebrafish *via* regulating MITF expression and ERK activation (Lee et al., 2017). Moreover, aloin (extracted from aloe) led to skin lightening *via* alpha-adrenergic receptor stimulation (Ali et al., 2012). Betulinic acid (extracted from *Dillenia indica* L.) exhibited non-competitive mode of tyrosinase inhibition (Biswas et al., 2017). Bixin and norbixin (from *Bixa orellana* L.) inhibited both melanin synthesis and tyrosinase activity (Anantharaman et al., 2016). 2-hydroxy-4-methoxybenzaldehyde (MBALD) and its crude extract (extracted from *Hemidesmus indicus* [L.] R. Br. ex Schult.) could inhibit monophenolase activity (Kundu and Mitra, 2014). As the research object is more clear, these findings are more convincing to support the whitening effect of herbs.

Screening active ingredients is an important part of the herbal study, and it has great application prospects. But unlike the

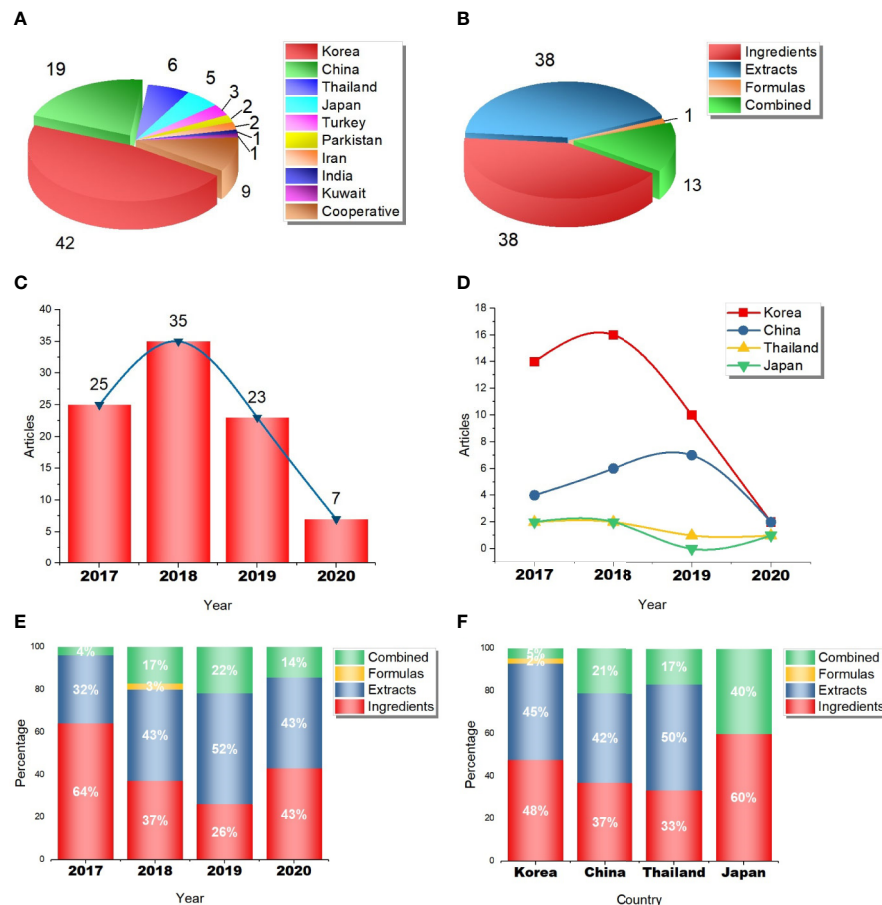

success in research, there are still many problems with herbal ingredients before they can be used. First, most natural ingredients are difficult to extract and purify on a large scale (Bai et al., 2014), and extraction costs are a key factor limiting the conversion of ingredients into products. Second, many herbal ingredients only show moderate effects and are unstable under normal conditions, their performance depends on the structure and properties (Manda et al., 2014; Ho et al., 2016; Lyles et al., 2017). Thus, the molecular structure of some ingredients will be further improved before use, research in this area is under development.

## THE STATUS OF ASIAN HERBAL RESEARCH IN SKIN WHITENING

In addition to finding problems by reviewing previous studies, it is also important to have a comprehensive understanding by statistics. Thus, we collected Asian herbal studies published between January 2017 and May 2020 and conducted a multifaceted analysis, aiming to understand the research status of Asian herbs in skin whitening, as well as to assess the overall quality and value of these studies. We used “skin whitening” and/or “Asian herb” as keywords to retrieve articles by Web of Science, the selected databases were Web of Science Core Collection, BIOSIS Citation Index, and MEDLINE®, the time frame was from January 2017 to May 2020. After that, we sorted the lists by academic citations and reviewed the 300 most cited articles in detail, then removed studies that were not associated with Asian herbs. Finally, we collected 90 studies for subsequent analysis. (The information of studies we collected were provided in *Supplementary Materials*.)

## Overview of Asian Herbal Research

Similar to the size of cosmetics markets, 72 studies were conducted in South Korea (42 studies, 46.7%), China (19 studies, 21.1%), Thailand (6 studies, 6.7%), and Japan (5 studies, 5.6%); 9 studies were conducted in Turkey, Pakistan, Iran, India, and Kuwait; the other 9 studies were cooperative projects between several Asian countries (**Figure 1A**). The geographical distribution of studies is related to the scientific research level, to some extent, it also can reflect the cosmetic market size and whitening demand. In another perspective, though only a few studies were conducted in countries other than Korea, China, Thailand, and Japan, the optimistic explanation is that the whitening markets in these countries have potential, and their herbal research are developing. It is known that India also has a lot of studies focused on herbs and depigmentation (Mukherjee et al., 2018). Further, we grouped studies based on reagent types. Unsurprisingly, studies mainly focused on herbal extracts (38 studies, 42.2%) and active ingredients (38 studies, 42.2%), and they share the same proportion. Besides, there are 13 studies reported both extracts and active ingredients (14.4%, labeled “Combined”), but only 1

**FIGURE 1 |** Overview of 90 Asian herbal studies in skin whitening. **(A)** The number of studies in different countries; **(B)** the number of studies on different reagent types; **(C)** the number of studies from 2017 to 2019; **(D)** the studies in four countries from 2017 to 2019; **(E)** the percentage of different reagent types from 2017 to 2019; **(F)** the percentage of different reagent types in four countries.

study involved herbal formulas (**Figure 1B**). The result may have something to do with the difficulties in studying three types of herbal reagents. As mentioned above, there are too many distractions in studying formulas.

The whitening market is still growing in Asia, research advances and market trends complement each other. According to our data, from 2017 to 2018, the number of studies increased from 25 to 35; but curiously, the number fell to 23 in 2019 and was not getting better in the first half of 2020 (**Figure 1C**). However, on the one hand, this could be a mistake caused by article collection, because we only reviewed the 300 most cited articles; on the other hand, we can't rule out the impacts of delay in database updating of Web of Science. Likewise, studies in Korea was increased in 2018 and decreased in 2019, but China was still on the rise (**Figure 1D**). Partly because China's scientific research, as a rising star, is developing fast. Though herbal research has not met a bottleneck, we should be aware that we already face some challenges. With the explosion of studies in skin whitening, the requirements are getting higher now.

Then, we further subdivided the studies by three reagent types and analyzed the differences between years and countries. Though

the overall attention paid to herbal extracts and active ingredients is almost the same (**Figure 1B**), it seems like the proportion of extract-related studies was increasing from 2017 to 2019, so did that of combined studies (reported both extracts and active ingredients). In contrast, the proportion of ingredient-related studies had a clear decline (**Figure 1E**). We don't yet know what this change means but have speculation. As new techniques and research facilities become more readily available, researchers may prefer to screen raw herbal materials rather than purchase purified ingredients, this helps to discover new reagents. Moreover, the attention paid to herbal extracts and active ingredients is slightly different between Korea and China, while Thailand and Japan have too few studies to be representative (**Figure 1F**).

## Quality and Value of Asian Herbal Studies

There is no doubt that Asian herbal research is developing well in skin whitening, and plenty of effective reagents have been found. But sadly, scattered studies are easy to ignore, their findings may also have limitations. Thus, to learn more about the overall quality of Asian herbal studies, we moved on and evaluated the scientificity and academic value of 90 collected studies.

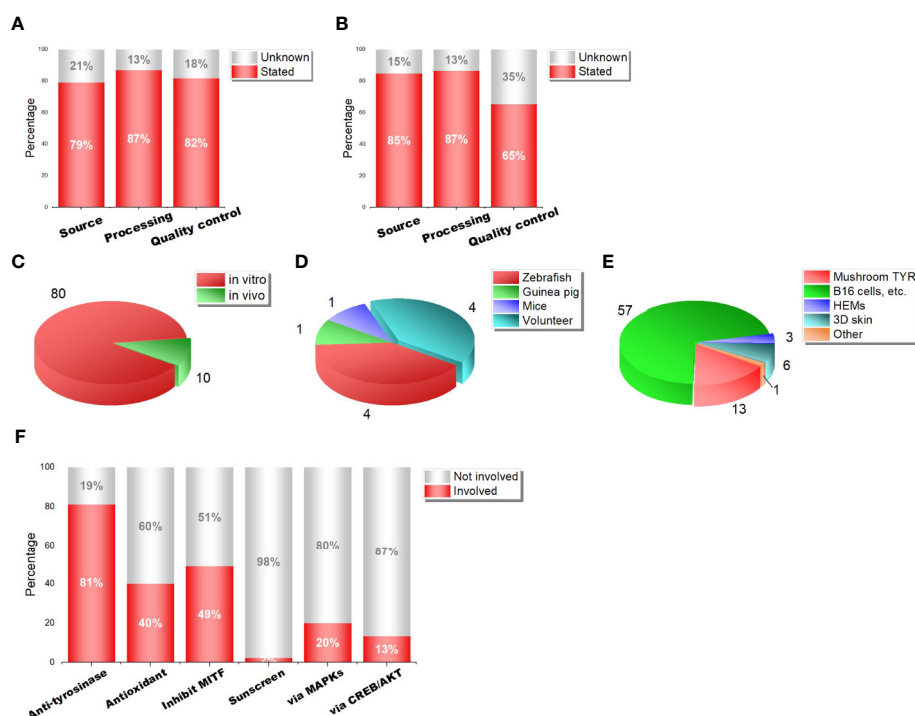

First, we divided studies into two groups: active ingredients and mixtures (including herbal extracts, formula, and combined studies). The evaluation criteria include information about (1) the source of herbal materials and ingredients (Source), (2) the processing method of raw materials (Processing), (3) the composition determination method of herbal extracts and ingredients, such as HPLC and UPLC (Quality control). For purchased herbal reagents, we assumed they met three criteria if detailed merchant information was provided. In this way, about 80% of the studies stated the sources and processing methods of herbal materials (**Figures 2A, B**). But only 65% of mixture-related studies provided quality control information (**Figure 2B**), which means that nearly 1/3 of the studies can not guarantee the quality of herbal extracts. Moreover, 82% of ingredient-related studies performed quality control (**Figure 2A**), but that does not mean they are scientific enough, because few of them stated the purity of the compounds. Therefore, we should be cautious about the credibility of these studies.

To assess the academic value, we also calculated the research models in 90 studies. It is surprised to find that only 10 (11.1%) of them carried out *in vivo* experiments (**Figure 2C**), the models include volunteers, zebrafish, mice, and guinea pigs (**Figure 2D**). The other 80 studies conducted *in vitro* experiments (**Figure 2E**),

57 (71.3%) of them used only mushroom tyrosinase, 13 (16.3%) of them used only mice cell lines (mostly B16 cells) and human melanoma cell lines, with or without mushroom tyrosinase; only 9 studies used human epidermal melanocytes (HEMs) and 3-dimensional human skin equivalents (3D skin). That is to say, only 1/10 of the studies showed the *in vivo* effects of herbs, and another 1/10 showed whitening evidence in human melanocytes. Although this is an acceptable proportion, there is room for further improvement.

In the 90 studies we collected, most herbal reagents regulate melanogenesis *via* part of the mechanisms previously mentioned. About 81% of the studies reported a decrease in tyrosinase activity, 40% reported antioxidant effect, and 49% observed downregulation of MITF expression. Otherwise, about 2% of the studies explored the sunscreen effect. When it comes to further mechanisms, only 20% of the studies reported a change in MAPK signaling pathway (mostly ERK and p38), and 13% involved CREB/AKT signaling pathway, etc. (**Figure 2F**). The main mechanisms of these herbal reagents are showed in **Figure 3**. Besides, the data show that studies are mainly focused on the anti-tyrosinase and antioxidant effects of herbal reagents, which are common characteristics of most herbs, thus their biological effects have not been thoroughly explored.

**FIGURE 2 |** Scientificty and academic value of 90 Asian herbal studies. **(A)** the quality control of ingredient-related studies; **(B)** the quality control of mixture-related studies (herbal formula, extracts, and combined studies); **(C)** the number of *in vitro* and *in vivo* studies; **(D)** the models of *in vivo* studies; **(E)** the models of *in vitro* studies; **(F)** the percentage of different mechanisms involved in studies.

**FIGURE 3 |** Schematic diagram of the mechanisms of herbal reagents in 90 studies.

## CHALLENGES AND PROSPECTS

In Asia, whitening cosmetics are in high demand, and leading to great progress in herbal research. However, the downside also deserves attention. In this work, we reviewed whitening-related studies from a comprehensive view and found some problems. One of them is that herbal components are complex and easily affected by multiple factors, which brings problems to studying herbal formula and extract, and also affects the reliability of the results. In contrast, active ingredients are the focus of research. The quality of most studies is reliable, but ingredient purification is a tough job. In a big way, Asian herbal research is not deep and systematic enough, because studies still focus on the discovery of new ingredients, rather than mechanism exploration and application. Also, there are few clinical studies on whitening. At present, the market for natural whitening cosmetics is a mess. On the one hand, research findings rarely translate into products; on the other hand, substandard products emerge one after another due to supervision loopholes (Desmedt et al., 2016). Many herbal reagents exhibit pharmacological properties (Zeng et al., 2019a) and can affect the structure and function of cells and organs, including the skin (Imokawa, 2008). Although herbal reagents are moderate, their side effects should be taken seriously, which have been ignored in the past.

In order to promote the application and development of traditional Asian herbs in whitening, all issues should be addressed carefully. Such as, the focus of herbal research should shift from quantity to quality and promote achievements transformation. At present, researchers are trying to synthesize herbal ingredients and derivatives, aiming to enhance their advantages and improve defects (Gonzalez-Sabin et al., 2011).

From another point of view, synthetic and semi-synthetic natural ingredients may become a new hotspot in the future (Lee et al., 2016; Pillaiyar et al., 2017). In Asia, traditional herbs have been used over thousands of years, but have been ignored in the past century. In skin whitening, the discovery of natural ingredients such as arbutin was a surprise (Akiu et al., 1991; Chakraborty et al., 1998). In China alone, more than 10,000 herbs have been recorded (Xie and Yu, 1996), compared with this huge “herbal ingredient pool,” the findings so far have only scratched the surface (Zhao et al., 2020). Given the advances of techniques and the explosion of research, traditional Asian herbs need a new stage towards application.

## SEARCH STRATEGIES

Most materials in this review were obtained from Web of Science and PubMed; only documents covered by Science Citation Index (SCI) were selected. A few materials were obtained from ancient medical books, which were collected in the library of Central South University. Some keywords used in retrieving are provided below: Asian herbs, traditional herbs, melanogenesis, skin whitening. The 90 studies collected for statistical purposes were not directly cited in the paper, and their information were provided in the **Supplementary Materials**.

## AUTHOR CONTRIBUTIONS

YH: collected the materials and drafted the manuscript. HZ: participated in the collection and screening of studies and provided analytical methods. JH: guided the analysis and

arrangement of literature. LJ: recorded information and made tables. QZ and JC: put forward ideas, provided a framework for writing, checked and corrected writing problems. All authors contributed to the article and approved the submitted version.

## FUNDING

The authors thank the financial support from the National Natural Science Foundation of China (No. 81703101), the New Xiangya Talent Projects of the Third Xiangya Hospital of Central South University (No. JY201623 and No. 20170301), the Natural Science

Foundation of Hunan Province (No. 2018JJ3788 and No. 2018JJ3793), the Project of Health and Family Planning Commission of Hunan Province (No. C2019173), and the Fundamental Research Funds for the Central Universities of Central South University (No. 2020zzts199).

Cudratrixanthone U (CTU) is a prenylated xanthone compound isolated from *Maclura tricuspidata* Bureau (Moraceae). Prenylated xanthones have been reported to exhibit a variety of biological activities. However, the effects of prenylated xanthone on osteoclast differentiation and function are still unclear. Excessive bone resorption by osteoclasts is considered a major cause of diseases such as osteoporosis. Accordingly, suppression of excessive osteoclast formation and function is one of strategies for treating osteoclast related bone diseases. In this study, CTU inhibited osteoclast differentiation and function in RAW264.7 macrophages and BMM cells induced by receptor activator of nuclear factor- $\kappa$ B ligand (RANKL). CTU regulated the formation of TRAF6-TAK1 complex in RANKL-induced RAW264.7 macrophages and BMM cells. Osteoclast-specific genes including those encoding matrix metalloproteinase 9 (MMP-9), dendritic cell-specific transmembrane proteins (DC-STAMP), cathepsin K (CTSK) and chemokine CC motif ligand 4 (CCL4) play an important role in bone resorption and migration, and were effectively regulated by CTU. These results suggest that CTU is a potential therapeutic agent in osteoporosis.

**Keywords:** Cudratrixanthone U, TRAF6, TAK-1, RANKL, CCL4, osteoclast

## INTRODUCTION

Bone homeostasis is associated with a balance between bone resorption by osteoclasts and bone formation by osteoblasts. Bone resorption by excessive osteoclast differentiation can lead to disorders such as osteoporosis and rheumatoid arthritis (Boyce et al., 2005; Warren et al., 2015). Therefore, inhibition of bone resorption by excessive osteoclast differentiation plays a key role in the treatment of osteoporosis. Osteoclasts are giant multinucleated cells derived from the mononuclear macrophage family via continual proliferation, differentiation and fusion of hematopoietic stem cells. They are involved in bone resorption, and play an essential role in bone formation and control of bone density (Novack and Teitelbaum, 2008; Geng et al., 2017).

Osteoclast formation requires specific activation of the RANKL/RANK (receptor activator of NF- $\kappa$ B ligand and its receptor) system of macrophage or monocyte lineage. These osteoclasts play an essential role in various diseases (Teitelbaum, 2000). Among the TNF receptor-related factors (TRAF) molecules, TRAF6 is an important component of the RANK signaling pathway. When RANKL binds to RANK in preosteoclasts, TRAFs 2, 3, 5, and 6 are recruited, which induces mitogen-activated protein kinase (MAPK) and nuclear factor kappa-light-chain-enhancer of activated B cells (NF- $\kappa$ B) pathways (Kim et al., 1999), and the activation of various signaling pathways. In addition, RANKL stimulation not only activates transforming growth factor beta-activated kinase 1 (TAK1), which is a member of the mitogen-activated protein kinase (MAPK) family, but also activates the TRAF6-TAK1 complex associated with RANK to induce both c-Jun N-terminal kinase (JNK) and NF- $\kappa$ B activation and downstream signaling pathway activator protein 1 (AP-1), and c-Fos/c-Jun dimer induces the expression of primary osteoclast regulatory nuclear factor of activated T cells c1 (NFATc1) (Takayanagi et al., 2002; Kanzaki et al., 2017). Thus, inhibition of these signaling pathways prevents pathological bone loss induced by excessive osteoclast formation. Activated NFATc1 regulates a variety of genes, such as tartrate-resistant acid phosphatase (TRAP), cathepsin K (CTSK), and dendritic cell-specific transmembrane proteins (DC-STAMP), which are essential for osteoclast differentiation and function (Li et al., 2006). Also, the matrix metalloproteinase (MMP)-9 and integrin  $\beta$ 3 secreted by osteoclasts are known to promote osteoclast migration and mediate osteoclast bone resorption (Ishibashi et al., 2006). Previous studies have suggested that the inhibition of osteoclast migration is a potential therapeutic target in bone disease, including osteoporosis, and the chemokine CC motif ligand 4 (CCL4) is known to promote the migration and viability of pre-osteoclast cells (Lee et al., 2018). Therefore, inhibition of these genes may play an important therapeutic role in osteoporosis in order to disrupt the differentiation and function of activated osteoclasts.

*Maclura tricuspidata* Bureau (Moraceae) is a traditional medicinal plant native to Northeast Asia that has long been used for lumbago, hemoptysis, and hematemesia (Jung and Shin, 1990; Chang et al., 2008). In particular, *M. tricuspidata* root is known as “Chuan-po-shi” in traditional Chinese medicine and has been used to treat rheumatism and lumbago, and is one of the most common traditional remedies for cancer in Korea (Kim et al., 2009; Xin et al., 2017). Previous studies have reported that the roots and fruits of *M. tricuspidata* showed various pharmacological activities, such as anti-inflammatory effects (Jeong et al., 2010), cytotoxicity inhibition (Lee et al., 2005), and hepatoprotection (Tian et al., 2005). The major constituents of *M. tricuspidata* include prenylated xanthenes and flavonoids, alkaloids, and organic acids (Xin et al., 2017; Li et al., 2018). Prenylated xanthenes isolated from *M. tricuspidata* have been reported to inhibit neurotoxicity (Jeong et al., 2008), and exhibit neuroprotective (Kwon et al., 2014), and anti-cancer effects (Seo et al., 2001). Despite these pharmacological activities, studies on

bone diseases are still incomplete. Therefore, this study investigated the effect of cudratrixanthone U isolated from *M. tricuspidata* on osteoclast differentiation, migration and bone resorption in RANKL-stimulated RAW264.7 and bone marrow-derived macrophages (BMM) cells.

## MATERIALS AND METHODS

### Chemicals and Reagents

Minimum Essential Medium Eagle—Alpha Modification (Alpha MEM), fetal bovine serum (FBS), penicillin, and streptomycin were purchased from Welgene Inc. (Korea). Mouse RANKL was purchased from PeproTech (Rocky Hill, NJ, USA). 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT) was obtained from Amresco Inc. (Solon, OH, USA). Fast Red-violet LB salt, naphthol AS-MX phosphate 4-6-diamidino-2-phenylindole (DAPI) and p-nitro-phenylphosphate were obtained from Sigma-Aldrich Fine Chemicals (St. Louis, MO, USA). Antibodies against p-ERK, ERK, p-p38, p38, p-JNK, JNK, NFATc1, c-Fos, integrin  $\beta$ 3, MMP-9, CTSK and  $\beta$ -actin were purchased from Cell Signaling Technology (Danvers, MA, USA). Anti-TRAF6, anti-TAK1, I $\kappa$ B- $\alpha$ , p-I $\kappa$ B- $\alpha$ , and NF- $\kappa$ B p65 were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Also, Antibodies of DC-STAMP and CTSK were obtained from Abcam (Cambridge, UK). Secondary antibodies were purchased from Santa Cruz and Cell Signaling Technology. Nuclear and cytoplasmic extraction reagent kit and enhanced chemiluminescence kit were provided by Pierce Biotechnology (Rockford, IL, USA). Protease inhibitors were purchased from Roche (Hoffmann, NC, USA). Alexa fluor-488 pallodin was acquired from Invitrogen (Waltham, MA, USA). Osteo assay surface multiwell plates were obtained from Corning Inc. (NY, USA). Radioimmunoprecipitation (RIPA) assay buffer and protease and phosphatase inhibitor cocktail were purchased from Fisher Scientific Inc. (Waltham, MA, USA).

### Plant Materials and Isolation of Compounds

A voucher specimen (accession number KH1-4-090814) was deposited at the Department of Biosystems and Biotechnology, Korea University, Seoul, Korea. We isolated cudratrixanthone U (CTU) from the bark of *M. tricuspidata*. CTU was extracted as reported previously and structurally identified using nuclear magnetic resonance (NMR) and high-resolution electrospray ionization mass spectrometry (HRESIMS) (Kwon et al., 2016).

### Cell Culture and Viability Assays

RAW 264.7 and BMM cells (ATCC, Manassas, VA, USA) were cultured in alpha-MEM supplemented with 10% heat-inactivated FBS, 2 mM L-glutamine, and 100 U/ml penicillin/streptomycin. Incubations were carried out at 37°C in 5% CO<sub>2</sub>. We performed an MTT assay following the manufacturer's instructions to detect CTU cytotoxicity. RAW264.7 and BMM cells were seeded on a 96-well plate at a concentration of  $5 \times 10^3$  cells/ml, followed by treatment with different concentrations and

incubation for 120 h. The concentration of MTT solution was 50 mg/ml, and the absorbance at 490 nm was measured by an ELISA plate reader (Männedorf, Swiss).

## Osteoclast Differentiation

RAW 264.7 and BMM cells were seeded on 24-well plates ( $5 \times 10^3$  cells/well) with complete alpha-MEM containing RANKL (50 ng/ml) in the presence of CTU for 5 days at 37°C and 5% CO<sub>2</sub>.

## Tartrate-Resistant Acid Phosphatase (TRAP) Staining and Activity

After differentiation and osteoclast formation as described above, cells were washed and fixed with 4% paraformaldehyde for 10 min, permeabilized with 0.1% Triton X-100, and finally stained for TRAP with the Leukocyte Acid Phosphatase Kit (Sigma, Cat. No. 387A-1KT). Fixed cells were assayed for tartrate-resistant acid phosphatase (TRAP) activity, according to the manufacturer's instructions (Saint Louis, MO, USA).

## Actin Ring and DAPI Staining

RAW264.7 and BMM cells were cultured in alpha-MEM, with or without CTU for 5 days. The cells were washed three times with phosphate-buffered saline (PBS) and fixed in 4% formalin for 15 min. The cells were then stained with fluorescein isothiocyanate (FITC)-phalloidin solution for 1 h, and the nuclei were sequentially stained with 2.5 µg/ml 4',6-diamidino-2-phenylindole (DAPI) solution for 10 min. The images were captured using a fluorescence Olympus IX microscope 71-F3 2PH (Tokyo, Japan).

## Bone Resorption Assay

RAW264.7 and BMM cells were seeded with alpha-MEM containing RANKL (50 ng/ml) in the presence of CTU (0.5, 1, 2, 5 µM) into the wells of an osteo assay surface well for 12 days at 37°C and 5% CO<sub>2</sub>. After 10 days, RAW 264.7 cells were removed by 5% sodium hypochlorite (Saint Louis, MO, USA) treatment and resorption pits were visualized under a light Olympus IX microscope 71-F3 2PH. The resorption area was calculated and analyzed using Image-J software Version 1.52i (USA).

## Cell Migration Assay

RAW264.7 and BMM cells ( $1.5 \times 10^4$  cells/well) were incubated in a 24-well plate for 24 h, followed by constant scratching. Next, cells were treated with α-MEM and 10% FBS with or without RANKL (50 ng/ml) and CTU, and the cells migrating for 5 days were counted with Incucyte® Live-Cell analysis systems (Göttingen, Germany).

## Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR)

Total RNA was extracted from the cells using TRIzol reagent (Bioneer, Korea) according to the manufacturer's instructions. PCR reaction conditions included 1 µl primer, 11 µl nuclease-free ultrapure water, 4 µl 5× reaction buffer, 1 µl RiboLock RNA enzyme inhibitor (20 U/µl), 2 µl 10mM dNTP mix, and 1 µl

RevertAid M-MuLV reverse transcriptase (200 U/µl) (Thermo Fisher Scientific, USA). The cycling conditions were 40 cycles at 50°C for 2 min, 95°C initial denaturation for 10 min, 95°C denaturation for 15 s, and 60°C annealing for 30 s. The primer sequences used are listed in **Table 1**.

## Cytosolic and Nuclear Protein Extraction

RAW 264.7 and BMM cells were seeded on culture dishes at a density of  $2.5 \times 10^5$  cells/dish and treated with indicated concentrations of CTU (0.5, 1, 2, and 5 µM), stimulated with RANKL (50 ng/ml), incubated at 37°C with 5% CO<sub>2</sub>, and then lysed using the RIPA buffer. We prepared the cytosolic and nuclear extracts using an NE-PER nuclear and cytoplasmic extraction reagents kit, according to the manufacturer's instructions.

## Co-Immunoprecipitation (Co-IP)

RAW264.7 and BMM cells treated with or without RANKL in the presence or absence of CTU (2, 5 µM) was digested using RIPA buffer and centrifuged for 30 min. First, the antibody for the targets TRAF6 and TRAF6-specific IgG was incubated with the Thermo dynabead protein G kit in a tube for 10 min, and the antibody was washed away by placing the tube in a Dynamagnet and removing the supernatant. For immunoprecipitation, cell lysates extracted were incubated with anti-TRAF6 or anti-TAK1 antibody for 1 h at 4°C, followed by 1 h incubation at 4°C with the Thermo Fisher Scientific (Waltham, MA, USA) dynabeads protein G kit, following the manufacturer's instructions.

## Western Blot Analysis

RAW 264.7 and BMM cells were lysed in RIPA buffer containing protease inhibitors and centrifuged at 14,000 rpm for 30 min. Protein concentration was measured by Bradford assay using a Bio-Rad Bradford assay reagent (Hercules, CA, USA). Amounts of each lysate were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). After electrophoresis, proteins were transferred using polyvinylidene difluoride (PVDF) membranes (Hercules, CA, USA). After blocking with TBS-T buffer containing skim milk (5%), we incubated with the primary antibody overnight at 4°C. It was

washed, incubated with a secondary antibody (horseradish peroxidase-conjugated anti-rabbit IgG and anti-mouse IgG), and detected with Healthcare Life Science ECL-plus (Tokyo, Japan). Immunoreactive bands were analyzed by LAS 4000 (GE Healthcare Life Science, Tokyo, Japan).

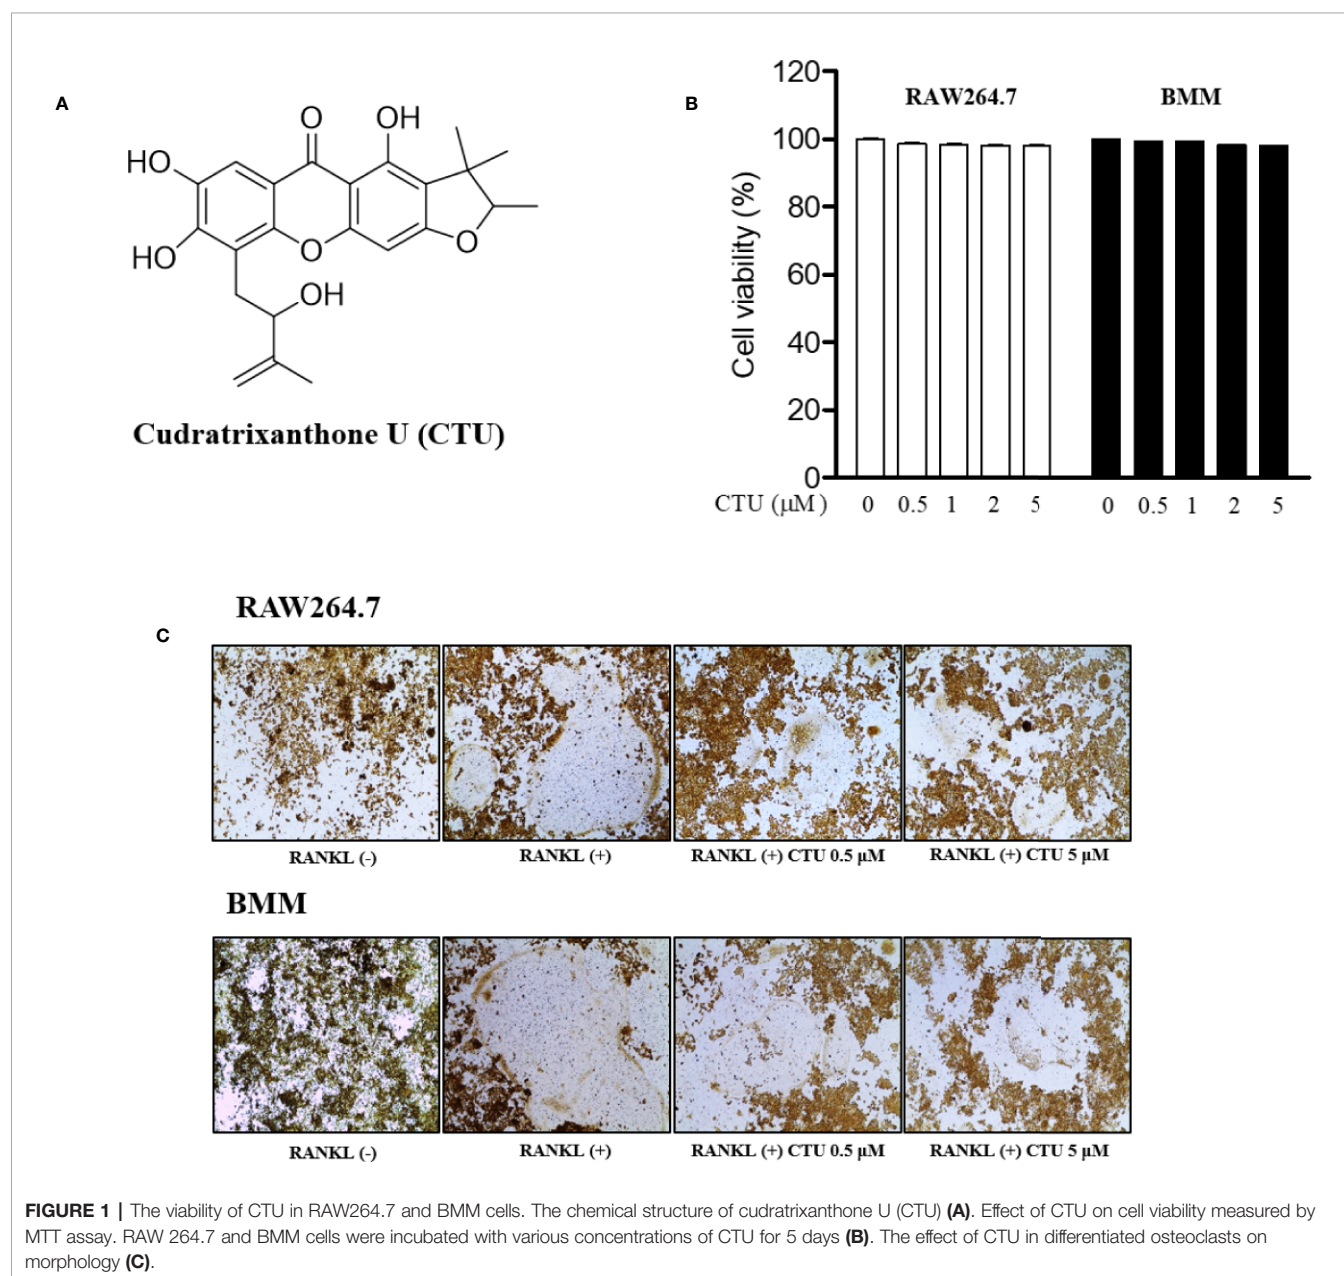

## Statistical Analysis

Each experiment was performed in triplicate and expressed as mean value and standard deviation. Statistical analysis was conducted using SPSS Statistics 19.0 software, and correlations were considered significant at  $p < 0.05$ .

## RESULTS

### Inhibitory Effect of CTU on RANKL-Induced Osteoclast Formation

To measure CTU (**Figure 1A**) cell viability, we treated RAW264.7 and BMM cells with various concentrations of CTU (0.5, 1, 2, and 5  $\mu\text{M}$ ) for 5 days. As shown in **Figure 1B**, there was no significant cytotoxicity due to CTU, also it was confirmed that the morphology of osteoclasts differentiated by RANKL was also inhibited by CTU (**Figure 1C**). Therefore, to verify the effect of CTU on osteoclast formation at the indicated concentrations, we treated CTU with RANKL at different concentrations in RAW264.7 and BMM cells.

After 5 days of culture, we measured TRAP staining and activity of mature osteoclasts. Osteoclast differentiation and activity were significantly inhibited by CTU treatment in a dose-dependent manner (**Figures 2A, B**).

### CTU Suppresses Formation of RANKL-Stimulated Osteoclastic F-actin Rings

The F-actin ring is a characteristic structure of mature osteoclasts, and therefore we measured the area *via* fluorescence staining of mature osteoclasts to investigate the effect of CTU on RANKL-induced osteoclasts. We found that the formation of the F-actin ring and the pit area were significantly inhibited by CTU in a dose-dependent manner (**Figures 3A, B**). Increased F-actin ring formation by RANKL treatment was concentration-dependently

reduced by CTU in RAW264.7 cells and In BMM cells, CTU 0.5  $\mu\text{M}$  and 1  $\mu\text{M}$  treatment group showed similar level of inhibition, and 5  $\mu\text{M}$  treatment group significantly reduced the pit area.

### CTU Inhibited Osteoclast Differentiation and Function

Because CTU inhibited the formation of osteoclasts and F-actin rings, we measured pit formation by inducing osteoclasts on a bone-biomimetic synthetic surface to investigate their effects on bone resorption. We found that CTU significantly inhibited the pit area in a concentration-dependent manner, and there was almost no pit area at the highest concentration (**Figures 4A, B**). Therefore, CTU inhibited osteoclast differentiation and function in bone resorption in RAW264.7 and BMM cells induced by RANKL.

**FIGURE 2 |** The effect of CTU on osteoclast differentiation in RANKL-induced RAW 264.7 (**A**) and BMM (**B**) cells. The cells were incubated with 50 ng/ml RANKL or both RANKL and various concentrations of CTU for 5 days and then stained for TRAP. TRAP activity was measured using an ELISA reader (optical density, 405 nm). \* $p < 0.05$  compared with the only RANKL-treated group.

**FIGURE 3 |** The effect of CTU on osteoclast-actin ring structures in RANKL-induced RAW 264.7 **(A)** and BMM **(B)** cells. RAW 264.7 cells were treated with different concentrations of CTU in the presence of RANKL. After fixation and incubation with Alexa Fluor 488-conjugated phalloidin stained with DAPI, cells were visualized under a fluorescence microscope. Quantitative analysis shows percentage of osteoclasts forming F-actin rings. \* $p < 0.05$  compared with the only RANKL-treated group.

## CTU Inhibits Osteoclast Migration by Regulating CCL4

Chemokine CCL4 has been suggested to play an important role in osteoclast migration. Therefore, we measured the RNA expression of CCL4 in RANKL-treated RAW264.7 and BMM cells. As a result, the expression of CCL4 increased the most after 5 days of RANKL treatment. On day 5 of RANKL treatment, CTU inhibited CCL4 in a concentration-dependent manner (**Figures 5C, D**). CTU effectively inhibited the expression of integrin  $\beta 3$  in RANKL-treated RAW264.7 and BMM cells (**Figures 5A, B**). In addition, to measure the inhibitory effect of osteoclast migration on CTU, the coefficient of migrated cells was measured, as a result, the increased migration coefficient by RANKL on day 5 in RAW264.7 and BMM cells was reduced by concentration-dependent treatment of CTU (**Figures 5E, F**).

## CTU Inhibits the Expression of RANKL-Induced Osteoclast-Specific Genes

The maturation of osteoclasts is accompanied by the expression of specific genes and protein, ATP6VOD2 and ACP5, DC-STAMP, CTSK and MMP-9, which are essential for osteoclast formation and function. Therefore, we investigated the role of specific genes and protein in osteoclast formation and function under the inhibitory effect of CTU on osteoclast differentiation and bone resorption.

Treatment with CTU significantly down-regulated the expression of ATP6VOD2 and ACP5, DC-STAMP, CTSK, and MMP-9 more than in RANKL-treated group (**Figures 6A, B**). As a result, CTU suppressed differentiation and function by down-regulating the expression of osteoclast specific genes and proteins.

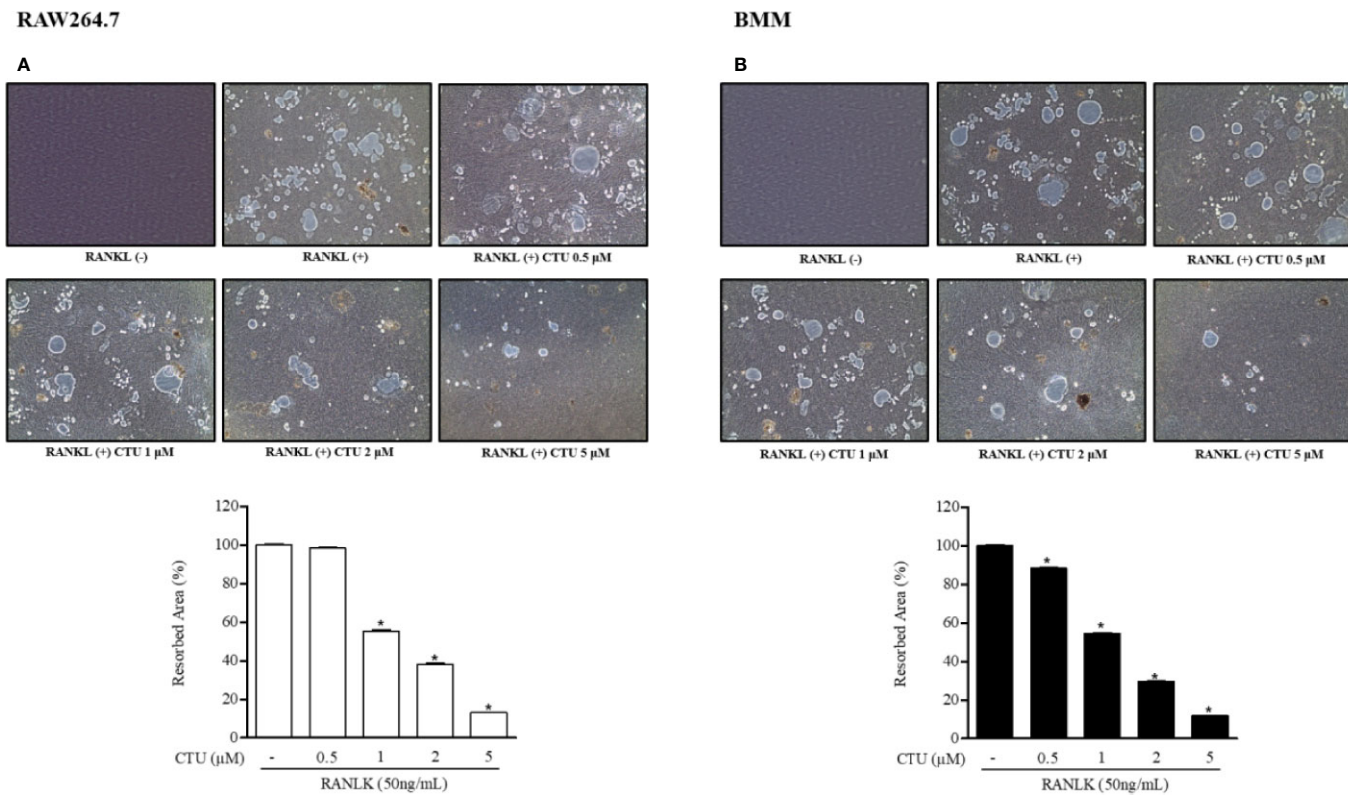

## CTU Suppress RANKL-Induced TRAF6-TAK1 Complex Formation

TRAF6/TAK1 complex formation is an important step prior to RANKL-mediated MAPK and NF- $\kappa$ B activation. Therefore, we used co-precipitation to investigate the effects of CTU on the formation of RANKL-induced TRAF6/TAK1 complex. In pull-down assays, co-immunoprecipitation of TAK1 with anti-TRAF6 antibody (and of TRAF6 with anti-TAK1) was increased in the presence of RANKL. However, CTU inhibited co-precipitation of RANKL-induced TRAF6/TAK1 complexes in a concentration-dependent manner (**Figures 7A, B**).

## CTU Suppresses RANKL-Induced Activation of NF- $\kappa$ B and MAPKs

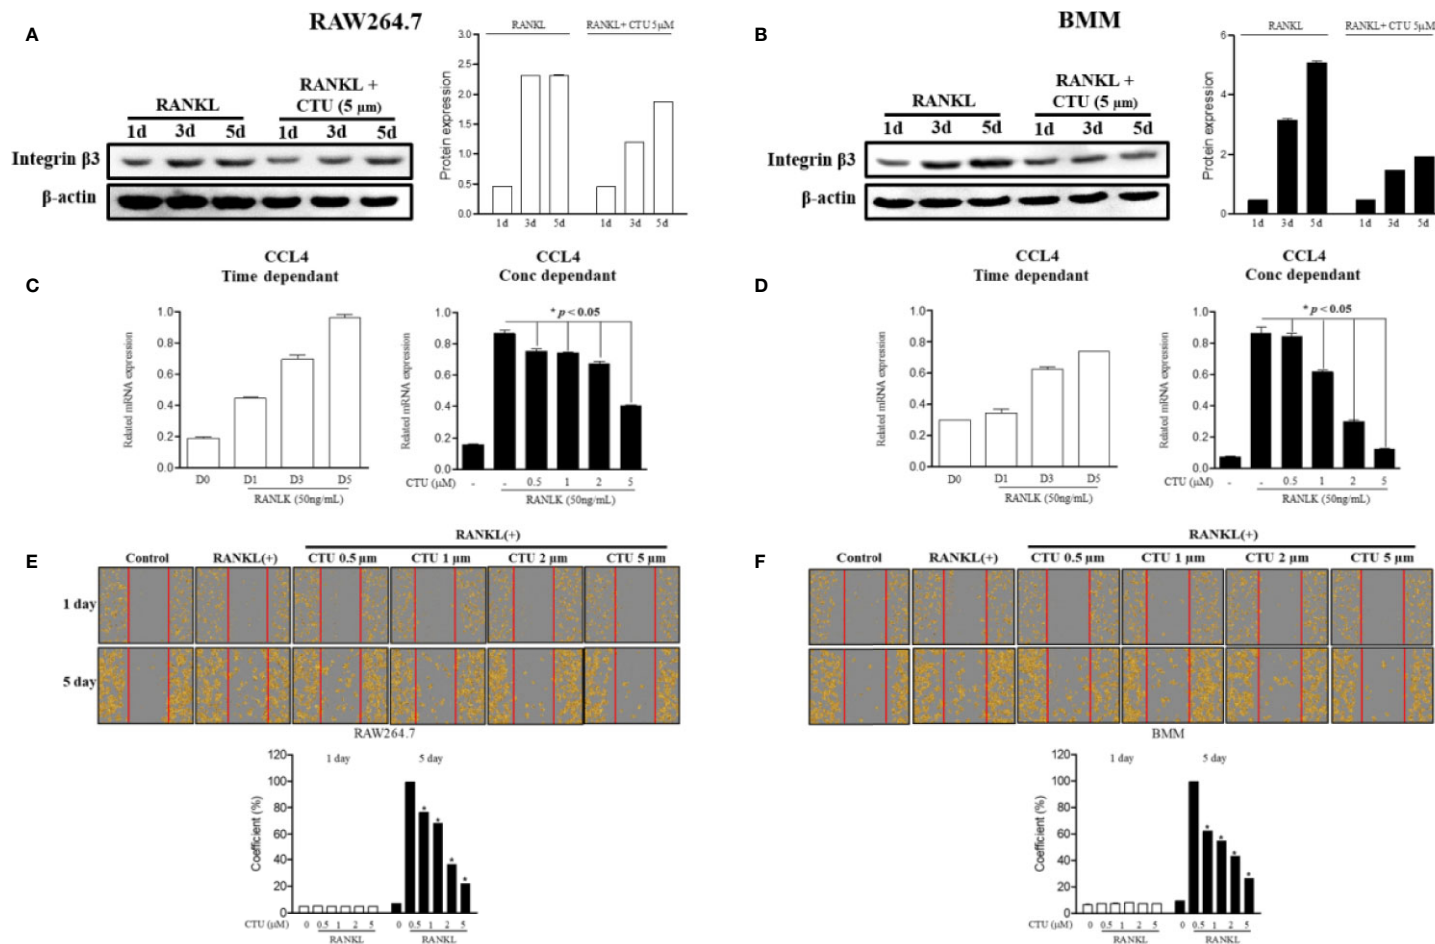

Downstream of TRAF6 signaling complexes, the activation of MAPK (ERK, JNK and p38 MAPK) and NF- $\kappa$ B plays an important role in osteoclast differentiation. Therefore, we used

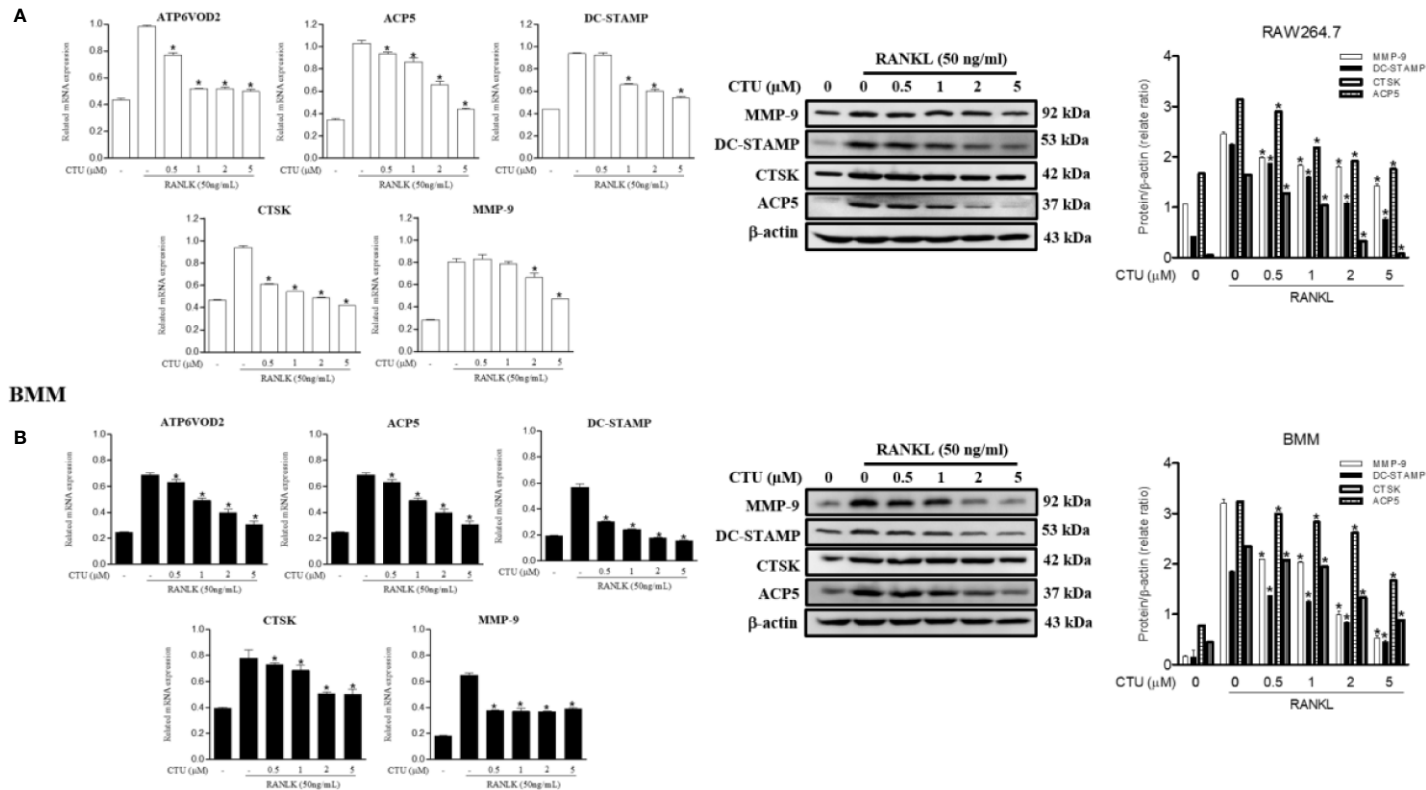

**FIGURE 4 |** The effect of CTU on osteoclast bone resorption in RANKL-induced RAW 264.7 (A) and BMM (B) cells. The cells were treated with different concentrations of CTU in the presence of RANKL. Total resorption pit area was measured and the results are shown as % of RANKL treatment. Pit formation assay of osteoclasts and quantification of pit area. \* $p < 0.05$  compared with the only RANKL-treated group.

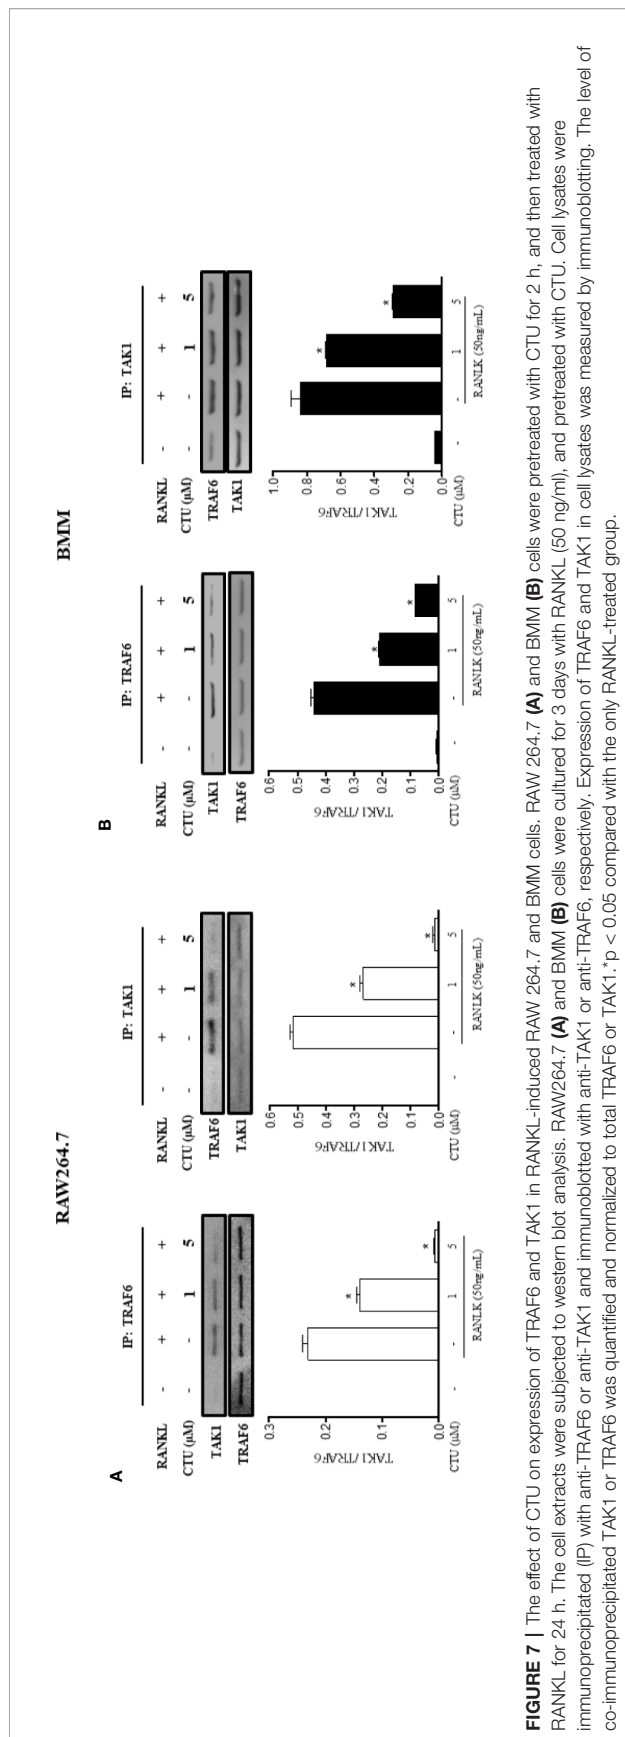

**FIGURE 5 |** The effect of CTU on RANKL-induced osteoclast migration. RAW 264.7 and BMM cells were cultured in the presence of CTU and RANKL for 1–5 days to induce osteoclast differentiation, and the protein expression of integrin  $\beta 3$  was measured by Western blot (A, B), and the levels of CCL4 mRNA were measured by real-time PCR (C, D). RAW264.7 and BMM cells were cultured without or with RANKL for 3 d, and further incubated for 24 h in the presence of CTU (0.5, 1, 2, and 5  $\mu$ M) after gentle scratching (E, F). The number of migrated cells was averaged using IncuCyte-image marking software. \* $p < 0.05$  compared with the only RANKL-treated group.

RAW264.7

**FIGURE 6 |** The effect of CTU on osteoclast-specific gene and protein expression in RANKL-induced RAW 264.7 **(A)** and BMM **(B)** cells. The cells were treated with different concentrations of CTU in the presence of RANKL, and osteoclast-specific gene expression was measured by real-time PCR. The results were normalized to GAPDH expression. \* $p < 0.05$  compared with only RANKL-treated group.

**FIGURE 7 |** The effect of CTU on expression of TRAF6 and TAK1 in RANKL-induced RAW 264.7 and BMM cells. RAW 264.7 (A) and BMM (B) cells were pretreated with CTU for 2 h, and then treated with RANKL for 24 h. The cell extracts were subjected to western blot analysis. RAW264.7 (A) and BMM (B) cells were cultured for 3 days with RANKL (50 ng/ml), and pretreated with CTU. Cell lysates were immunoprecipitated (IP) with anti-TRAF6 or anti-TAK1 and immunoblotted with anti-TRAF6 and TAK1, respectively. Expression of TRAF6 and TAK1 in cell lysates was measured by immunoblotting. The level of co-immunoprecipitated TAK1 or TRAF6 was quantified and normalized to total TRAF6 or TAK1. \* $p < 0.05$  compared with the only RANKL-treated group.

western blots to further explore the activation of the MAPKs and NF- $\kappa$ B pathways by which CTU regulates osteoclast differentiation and function. Phosphorylation of MAPKs and NF- $\kappa$ B p65 activity were induced in RANKL-stimulated RAW264.7 and BMM cells, and the expression of p-ERK, p-JNK, and p-p38 was inhibited by CTU (Figures 8A, B). CTU also inhibited the activity of p65 and the phosphorylation of I $\kappa$ B- $\alpha$  (Figures 8C, D). Thus, the osteoclast-differentiation and bone-resorption functions of CTU were related to MAPKs and NF- $\kappa$ B activity.

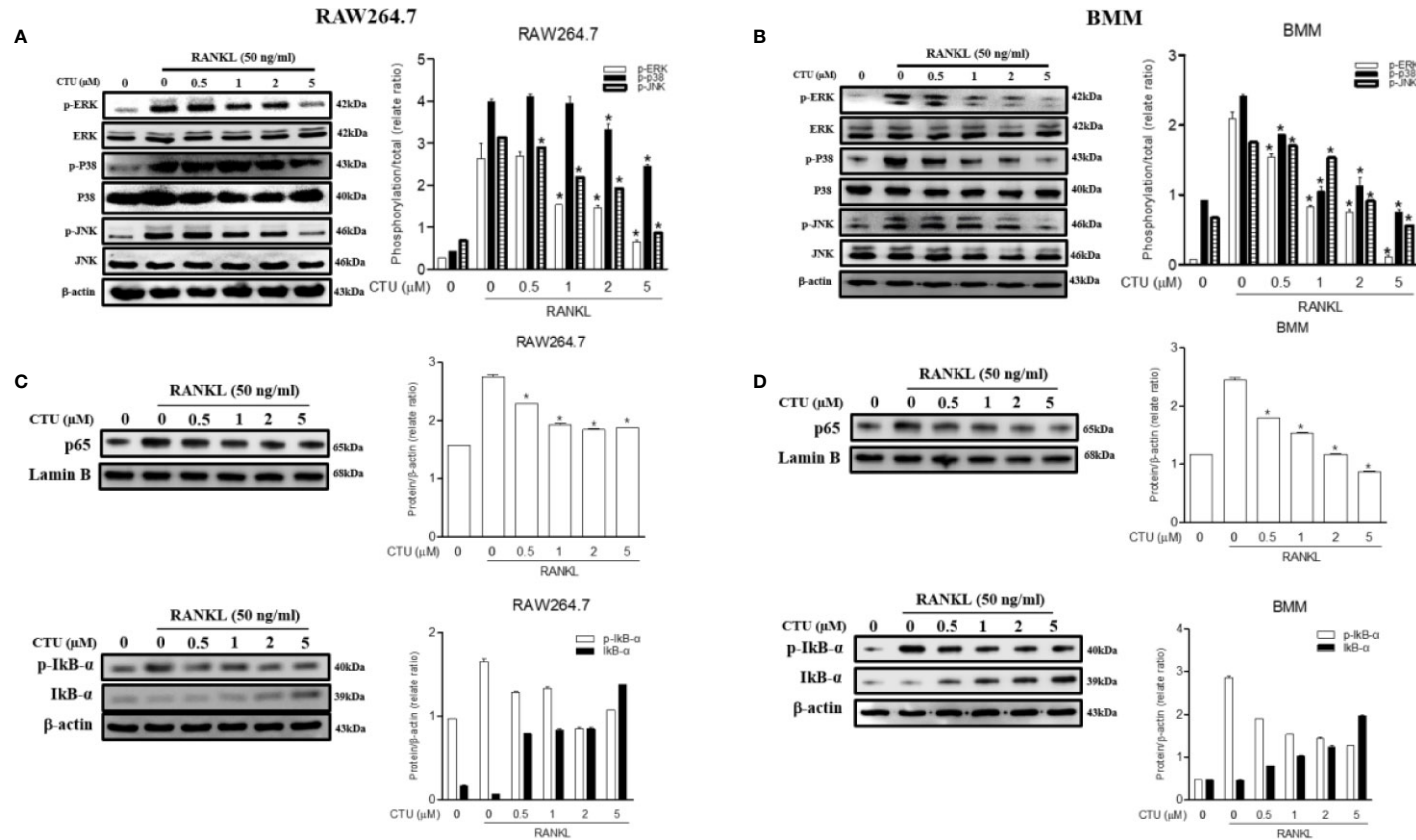

## CTU Downregulates RANKL-Induced Expression of NFATc1 and c-Fos

NFATc1 and c-Fos are the most important osteoclast-specific transcription factors following RANKL binding to RANK. Therefore, we used the western blot to evaluate the effects of CTU on the two transcription factors. RAW 264.7 and BMM cells induced by RANKL for 24 h significantly increased the expression of c-Fos and NFATc1, whereas in the group treated with CTU 0.5 and 1  $\mu$ M in RAW264.7 and BMM cells, similar levels of NFATc1 and c-Fos expression were suppressed, and 2 and 5  $\mu$ M treatment group showed a marked inhibitory effect (Figures 9A, B).

## DISCUSSION

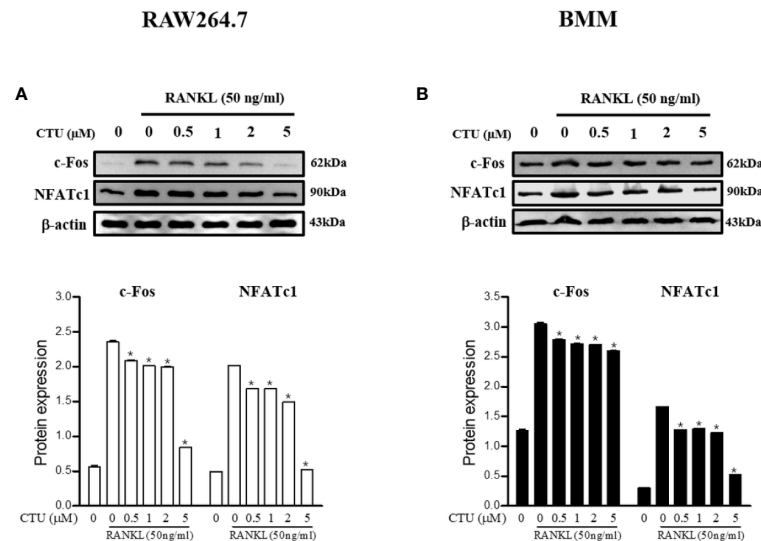

Disruption of bone homeostasis is caused by increased bone resorption by osteoclasts rather than new bone formation by osteoblasts, and RANKL is a major pro-osteoclastogenic cytokine that mediates osteoclast differentiation (Park et al., 2017; Ono and Nakashima, 2018). Thus, the inhibition of osteoclast formation, bone resorption and migration by inhibiting RANKL signaling and downstream pathways is an important target in the treatment of osteoporosis (Zou et al., 2001; Xuan et al., 2017). In the present study, we evaluated the mechanism of CTU inhibition of osteoclast differentiation and migration in a RANKL-induced RAW 264.7 and BMM cell line. Osteoclast differentiation by RANKL activates TRAP, a representative osteoclast marker involved in bone resorption, forms and maintains actin ring formation on the bone surface, and promotes bone resorption (Hayman, 2008). In our study, CTU attenuated osteoclast differentiation and function by inhibiting TRAP activity, F-actin formation, and bone resorption. Also, proteolytic enzymes, such as cathepsin K and MMP-9, and osteoclastogenesis-related markers, such as ACP5, DC-STAMP, and ATP6V0d2 play an important role in bone resorption and osteoclast differentiation. CTU inhibited these osteoclast gene markers in a concentration dependent manner.

In osteoclast signaling by RANKL, the cytoplasmic domain of RANK recruits TRAF6 to initiate complex formation with TAK1, activates NF- $\kappa$ B and MAPK, and plays a critical signaling role in osteoclast maturation (Mizukami et al., 2002; Nakashima et al., 2012). The TRAF family consists of six proteins each. TRAF6 is a unique member of the RING domain ubiquitin ligase family, which catalyzes the poly-ubiquitin chain linked *via* ubiquitin Lys-63 (Arch et al., 1998; Lamothe et al., 2007; Landstrom, 2010). In addition, the TRAF6 pathway induces phosphorylation of

**FIGURE 8 |** Effect of CTU on MAPKs (A, B) and NF-κB (C, D) activation in RANKL-induced RAW 264.7 and BMM cells. The cells were pre-incubated with or without CTU for 2 h, followed by treatment with 50 ng/ml RANKL for 30 min. The protein expression of cytosolic and nuclear p65, IκBα, and p-IκBα was compared with that of controls subjected to western blot analysis. \*p < 0.05 compared with the only RANKL-treated group.

**FIGURE 9 |** The effects of CTU on NFATc1 and c-Fos protein expression in RANKL-induced RAW 264.7 (A) and BMM (B) cells. The cells were cultured in the presence of RANKL with the CTU. After 24 h, the total protein was isolated and the protein expression levels were evaluated by western blots. \* $p < 0.05$  compared with the only RANKL-treated group.

MAPKs, such as ERK, p38, and JNK, and regulates the expression of transcription factors such as NF- $\kappa$ B upon binding of RANKL and RANK in osteoclast precursor cells (Kobayashi et al., 2001). During RANKL signaling, MAPK is an important target for osteoclast differentiation as a major regulator of various cellular responses, including cell proliferation, apoptosis, and differentiation (Sui et al., 2014; Thummuri et al., 2015). We found that CTU inhibited the formation of TRAF6-TAK1 complex by RANKL stimulation in RAW264.7 and BMM cells and inhibited phosphorylation and transcription of NF- $\kappa$ B and phosphorylation of MAPK (JNK, ERK, p38) in a concentration-dependent manner. In addition, NFATc1 inhibition by CTU may be caused by down-regulation of c-Fos. Therefore, inhibition of the TRAF6-TAK1 complex formation plays an important role in osteoclast differentiation. In our immunoprecipitation assay, RANKL increased TRAF6 and TAK1 association, which was inhibited by CTU. These results suggest that CTU targets TRAF6-TAK1 complex formation to inhibit osteoclast differentiation.

RANKL regulates a variety of transcription factors, such as NF- $\kappa$ B, c-Fos, and NFATc1, and induces NFATc1 early to form mature and active osteoclasts (Teitelbaum and Ross, 2003). NFATc1 has been reported to regulate genes, such as TRAP, cathepsin K, and integrin  $\beta$ 3 involved in osteoclast differentiation and function (Kim et al., 2014). In addition, osteoclast migration plays an important role in diseases associated with abnormal bone resorption such as rheumatoid arthritis and osteoporosis. In recent studies, chemokine CCL4 has been shown to mediate cell migration and bone invasion in RANKL-induced bone resorption (Xuan et al., 2017). In this study, CTU downregulated the expression of transcription factors and genes involved in RANKL-induced osteoclast differentiation and migration.

Recent studies investigating the osteoclast-differentiation inhibitory effects of natural compounds, such as flavonoids or

polyphenols, have been actively conducted (Kim et al., 2018). However, prenylated xanthenes have yet to be investigated for their role in inhibition of bone disease or osteoclast differentiation, despite their various antioxidant, anti-atherosclerotic, anti-inflammatory, and hepatoprotective activities (Lee et al., 2009; Jeong et al., 2010; Kim et al., 2019). Therefore, in this study, CTU isolated from *M. tricuspidata* suggests a potential therapeutic agent for osteoporosis by inhibiting proteins and specific genes that play an important role in the regulation of osteoclast differentiation and bone resorption and migration.

*Onosma bracteata* Wall. (Boraginaceae) is a highly valuable medicinal herb that is used for the treatment of fever, bronchitis, asthma, rheumatism, stomach irritation, and other inflammatory disorders. The present study aims to explore the hepatoprotective potential of ethanolic extract (*Obeth*) from *O. bracteata* aerial parts against carbon tetrachloride (CCl<sub>4</sub>) which causes hepatic damage in the male Wistar rats. *Obeth* showed effective radical quenching activity with an EC<sub>50</sub> of 115.14 and 199.33 µg/mL in superoxide radical scavenging and lipid peroxidation analyses respectively along with plasmid DNA protective potential in plasmid nicking assay. The *Obeth* modulated mutagenicity of 2 Aminofluorine (2AF) in the pre-incubation mode of investigation (EC<sub>50</sub> 10.48 µg/0.1 mL/plate) in TA100 strain of *Salmonella typhimurium*. In *in vivo* studies, pretreatment of *Obeth* (50, 100, and 200 mg/kg) had the potential to normalize the biochemical markers aggravated by CCl<sub>4</sub> (1mL/kg b.wt.) including liver antioxidative enzymes. Histopathological analysis also revealed the restoration of CCl<sub>4</sub>-induced liver histopathological alterations. Immunohistochemical studies showed that the treatment of *Obeth* downregulated the expression levels of p53 and cyclin D in hepatocytes. and downregulation in the Western blotting analysis revealed the downregulation of p-NF-kB, COX-2, and p53. HPLC data analysis showed the supremacy of major compounds namely, catechin, kaempferol, epicatechin, and Onosmin A in *Obeth*. The present investigation establishes the hepatoprotective and chemopreventive potential of *O. bracteata* against CCl<sub>4</sub>-induced hepatotoxicity via antioxidant defense system and modulation of the expression of proteins associated with the process of carcinogenesis in hepatic cells.

**Keywords:** antimutagenicity, apoptosis, carcinogenesis, hepatoprotective effect, *Onosma bracteata*, phytoconstituents

## INTRODUCTION

Global increase in the demand of industrial solvents in pharmaceuticals, paint and coating industry can raise the global solvent market to an estimated USD 12.31 billion by year 2026 as per Global Market Outlook report (2018). Recently, the use of industrial solvents has brought higher risks to both humans and animals. Industrial solvents cause environmental pollution and their acute and chronic exposure can cause cellular injuries and progressive genetic alterations (mutations) *via* activation of reactive oxygen species (ROS) with significant changes that may transform healthy cells to cancerous cells (Pizzino et al., 2017). The mutations caused alter the DNA which along with oxidative stress triggers destruction of tumor-suppressor genes and/or the stimulation of proto-oncogenes which contribute to the initiation of liver, breast, colon and prostate cancer (Maron and Ames, 1983; Canli et al., 2017).

The liver is the main organ essential for survival, which plays a crucial function in the body's metabolism and detoxification process. The liver is a primary site in the body that is mostly involved in modulation and biotransformation of xenobiotic compounds mediated by cytochrome P<sub>450</sub> (CYP) family of enzymes (Gu and Manautou, 2012). The chemicals like carbon tetrachloride (CCl<sub>4</sub>), acetylaminofluorene, thioacetamide, and polycyclic aromatic hydrocarbons are biotransformed into the transitional molecules and generate reactive oxygen species (ROS), including oxygen free radicals that induce hepatic damage (Karakus et al., 2011; Kaur et al., 2017; Kaur S. et al., 2019). Various hepatotoxic compounds and transitional radicals of oxidative reactions affect many proteins and encourage negative effects *via* oxidative stress (OS) or DNA damage (Rahal et al., 2014). The homeostatic balance of cellular redox is the main feature for combating the lethal insults of ROS, which are internally maintained by antioxidative defense systems. Any aberrant functioning to curb stress can lead to malfunctioning like cancer (Snezhkina et al., 2019). Carbon tetrachloride (CCl<sub>4</sub>) is a typical solvent which is used in the research for hepatic ailments. Firstly, liver can metabolize CCl<sub>4</sub> by cytochrome P<sub>450</sub> enzyme complex to produce toxic metabolites such as trichloromethyl free radicals (CCl<sub>3</sub>•) and trichloromethyl peroxy radicals (CCl<sub>3</sub>OO•). These free radicals have capacity of eliminating hydrogen ions from fatty acids to induce lipid peroxidation. Hence, mutually CCl<sub>3</sub>• and CCl<sub>3</sub>OO• cause injury in the cell membrane, alteration in enzyme action and lastly cause hepatic

damage or necrosis (Chao et al., 2019). The treatment of hepatic cancer still is one of the important tasks despite the newest developments in recognizing its biological basis. The deregulation of p53, COX-2, and NF-κB signaling is one of the central factors for the beginning of hepatic cancer (Alqahtani et al., 2019). p53 (a tumor suppressor gene) associated mutations are found in most of the hepatocellular carcinoma (HCC) (Aravalli et al., 2008). From the past few decades, the natural phytoconstituents from plants are recognized for restoring the health of humans (Che and Zhang, 2019). So, the diet rich in natural compounds has been shown to exert various healing effects *via* activating redox-signaling, phase-II detoxification enzymes, antioxidants, anti-inflammatory, and anti-carcinogenic properties (Wu et al., 2017).

*Onosma bracteata* Wall. family Boraginaceae widely knowns as 'gaozaban' is mainly distributed in India and Nepal in high altitude regions, spread in Jammu & Kashmir, Himachal Pradesh and Uttar Pradesh in north-western Himalayas (Ved et al., 2016). It is used as the main component for the preparation of drug in Unani and Ayurvedic medicinal system. It is usually used in Indian traditional medication due to its medicinal benefits *viz.* demulcent, diuretic, anti-aging, antioxidant, antibacterial, wound healing, antileprotic, spasmolytic, and tonic nature (Fareed et al., 2012). The entire parts of *O. bracteata* have pharmacological properties like anthelmintic, anti-inflammatory, antimicrobial, antiperoxidative, and radical scavenging (Albaqami et al., 2018; Imran et al., 2018; Farooq et al., 2019). It is reported that *Onosma* genus is a rich source of flavonoids, benzoquinones, naphthoquinones, shikonins, and onosmins (Kumar et al., 2013). However, to date, there are no records about its hepatoprotective activity.

Thus, we planned to explore the protective effects of *Obeth* from *O. bracteata* by using *in vitro* assays *viz.* antioxidant, antimutagenic and DNA protective potential. Further, *in vivo* studies were carried out to explore the hepatoprotective effects of *Obeth* *via* evaluation of serum marker enzymes, antioxidative enzymes and histopathological parameters. Modulatory effects on the expression level of p53, COX-2, NF-κB, and Cyclin D were studied using immunohistochemical (IHC) and Western blotting.

## MATERIALS AND METHODS

### Chemical and Reagents

1-chloro-2, 4- dinitrobenzene (CDNB), 2- thiobarbituric acid (TBA), 5, 5-dithiobisnitrobenzoic acid (DTNB), Bovine Serum Albumin (BSA), Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), malondialdehyde, nitro blue tetrazolium (NBT), and Silymarin were procured from Sigma (St. Louis, MO, USA). Carbon tetrachloride (CCl<sub>4</sub>), ethidium bromide (EtBr), low melting point agarose (LMPA), malondialdehyde (MDA), nicotinamide adenine dinucleotide (NADH), normal melting point agarose (NMPA), hydroxylamine hydrochloride, oxidized glutathione (GSSG), phenazine methosulfate (PMS), reduced glutathione (GSH), sodium pyruvate, and xylene orange were obtained from HiMedia Pvt. Ltd., (Mumbai, India). The pBR322

**Abbreviations:** 2AA, 2-aminoanthracene; 2-AF, 2-aminofluorene; AA, Ascorbic acid; BC, bacterial culture; b.wt., body weight; CCl<sub>4</sub>, carbon tetrachloride; COX-2, cyclooxygenase-2; CPCSEA, committee for the Purpose of Control and Supervision of Experiments on Animals; ANOVA, analysis of variance. CYP, cytochrome P<sub>450</sub>; df, Degree of freedom; EDTA, ethylenediamine tetraacetic acid; ECL, Enhanced chemiluminescence; FeCl<sub>3</sub>, Ferric chloride; GSH, reduced glutathione; GSSG, oxidized glutathione; HPLC, high-performance liquid chromatography; i.p., intraperitoneal; MDA, malondialdehyde; NBT, nitro blue tetrazolium; NF-κB, nuclear factor-kappaB; NPD, 4- Nitro-o-phenylenediamine; PAGE, polyacrylamide gel electrophoresis; PBS, phosphate buffer saline; PMS, Phenazine methosulfate; PVDF, polyvinylidene fluoride; ROS, reactive oxygen species; rpm, revolutions per minute; SA, sodium azide; SDS, sodium dodecyl sulphate; TA, top agar; TCA, trichloroacetic acid; WB, western blotting.

(plasmid) DNA was purchased from Genei Pvt. Ltd. Bangalore, India. Cyclin-D (cyclin-dependent), p53 (tumor suppressor p53), COX-2, and Nf-κB antibodies were purchased from Cell signaling technology (Danvers, MA, USA). (PVDF) membrane (MDI, Ambala), ECL kit was procured from (Biorad, USA). Kits for analysis of serum parameters were purchased from Erba Mannheim (London, UK). The other chemicals used in the experiments were of Analytical grade.

## Collection, Identification, and Authentication of Plant Material

The aerial parts including stems and leaves of *Onosma bracteata* Wall. were collected from Herbal Health Research Consortium (HHRC) Pvt. Ltd. Amritsar, Punjab (India), a Government of India approved Drug analysis laboratory. Mr. Viney (Research Officer), at the HHRC Pvt, Ltd. identified and authenticated the plant material by analyzing organoleptic, microscopic and pharmacognostic characteristics. The specimen with accession no: GAZ-03 was submitted in the herbarium of HHRC Pvt. Ltd. Amritsar, Punjab (India).

## Extraction Procedure

The plant material was washed with running tap water and dried at 40°C. The material was crushed to powder form (2 Kg) and soaked with 80% ethanol by using the maceration method. The filtered material was evaporated using Rotavapor (Buchi Rotavapor R-210, Switzerland) and was dried to yield 120 g (6%) of the ethanolic extract (*Obeth*).

## Antioxidant Assays

### Superoxide Radical Anion Scavenging Assay

The radical scavenging activity of *Obeth* was conducted according to the method suggested by Nishikimi et al. (1972), with little modifications. Initially, 0.06 M NBT and 0.156 M NADH were mixed to the different *Obeth* concentrations (25–400 µg/mL), along with the addition of 0.468 M PMS. In the control samples, *Obeth* was substituted by methanol in all of the above solutions. The mixtures were kept at room temperature for 20 min. In the incubation phase, the yellow-colored NBT was reduced to blue colour and the absorbance was recorded at 560 nm.

The percentage decrease of NBT was represented as:

$$\text{Percent change} = ((\text{OD}_C - \text{OD}_S) / \text{OD}_C) \times 100$$

where OD<sub>C</sub> = Absorbance of control solution.

OD<sub>S</sub> = Absorbance of the sample solution.

### Lipid Peroxidation (TBARS) Assay

For this experiment, the procedure was adopted as proposed by Halliwell and Gutteridge (1989), with a little amendment. The lipid origin (10% homogenous egg), 150 mM KCl, and *Obeth* (25–400 mg/mL) were combined in this assay. In place of *Obeth*, methanol was used as a control. To continue lipo-oxidation to the above reaction mixture, 10 mM FeCl<sub>3</sub> was added followed by incubation at 37°C for 30 min. Subsequently, HCl solution (comprising TCA, TBA and BHT) was added to the mixture and the resultant mixture was heat treated for 1 h at 90°C

accompanied by cooling and centrifugation at 2,500 rpm for 15 min. Lastly, the absorbance of pink coloured supernatant formed was recorded at 532 nm.

The estimation of the percent inhibition (anti-liperoxidation activity) was based on the formula below:

$$\text{Percent change} = ((\text{OD}_C - \text{OD}_S) / \text{OD}_C) \times 100$$

where OD<sub>C</sub> = Absorbance of control solution.

OD<sub>S</sub> = Absorbance of the sample solution.

## Plasmid Nicking Assay

To determine the DNA protective ability of *Obeth* or capacity to scavenge the hydroxyl radical (\*OH), the plasmid nicking assay was conducted as per the procedure given by Lee et al. (2002) with few amendments recommended by Robin et al. (2015). Different concentrations (25–100 µg/mL) of *Obeth* from *O. bracteata* were mixed with freshly prepared Fenton's reagent (30 mM H<sub>2</sub>O<sub>2</sub>, 50 mM Ascorbic acid, and 80 mM FeCl<sub>3</sub>) and pBR322 plasmid DNA, followed by incubation for 30 min at 37 °C. The samples were resolved onto 1% (w/v) agarose gel using electrophoresis unit at 60 V for 1 h. For this assay, rutin (100 µg/mL) was used as a standard. Immediately, DNA bands were viewed with Gel Doc XR (Bio-Rad, USA), and the band density was determined by using LabImage Bioimaging Platform (Version: 4.1.1) software.

## Antimutagenic Activity

The antimutagenic potential of *Obeth* from *O. bracteata* was studied using Ames test, with two *Salmonella typhimurium* strains as per the method given by Maron and Ames (1983) with few amendments recommended by Kaur et al. (2000). The strains of *S. typhimurium* were procured from Microbial Type Culture Collection (MTCC), Chandigarh. Under sterile conditions, direct-acting mutagens, i.e., 4- Nitro-o-phenylenediamine and sodium azide were used for TA98 and TA100, respectively. The antimutagenic activity of *Obeth*, at different concentration levels (25–250 µg/0.1 mL/plate), was studied using two experimental approaches viz. co-incubation and pre-incubation modes to distinguish between the bio-antimutagenicity and desmutagenicity, respectively. Negative control contains only bacterial culture, *Obeth* and top agar which showed that *Obeth* did not exhibit mutagenic characteristics. In co-incubation mode, mutagen with *Obeth* was blended into 2mL of top agar containing bacterial culture whereas, in pre-incubation, the mixture of *Obeth* and mutagen was incubated at 37 °C for 30 min before adding to the top agar with bacterial culture. The positive control contains bacterial culture and mutagens which help to assess the dosage rate of toxicity/mutagenicity. *Obeth* antimutagenicity was also tested using S9-mix in the top agar as per the procedure suggested by Garner et al. (1972). The protocol includes a similar method as previously mentioned, except with the inclusion of S9-mix among other components of top agar for the activation of indirect acting mutagens. The reverting colonies were counted using a colony counter.

### Antimutagenic Effect

Antimutagenic activity is defined by the percentage decrease in the number of colonies as shown below:

### Percentage of Antimutagenic activity of *Obeth*

$$= (a-b)/(a-c) \times 100$$

where,

a= number of mutagenic-induced colonies (positive control)

b= number of colonies induced with mutagen and different concentration of *Obeth*

c= number of colonies in (negative control).

## Hepatoprotective Activity

### Animal Ethics Statement

This experiment was performed in compliance with the guideline of the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSE), Ministry of Environment and Forestry, Government of India, and authorized by Institutional Animal Ethics Committee (IAEC), GNDU (approval number 226/CPCSEA/2014/06). As indicated by the IAEC, all rats were entitled to humane care.

### Procurement and Care of Experimental Animals

Male Wistar rats, weighing between 150–240 g were purchased from the National Institute of Pharmaceutical Education and Research (NIPER), S.A.S. Nagar, Mohali, Punjab (India). The acclimatization of rats was conducted for one week in polypropylene cages containing husk in the aerated Central Animal House of Guru Nanak Dev University, Amritsar. Commercial rodent feed was provided for the rats, and water was given *ad libitum* with an environmentally regulated condition ( $55 \pm 5$  percent humidity,  $23 \pm 2^\circ$  C) with a 12 h light/dark cycle photoperiod.

### Experimental Design

After acclimatization, rats were divided into 7 groups (n=6). Group I served as control; Group II intoxicated with 1 mL kg<sup>-1</sup> CCl<sub>4</sub> (mixed in same volume of olive oil *via* intraperitoneal (i.p.) doses, 3 days in a week) which induced liver mutilation and is mostly used for analyzing the hepatoprotective potential of various drugs (Ritesh et al., 2015; Zamzami et al., 2019); Group III was provided pretreatment of 50 mg kg<sup>-1</sup> body weight (b.wt.) of silymarin (natural chemopreventive compound) for 21 days *via* oral route accompanied by CCl<sub>4</sub> (i.p.) doses, 3 days in week without fasting of rats; Group IV was administered with an oral dose of only *Obeth* (100 mg kg<sup>-1</sup> b.wt.) of *O. bracteata* as negative control; Group V was provided with the *Obeth* (50 mg kg<sup>-1</sup> b.wt.) accompanied by CCl<sub>4</sub> (i.p.) doses; Group VI was provided *Obeth* (100 mg kg<sup>-1</sup> b.wt.) intoxicated with CCl<sub>4</sub>; Group VII was given *Obeth* (200 mg kg<sup>-1</sup> b.wt.) accompanied with CCl<sub>4</sub> (i.p.) treatment. The experimental concentrations of *Obeth* have been decided based on the literature report on *O. bracteata* in *in vivo* studies (Asif et al., 2019).

### Blood Extraction and Serum Marker Enzyme Analysis

The rats were kept on fasting overnight before termination of experiment, the blood was extracted from retro-orbital venous puncture into heparinized tubes under moderate diethyl-ether

anesthesia. The blood samples were centrifuged at 3,000 rpm for 20 min for the separation of serum. The extracted serum was used for examining the different hepatic markers enzymes (Serum Glutamic Pyruvic Transaminase (SGPT), Serum Glutamic-Oxaloacetic Transaminase (SGOT), Alkaline Phosphatase (ALP), total bilirubin, total protein, Albumin, urea, creatinine, and cholesterol) using Erba diagnostics kits with Bene Sphera autoanalyzer.

### Animal Sacrifice and Preparation of Liver Homogenate

The liver was dissected after euthanizing by cervical dislocation. The collected liver was washed with ice-cold saline solution. After this, the liver was rinsed with the mixture of (150 mM KCl + 10 mM Tris-HCl) buffer. Finally, 10 percent (w/v) of dried liver homogenate was mixed with chilled Tris-KCl buffer and centrifugation at 2,500 rpm for 10 min. Supernatant was separated and used for further analysis.

## Biochemical Analysis of Liver Functions

### Protein Quantification

The standard protocol given by Bradford, 1976 was used for the quantification of protein concentration in the liver. In this experiment, 900 µL of Bradford reagent was mixed with 100 µL of homogenate. The reaction solution was then kept for 30 min at room temperature and the absorbance was calculated on ELISA plate reader at 595/450 nm.

### Estimation of Lipid Peroxidation

To check lipid peroxidation in liver homogenate, TBARS (thiobarbituric reactive species) procedure recommended by Devasagayam et al. (1983) was used. 2 mL of TBA solution was mixed to 500 µL of the sample. The mixture was fully stirred and incubated for 30 min at 80°C followed by centrifugation for 15 min at 2,000 rpm. Lastly, supernatant reading was taken at 532 nm and 600 nm. MDA was used as a standard for measuring the amount of TBARS represented as MDA value (MDA equal µmol/g of tissue).

### Estimation of Lipid Hydroperoxides

Lipid hydroperoxide generation in liver homogenate was assessed as a method proposed by Jiang et al. (1992). 900 µL of Fox reagent (0.1 M Xylenol orange, 0.025M of H<sub>2</sub>SO<sub>4</sub>, 0.25 M of (NH<sub>4</sub>)<sub>2</sub> Fe(SO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O, and 0.004 M of C<sub>15</sub>H<sub>24</sub>O) was mixed to 100 µL of liver homogenate. This reaction mix was kept for 40 min at 37°C and final reading was measured at 560 nm. The lipid hydroperoxide generation is shown as nM H<sub>2</sub>O<sub>2</sub> equivalent/g of tissue.

### Estimation of Reduced Glutathione Content (EC1.6.4.2)

The reduced glutathione content in liver homogenate was detected as per the protocol given by Anderson (1985) with little changes. Potassium phosphate buffer (200 µM, pH 8) and DTNB solution (600 µM) were mixed to 100 µL homogenate, preceded by incubation for 10 min and the absorbance was recorded at 412 nm. Glutathione was used as a reference for making a standard curve and total GSH content was expressed as µmol of GSH content/g of tissue.

## Phase I Enzymes

### Evaluation of Cytochrome $P_{450}$ and $P_{420}$ Content

Phase I enzymes were determined as per the method performed by Choi et al. (2003). In this protocol, the liver homogenate was added into two 96-well plates. In one plate 15  $\mu$ L of sodium hydrosulphite (500 mM) was added in each well preceded with 30–35 bubbles of carbon monoxide. Another plate was saturated with only 30–35 bubbles of carbon monoxide without adding sodium hydrosulphite. The absorbance was observed at 420 nm, 450 nm, and 490 nm.

### Cytochrome b5 Analysis

The cytochrome b5 (Cyt b5) quantities were analyzed as the method suggested by Omura and Sato (1964). In this experiment, 500  $\mu$ L of liver homogenate was added to 4.3 mL of Tris-HCl buffer. After that, 50  $\mu$ L of this mixture was poured onto two separate 96-well plates. Now, 50  $\mu$ L of NADPH (500 mM) was added in each well of one plate and 50  $\mu$ L of Tris-HCl in each well in the other plate followed by incubation for 20 min. The absorbance was measured at 409 nm and 424 nm. The enzyme activity was determined by using the extinction coefficient ( $6.22 \text{ mM}^{-1} \text{ cm}^{-1}$ ).

### NADPH Cytochrome b5 Reductase

The NADPH Cyt b5 was determined using procedure recommended by Mihara and Sato (1972) with little modification. For this, 200  $\mu$ L of NADPH (100  $\mu$ M) and 200  $\mu$ L of Potassium ferricyanide (200  $\mu$ M) were mixed with 500  $\mu$ L of potassium phosphate buffer (300 mM). The process was initiated with the addition of 100  $\mu$ L of homogenate. The NADPH Phase II Enzymes

### Glutathione-S-Transferase (EC 2.5.1.18)

Phase II metabolic isozyme glutathione-S-transferase (GST) was quantified as per the method suggested by Habig et al. (1974). In this experiment, 2.7 mL of sodium phosphate buffer (100 mM) was mixed with 100  $\mu$ L each of 1-Chloro-2,4-dinitrobenzene (CDNB) (0.03 M) and 100  $\mu$ L reduced glutathione (0.03 M) followed by incubation at 37°C for 5 min. After incubation, 100  $\mu$ L of homogenate was added to initiate the reaction and enzyme activity was recorded at 340 nm at 30 s interval for 3 min.

## Antioxidative Enzymes

### Catalase (CAT) (EC 1.11.1.6)

Catalase was analyzed in the liver homogenate as the method described by Aebi (1984) with little modifications. 300  $\mu$ L of  $\text{H}_2\text{O}_2$  (150 mM) and 2.6 mL of 50 mM potassium phosphate buffer (50 mM) were mixed thoroughly. After this, homogenate was added to initiate the reaction. Eventually, the absorbance was recorded for the catalase activity at an interval of 15 s, for 2 min at 240 nm.

### Glutathione Reductase (GR) (EC 1.6.4.2)

A slight modification was done to assess the GR level in the samples using the protocol given by Carlberg and Mannervik (1975). In this assay, the reaction mixture was prepared by adding 1.2 mL of sodium phosphate buffer (200 mM), 200  $\mu$ L oxidized glutathione (10 mM), 200  $\mu$ L EDTA (20 mM), and 200  $\mu$ L of homogenate. Finally, 200  $\mu$ L NADPH (1000  $\mu$ M) was mixed in a reaction solution and at an interval of 15 s, absorbance was measured at 340 nm for 3 min.

### Lactate Dehydrogenase (EC 1.1.1.27)

To determine the lactate dehydrogenase (LDH) activity in liver homogenate, the protocol recommended by Kaur S. et al. (2019) with slight modifications was adopted. In this experiment, reaction mixture comprising of 2.3 mL of Tris HCl buffer (100 mM, pH 7.1), 300  $\mu$ L of sodium pyruvate (100 mM), 100  $\mu$ L Triton X (7.5%), and 300  $\mu$ L of NADH (3 mM) was incubated at 30°C for 15 min. In this reaction mixer, 100  $\mu$ L of homogenate was added and absorbance was measured at an interval of 10 s at 340 nm for 1 min.

### Guaiacol Peroxidase (EC 1.11.1.7)

Guaiacol peroxidase activity in liver homogenate was determined as per the method suggested by Gee et al. (1970) with slight modifications. The reaction mixture was prepared by adding 75  $\mu$ L (20 mM) of guaiacol solution to 25  $\mu$ L 100 mM phosphate buffer with 100  $\mu$ L of liver homogenate and then 25  $\mu$ L of  $\text{H}_2\text{O}_2$  was added. The absorbance was taken at 436 nm.

## Histopathological Assessment

To check the hepatocytes' structural integrity, the isolated livers from the respective groups were fixed in a 10% buffered formalin solution, dipped in ethanol for dehydration and implanted in paraffin wax. The microtome was used to make sections of the livers (0.4 mm thick) using paraffin blocks and stained with H&E (hematoxylin and eosin) by the standard procedure. The slides were observed with a Nikon Eclipse E200 Compound microscope.

## Immunohistochemical (IHC) Examination

To evaluate the pattern of expression of p53 and cyclin D proteins (after treatment with  $\text{CCl}_4$  and *Obeth*) in hepatocytes, IHC analysis was performed. In this method, the liver sections (3–6  $\mu$ m) were deparaffinized on glass slides. The sections were kept for 30 min in  $\text{H}_2\text{O}_2$  (0.3% of methanol). The section slides were blocked with 5% skimmed milk for 30 min. Finally, slides were incubated overnight with anti-p53 and anti-cyclin D antibodies at 4°C. Slides were then washed twice with 1 x PBS followed by the addition of anti-rabbit IgG HRP- conjugated secondary antibody and incubated for 30 min and washed thrice with 1x PBS. The expression of proteins was developed by using 3-diaminobenzidine (DAB) for 2–3 min and washed with 1 x PBS. The slides were observed under a Nikon Eclipse E200, Japan microscope.

## Single-Cell Gel Electrophoresis (Comet Assay)

The comet assay (single-cell gel electrophoresis) was performed according to the protocol given by Collins and Dušinská (2002) with slight modifications. In this assay, 500 mg of rat liver was minced in trypsin solution and kept for 15–20 min at room temperature. The homogenate was passed through a muslin cloth to remove tissue debris followed by centrifugation at 2,500 rpm for 10 min to obtain a cell pellet. After that, 50  $\mu$ L of cell suspension was added to a low melting point agar (LMPA) solution and transferred to normal melting point agar (NMPA) coated glass slides. The slides were kept in the fridge for 10–15

min. The slides were immersed in lysine buffer (100 mM EDTA, 10 mM Tris-HCl, 1% Triton X-100, 250 mM NaCl, 10 percent DMSO; pH 10) at 4°C for 3–4 hr. Now slides were dipped in electrophoresis buffer for 10–15 min before starting electrophoresis (voltage = 25 V, current = 300 mA, time = 20 min). After electrophoresis, the slides were dried and kept in neutralization buffer for 15 min (thrice). After 24 h slides were stained with 100  $\mu$ L (20  $\mu$ g/mL) ethidium bromide and observed in the fluorescent microscope (Nikon, Tokyo, Japan). Per slide thirty cells were selected randomly to assess DNA impairment, tail length, tail DNA (%) and tail moment using Comet Assay Software Project (CASP) Lab version CASP1.2.3 beta 1.

## Western Blot Analysis

The liver was dissected and rapidly stored according to respective groups at -80°C. The samples were homogenized in RIPA lysis buffer followed by centrifugation at 12,000 rpm for 20 min and the upper transparent solution was then poured into new tubes. The quantity of proteins was analyzed using Bradford method. Equal concentration of protein (40  $\mu$ g) was resolved by SDS-PAGE and transferred to PVDF membrane through western blotting. After that, the membrane was blocked using BSA (5% in TBST, 0.1% Tween-20) for 2 h at 25°C and kept overnight with antibodies against p53 (1:1,000), NF $\kappa$ B (1:2,000) and COX-2 (1:500). After that, the membrane was washed thrice with TBST and HRP-conjugated secondary antibody (1:1,500) was added followed by incubation for 2 hr at room temperature. ECL reagent was used to develop blots and imaging was done using Image-Quant LAS 4000, GE Healthcare. Band densities were quantified with AlphaEase FC Software (version 4.0).  $\beta$ -actin (1:500) as endogenous control was used for normalizing the expression of the protein of interest.

## Phytochemical Analysis

### HPLC Analysis

The filtered *Obeth* was analyzed for the presence of polyphenols using UHPLC Nexera system (Shimadzu, MA, USA), column (C18). The solvent used in mobile phase consisted of solvent A

(0.2% acetic acid) and solvent B (methanol). The flow rate of 1.0 mL/min was sustained for 21 min of running time. The gradient flow used was: 20% B (0–10 min), 55% B (10–12 min), 70% B (12–14 min), 50% B (14–15 min), 40% B (15–17 min), and 30% B (17–21 min). For testing, the injection volume of the sample was 10  $\mu$ L with column temperature maintained at 25°C. The spectra were observed at 280 nm with a photodiode array (PDA) analyzer. The peaks of the compound were identified by comparing retention time and distribution of UV-VIS spectra of samples with those of standard compounds.

## Statistical Analysis

All results are represented as Mean  $\pm$  SE of minimum three independent replicates. To compare difference among the means, one-way and two-way analysis of variance (ANOVA) with Tukey's test was used at 5% confidence level (p-value  $\leq$  0.05).

## RESULTS

### Antioxidant Potential of *Obeth*

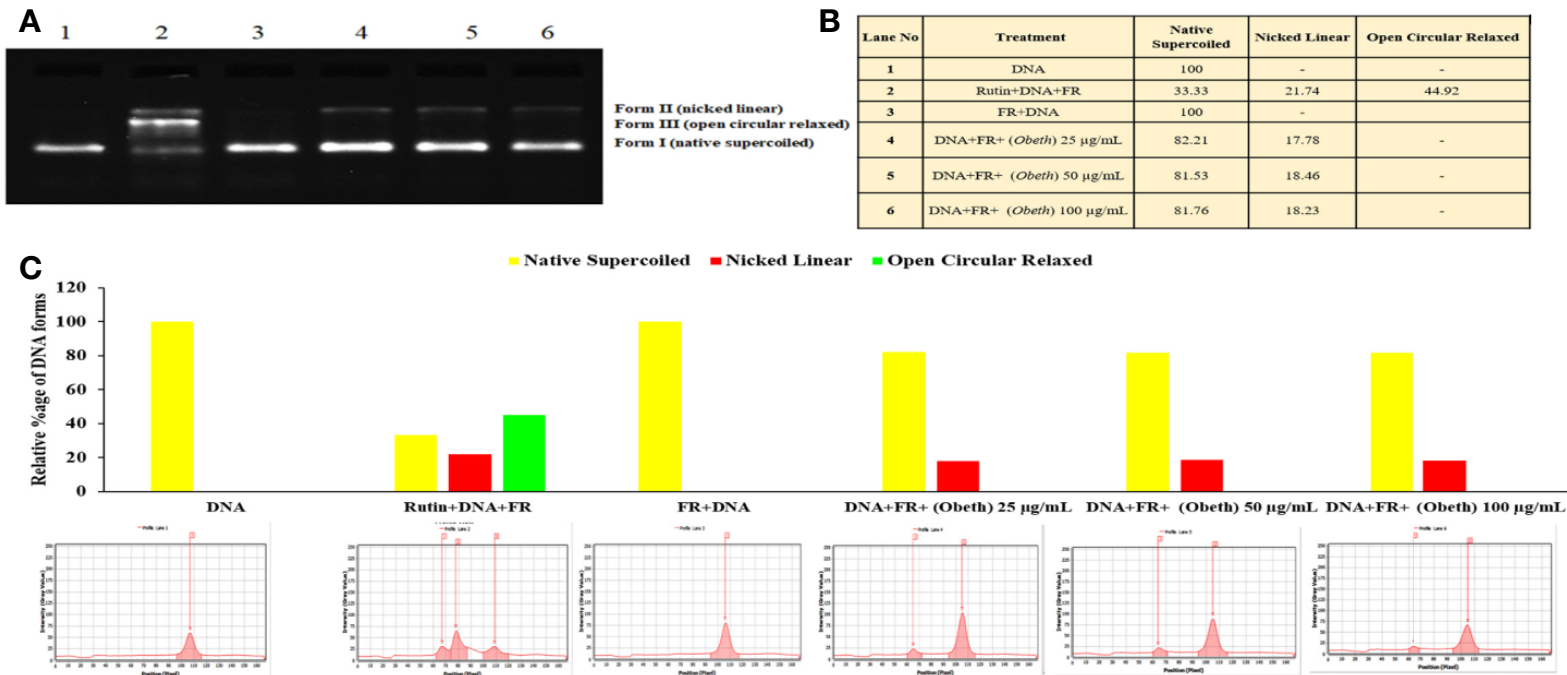

Superoxide radical scavenging and lipid peroxidation activity of *Obeth* is shown in **Figure 1**, **Table S1**. SRS assay there is dose-dependent increase in free radical scavenging activity *via* NBT inhibition with EC<sub>50</sub> (115.14  $\mu$ g/mL) whereas EC<sub>50</sub> of Rutin was observed to be 46.18  $\mu$ g/mL. The lipid peroxidation activity of Rutin and *Obeth* was EC<sub>50</sub> (115.68  $\mu$ g/mL) and EC<sub>50</sub> (199.33  $\mu$ g/mL) respectively (**Table S2**) exhibiting *Obeth* with better antioxidant activity as compared to standard rutin.

### Plasmid Nicking Assay

DNA protective effect of *Obeth* at various concentrations *viz.* 25, 50, 100  $\mu$ g/mL was demonstrated in **Figure 2**. It was observed that the *Obeth* exhibits quite strong radical scavenging properties with the highest tested concentration (100  $\mu$ g/mL) on pBR322 plasmid DNA. The experiment exhibited the formation of nicked DNA because of hydroxyl ( $\cdot$ OH) radicals produced by Fenton's

**FIGURE 1 |** Graphs shows the *in vitro* antioxidant potential of *Obeth* from *O. bracteata*. **(A)** Superoxide radical scavenging assay. EC<sub>50</sub> = 115.14  $\mu$ g/mL; F-ratio = 187.19; HSD = 8.77. **(B)** Lipid peroxidation inhibition assay. EC<sub>50</sub> = 199.33  $\mu$ g/mL; F-ratio = 331.68; HSD = 5.89. Values are expressed as Mean  $\pm$  SE at level of significance  $p \leq 0.05$ . Data labels with different letters represent significant difference among them.

**FIGURE 2 |** Effect of *Obeth* from *O. bracteata* on DNA protection against oxidative damage caused by Fenton's reagent (FR) in DNA nicking assay. **(A)** Relative mobility of different forms of plasmid DNA exposed to *Obeth* extract in electrophoresis. Lane 1: Negative control (pBR322 DNA + distilled water); Lane 2: Positive control (pBR322 DNA + FR); Lane 3: pBR322 DNA + FR + 100 µg/mL rutin; Lanes 4, 5, 6: pBR322 DNA + FR + 25, 50, 100 µg/mL *Obeth* fraction respectively. **(B)** Densitometric analysis showing relative percentage of different DNA forms in plasmid after treatment with various concentrations of *Obeth* fraction in the form of table and **(C)** graph respectively (software used = Lab Image). CN = Control, FR=Fenton reagent.

reagent. The various concentrations of *Obeth* showed a dose-dependent minimization of supercoiled DNA to open circular.

## Ames Assay

The antimutagenic potential of *Obeth* was tested against sodium azide and 2-aminofluorene mutagenicity in *S. typhimurium* strains as shown in **Table S3**. The *Obeth* in TA100 strain (-S9 mix) displayed a high inhibition rate (82.30% at 250 µg/0.1 mL/plate) showing strong modulation of genotoxicity of base-pair substitution mutagen sodium azide as compared to NPD (frame-shift mutagen) in TA98 tester strain **Table 1**. The *Obeth* exhibited high antimutagenicity potential for preincubation mode than in co-incubation approach without -S9 in both TA100 and TA98 as shown in **Figure 3A** and with +S9 mix in **Figure 3B**. Minimum EC<sub>50</sub> values were depicted by the extract against 2AF mutagenicity in pre-incubation mode in TA100 strain as shown in **Table S3**. In case of TA98 strain also, *Obeth* showed good antimutagenic potential in pre-incubation experiments as compared to co-incubation approach (**Figure 3, Table 1**). The calculated EC<sub>50</sub> value showed the high suppression of mutagenicity with a minimum EC<sub>50</sub> value (29.51 µg/0.1 mL/

plate) with TA98 (+S9) in the pre-incubation approach of treatment as shown in **Table S3**. The evaluation between all treatments, with and without S9, is shown in **Figure 3, Table S3** respectively. The assessment permits noticeable potential of *Obeth* +S9, even at minimum concentrations, as compared to -S9 treatments. Therefore, the complete investigation showed the conspicuous activity of *Obeth*, with S9 mix in pre-incubation approach. The findings were statistically evaluated by two-way ANOVA for statistical difference and the interactions as seen in **Table 1, S3**. The study revealed a statistically significant difference between co-incubation and pre-incubation methods of investigation, in addition to among different treatments used. So, the *Obeth* of *O. bracteata* exhibited marked antimutagenicity potential.

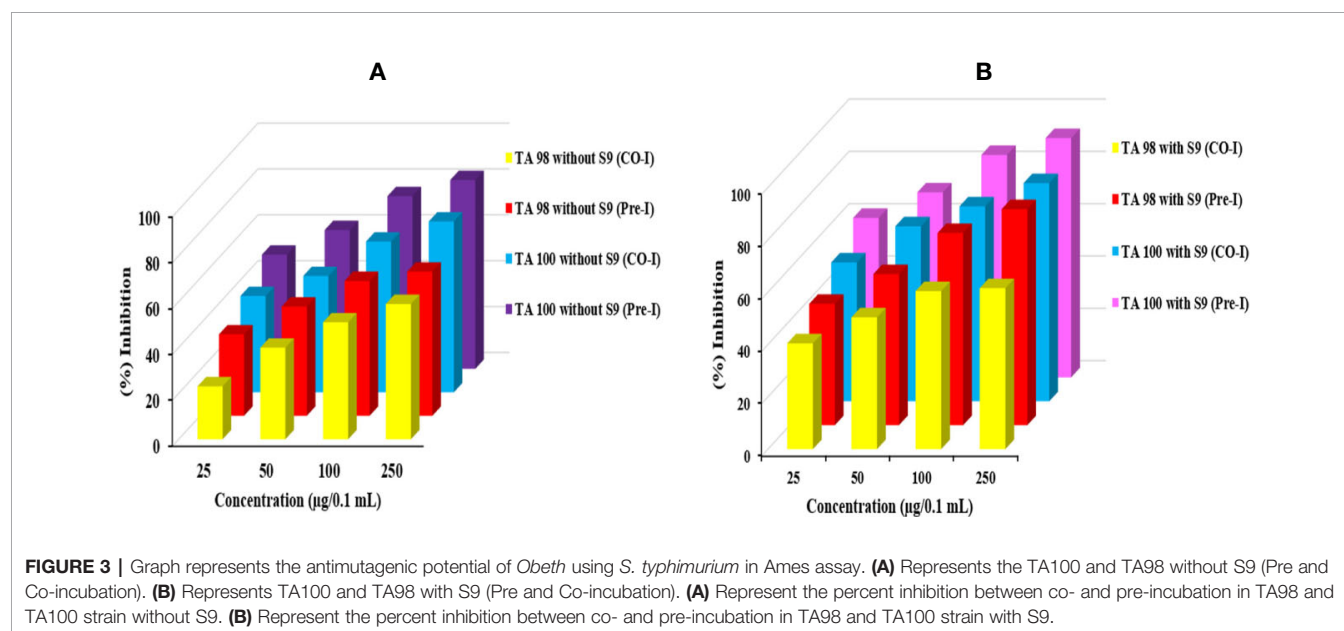

## Variations in Body Weight (b.wt.) of Animals

In the present study CCl<sub>4</sub> treated group, the percentage fold decrease in b. wt. of rats was recorded after 3 weeks, and a statistically significant difference was observed in the b.wt. of CCl<sub>4</sub> rats treated group (0.88-fold) relative to control group I (one-fold). Additionally, dose-dependent variability in the b.wt.

**TABLE 1** | Percentage inhibition of mutagenicity by *Obeth* extract of *O. bracteata* in TA98 and TA100 tester strains of *Salmonella typhimurium* with and without S9.

Treatment	Dose/0.1 mL/plate	TA 100 (without S9) % Inhibition	TA 98 (without S9) % Inhibition	TA 100 (with S9) % Inhibition	TA 98 (with S9) % Inhibition
Co-incubation	25 µg	42.01 ± 4.25 <sup>b</sup>	23.07 ± 3.42 <sup>c</sup>	53.02 ± 5.71 <sup>c</sup>	40.40 ± 3.42 <sup>c</sup>
	50 µg	50.69 ± 4.24 <sup>b</sup>	39.92 ± 3.76 <sup>b</sup>	66.85 ± 1.66 <sup>b</sup>	50.35 ± 2.05 <sup>b</sup>
	100 µg	65.71 ± 2.48 <sup>a</sup>	50.98 ± 1.65 <sup>ab</sup>	74.48 ± 2.59 <sup>ab</sup>	60.37 ± 1.40 <sup>a</sup>
	250 µg	74.47 ± 2.51 <sup>a</sup>	58.97 ± 1.81 <sup>a</sup>	83.37 ± 1.21 <sup>a</sup>	61.51 ± 2.08 <sup>a</sup>
Pre-incubation	25 µg	49.77 ± 2.88 <sup>c</sup>	35.53 ± 2.79 <sup>c</sup>	60.91 ± 2.01 <sup>c</sup>	46.39 ± 2.45 <sup>c</sup>
	50 µg	60.51 ± 2.06 <sup>b</sup>	47.60 ± 2.76 <sup>b</sup>	70.66 ± 3.44 <sup>b</sup>	57.74 ± 1.79 <sup>b</sup>
	100 µg	75.28 ± 2.91 <sup>a</sup>	58.79 ± 1.74 <sup>a</sup>	85.01 ± 1.11 <sup>a</sup>	73.43 ± 3.45 <sup>a</sup>
	250 µg	82.30 ± 1.63 <sup>a</sup>	62.85 ± 3.33 <sup>a</sup>	91.41 ± 1.26 <sup>a</sup>	82.56 ± 2.24 <sup>a</sup>

Values are represented as Mean ± SE, level of significance  $p \leq 0.05$ . Means with different superscripts represent significant difference among them in all groups.

of *Obeth* + CCl<sub>4</sub> intoxicated groups was maintained b.wt. as the control group (Table S4).

## Serum Marker Enzymes

### Effect of *Obeth* and CCl<sub>4</sub> on SGOT, SGPT, and ALP Levels

Group II (CCl<sub>4</sub>) significantly increased the amount of SGOT, SGPT, and ALP to  $351.45 \pm 21.01$ ,  $133.86 \pm 29.88$ , and  $529.16 \pm 56.74$  IU/L respectively in comparison with Group I (control) at 5% level of significance ( $p \leq 0.05$ ) (Table S5). Increased concentration of these enzymes in serum, highlighted the poor functioning of the liver and liver injury because of their seepage into the blood. However, the results showed that the treatment of *Obeth* minimized the amount of these enzymes relative to the CCl<sub>4</sub> Group II. III and IV exhibited the amounts of SGOT, SGPT, and ALP in serum in the acceptable limits, signifying reduction in liver injury (Figure 4A).

### Direct Bilirubin and Total Bilirubin Enzymes in *Obeth* and CCl<sub>4</sub> Treated Rats

*Obeth* pretreatment followed by CCl<sub>4</sub> doses in Groups V, VI, and VII was effective in maintaining natural level of direct bilirubin and total bilirubin disturbed in Group II (Figure 4B). In Group III and *Obeth* treated Group VII indicated an optimum capacity for regeneration by stopping a rise in these enzymes (Table S6).

### Total Protein and Albumin Level in Serum

CCl<sub>4</sub> stimulated changes in the hepatic enzymes resulting in decreased albumin ( $2.15 \pm 0.3$  g/dL) and protein ( $5.93 \pm 0.34$  g/dL) content that lead to hepatic injury (Table S7). Pretreatment of *Obeth* followed by CCl<sub>4</sub> intoxication exhibited substantial protective capacity retaining the normal levels of these enzymes as identified in Groups V, VI, and VII (Figure 4C).

## Effect of *Obeth* and CCl<sub>4</sub> on Serum Proteins, Urea, Creatinine, and Cholesterol

The levels of urea, creatinine and cholesterol in the serum of various groups is given in Table S8. There was a significant increase in the level of urea, creatinine and cholesterol in CCl<sub>4</sub> treated Group II. As depicted from the results of Group IV pretreated with *Obeth* followed by CCl<sub>4</sub> showed a restored level of urea, creatinine and cholesterol, hence showing the recovered hepatic damage in a dose-dependent manner (Figure 4D).

## Biochemical Parameters

### Estimation of Protein Content in Liver Homogenate

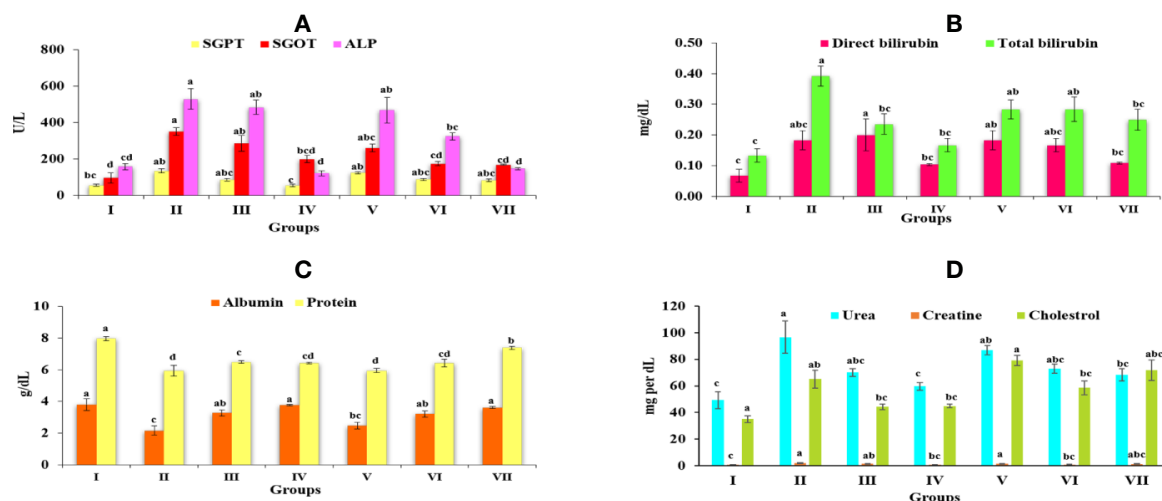

The protein content in the CCl<sub>4</sub>-treated group ( $24.89 \pm 4.16$  mg/g tissue) was observed to decrease significantly as compared to the control group ( $52.74 \pm 11.37$  mg/g tissue) Table S9. Group IV, however, showed a high protein content of  $53.38 \pm 4.21$  mg/g. On the other side, pretreated groups (V, VI, and VII) were shown to greatly recover the normal protein amount as seen in Figure 5A.

### Estimation of Lipid Peroxidation in Liver Homogenate

The level of MDA content exhibited the level of lipid peroxidation. Group II revealed a significant increase ( $p \leq 0.05$ ) in the MDA content relative to the Group I. Group IV *Obeth* treated exhibited less concentration of MDA content ( $0.67 \pm 0.33$  nM MDA equivalent/g of tissue). However, pretreatment of *Obeth* followed by CCl<sub>4</sub> resulted in a dose-dependent decrease in raised MDA content as seen in Figure 5B and Table S9.

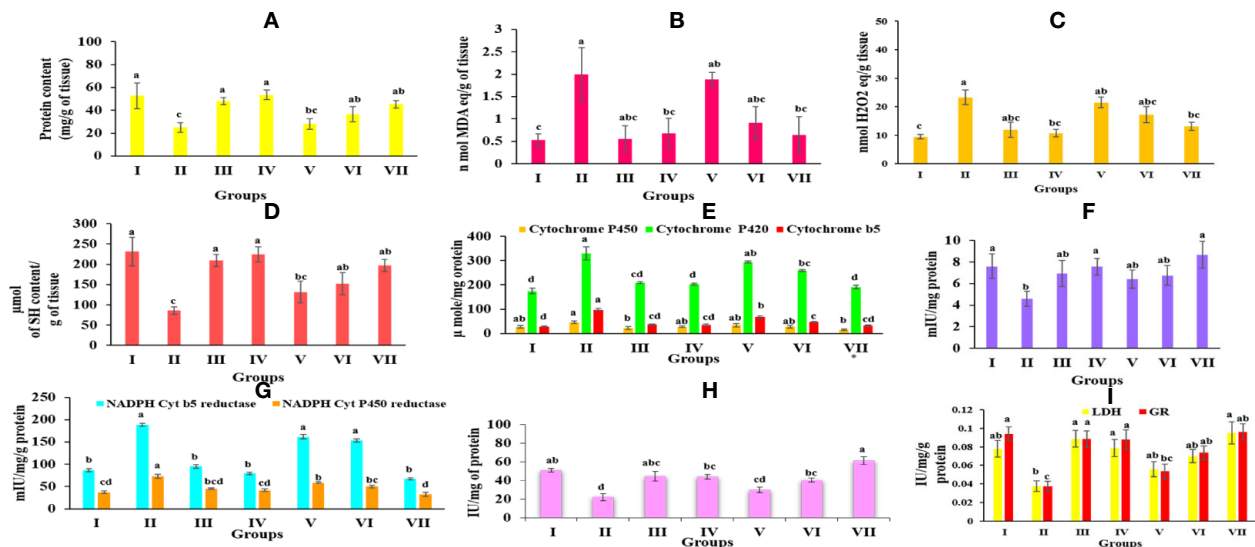

### Estimation of Lipid Hydroperoxide in Liver Homogenate

It was observed that the group treated with CCl<sub>4</sub> displayed a substantial increase in the lipid hydroperoxide content ( $23.24 \pm 2.54$  nM equivalent H<sub>2</sub>O<sub>2</sub>/g of tissue) relative to the control

**FIGURE 4 |** Graph represents the effect of *Obeth* of *O. bracteata* on level of serum enzymes level in CCl<sub>4</sub>-treated male Wistar rats. (A) Represent the levels of SGOT, SGPT, and ALP. (B) Represent the levels of direct bilirubin and total bilirubin. (C) Represent the levels of albumin and total protein. (D) Represent the levels of urea, creatine and cholesterol. Values are expressed as Mean  $\pm$  SE at level of significance  $p \leq 0.05$ . Data labels with different letters represent significant difference among them.

**FIGURE 5 |** Graph represents the effect of *Obeth* of *O. bracteata* on level of enzymes in CCl<sub>4</sub>-treated male Wistar rats. **(A)** Represent the levels of protein in liver homogenates. **(B)** Represent the levels of malondialdehyde (MDA) content in liver homogenate. **(C)** Represent the levels of lipid peroxide in liver homogenates. **(D)** Represent the levels of reduced glutathione (GSH) in liver homogenate. **(E)** Represent the levels of NADH Cyt b5 and NADH Cyt P<sub>450</sub> in liver homogenate of Wistar rats. **(F)** Represent the levels of GST in liver homogenate of Wistar rats. **(G)** Represent the levels of NADH Cyt b5 and NADH Cyt P<sub>450</sub> in liver homogenate of Wistar rats. **(H)** Represent the levels of Catalase in liver homogenate. **(I)** Represent the levels of lactate dehydrogenase and glutathione reductase in liver homogenate. group ( $9.43 \pm 0.79$  nM equivalent H<sub>2</sub>O<sub>2</sub>/g of tissue). Pretreatment by *Obeth* maximum dose showed to decrease CCl<sub>4</sub> toxic impact by exhibiting a maximal decrease in lipid peroxide content (**Figure 5C** and **Table S9**).

### Reduced Glutathione (GSH) Content

The group administered with silymarin displayed substantial improvement in GSH content ( $209.75 \pm 14.71$  μmol of SH content/g of tissue) compared with CCl<sub>4</sub>-treated group with GSH content of  $85.99 \pm 9.57$  μmol of SH content/g of tissue (**Table S9**). *Obeth* recovered the reduced amount of GSH effectively as close to that of the control group (**Figure 5D**).

### Phase I Enzymes

As shown in **Table S10**, *Obeth* exhibited a dose-dependent effect on cytochrome P<sub>450</sub>, b5 and P<sub>420</sub> levels in the liver homogenate. CCl<sub>4</sub>-treated group exhibited reduction in the level of cytochrome P<sub>450</sub> ( $45.90 \pm 5.07$  μmol) and P<sub>420</sub> ( $329.18 \pm 26.63$  μmol) as compared to the control group. Pre-treatment of *Obeth* followed by CCl<sub>4</sub>, showed increasing cytochrome levels P<sub>450</sub> and P<sub>420</sub> showing an important defensive effect against hepatic toxicity (**Figure 5E**). A rise in the production of cytochrome b5 ( $98.32 \pm 5.74$  μmol) in CCl<sub>4</sub> treated group compared to the control group ( $29.34 \pm 2.27$  μmol) was observed. NADH cytochrome P<sub>450</sub> reductase activity showed an increase in the CCl<sub>4</sub>-intoxicated group relative to the control group. Silymarin ( $45.27 \pm 1.91$  mIU) and *Obeth* Group IV ( $41.82 \pm 3.23$  mIU) showed same activity as compared to the control group of rats ( $37.23 \pm 2.96$  mIU) whereas group VII showed decrease in level of enzyme ( $32.47 \pm 4.99$  mIU) as shown in **Table S11**. Moreover, the CCl<sub>4</sub>-treated group exhibited

an increase in the specific action of NADH cytochrome b5 reductase to  $188.43 \pm 3.86$  mIU in comparison to the control group ( $86.40 \pm 3.17$  mIU) whereas group VII exhibited minimization in level of enzyme ( $67.20 \pm 2.36$  mIU) as shown in (**Figure 5G**, **Table S11**).

### Phase II Enzymes

#### Glutathione S-Transferase (GST)

CCl<sub>4</sub> treated group showed decreased GST behavior ( $4.59 \pm 0.684$  mIU/mg protein) compared to the control group ( $7.6 \pm 1.14$  mIU) (**Table S12**) (**Figure 5F**). However, it was observed that there was a significant increase in GST activity in group III, IV, and VII which showed enhancement of hepatic antioxidant enzymes to combat the increased level of reactive oxygen species.

### Antioxidative Enzymes

#### Catalase

As shown in **Table S13**, the catalase activity decreased in the CCl<sub>4</sub>-intoxicated group ( $21.92 \pm 3.76$  IU/mg protein) as compared to control group ( $50.76 \pm 1.95$  IU/mg protein). The higher pretreated dose of *Obeth* (200 mg/kg b.wt.) followed by CCl<sub>4</sub> showed an increase in catalase function over the untreated group, thereby offering protective activity against CCl<sub>4</sub> intoxication (**Figure 5H**).

#### Glutathione Reductase (GR)

The enzymatic expression of GR in the CCl<sub>4</sub>-administered group showed 0.03 IU of GR level as compared to control group (0.09 IU). The increased GR specific activity was detected in groups VI and VII which suggested *Obeth* has a protective role against hepatic damage done by CCl<sub>4</sub> (**Table S13**, **Figure 5I**).

## Lactate Dehydrogenase (LDH)

The level of lactate dehydrogenase is correlated with the integrity of the cell membrane. The increased LDH level in the CCl<sub>4</sub>-intoxicated group (0.03 IU) mediated cell injury occurred due to the lethal metabolites created by Phase I and II enzyme stimulation. Pre-treated groups with different doses of *Obeth* were shown to significantly reduce the level of LDH equivalent to the control group (**Table S13**) and (**Figure 5I**).

## Histopathological Studies

The histopathological analysis showed supportive results for the biochemical and serum enzyme markers. The liver of the CCl<sub>4</sub>-treated group showed necrosis, inflammation and loss of hepatocytes with vacuolization when observed between central vein and portal triad area with hematoxylin and eosin staining (**Figure 6B**). In **Figure 6**, compared to other groups, CCl<sub>4</sub>-intoxicated group showed a maximum region of fibrotic markers and collagen localization. *Obeth* and Silymarin treated groups maintained normal liver hepatocyte architecture relative to control group around the central vein area (**Figures 6C–G**).

## Immunohistochemical (IHC) Analysis

Within hepatocytes, over-expression of p53 protein and cyclin-D contribute to hepatocellular carcinoma development. In this experiment, CCl<sub>4</sub>-treated group exhibited an upregulated expression level of cyclin D (**Figure 7A**) and p53 markers (**Figure 7B**) which finally show fibrosis and lobular inflammation whereas, treatment of *Obeth* decreased the CCl<sub>4</sub> induced p53 and cyclin D protein expression dose-dependently in liver hepatocytes as compared to the toxic group (**Figures 7A, c–g** and **7B, c–g**).

## Comet Assay

As shown in **Figure 8**, larger Comet tail length in CCl<sub>4</sub> treated groups indicated the higher necrosis, apoptosis and DNA fragmentation in hepatocytes. Whereas, reduced Comet tail

length in *Obeth* + CCl<sub>4</sub> treated groups (100 mg/kg b.wt. and 200 mg/kg b.wt.) showed inhibition of necrosis, apoptosis and DNA fragmentation.

## Western Blotting

### Protein Expression of p-53, Cox-2, and NfκB

To explore the relationship between p53, COX-2, and NfκB and the hepatoprotective effects of *Obeth* on toxicity induced by CCl<sub>4</sub>, we studied protein expression using western blotting. As shown in **Figure 9**, there was a significant increased ( $p < 0.05$ ) in p53, Cox-2, and NfκB protein expression in CCl<sub>4</sub> treated group as compared to the untreated control group. However, there was a dose-dependent decrease in the expression of proteins on administration of *Obeth* with CCl<sub>4</sub> treated groups as compared to only CCl<sub>4</sub> intoxicated group.

## Phytochemical Analysis by HPLC Analysis

The phytochemical analysis by HPLC exhibited the occurrence of catechin, epicatechin, Onosmin A, rutin and kaempferol as major phytoconstituents in *Obeth* (**Figure 10, Table 2**).

## DISCUSSION

The active polyphenols present in the plants act as scavengers of ROS, DNA protective agents and help to maintain the expression of genes/proteins that break down toxins and keep cellular redox homeostasis (Liu et al., 2018). These polyphenols have the antioxidant, antimutagenic and chemopreventive properties that might help to protect and conserve the constancy of genome (Mehta et al., 2010; Rodríguez-García et al., 2019). Previous studies have reported the potential of *Onosma* genus as antioxidant compounds and their use in averting numerous pharmacological situations (Naz et al., 2006; Ebrahimzadeh et al., 2010; Ahmad et al., 2013; Imran et al., 2018; Farooq et al., 2019).

**FIGURE 6 |** Effect of *Obeth* from *O. bracteata* on histology of liver tissues as assessed by H & E staining. **(A)** Control group (tap water ad libitum) (Gl) showing normal lobular architecture with clear portal triad. **(B)** CCl<sub>4</sub>: Olive oil (1:1; 1 mL kg<sup>-1</sup>b.wt.) induced necro-inflammatory activity in GlI was noted. Treatment of *Obeth* extract was associated with diminution of portal hypertension with increasing dose. **(C)** Silymarin (100 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, **(D)** low dose (50 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, **(E)** medium dose (100 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, **(F)** High dose (200 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, **(G)** Negative (only extract 100 mg kg<sup>-1</sup>b.wt. Arrows indicate Kupffer cell (KC), central vein (CV), hepatic cells (HC), blood sinusoids (BS), steatosis (S) (black arrow), and necrosis (N) (red arrow).

**FIGURE 7 |** Effect of *Obeth* from *O. bracteata* on expression levels of proteins using immunohistochemical analysis of liver tissues. **(A)** shows cyclin D and **(B)** shows p53 antibodies. Arrows showed the increase in expression of cyclin D and p53 proteins in  $\text{CCl}_4$  treated liver samples (Original magnification = 40 x). Expression of these proteins was downregulated when observed in liver samples co-treated with  $\text{CCl}_4$  and *Obeth* (200 mg/kg b.wt.). Red arrow indicates the increase in the expression of protein in the  $\text{CCl}_4$  treated group. (b) Control group (tap water ad libitum) (GI) showing normal lobular architecture with clear portal triad. (b)  $\text{CCl}_4$ : Olive oil (1:1;  $1\text{ mL kg}^{-1}$  b.wt.) induced elevation in the expression level of cyclin D was noted. Treatment of *Obeth* extract was associated with diminution of portal hypertension with increasing dose. (c) Silymarin ( $100\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , (d) low dose ( $50\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , (e) medium dose ( $100\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , (f) High dose ( $200\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , (g) Negative (only extract  $100\text{ mg kg}^{-1}$  b.wt.).

**FIGURE 8 |** Single cell gel electrophoresis assay was used for determined DNA damage/protect in liver of rats. Results of the comet assay confirm that pretreatment with *Obeth* decreases  $\text{CCl}_4$ -induced hepatotoxicity in rats. **(A)** Control group (tap water ad libitum) (GI), **(B)**  $\text{CCl}_4$ : Olive oil (1:1;  $1\text{ mL kg}^{-1}$  b.wt.) in GI, **(C)** Silymarin ( $100\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , **(D)** low dose ( $50\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , **(E)** medium dose ( $100\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , **(F)** High dose ( $200\text{ mg kg}^{-1}$  b.wt.) +  $\text{CCl}_4$ , **(G)** Negative (only extract  $100\text{ mg kg}^{-1}$  b.wt.). Histograms showing densitometric analysis of % of DNA in tail in comet assay. Values are expressed as Mean  $\pm$  SE at level of significance  $p \leq 0.05$ . Data labels with different letters represent significant difference among them.

In the current study, we investigated the antioxidant, antimutagenic, genoprotective, and hepatoprotective properties of *Obeth* from *Onosma bracteata* along with evaluation of the expression of proteins involved in the inflammation and apoptotic induction in *in vivo* studies using male Wistar rats. In antioxidant assays, *Obeth* had shown potential to scavenge free radicals, namely in SRS and LPO assays. *Obeth* showed strong radical scavenging activity with  $\text{EC}_{50}$  ( $115.14\text{ }\mu\text{g/mL}$ ) whereas LPO inhibition activity with  $\text{EC}_{50}$  ( $199.33\text{ }\mu\text{g/mL}$ ) (Tables S1 and S2). Radical scavenging potential of *Obeth* might be correlated to the nature of phenolics, contributing to their electron transfer/hydrogen donating ability.

Plants contain natural antioxidants, primarily flavonoids, which are being explored to inhibit various diseases *viz.* chronic inflammation and cancer (Surh, 2003). *Onosma* genus plants are enriched with bioactive components *viz.* flavonoids, alkannin, and shikonin responsible for wound healing, analgesic and its antibacterial actions (Kumar et al., 2013). The HPLC analysis of *Obeth* revealed the existence of different phytoconstituents *viz.*, kaempferol, Onosmin A, catechin and epicatechin. Numerous reports have shown that *Onosma* genus and its isolated compounds are responsible for excellent antioxidant activities (Riedl et al., 2004; Kandemir and Türkmen, 2008; Menghani et al., 2011). The ethyl acetate, methanol and water extracts from *Onosma heterophylla*

**FIGURE 9 |** Expression level p53, NFκB, and COX-2 protein in liver homogenate of Wistar rats detected using Western blotting. (A) Control group (tap water ad libitum) (GI), (B) CCl<sub>4</sub>: Olive oil (1:1; 1 mL kg<sup>-1</sup>b.wt.) induced elevation in the expression level of p53 was noted. (C) Silymarin (100 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, (D) low dose (50 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, (E) medium dose (100 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, (F) High dose (200 mg kg<sup>-1</sup>b.wt.) + CCl<sub>4</sub>, (G) Negative (only extract 100 mg kg<sup>-1</sup> b/wt.). Histograms showing densitometric analysis of p53, NFκB, and COX-2 protein bands using western blotting. Band density was measured and normalized to that of β-actin. Values are expressed as mean ± SE at level of significance p ≤ 0.05. Data labels with different letters represent significant difference among them.

**FIGURE 10 |** Chromatogram of *Obeth* of *O. bracteata* showing presence of polyphenols as identified using HPLC analysis by reference compound.

**TABLE 2 |** Amount (mg/L) of different phytochemical quantified by HPLC in different *Obeth* of *O. bracteata*.

Compounds ( <i>Obeth</i> )	Concentration (mg/L)
Gallic acid	—
Catechin	203.29
Chlorogenic acid	—
Epicatechin	844.04
Caffeic acid	—
Umbelliferone	—
Rutin	49.84
Ellagic acid	—
Quercetin	—
Onosmin A	21.82
Kaempferol	34.82
Coumaric acid	—

Griseb. have an appreciable amount of kaempferol, caffeic acid, o-Coumaric acid, rutin and rosmarinic acid which are responsible for antioxidant activity (Ozer et al., 2018). Saravanakumar et al., 2019 also reported that the methanol extract of *Onosma isaurica* Boiss. & Heldr. and *Onosma bracteosa* Hausskn. & Bornm. showed effective

free radical scavenging ability due to the presence of the phytoconstituents. This plant has been widely used because of its medicinal properties.

In Ames assay, the antimutagenic potential of *Obeth* against sodium azide, 4-nitro-o-phenylenediamine and 2-aminofluorene mutagens was evaluated against two *Salmonella typhimurium* strains, i.e., TA100 and TA98. The study showed that *Obeth* effectively modulated the mutagenicity of direct-acting base-pair mutagen, sodium azide with 82.30% inhibition at 250 µg/0.1 mL/plate (**Table S3**) in TA 100 while it showed moderate antimutagenic effect against 4NPD with 62.85% inhibition at the same concentration in TA98 tester strain. *Obeth* exhibited antimutagenicity against 2AF (S9 dependent) in both the tester strains. Kaur et al., 2001 reported that phenolic fractions isolated from *Terminalia arjuna* showed mutagen specificity via decreasing the frameshift mutagen NPD whereas it failed in the prevention of sodium azide (base pair substitution)-induced his<sup>+</sup> revertants. Kaur et al., 2016 described that ethyl acetate fraction of *Cassia fistula* (CaFE) showed strong antimutagenic and antioxidant properties due to the presence of polyphenolic compounds

(umbelliferone, catechin and epicatechin). *Obeth* also demonstrated the potential to protect plasmid DNA against free radicals of Fenton's reagent in plasmid DNA nicking assay. *Obeth* at 100 µg/mL concentration efficiently retained DNA's supercoiled form.

In *in vivo* studies, serum analysis showed that the oxidative stress serum markers (SGOT, SGPT, ALP, creatinine and direct bilirubin) were significantly increased, following the dosage of CCl<sub>4</sub> to rats (Group II) (Tables S5, S6, and S8). The potential to produce albumin proteins (which function as transport molecules) vanished in damaged hepatocytes, and the capacity to make inflammatory proteins increased. CCl<sub>4</sub> generated free radicals (trichloromethyl and peroxytrichloromethyl) that induced damage in hepatocytes resulting in leakage of cytoplasmic SGPT and SGOT into the bloodstream (Shah et al., 2015). *Obeth* ameliorated the toxic effects of CCl<sub>4</sub> by enhancing the activity of antioxidant molecules in the liver. *Obeth* significantly decreased the damage caused by CCl<sub>4</sub> (Group II) in cellular TBARS. A decrease in GSH enzymes and protein levels was observed in the CCl<sub>4</sub> treated group (Group II), while an increase in these markers was observed following *Obeth* treatment (Table S9). Sabir et al. (2017) reported in their study that aqueous extracts of *Zanthoxylum armatum* DC. (syn. *Zanthoxylum alatum* Roxb.) restored the level of glutathione and showed hepatoprotective property against paracetamol-induced hepatic damage in albino mice which decreased the hepatic glutathione level. The activation of lipid hydroperoxides, Cytochrome P<sub>450</sub>, P<sub>420</sub>, and b5 were observed in CCl<sub>4</sub> treated group whereas *Obeth* treatment declined the level of these markers (Table S10). The values of the above parameters in the *Obeth*-treated group were the same as of the control (Group I) which reflects a high safety potential of *Obeth*. CCl<sub>4</sub> treated group showed decline GST levels as compared to control but in a dose-dependent manner whereas *Obeth* treated groups exhibited restored level of GST. Allocati et al., 2018 reported that GSTs can protect DNA against oxidative stress and eliminate toxic molecules that can lead to mutations or carcinogenesis. Laouar et al., 2017 reported that treatment of CCl<sub>4</sub> lead to significantly reduced levels of hepatic GSH, GPx, and GST activities than control group in Wistar rats, whereas aqueous extract of *Juniperus phoenicea* L. berries treatment significantly restored the levels of these enzymes. The Group II showed a significant increase in the amount of NADPH cytochrome b5 and NADH cytochrome 450, whereas, *Obeth* treated groups exhibited a dose-dependent decline in the level of these enzymes (Table S11). The CCl<sub>4</sub> treatment generates CCl<sub>3</sub><sup>•</sup> radicals which not only damaged DNA but also caused necrosis and apoptosis as evidenced from increase in Comet tail length in CCl<sub>4</sub> treated group whereas in case of *Obeth* -treated groups, the reduced Comet tail length showed the DNA protective activity of *Obeth* in a dose-dependent manner (Figure 8). Damage of cells by CCl<sub>3</sub><sup>•</sup> free radical (toxic) formed by the reduction of CCl<sub>4</sub>, in hepatocytes has also been reported Brai et al. (2014) and Josan et al. (2015). The previous report from Younis et al., 2018 showed that CCl<sub>4</sub> treated rats showed a high degree of DNA damage and remarkable changes in (comet, head, tail) length and %DNA in the tail, while methanolic extract of *Fraxinus xanthoxyloides*

(G.Don) Wall. ex A.DC. ameliorates the effect of CCl<sub>4</sub> similar to that of control group.

Histopathological studies showed that *Obeth* was itself non-toxic and showed close histological similarity to the control group and displayed the same histological arrangement with no sign of inflammation (Figure 6G). In contrast, CCl<sub>4</sub> treated group displayed steatosis, necrosis, inflammation in blood sinusoids and vacuolization (Figure 6B). However, pretreatment of *Obeth* followed by CCl<sub>4</sub> treatment effectively restored the regular hepatocytes' architecture and also reduces the vacuoles formation between the central vein and portal triad indicating hepatoprotective potential of *Obeth*, as shown in Figures 6D–F. Earlier, Josan et al. (2015) reported that CCl<sub>4</sub> treated Sprague Dawley rats showed necrosis of hepatocytes nearby central vein and increased the level of alanine transaminase (ALT) whereas control group showed normal architecture of hepatocytes. Ganaie et al., 2015 also reported that dose-dependent treatment of ethanolic extract of *Rumex vesicarius* L. showed a restored pattern of histological architecture, while silymarin treatment followed by CCl<sub>4</sub>-intoxication in Wistar rats showed less disarrangement of hepatocytes. The results of the Immunohistochemistry (IHC) studies showed that p53 protein and Cyclin D expressions in the liver tissues were maximum in the CCl<sub>4</sub> intoxicated group. Upregulated expression of pro-apoptotic p53 in CCl<sub>4</sub> treated group might be formed in response to hepatocyte inflammation and the induction of necrosis in liver cells (Figures 7A, B). Similar results were observed in western blotting studies showing p53 upregulation in the CCl<sub>4</sub> group as compared with the control group. The tumor suppressor gene p53 is upregulated in response to DNA damage, and its upregulated expression is only found in cells that show mutant forms (Aly et al., 2019). The upregulated expression of Cyclin D protein in the CCl<sub>4</sub> intoxicated group also highlighted the mutation in hepatocytes while *Obeth* treatment showed the downregulation of Cyclin D exhibiting its protective effects against CCl<sub>4</sub> intoxication. Cyclin D has been described to have the main role in cell progression through the G1/S phase of the cell cycle, and its deregulation can lead to tumorigenesis (Ying et al., 2008; Chibazakura et al., 2011; Gao et al., 2016).

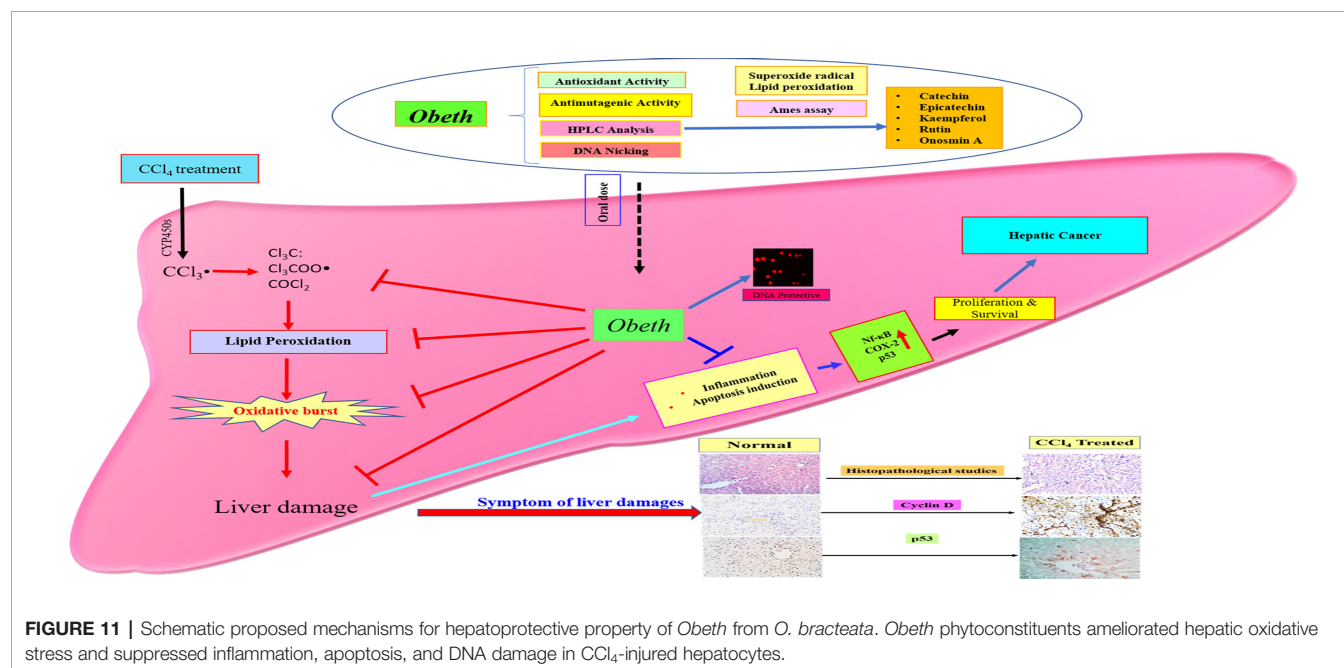

The expression of p53, COX-2, and NF-κB was upregulated due to cellular stress, inflammation and mutation in cellular DNA (Banerjee et al., 2002; Cha and DeMatteo, 2005). Hepatic cancer can be controlled by the suppression of COX-2, NF-κB and p53 which might offer an effective control approach. The investigation of the effects of *Obeth* towards stimulated forms of p53, cyclin-D, COX-2 and NF-κB proteins was performed. The expression levels of COX-2 and NF-κB proteins were upregulated after CCl<sub>4</sub> administration (Figure 9) highlighting the production of mediator cytokines which facilitate tumor growth *via* inhibiting apoptosis and promoting cell proliferation (Brücher et al., 2019; Lerdwanangkun et al., 2019). Eltahir et al. (2020) reported that CCl<sub>4</sub> treated Wistar rats showed significantly high expression levels of NF-κB and COX-2 while *Boswellia serrata* Roxb. (BS) gum resin treatment followed by CCl<sub>4</sub> significantly restored the level of NF-κB and

COX-2 expression due to the presences of a natural compound that exhibited anti-inflammatory effects by targeting multiple pathways. The stressed cells promoted the overactivation of signaling proteins or inflammatory cytokines including, IL-6, TNF $\alpha$ , and IL-1 $\beta$  that stimulate the overproduction of IL-6 in Kupffer cells leading to the enhanced proliferation of hepatocytes, some of which harbor oncogenic mutations (Sun and Karin, 2008). *Obeth* has efficient antioxidant properties that protect the hepatocytes against any damage by inducing antioxidative mechanisms. Previous reports have proved the connotation among natural compounds isolated from plants and cancer inhibition *via* antioxidant properties (Seufi et al., 2009). In the present study, it was found that the *Obeth* contains catechin, epicatechin, rutin, kaempferol, and Onosmin A (Figure 10, Table 2). All these compounds have antioxidant potential are known to ascertain their remedial effects by scavenging the free radical species due to the presence of H donating hydroxyl groups on the different polyphenolic rings of these molecules stabilize the negative charge on the different reactive species and hence, nullify their damaging consequences (Kaur P. et al., 2019). One such study showed catechin to regulate the expression of NF- $\kappa$ B and Cox-2 by scavenging the ROS and hence delivering the anti-inflammatory and antioxidant effects (Chu et al., 2017). Similarly, rutin has also proven as an effective hepatoprotective agent against CCl<sub>4</sub> induced Wistar rat liver damage by altering the expression of IL-6/STAT3 pathway genes expression due to its antioxidative, anti-inflammatory and anti-apoptotic properties (Hafez et al., 2015). On the other hand, epicatechin has the potential to inhibit Sprague-Dawley rat liver inflammation *via* NF $\kappa$ B signaling pathway initiated by HSP60 (Huang et al., 2019). Zang et al., 2018 reported that soybean leaves and its isolated compound kaempferol galactoside and kaempferol have the ability to reduce serum parameters (serum aspartate aminotransferase and serum alanine aminotransferase) increased by CCl<sub>4</sub> intoxication. In

addition to this, all these compounds were also found to ameliorate the lipid peroxidation and regulate the levels of different liver enzymes (Sinha et al., 2012; Khan et al., 2012; Liu et al., 2015; Wang et al., 2015). The polyphenolics such as catechin, caffeine, epicatechin (EC), epigallocatechin gallate (EGCG), and epicatechin gallate (ECG) showed preventive effects of Liubao Tea against CCl<sub>4</sub>-induced liver injury in Kunming mice, comparable to silymarin (Pan et al., 2018). Ahmad et al., 2005, reported that Onosmin A isolated from *Onosma hispidum* Wall. ex G.Don has potential to inhibit lipogenase enzyme in a concentration-dependent manner. It can be stated that the chemical association of phytochemicals, presumable flavonoids in *Obeth* from *O. bracteata* have protective effects on liver damage *via* suppression of CCl<sub>4</sub>-induced oxidative stress (Figure 11). This study reported that antioxidant, antimutagenic, DNA protective, and anti-inflammatory properties of *Obeth* are correlated with the phytoconstituents present in and have also been shown to have modulatory impact on pro-carcinogenic proteins p53, NF- $\kappa$ B, and COX-2 for the first time.

## CONCLUSIONS

In the current study, *Obeth* of *O. bracteata* has shown significant antioxidant, genoprotective, antimutagenic and hepatoprotective properties. As revealed by HPLC investigations, *Obeth* harbors catechin, epicatechin, rutin, Onosmin A and kaempferol as major phytoconstituents. *Obeth* exerted its protective potential *via* its radical scavenging and DNA protective abilities, minimizing oxidative stress through induction of antioxidative enzymes and ameliorating the hepatic changes triggered by CCl<sub>4</sub>. The modulation of crucial proteins such as p53, cyclin D, Cox-2, and NF- $\kappa$ B demonstrated potential of *Obeth* as an effective chemotherapeutic agent against hepatic cancer.

The ultimate goal of precision medicine is to determine right treatment for right patients based on precise diagnosis. To achieve this goal, correct stratification of patients using molecular features and clinical phenotypes is crucial. During the long history of medical science, our understanding on disease classification has been improved greatly by chemistry and molecular biology. Nowadays, we gain access to large scale patient-derived data by high-throughput technologies, generating a greater need for data science including unsupervised learning and network modeling. Unsupervised learning methods such as clustering could be a better solution to stratify patients when there is a lack of predefined classifiers. In network modularity analysis, clustering methods can be also applied to elucidate the complex structure of biological and disease networks at the systems level. In this review, we went over the main points of clustering analysis and network modeling, particularly in the context of Traditional Chinese medicine (TCM). We showed that this approach can provide novel insights on the rationale of classification for TCM herbs. In a case study, using a modularity analysis of multipartite networks, we illustrated that the TCM classifications are associated with the chemical properties of the herb ingredients. We concluded that multipartite network modeling may become a suitable data integration tool for understanding the mechanisms of actions of traditional medicine.

**Keywords:** unsupervised learning, network modelling, precision medicine, traditional medicine, systems medicine

## INTRODUCTION

Classification and clustering are our fundamental learning process to understand human biology and diseases. To achieve the ultimate goal of precision medicine, i.e., the right intervention for a patient at the right time (Stefano and Kream, 2015), there has been a long history of symptom-based diagnosis that utilizes available information to classify patients, diseases, and drugs (**Figure 1**). In the early days of traditional medicine, physicians tried to characterize diseases using empirical terms, such as temperament and meridian (Rezadoost et al., 2016; Arji et al., 2019; Wang Y. et al., 2019), based on which they prescribed corresponding herbs that are known to target them (Xu, 2011; Li and

**FIGURE 1 |** A brief history of medicine and its relation with other branches of science. Traditional medicine as the first era of medicine was mainly built on the physical characterization of diseases and patient biographical data. The modern medicine was established by including more chemical and physical characterizations. Defining biomolecule using biochemistry and molecular biology revealed more details of diseases and pathological processes. This eventually led to the development of diagnosis codes and the pharmaceutical industry. Recently, precision medicine has emerged with the advances of data science, which involves more holistic analyses in order to understand human medicine at the systems level.

Weng, 2017). With increasing knowledge on biochemistry, the era of modern medicine has started, further advancing our understanding of human diseases to the molecular level. Molecular profiles, along with clinical phenotypes, are leveraged to formally characterize diseases, disorders, and symptoms (Steindel, 2010).

One of the greatest challenges in precision medicine is to integrate all available patient-derived data for accurate diagnosis and treatment, which would require novel data-driven approaches rather than more conventional hypothesis-driven approaches (Rouillard et al., 2015). Genomic information for patients, albeit fundamental and often necessary, may not be sufficient due to the fact that the human genome is dynamically adjusting its functions by epigenetic regulations (Jafari et al., 2017; Nussinov et al., 2019). Therefore, interactions among other molecular features including transcriptome, proteome, and metabolome should also be considered to obtain a more systematic characterization of the diseases (Eric, 2014). On the other hand, phenotypic data including cell and tissue images have been utilized for illustrating the impact of molecular alternations in human diseases (Langlois et al., 2011; De Fauw et al., 2018). Likewise, to improve our understanding on human diseases, we may also investigate sources of clinical, phenotypic, and pharmacological data that are derived from traditional medicine (Ma et al., 2010; Zhao et al., 2014). A systematic integration of all of these available information may provide a promising approach to turn precision medicine into a reality ultimately.

Here, we started by reviewing the application of clustering analysis in high-throughput biological studies in modern and

traditional medicine. Next, we described the application of clustering in network modeling for the stratification of drugs or patients. We focused on the advantages and promises of a particular network modelling approach called multipartite networks which can inherently integrate heterogeneous data types at multiple levels. In a case study, a multipartite network was developed to model traditional medicine herbs. We showed that this modeling approach provides novel insights on the rationale of herb classifications, which may facilitate the drug discovery in TCM, such as discovering herb combinations or prioritization of active ingredients.

## USING CLUSTERING TO IMPROVE PATIENT STRATIFICATIONS

Thanks to advanced experimental and computational technologies, we are able to collect, standardize, and integrate a variety of cell-based patient-derived datasets. For example, the LINCS program (Keenan et al., 2018) is one of the recent multi-center studies to facilitate the understanding of cancer biology by providing transcriptional and morphological changes of multiple cancer cell lines in responding to a variety of pharmaceutical agents. Moreover, there are national and international efforts to sequence patients' genomic features. For example, UK Biobank and FinnGen focused on the contributions of genetic predisposition and environmental exposure to the occurrence of common diseases for over half a

million subjects (The FinnGen Research Project Takes Finns to a Discovery Trip to Genome Data; Manolio, 2018). On the other hand, with the development of computational methods such as text mining technologies, researchers are able to standardize data resources in traditional medicine, making them easily accessible and reusable (Zhou et al., 2005; Mirzaeian et al., 2019). For example, the SymMap database was constructed to provide a mapping relationship between 499 natural products, 19,595 ingredients, 1,717 clinical symptoms, and 5,235 diseases (Wu et al., 2019). This work showed the potential to integrate traditional and modern medicine at both phenotypic and molecular levels toward phenotype-based drug discovery. Another example was the UNaProd database which contains information concerning 3,411 natural products used in Iranian traditional medicine (ITM) (Naghizadeh et al., 2020).

Clustering has been commonly used to identify subpopulations of patients with distinctive genetic variants or gene expression profiles. For example, Naval et al. showed how clustering analysis helped identifying single nucleotide polymorphisms (SNPs) associated with skin properties (Naval et al., 2014). Combining transcriptomic data with images, Voineagu et al. showed how the clustering methods characterize distinct complex disease subtypes in autism spectrum disorder (Voineagu et al., 2011). Additionally, in clinical proteomics, clustering analysis also identifies a group of proteins as functional modules in pathogenesis. For example, Baldelli et al. clustered non-small cell lung cancer tumors according to the expression, activation, and phosphorylation levels of 26 signaling proteins (Baldelli et al., 2015). Implementing clustering methods in the context of precision medicine is not only applicable to omics data, but also to physiological data. For example, Xu et al. developed human stress management using clustering of physiological signals during series of task-rest cycles (Xu et al., 2015). On the other hand, image data as a major part of health records of individuals is commonly utilized (Hsu et al., 2013). For example, Enguehard et al. presented a strategy of integrating neural network and clustering analysis for automatic magnetic resonance imaging data analysis (Enguehard et al., 2019). Furthermore, it has been shown that utilizing biomedical annotations can potentially improve clustering analysis to obtain more biologically relevant disease categories (Futschik and Carlisle, 2005; Bandyopadhyay et al., 2007; Lee, 2011). Therefore, the integration of existing biomedical annotations, such as gene ontology or pathway enrichment, is also expected to improve patient disease clustering with refined distance functions (Handl et al., 2005).

As abovementioned, exploring subclasses of diseases and drugs is a prevalent task in precision medicine, and traditional medicine is no exception. For example, Liu et al. studied the gene expression signature of breast cancer cell lines for an herbal formula Si-Wu-Tang (SWT). This analysis showed that the effect of SWT is comparable to  $\beta$ -estradiol treatment on estrogen-responsive genes (Liu et al., 2013). Ruan et al. proposed a clustering algorithm called THCluster that can effectively discover meaningful categorization of herbs and their potential clinical indications (Ruan et al., 2017). Zhang et al. validated TCM syndrome types using a clustering method based on latent tree models, based on which they proposed a standard for syndrome

differentiation in TCM which was then validated successfully in a study of kidney deficiency (Zhang et al., 2008). Likewise, Zhao et al. proposed a top-down subspace clustering for improving the precision of syndrome differentiation. Considering 5,600 symptoms and 150 syndrome elements of AIDS (acquired immune deficiency syndrome) patients, they showed that their method identified clusters of patients more precisely, compared to conventional clustering algorithms such as k-means (Zhao et al., 2014).

While identifying the heterogeneity of patients is critical, understanding the driving molecular mechanisms of such heterogeneity shall provide more rational on the design of precision medicine. To understand the underlying factors that are shared by patients with similar diseases, more information about the interaction of biological entities including genes, proteins, and drugs is required. By introducing network models, such a complex layer of information can be systematically evaluated, for which clustering analysis may further help infer the distinctive disease patterns. In the following we focused on the combination of network modeling and clustering analysis and showed that how they may contribute to the understanding for precision medicine.

## EXPLORING NETWORK MODULES AS A BASIS FOR CLASSIFICATION

A simple network consists of a set of elements called nodes or vertices which are connected by a set of links or edges (Jafari et al., 2013). Depending on the definition of node and edge sets, numerous types of biological networks can be constructed and used for further analysis. For example, the degree of a node, which is defined as the number of links attached to the node, suggests the importance of node and helps detect global and provincial hubs within the network. The heterogeneity of a network which is defined as the root of the variance of degrees divided by their mean, also explains the overall topology of the network and organization of relationships among the nodes (Dong and Horvath, 2007).

One of the major network modeling approaches is the modularity analysis or community detection which is the intersection of clustering analysis and network science (Fortunato, 2010; Fortunato and Hric, 2016). In this analysis, exploring the local densely connected nodes, i.e., networks community structure is the main aim. In other words, a community within a given network includes nodes with high intra-relationship and low inter-relationship with the other nodes outside the community (Girvan and Newman, 2002). Therefore, finding network modules is important to elucidate and understand the complex topology of networks by discriminating dense and sparse local structures. The network topology determines the adjacency matrix, which can be utilized for clustering analysis alone or in combination with the similarity matrix derived from the node properties (Von Luxburg, 2006; Fortunato, 2010). Since in real biological and disease networks, there are multifunctional nodes belonging to more than one group, soft clustering is also recommended (Yang and Leskovec,

2015). In the soft clustering, overlapping communities, also called covers, are detectable because the multiple memberships for a node are allowed. There are other methods including dynamical clustering (Jeub et al., 2015). For example, the Markov Clustering algorithm (MCL) is one of the commonly used dynamic clustering algorithms based on biological annotations (Jafari et al., 2015). After exploring the modules of a given network, it is common to convert the network into its reduced version, where a node of the reduced network corresponds to a module of the original network, and an edge is inferred from the number of interactions between the modules (**Figure 2**).

Utilizing molecular information in conjunction with the module detection to predict biological functions is a common task (Vespignani, 2003; Jafari et al., 2015). The main assumption is that members of the same cluster tend to be involved in the same biological process which is known as guilt-by-association. For example, in protein-protein interaction networks, clique-based clustering was used to detect protein complexes (Altaf-Ul-Amin et al., 2006; Phan and Sternberg, 2012; Jafari et al., 2013). Hierarchical clustering was utilized to identify signaling cascades or metabolic pathways (Guimera and Amaral, 2005; Koch and Ackermann, 2013; Azimzadeh Jamalkandi et al., 2016). Also, according to the local topological features of biological networks, clustering methods are commonly used to predict cellular co-localization and co-expressed gene regulatory mechanisms (Dittrich et al., 2008; Amiri et al., 2013; Mitra et al., 2013). At the phenotypic level, network modeling linking phenotypes to molecular components of a biological system, e.g., disease-causing genetic variations is also one of the exciting research areas (Goh et al., 2007; Loscalzo and Barabasi, 2011; Goh and Choi, 2012; Emmert-Streib et al., 2013). In the context of traditional medicine, Huang et al. highlighted how network pharmacology modeling allows us to integrate concurrent and traditional knowledge of herbal medicines for the development of new drugs for complex human diseases (Huang et al., 2013). Using a network-based integration of chemical structure and omics data, they inferred novel drug-disease interactions *via* molecular targets and pathways. Similarly, Li et al. introduced a

distance-based mutual information model to score herb interactions based on their frequencies and distances, and thus identify the rationale of herb combinations (Li et al., 2010).

Network biology approaches have also shown potential for exploring disease subcategories and patient subclasses in TCM. For instance, Zhou et al. constructed a clinical phenotype network to investigate the underlying mechanisms of TCM diagnosis and treatment (Zhou et al., 2014). Wang et al. proposed a co-occurrence network approach to identify the TCM symptoms as biomarkers for the fatty liver disease (Wang W. et al., 2019). Interestingly, Jiang et al. also demonstrated the association between the TCM symptoms and tongue-coating microbiome using co-occurrence networks (Jiang et al., 2012). Network modeling of cold and hot syndromes of traditional medicine has also been developed. For example, Ma et al. provided a gene expression signature of the cold syndrome in TCM associated with the neuroendocrine-immune system. By analyzing the protein interaction networks, they showed that the genes related to the cold syndrome are involved in pathways of energy metabolism, neurotransmitters, hormones, and cytokines (Ma et al., 2010). Likewise, Lu et al. provided distinctive molecular signatures in CD4-positive T cells of Rheumatoid Arthritis patients associated with the cold and heat patterns in TCM respectively (Lu et al., 2012a; Lu et al., 2012b).

## MULTIPARTITE NETWORK MODELS FOR INTEGRATING HETEROGENEOUS DATA

With the development of high-throughput technologies, precision medicine has been made more plausible with increasingly diversified data sets. These data sets range from gene expression profiles to medical images, where the scales, characteristics, and formats are different since they are gathered at the different levels of biological systems (Lee, 2011). The integration of information from these heterogeneous biological and clinical data sets need to be applied in order to discover new mechanistic insights of systems medicine. For example, to predict more effective disease

**FIGURE 2 |** A Poisson-distributed random network is represented in three formats. **(A)** A complex view of the network by placing nodes on a sphere layout that obscure the complexity of the network topology. **(B)** The same network using the force-directed layout algorithm in which communities were identified *via* a greedy optimization of modularity score. This representation is usually used to show the modular structure of the network. **(C)** The simplified network in which each node represents a community in the original network, and each edge denotes the interaction of communities.

treatment options using multi-targeted drug combinations (Tang and Aittokallio, 2014), we need to gather multiple data types such as *in vitro* drug response of cancer cells and *in vivo* response of patients including symptoms and molecular profiles. To predict the effectiveness of drug combinations, understanding about the signaling pathways and drug target interactions along with the pathophysiological states is essential. There is a major type of network models called multipartite networks which are commonly used in systems medicine (Junker and Schreiber, 2008). This kind of network modeling is crucial due to its flexibility to integrate mixed datasets and discover complex hidden relationships which are required for understanding precision medicine. Unlike ordinary uni-partite networks which contain single sets of nodes and edges represented by an adjacency matrix, a multipartite network constitutes of multiple sets of nodes and edges which are exemplified by incidence matrix (Agnarsson and Greenlaw, 2007). Depending on the data types, the network can represent gene-disease (Bauer-Mehren et al., 2011; Barnehi et al., 2016; Chen et al., 2018), drug-target (Barnehi et al., 2016), protein-cell localization (Mirzaei Mehrabad et al., 2018), drug-disease (Lamb, 2007) and drug-side effect associations (Luo et al., 2014), as well as associations at the patient level including patient-drug interactions and patient-symptom interactions (Bhavani et al., 2010).

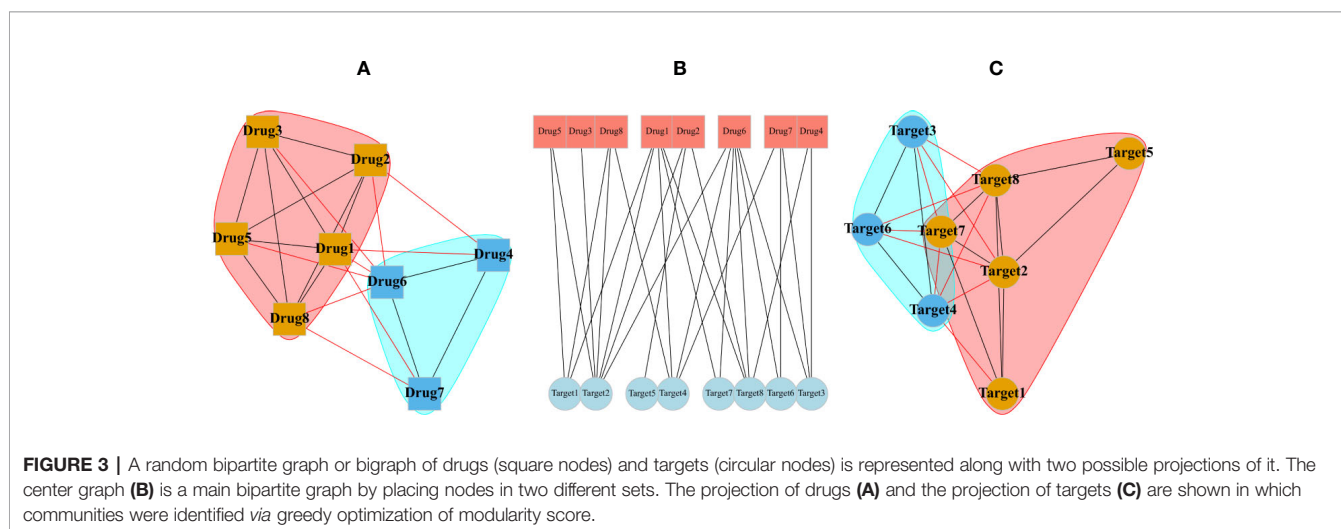

Based on the constructed multipartite networks, different kinds of clustering algorithms can be applied to identify the hidden subnetwork structures for each node set. For instance, Long et al. proposed a clustering method by a combination of co-clustering and probabilistic hidden Markov models (Long et al., 2007). Also, Hartsperger et al. developed a fuzzy multipartite clustering to decompose the nodes of multiple types in tripartite networks (Hartsperger et al., 2010). They showed that the fuzzy clustering algorithm was able to identify functionally correlated modules of a tripartite gene-disease-protein complex network for the identification of biologically meaningful clusters. Duan et al. identified two major subtypes of breast cancer by reconstructing a tripartite graph of drug-cell line-patient tumors. They showed how drug response data helped discover dysregulated pathways

for breast cancer (Duan et al., 2013). A multipartite network can be also utilized as a visualization tool, with which one can navigate efficiently the high-throughput drug response data from public databases including Cancer Cell Line Encyclopedia (CCLE) and Genomics of Drug Sensitivity in Cancer (GDSC) (Duan et al., 2014).

Typical multipartite network analyses involve network projection, which aims for simplifying the network topology from the viewpoint of each node set separately. In **Figure 3**, the projection of a schematic bipartite network and module detection analysis is briefly presented. Constructing the projected networks facilitates the exploration of hidden relationships among each set of nodes in a multipartite network. For example, Barnehi et al. constructed a drug-target network and further developed its projected version called Drug Similarity Network (DSN) and Target Similarity Network (TSN), which can be used for drug-target prediction (Barnehi et al., 2016). Recently, they have applied the method to predict drug combinations, and confirmed them experimentally (Barnehi et al., 2018; Barnehi et al., 2019). To facilitate drug repositioning, network topological similarity-based inference (NTSIM) and its classification-equipped version, i.e., NTSIM-C methods were also proposed to unveil novel drug-disease associations (Zhang et al., 2018).

## NETWORK ANALYSIS RATIONALIZES TCM CLASSIFICATIONS: A CASE STUDY

The idea of utilizing multipartite networks in traditional medicine is potentially feasible, as the data standardization and annotation has been increasingly pursued. However, to the best of our knowledge, the models are not yet utilized to provide more profound insights on traditional medicine, although some tools such as SymMap (Wu et al., 2019) may provide an appropriate dataset to build such multipartite networks. In the following, we conducted a case study to reconstruct a bipartite network of natural products and ingredients of TCM to show the potential

of this modeling for understanding TCM rationale for disease treatment and drug discovery.

TCM-related databases provide a large set of information about the TCM herbs including their classifications and disease indications, as well as molecular characterization, such as ingredient profiles and molecular targets. Recently, this information has been successfully applied for developing computational models to understand the TCM classifications (Wang Y. et al., 2019). As a case study to show the potential of multipartite networks in the integration of heterogenous data, we obtained a list of 4,485 natural products consisting of 2,857 chemical ingredients from the TCMID database (Huang et al., 2018). We used the second version of the TCMID database, as the largest dataset in this field, which contains richer experimental data originating from ingredient-specific and herbal mass spectrometry spectra. The natural products and ingredients are considered to be the two parts of a bipartite network. After removal of disconnected nodes, we extracted a giant component of the graph consisting of 7,004 nodes and 17,555 edges. Following the projection of this bigraph as outlined in **Figure 3**, two projected graphs called the natural product similarity network (NSN) and ingredient similarity network (ISN) were reconstructed, such that each edge indicates at least one common ingredient or natural product in NSN and ISN, respectively. The NSN contains 4,308 natural products and 204,807 edges, while the ISN consists of 2,696 nodes and 78,228 edges. The community detection was subsequently done for both similarity networks *via* optimizing a modularity score (Clauset et al., 2004), resulting in 42 and 24 communities for NSN and ISN, separately. The fast greedy algorithm outperformed compared to the other high-performance algorithms, i.e., infomap and walktrap (Labatut and Balasque, 2013; Wagenseller et al., 2018) according to the highest average of modularity index in the NSN and ISN (**Supplementary file 2**). These communities reflect the internal similarity of herbs and ingredients which could be investigated further. For example, a community of NSN indicates a set of natural products with similar profiles of ingredients. Therefore, the members of the same natural product cluster can be used for therapeutic interchanging due to the similarity of ingredient profiles in the cluster. Also, members of different clusters can be candidates for new drug combinations as they are expected to affect distinctive biological pathways. Similarly, the cluster of active ingredients in ISN can be used to predict the mechanism of action of newly discovered or synthesized compounds based on TCM classifications. In other words, a functionally-unknown molecule with high structural similarity to any of active ingredient clusters indicate the analogous TCM properties and implications. Therefore, any follow-up experimental analysis can be prioritized to disclose therapeutic hits of the new molecules based on known properties and implications of the corresponding cluster. Also, the priority of active ingredients for treatment can be redefined in each cluster independently using availability, and the relevant protein targets characterizations (code and data set for this case study can be found in **Supplementary File 1**).

We sought to validate our prediction about the herb and ingredient communities, i.e., whether the herbs or active ingredients that are clustered in the same community tend to

share similar features. Four types of features for the natural products and their ingredients including meridians and properties were extracted from TCMID. Furthermore, the SMILE strings of these ingredients along with the identified or predicted protein targets of them were extracted using PubChem (Kim et al., 2018) and STITCH databases (Szklarczyk et al., 2016). Then, the average of pairwise intersection of meridian and property profiles was computed separately for each cluster in NSN. Likewise, the average similarity of SMILE string using the Dice index and the pairwise intersection of their protein targets in each cluster of ISN were also calculated. We showed in **Figure 4** the average similarity of all the 42 and 24 communities in NSN (**Figures 4A, B**) and ISN (**Figures 4C, D**), as compared to that of random clustering from 100 simulations. We found that the similarity of natural products or active ingredients within a cluster is significantly higher than that for the random clustering. For example, the median of meridian-based similarity of random grouping is 0.56, while the median similarity of the 42 clusters found in NSN is 0.96 (p-value = 1.99e-05, Wilcoxon test). Similarly, in ISN, the median of the Dice similarity of SMILE strings in random groups is 0.22, while the median of the 24 clusters in ISN is 0.36 (p-value = 5.84e-05, Wilcoxon test). Our findings suggested that the clusters of ISN and NSN consist of similar ingredients or natural products, and thus validating the feasibility of bipartite modeling in analyzing TCM data.

Interestingly, these network analyses also suggested a molecular basis of TCM classifications, which originated from the physical features of natural products or empirical knowledge about the disease indications. Although the chemical and molecular characteristics of the natural products, i.e., chemical structures and protein targets have only been available recently, the TCM classification according to meridians were indeed associated with them. The same observation was found for the property classification in TCM in our findings, as the natural products in a given cluster based on ingredient profiles are associated with their property profiles. On the other hand, our approach promises to bridge a gap between pharmaceutical chemistry and traditional pharmacology in TCM. For example, we can use attributes of active ingredient profile of natural products as a rich training set, and newly discovered, or synthesized molecules can be characterized accordingly as a test set. To summarize, this bipartite network analysis provides novel insights for the understanding of molecular evidence of traditional classification in TCM. Using the bipartite network modeling, we may integrate phenotypes of different types, i.e., signs and symptoms, with the chemical knowledge of drug molecules in order to provide a formal framework for phenotype-based drug discovery in TCM.

## SUMMARY AND OUTLOOK

Nowadays, TCM, along with the other traditional medical schools, was modernized and expanded by the molecular shreds of evidence provided by experimental biology (Xue et al., 2013). These

**FIGURE 4 |** Validation of the network communities in TCM herbs. The distribution of Meridian similarity (A) and Property similarity (B) within the communities of NSN (natural product similarity network) compared to random groups; The distribution of drug target similarity (C, D) the Dice index similarity within the communities of ISN (ingredient similarity network) compared to random groups. experiments usually are started by extraction and fractionation techniques such as chromatography, and followed by identification methods such as mass spectrometry to determine a comprehensive profile of ingredients within the natural products (Jafari et al., 2016; Kabiri et al., 2017). The challenging part of this experimental design is identifying the ingredients responsible for the bioactivities of natural products. To further explore the drug-target interactions of these ingredients, high-throughput omics is now a preferable approach to study the effects on gene expression and protein activity. Through these experimental techniques, large volumes of molecular features related to disease indications can be disclosed, including antimicrobial, antiviral, antioxidant, anti-inflammatory, and neurological activities (Neghabi-Hajiagha et al., 2016; Pourramezan et al., 2018). In the next step, we always face the challenge of applying appropriate data integration methods to associate these molecular features with the phytochemical and pharmacological properties of the TCM ingredients.

A remarkable portion of biological studies deal with generating, organizing, and retrieving patient data, which is usually large scale and noisy. Data mining algorithms such as clustering and classification are being applied. Furthermore, the integration of heterogeneous biological data is imperative. Rigorous and efficient analysis tools are required for the integration of different data characteristics and formats as standard statistical inference techniques may be limited (Lee, 2011; Eric, 2014). Harnessing the network modeling in computational biology becomes a feasible strategy for data integration to navigate the complex space of

biological systems (Barabási et al., 2011). Here, we highlighted the application of the multipartite network reconstruction for data integration in biomedical researches, particularly in traditional medicine. More specifically, we demonstrated how we can combine current chemical knowledge of ingredients and TCM classifications of natural products to bridge the gap between traditional and modern medicine. We provided a case study to show its potentials for uncovering TCM concepts and discovering potential treatments.

Although network science, and more precisely, network medicine is on its developing stage, using multipartite network modeling may provide more rational on the therapies in traditional medicine. Generally in traditional medicine, much efforts are spent on collecting the symptoms of patients, while in modern medicine, biochemical profiles and image data are more relied on. Providing a framework for integrating all these data using multipartite network model shall facilitate the interchange of knowledge from traditional and modern medicine. Reconstructing multipartite networks is a convenient way to characterize patient similarity, which serves the basis for further explorations on their diseases mechanisms (Pai and Bader, 2018). Depending on the nature of the node sets, a multipartite network can be utilized to investigate complex interactions, that might be critical for understanding diseases with high-level patient heterogeneity such as cancer (Yaffe, 2019). Considering all available data from cellular behaviors to patient responses using multipartite network modeling can play a significant role

in the integration of these heterogeneous datasets, a successful application of which may make precision medicine a reality ultimately.

Jian-pi-bu-xue-formula (JPBXF), a TCM formula composed of twelve Chinese medicinal herbs, has been used in clinic to ease patients' state of weakness and fatigue especially after receiving anti-tumor chemotherapy in China. The lack of the phytochemical characterization, detail therapeutic evaluation and mechanism of JPBXF remains the main limitation for its spreading. In this study, we systematically evaluated the effectiveness and underline mechanism of JPBXF on cyclophosphamide (CTX)-induced myelosuppression and identified the main constituents of JPBXF aqueous extract. JPBXF treatments reversed CTX-induced myelosuppression through increasing the number of haematopoietic stem cells (HSCs) and expression of C-kit in bone marrow cells. Simultaneously, JPBXF treatments alleviated CTX-induced blood cells reduction by increasing numbers of RBCs and WBCs and levels of GM-CSF, TPO and EPO in plasma. JPBXF treatments reduced CTX-induced immunosuppression by increasing expressions of CD3, CD4, and CD8a in PBMCs, and recovering structure damages of thymus and spleen. Moreover, JPBXF notably increased the expression of NRF2 compared with CTX group, and subsequently up-regulated HO1 and NQO1 both in mRNA and protein levels. In addition, eighteen compounds were recognized from JPBXF aqueous extract and the potential targets of the identified compounds were predicted. Overall, JPBXF can greatly reverse CTX-induced myelosuppression in C57BL/6 mice, especially in improving the blood and immune function through activating NRF2/HO1/NQO1 signaling pathway, which provides a reliable reference for JPBXF application in clinical. By recognizing eighteen compounds in JPBXF aqueous extract and predicting the underline mechanisms of the identified compounds, our study would provide theoretical guidance for further research of JPBXF.

**Keywords:** Jian-pi-bu-xue-formula, cyclophosphamide, complementary therapy, myelosuppression, NRF2

GRAPHICAL ABSTRACT |

## INTRODUCTION

Cancer, an aggressive malignancy, approximately causes 4,285,033 new cases and 2,865,147 cancer-related deaths annually in China (Bray et al., 2018). The conventional therapies for cancer treatment include chemotherapy, radiotherapy and surgery. Among these treatments, chemotherapy acts as a practical method and was widely used to kill cancer cells by impeding their growth and reproduction (Potti et al., 2011). However, most of chemotherapeutic agents pose many side effects including myelosuppression, immunosuppression, gastrointestinal reaction and hepatic or renal toxicity, that greatly threaten patients' quality of life, reduce treatments' efficiency, and furthermore lead to termination of ongoing useful therapy (Tachi et al., 2015). For instance, cyclophosphamide (CTX), a common anti-cancer chemotherapeutic agent, is often used alone or in combination with platinum and paclitaxel as standard first-line therapy (Handolias et al., 2016). Myelosuppression, the most common side effect of CTX characterized by decrease of stem and progenitor cells in bone marrow, often arises complications such as neutropenia, anemia and thrombocytopenia (Carey, 2003; Neboh and Ufelle, 2015). It has proof that NRF2 deficiency deteriorated CTX-induced myelosuppression, while activation of NRF2 mitigates ionizing CTX -induced myelosuppression (Que et al., 2016). The up-regulation of HO1 and NQO1 could resist to CTX-induced bone marrow suppression, oxidative stress,

inflammation and apoptosis (Chen et al., 2014; HAS et al., 2019). Therefore, methods, which could prevent or eliminate chemotherapy-induced side effects through regulating NRF2 pathway, have great significance for patients struggling against cancer.

Complementary medicine, forms of treatment that used along with standard medical treatments, is common among cancer patients to help lessen some side effects of cancer treatment (Hubner et al., 2015). In clinical, hematopoietic growth factors (HGFs) including granulocyte colony-stimulating factor (G-CSF) and granulocyte macrophage colony-stimulating factor (GM-CSF), are effective complementary medicines for therapy to alleviate chemotherapy-induced myelosuppression (Miller and Steinbach, 2014). Unfortunately, G-CSF and GM-CSF can also accelerate growth of cancer cells (Gutschalk et al., 2006). Therefore, new approaches on finding more effective and safe drugs for preventing and treating chemotherapy-induced myelosuppression are necessary. Traditional Chinese medicine (TCM) complementary treatment has been reported to alleviate chemotherapy induced side effects and improve quality of life (Zhang et al., 2007; Konkimalla and Efferth, 2008). For instance, *Ipomoea obscura* (L.) Ker Gawl. extract could reduce CTX-induced myelosuppression, improve white blood cell counts and recover bone marrow cellularity (Hamsa and Kuttan, 2010). Sip-jeon-dea-bo-tang, a traditional herbal medicine, has been reported to prevent the cisplatin-induced reduction of food intake and weight loss (Woo et al., 2016). Considering the limitations of hematopoietic growth factors, finding effective TCMs on alleviating chemotherapy-induced myelosuppression is helpful and meaningful.

Jian-pi-bu-xue-formula (JPBXF), a TCM consisted of twelve Chinese medicinal herbs, is consumed in clinical for strengthening spleen and fortifying the blood in China for decades. According to basic theories of Chinese medicine,

**Abbreviations:** BATMAN-TCM, Bioinformatics Analysis Tool for Molecular Mechanism of Traditional Chinese Medicine; CTX, cyclophosphamide; DAVID, Database for Annotation, Visualization and Integrated Discovery; ELISA, enzyme-linked immunosorbent assay; EPO, erythropoietin; G-CSF, granulocyte colony-stimulating factor; GM-CSF, granulocyte macrophage colony-stimulating factor; JPBXF, Jian-pi-bu-xue-formula; PBMC, peripheral blood mononuclear cell; PPI, protein-protein interaction; TCM, traditional Chinese medicine; TPO, thrombopoietin.

JPBXF is a combined formula based on Si-Jun-Zi-Tang, Si-Wu-Tang and Dang-Gui-Bu-Xue-Tang without unnecessary drugs, aiming to improve the hematopoiesis effects and make it gently to patients with chemotherapy. JPBXF is composed of monarch drugs *Hedysarum multijugum Maxim* (Huang-Qi) and *Codonopsis pilosulae* (Franch.) Nannf. (*Codonopsis pilosulae* Radix, Dang-Shen), minister drugs including *Ficus simplicissima* Lour. syn. *Ficus hirta* Vahl (Wu-zhi-mao-tao), *Atractylodes macrocephala* Koidz. (Bai-Zhu), *Angelica sinensis* (Oliv.) Diels (Dang-Gui), and *Rehmannia glutinosa* (Gaertn.) DC. (Shu-Di-Huang), assistant drugs including *Pinellia ternata* (Thunb.) Makino syn. *Arum ternatum* Thunb. (Ban-Xia), *Citrus × aurantium* L. syn. *Citrus reticulata* Blanco (Chen-Pi), *Pogostemon cablin* (Blanco) Benth. (Huo-Xiang) and *Zingiber officinale* Roscoe (Sheng-Jiang), and guide drugs *Ziziphus jujuba* Mill (Da-Zao) and *Glycyrrhiza uralensis* Fisch (Gan-Cao). In JPBXF, *H. multijugum*, *C. pilosula* and *R. glutinosa* had been reported to enhance immunity *in vivo* after CTX treatment (Cohen et al., 2002; Wang et al., 2012). *A. sinensis* has great impacts on promoting hematopoiesis (Gong et al., 2016). *Z. jujuba*, *Z. officinale*, *A. ternatum*, *P. cablin*, *C. aurantium*, *A. macrocephala* and *G. uralensis* are often used in formulas for antiemetic during chemotherapy (Cohen et al., 2002). Our previous study also showed that JPBXF could improve hematopoiesis of chemotherapy mice by affecting the expression levels of GM-CSF, TPO, and EPO (Feng and Liu, 2015). Although JPBXF has been used as a formula in clinical for decades, the lack of detail therapeutic evaluation and underline mechanism of JPBXF remains the main limitation for its spreading. Furthermore, the phytochemical characterization of JPBXF is still unclear.

In our study, a CTX-induced myelosuppression animal model was established to assess the effectiveness and safety of JPBXF in alleviating chemotherapy-induced myelosuppression. Changes in thymus, spleen, bone marrow, blood cell counts, expressions of T-cell surface markers such as CD3, CD4, and CD8a in peripheral blood mononuclear cells (PBMCs), expression of C-kit in bone marrow cells, as well as levels of GM-CSF, TPO, and EPO in plasma in the mice were systematically evaluated. Meanwhile, effects of JPBXF on NRF2, HO1, and NQO1 expressions in thymus and spleen were also detected. Furthermore, main chemical constituents of JPBXF aqueous extract were identified using UHPLC/MS/TOF and the underline mechanisms of the identified compounds were predicted using bioinformatics analysis.

## MATERIAL AND METHODS

### Reagents

Cyclophosphamide (Pude Pharmaceutical Co., Datong, Shanxi, China) was purchased from the First Affiliated Hospital of Guangzhou University of Chinese Medicine. The anti-CD3 and anti-CD4 antibodies, goat anti-rabbit and anti-mouse secondary antibody horseradish peroxidase conjugate (IgG antibodies) were

purchased from Abcam (Cambridge, Massachusetts, UK). The anti-CD8a antibody and anti-C-kit receptor antibody were purchased from Santa Cruz Biotechnology (Santa Cruz, California, USA). GM-CSF, TPO, and EPO Elisa kits were purchased from R&D Systems (Minneapolis, MN., USA). All other reagents were from a standard source and were analytical pure grade.

### Plant Materials and JPBXF Preparation

*F. simplicissima* (30 g), *H. multijugum* (30 g), *C. pilosula* (20 g), *A. macrocephala* (15 g), *A. sinensis* (6 g), *R. glutinosa* (10 g), *A. ternatum* (10 g), *C. aurantium* (10 g), *P. cablin* (10 g), *Z. officinale* (6 g), *Z. jujuba* (10 g) and *G. uralensis* (10 g) were all purchased from the First Affiliated Hospital of Guangzhou University of Traditional Chinese Medicine (Guangdong, China) and identified by Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences (Beijing, China). A voucher specimen was deposited at the Laboratory of International Institute for Translational Chinese Medicine, Guangzhou University of Chinese Medicine (Guangzhou, China). The Chinese herbal mixture was immersed in a 8-fold amount of distilled water for 30 min and gently boiled for 30 min. The extract was collected. The herb residues were boiled again with a 6-fold amount of distilled water for 1 h, and the extract was collected again. Following, the collection extract were combined, filtered with three layers of gauze, and evaporated in 60 °C. After cooling at room temperature, liquid was spared and stored at 4 °C.

### JPBXF Chemical Components Analysis

Characterization of main chemical components in JPBXF was detected by UHPLC/MS/TOF (Agilent Technologies 6540). Chromatographic separation was achieved on a Zorbax C18 column (100 × 3.0 mm<sup>2</sup>, 1.8 μm) (Agilent Technologies), with column temperature maintained at 25°C. The mobile phases consisted of water (A) and acetonitrile (B) using a gradient elution. The flow rate was 0.3 ml/min. The mass spectrometer was operated in negative ion mode. The full scan setting parameters are as follows: capillary voltage, 2.5 kV; nozzle voltage, 1,000 V; gas temperature, 290°C; sheath temperature, 340°C; sheath gas flow, 11 L/min; and gas flow, 10 L/min; fragmentation voltage: 135 V. Self-building database containing mass spectrometry information of reported compounds from each herb was used for compounds matching.

### Animals

Male C57BL/6 mice (4–6 weeks, 18–22 g) were purchased from the Laboratory Animal Center of Guangzhou University of Chinese Medicine (Guangzhou, China; License: SCXK, Guangdong, 2018-0034). The mice were kept in the animal facility in the SPF animal laboratory (License number: SYXK (GZ) 2019-0144) at International Institute for Translational Chinese Medicine, Guangzhou University of Chinese Medicine (Guangzhou, China). The animal experiments were approved by the International Institute for Translational Chinese Medicine Animal Care and Use Committee, Guangzhou University of Chinese Medicine (Guangzhou, China). The mice randomly

divided into five groups: control, CTX, GM-CSF, high- and low-dose JPBXF. Control group ( $n = 6$ ) received treatments with 0.9% physiologic saline (i.p.) once a day for 10 days and intragastric administrations with 0.9% physiologic saline once a day for 12 days. CTX, GM-CSF, JPBXF groups (each with  $n = 6$ ) received administrations with CTX (25 mg/kg, i.p.) once a day for 10 days and intragastric administrations with 0.9% physiologic saline, GM-CSF (5  $\mu$ g/kg), high- and low-dose of JPBXF (2.5 g/mL and 0.62 g/mL) once a day for 12 days, respectively. The body weights of the mice were recorded every other day. Finally, the mice were sacrificed and the organs (including spleen and thymus) of each mouse were isolated and weighed.

## Peripheral Blood Cell Count

Before the mice were sacrificed, the blood samples (200  $\mu$ L of each mouse) were collected in heparin-treated tubes by and then stored at 4°C. After all samples collection, the numbers of leukocyte, platelet, and erythrocyte were counted using SYSMEX XT-1800I (Kobe, Japan).

## Isolation of Plasma and PBMCs

After the mice were sacrificed, the whole blood of each mouse was collected in heparin-treated tubes and then centrifuged at 3,000 rpm for 10 min. The plasma samples were harvested, and stored at -80 °C. The remaining precipitation was resuspended in PBS (v/v, 1:1), and loaded into the tubes filled with Ficoll (GE Healthcare, Chicago, USA). After centrifuged at 400 g for 30 min, PBMCs were isolated, and rinsed twice with PBS.

## ELISA Assay

Levels of GM-CSF, TPO, and EPO in plasma were measured by enzyme-linked immunosorbent assay (ELISA), using Quantikine ELISA kits (R&D Systems, Minneapolis, MN, USA), according to the manufacturer's instructions. Results were expressed as ng/L of plasma.

## Flow Cytometry

After isolated, PBMCs were treated according our previous study (Feng et al., 2016). After incubated with anti-CD3 antibody (1:200), anti-CD4 antibody (1:200), anti-CD8a antibody (1:50), and secondary antibodies (1:200), the PBMCs samples were detected using Flow cytometry (BD Biosciences, San Diego, CA, USA).

## H&E Staining

Tissues such as thymus, spleens, and femurs were treated and observed according our previous study (Feng et al., 2016). Briefly, after fixed, embedded, and sliced, sections (4  $\mu$ m) of thymus, spleens, and femurs were deparaffinized and rehydrated. Following, hematoxylin and eosin staining were performed. The slices were then observed under a light microscope (Leica DM750, Wetzlar, GER).

## Western Blot

Total proteins of thymus or spleens were extracted using RIPA lysis buffer and phenylmethanesulfonyl fluoride (PMSF), and

quantified using Coomassie Brilliant Blue Kit (Bio-Rad, Hercules, CA, USA). Protein samples of each tissue were separated by 10% SDS-PAGE, transferred onto PVDF membranes, and blocked with 5% BSA for 1 h. The membranes were incubated with the primary antibody of NRF2 (1:1,000) at 4 °C overnight, subsequently, with the corresponding secondary antibodies (1:5,000) at room temperature for 1 h.  $\beta$ -actin acted as a loading control. ECL chemiluminescence reagent was applied to detect for fluorescent signals using FluorChem E (Santa Clara, CA, USA). Protein bands were quantified using Quantity One software (Bio-Rad, Hercules, CA, USA).

## Real-Time PCR Analysis

Total RNA of thymus or spleens was isolated through the TRIzol extraction method. Then, RNA reverse transcribed into cDNA according to a reverse transcription kit (TaKaRa, Shiga, Japan). SYBR Green real-time PCR amplification and detection were then performed with an ABI 7500 system (Applied Biosystems, Foster City, USA).  $\beta$ -actin was regarded as house-keeping gene. Primers are as follows. HO1: 5'-TGATGGCTTCCTTGTA CCATATC-3' and 3'-AGCTCCTCAGGGAAGTAGAG- 5'; NQO1: 5'-GAGAAGAGCCCTGATTGTACTG-3' and 3'-ACC TCCCATCCTCT CTTCTT-5';  $\beta$ -actin: 5'-CTGTCCCTGTAT GCCTCTG-3' and 5'-ATGTCACGCAC GATTTCC-3'.

## Immunohistochemistry (IHC)

Thymus and spleens tissues were fixed in 4% paraformaldehyde, embedded in paraffin. After sliced up, the slices (4  $\mu$ m) were dewaxed, hydrated, and then incubated with sodium citric (0.01 M) for antigen retrieval. Following, the slices were rinsed with PBS, and incubated with anti-HO1 and anti-NQO1 overnight at 4 °C. Following steps were performed using the immunostaining kit (BOSTER Biological Technology) based on the manufacturer's instructions.

## Target Prediction by Network Pharmacology

The myelosuppression-related genes were obtained from the GeneCards database (<https://www.genecards.org/>), and the potential target genes of compounds were predicted using a Bioinformatics Analysis Tool for Molecular mechANism of Traditional Chinese Medicine (BATMAN-TCM) (<http://bionet.ncpsb.org/batman-tcm/>) and Swiss Target Prediction database (<http://www.swisstargetprediction.ch/>). Genes obtained from these three databases were analyzed using Venny 2.1 (<https://bioinfogp.cnb.csic.es/tools/venny/index.html>). The gene ontology (GO) and Genomes (KEGG) enrichment analyses were performed for the potential targets using the Database for Annotation, Visualization and Integrated Discovery (DAVID) (<https://david.ncifcrf.gov/>) and the online software Omicshare. The protein-protein interaction (PPI) among these potential targets was constructed using the STRING database (<https://string-db.org/>) (Du et al., 2019). The compound-target-pathway network was constructed using Cytoscape 3.7.2 (Zhang et al., 2019).

## Data Analysis

All data were expressed as mean  $\pm$  standard deviation (SD). Significant differences were analyzed by one-way ANOVA followed by LSD test (for more than two groups) by SPSS. Statistical difference was considered significant at  $P < 0.05$ .

## RESULTS

### Phytochemical Characterization of JPBXF

To identify the main constituents of JPBXF aqueous extract, we analyzed the JPBXF aqueous extract using UHPLC/MS/TOF. Eighteen compounds were recognized from JPBXF aqueous extract as shown in **Table 1**. The typical scaffold backbones for the eighteen compounds are flavonoids, saponins and polyphenols. Among the eighteen compounds, there are thirteen flavonoids, including liquiritin apioside, liquiritin, acteoside, naringin, isoacteoside, hesperidin, isoliquiritin apioside, isoliquiritin, liquiritigenin, calycosin, formononetin, glycycomarin, and licoisoflavone B. Meanwhile, licoricesaponine A3, licoricesaponine G2 and glycyrrhizic acid are three saponins. Paeonol and 4-gingerol are two polyphenols. According to UHPLC/MS/TOF, liquiritin, acteoside, naringin, hesperidin, glycyrrhizic acid and 4-gingerol were identified with high contents (**Figure 1**). Three pairs of flavonoid isomers need further identification.

### Effects of JPBXF on CTX-Induced Myelosuppression

To assess the effects of JPBXF on chemotherapy-induced myelosuppression in mice, body weight change and H&E staining of femurs were performed. Although there was no significant change in body weight among each group, CTX treatment induced a slight decrease in body-weight of mice compared with the control group (**Figure 2A**). However, after treated with JPBXF, the body-weight loss of mice induced by CTX

was decreased slightly (**Figure 2A**). H&E staining results shown that CTX treatment significantly reduced the number of haematopoietic stem cells (HSCs) in femurs compared with control group. To the contrary, JPBXF treatments increased the number of HSCs compared with that of CTX treatment alone (**Figure 2B**). To further confirm whether JPBXF treatments could influence the number of HSCs, the expression of C-kit, a marker of HSCs, was detected in bone marrow cells. The results shown that compared with control, the expression of C-kit was markedly decreased by  $57.02 \pm 6.16\%$  in CTX treated bone marrow cells ( $P < 0.01$ , **Figure 2C**). Meanwhile,  $5 \mu\text{g/kg}$  of GM-CSF and  $2.5 \text{ g/mL}$  of JPBXF treatments increased the expression of C-kit by  $35.68 \pm 7.82\%$  and  $42.44 \pm 8.71\%$  respectively compared with that of CTX alone ( $P < 0.05$ , **Figure 2C**).

### JPBXF Alleviated CTX-Induced Blood Cells Reduction

Along with myelosuppression, CTX treatments often induce blood cells reduction (Hill et al., 2011). To investigate the effects of JPBXF on blood cells, we detected the numbers of WBCs, RBCs, and PLTs and analyzed the secretion levels of hematopoietic growth factors including GM-CSF, EPO, and TPO. The whole blood analysis revealed that compared with control group, the numbers of WBCs and RBCs were significantly decreased after CTX treatments. However,  $5 \mu\text{g/kg}$  of GM-CSF and  $2.5 \text{ g/mL}$  of JPBXF treatments increased the numbers of WBCs and RBCs at different degrees. Nevertheless, the number of PLTs showed a slight increase in GM-CSF group, but had few changes in CTX and JPBXF groups (**Figure 3A**). Meanwhile, ELISA assays showed that the secretion levels of GM-CSF, EPO, and TPO were significantly reduced by  $35.05 \pm 7.99\%$ ,  $89.84 \pm 2.48\%$ , and  $49.48 \pm 4.79\%$  respectively in CTX group compared with the control group. However, JPBXF treatments abrogated the suppression effect of CTX and markedly increased the secretion levels of GM-CSF, EPO, and TPO at different degrees in plasma. Compared with CTX group,

2.5 g/mL of JPBXF treatments increased the levels of GM-CSF, EPO and TPO by 2.94-, 69.84-, and 4.21-fold in plasma (Figure 3B).

### JPBXF Reduced CTX-Induced Immunosuppression

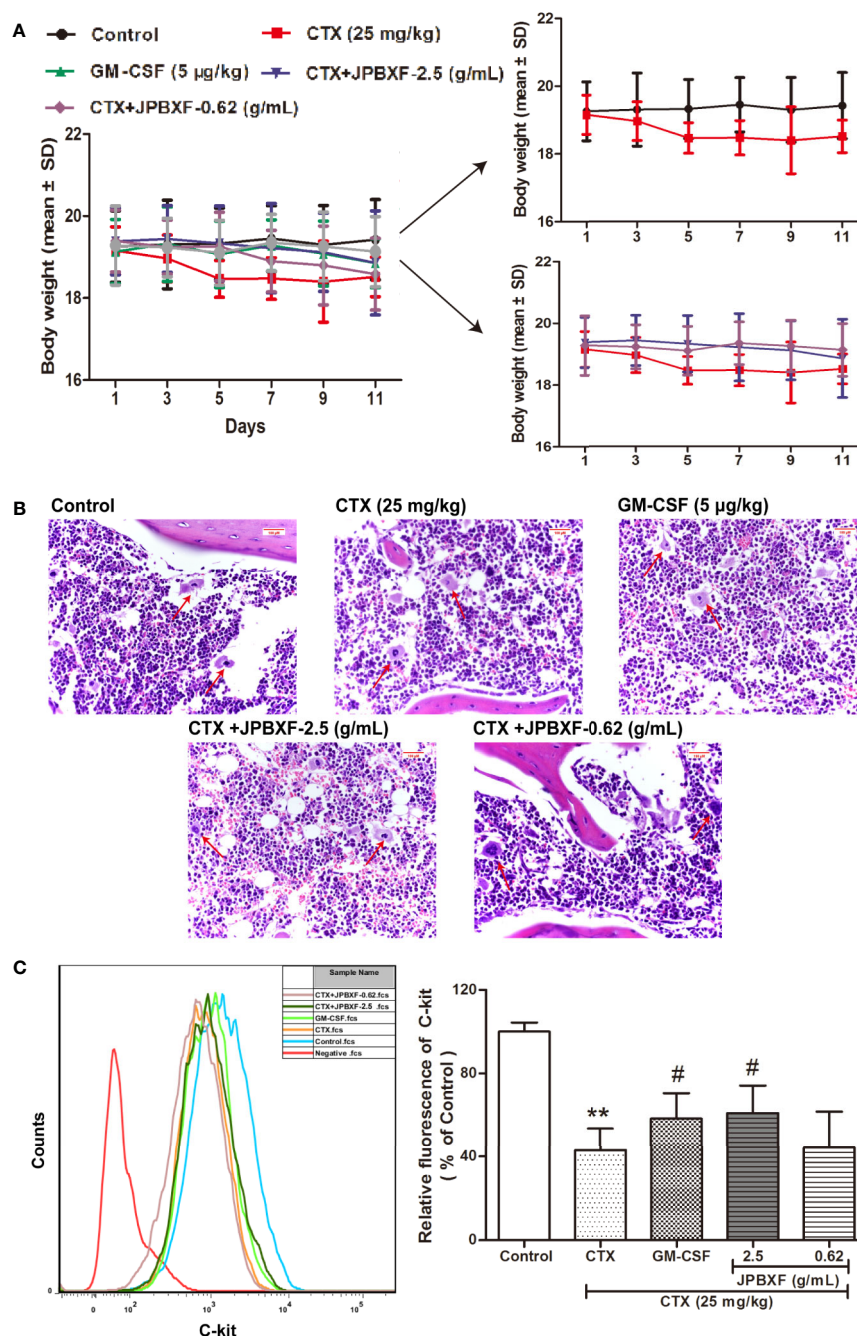

According to the white blood cell analysis results, we found that JPBXF treatments might raise the immunity of mice suppressed by CTX. Among these white blood cells, T cell play important role in immunity. To further confirm the effect of JPBXF on T cells, we detected the expressions of T-cell surface markers, such as CD3, CD4, and CD8 $\alpha$  in PBMCs. The results demonstrated that compared with control group, CTX treatment significantly decreased the expressions of CD3, CD4, and CD8 $\alpha$  by  $44.03 \pm 2.96\%$ ,  $14.63 \pm 4.14\%$ , and  $46.70 \pm 3.10\%$ , respectively. However, CTX-induced expression decrease of CD3, CD4 and CD8 $\alpha$  were recovered by JPBXF treatments (Figure 4). In detail, 2.5 g/mL of JPBXF treatments increased CD3, CD4, and CD8 $\alpha$  expression levels by  $31.33 \pm 5.59\%$ ,  $28.62 \pm 3.44\%$ , and  $18.13 \pm 2.24\%$ , respectively. Meanwhile, 0.62 g/mL of JPBXF treatments increased the expressions of CD3, CD4, and CD8 $\alpha$  by  $37.99 \pm 5.07\%$ ,  $34.06 \pm 3.09\%$ , and  $45.16 \pm 3.29\%$ , respectively.

Thymus and spleen are two main immune organs that play important roles in cellular and humoral immunity. To assess the effects of JPBXF on cellular and humoral immunity in mice, size comparison and H&E staining of thymus and spleen were further conducted. The pictures of thymus directly showed that CTX treatment induced a size reduce of thymus compared with that of control, however, JPBXF treatments increased the size of thymus. Compared with the control group, thymus index (ratios of thymus to body-weight) in CTX group decreased markedly. Meanwhile, thymus index in GM-CSF group and high-dose JPBXF group were significantly increased compared with CTX group; however, thymus index in the low-dose JPBXF group had no significant change (Figure 5A). H&E staining results showed that the tissue structures of thymus, including cortex, medulla, and thymic corpuscle, were clear observed in

control group, and destroyed in CTX group. However, the structure damages of thymus by CTX were significantly recovered by JPBXF treatments (Figure 5B). The same as thymus, the size of spleen was reduced by CTX and increased by JPBXF. Spleen index (ratios of spleen to body-weight) in CTX group was decreased markedly compared with that of control group, meanwhile, increased in GM-CSF and JPBXF groups compared with CTX group (Figure 6A). In addition, white pulp atrophy, hemorrhage and necrosis were observed in spleen after CTX treatment. However, these damages were reduced in GM-CSF and JPBXF groups, especially in 2.5 g/mL JPBXF group (Figure 6).

### JPBXF Alleviated CTX-Induced Myelosuppression Through Activating NRF2/HO1/NQO1 Signaling Pathway

NRF2, a pivotal transcription factor, is involved in regulating redox homeostasis, drug metabolism, responses to oxidative and electrophilic stress and so on (Hayes and Dinkova-Kostova, 2014). NRF2 deficiency deteriorated CTX-induced myelosuppression, while activation of NRF2 mitigated CTX-induced myelosuppression (Que et al., 2016). Herein, to further determine the underlying mechanism of JPBXF in alleviating CTX-induced myelosuppression, NRF2 expressions in thymus or spleen were evaluated. Our results showed that the expressions of NRF2 were significantly decreased by CTX both in thymus and spleen compared with control group, meanwhile, notably increased by GM-CSF and JPBXF treatments compared with CTX group, suggesting that JPBXF could mitigate CTX-induced myelosuppression through activating of NRF2 (Figure 7A). The up-regulation of HO1 and NQO1 could resist to CTX-induced bone marrow suppression, oxidative stress, inflammation and apoptosis (Chen et al., 2014; HAS et al., 2019), and we found that JPBXF reversed CTX-induced HO1 and NQO1 suppressions both in mRNA and protein levels (Figures 7B–D), indicating that JPBXF alleviated CTX-induced myelosuppression through activating NRF2/HO1/NQO1 signaling pathway.

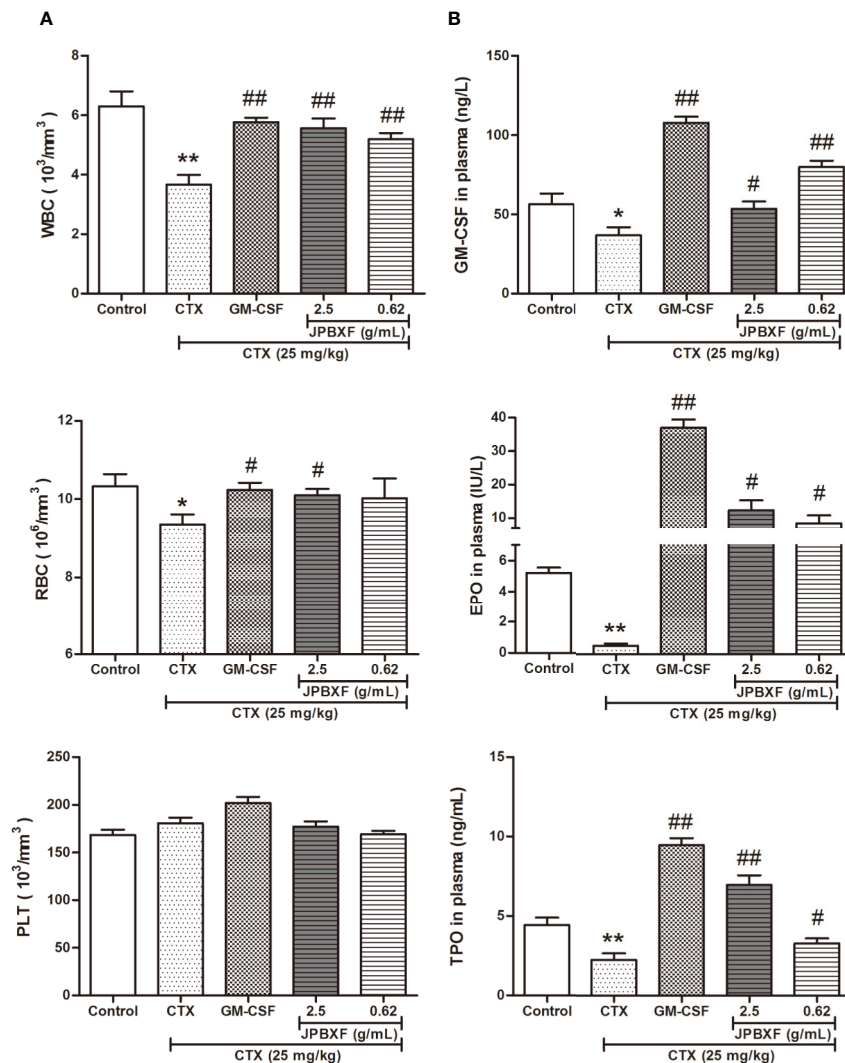

**FIGURE 2 |** Effects of JPBXF on myelosuppression in CTX-treated mice. **(A)** The body weight curves of CTX-treated mice after JPBXF treatments. **(B)** Histopathological changes in bone marrow tissues (stained by H&E,  $\times 400$ ). **(C)** Expression of C-kit in bone marrow cells. ## Target Prediction of Eighteen Compounds on Alleviating Myelosuppression by Network Pharmacology

We queried 3,519 genes related to myelosuppression using GeneCards database, 482 predicted target genes of compounds using BATMAN-TCM database and 582 predicted target genes of

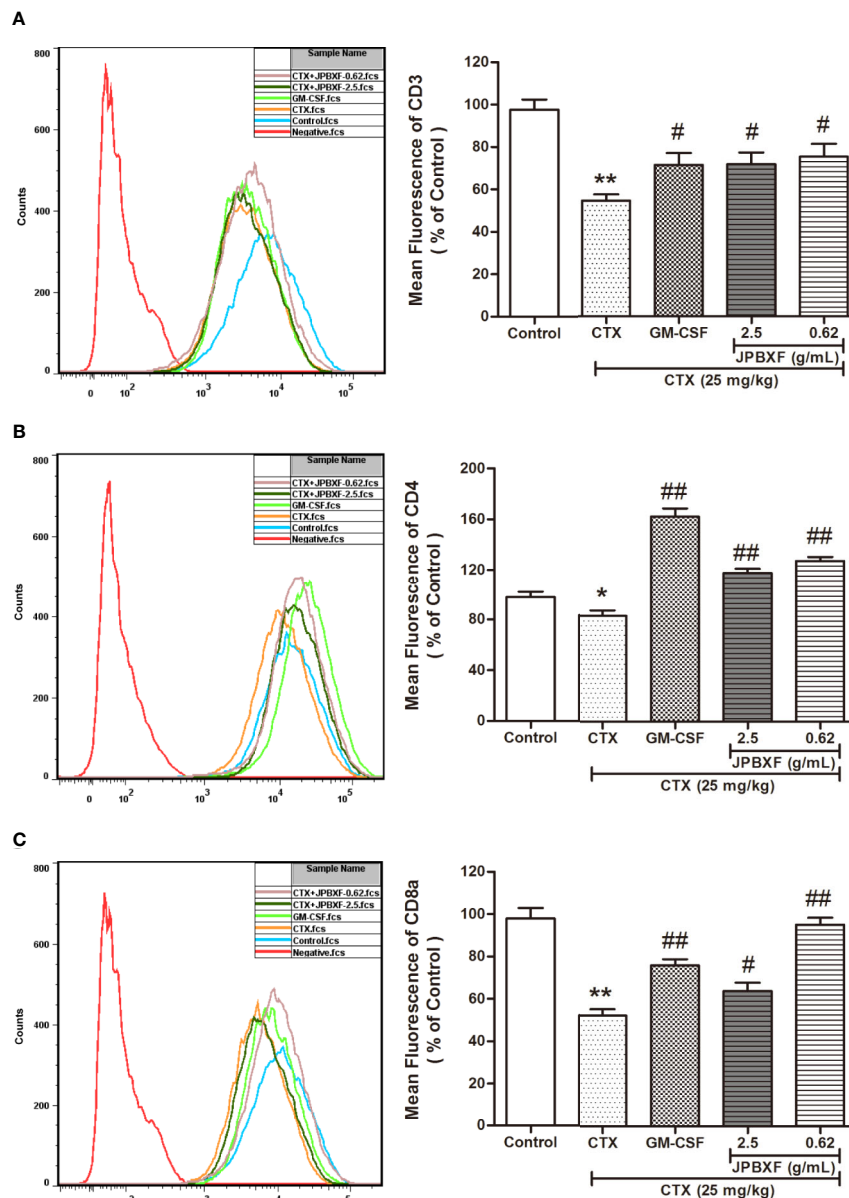

compounds using Swiss Target Prediction database. 87 of the potential targets yielded from these three database were selected for GO and KEGG analyses (**Figure 8A**).  $P < 0.05$  was set as threshold criteria to identify the functional gene ontology and pathway, and Top 20 ontology and pathway were showed in **Figures 8B, C**. GO enrichment analysis indicated that the 87

**FIGURE 3 |** Effects of JPBXF on blood system in CTX-treated mice. **(A)** The numbers of white blood cells, red blood cells and platelets in CTX-treated mice after JPBXF treatments. **(B)** The secretion levels of GM-CSF, EPO, and TPO in plasma in CTX-treated mice after JPBXF treatments. Data shown are means  $\pm$  SD from day 13. \* $P < 0.05$ , \*\* $P < 0.01$  vs. Control, # $P < 0.05$ , ## $P < 0.01$  vs. CTX.

potential targets were primarily associated with the “response to organic substance,” “response to chemical,” “multicellular organismal process,” “regulation of multicellular organismal process,” and “regulation of biological quality” terms. KEGG enrichment analysis revealed that the 87 potential targets were significantly enriched in the “Neuroactive ligand-receptor interaction,” “Pathways in cancer,” “Calcium signaling pathway” “cAMP signaling pathway” and “Vascular smooth muscle contraction” terms. The PPI network identified 14 key genes for the compounds, including AGTR2, PTGS2, MTOR, DRD2, EP300, OPRM1, AGTR1, DRD3, OPRD1, OPRK1, PPARG, PTGER3, RXRA, and TNF (**Figure 8D**). The three-level network consisted of 125 nodes (18 compounds, 87 genes and 20 pathways) and 552 edges. Among the 18 compounds, naringin

showed the broadest effect on the target genes (38 genes). Liquiritin apioside, liquiritigenin, licoricesaponine G2, and isoliquiritin also affected 36, 35, 33, and 33 genes, respectively. Among the 87 genes, PRKCA, PRKCB and IMPDH1 were influenced by 16, 13, and 12 compounds, respectively. OPRD1, PPP2CA, ESR1, OPRM1, OPRK1, and ALOX5 were affected by 11 compounds. CNR2 was affected by 10 compounds. IMPDH2 was influenced by 9 compounds. DRD2, NR3C1 and TOP2A were affected by 8 compounds. While three targets were influenced by 7 compounds, one target was influenced by 6 compounds, ten targets were affected by 5 compounds, nine targets were affected by 4 compounds, twenty three targets were affected by 3 compounds, and the rest twenty seven were affected by only one compound.

**FIGURE 4 |** Effects of JPBXF on the PBMCs in CTX-treated mice. The expression levels of CD3 (A), CD4 (B), and CD8α (C) in peripheral blood mononuclear cells (PBMCs) of CTX-treated mice after JPBXF treatments. Data shown are means ± SD from day 13. \* $P < 0.05$ , \*\* $P < 0.01$  vs. Control, # $P < 0.05$ , ## $P < 0.01$  vs. CTX.

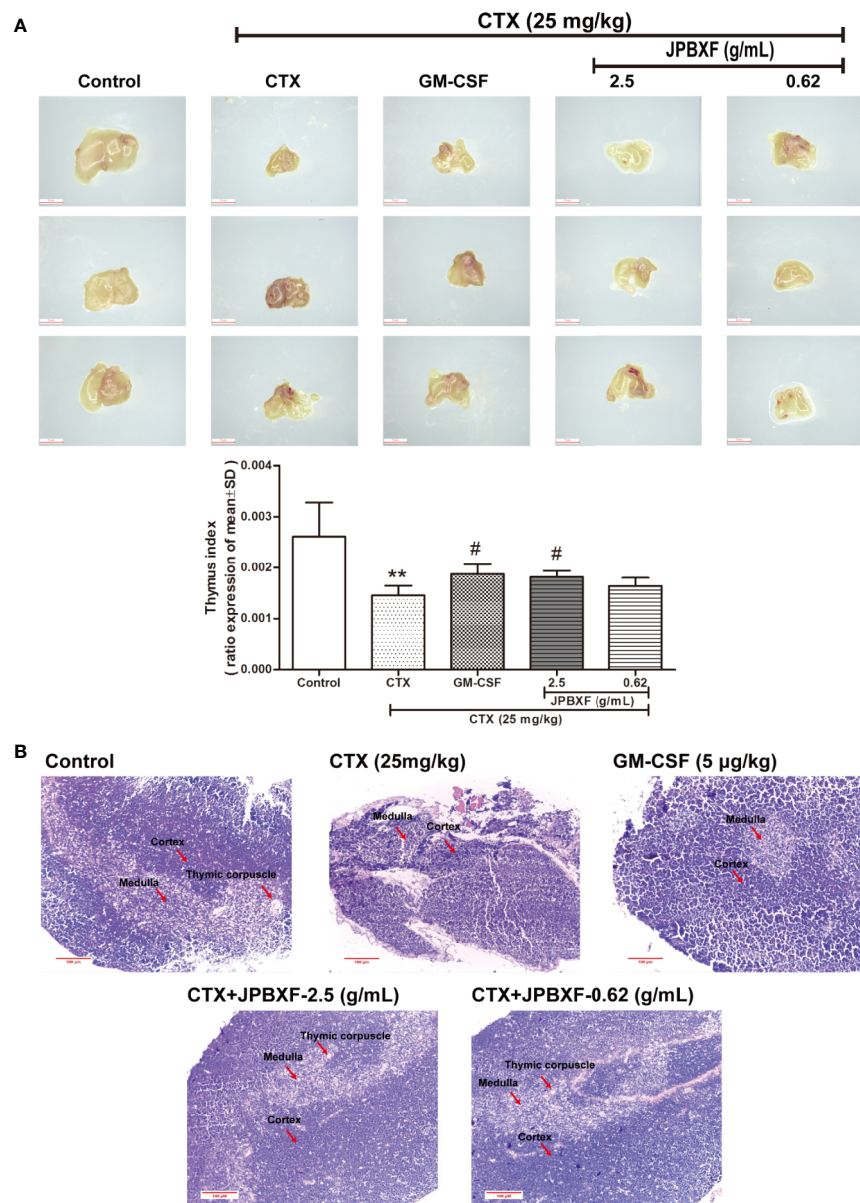

## DISCUSSION

TCMs are widely used in Asian countries, especially China, Japan and Korea. With the development of medicine, Chinese medicine is gradually accepted by western countries (Dobos and Tao, 2011). Given the ability of alleviating chemotherapy-induced side effects, TCMs complementary treatment is widely adopted for patients suffering from cancers (Woo et al., 2016). To be an empirical TCM formula, JPBXF has been used to ease chemotherapy-induced weakness and fatigue for cancer patients in clinic in China for decades. However, the phytochemical

characterization, detail therapeutic evaluation and underline mechanism of JPBXF remain unclear.

Our study directly provides evidence that JPBXF treatments could alleviate CTX-induced myelosuppression in C57BL/6 mice as following aspects: (i) JPBXF treatments increased the number of HSCs; (ii) JPBXF treatments recovered CTX-induced blood cells reduction; (iii) JPBXF treatments reduced CTX-induced immunosuppression. Cancer patients who receive CTX-chemotherapy, often suffered side effects including myelosuppression, weight loss, asthenia, and so on (Strati et al., 2013; Que et al., 2016). In our study, JPBXF treatments

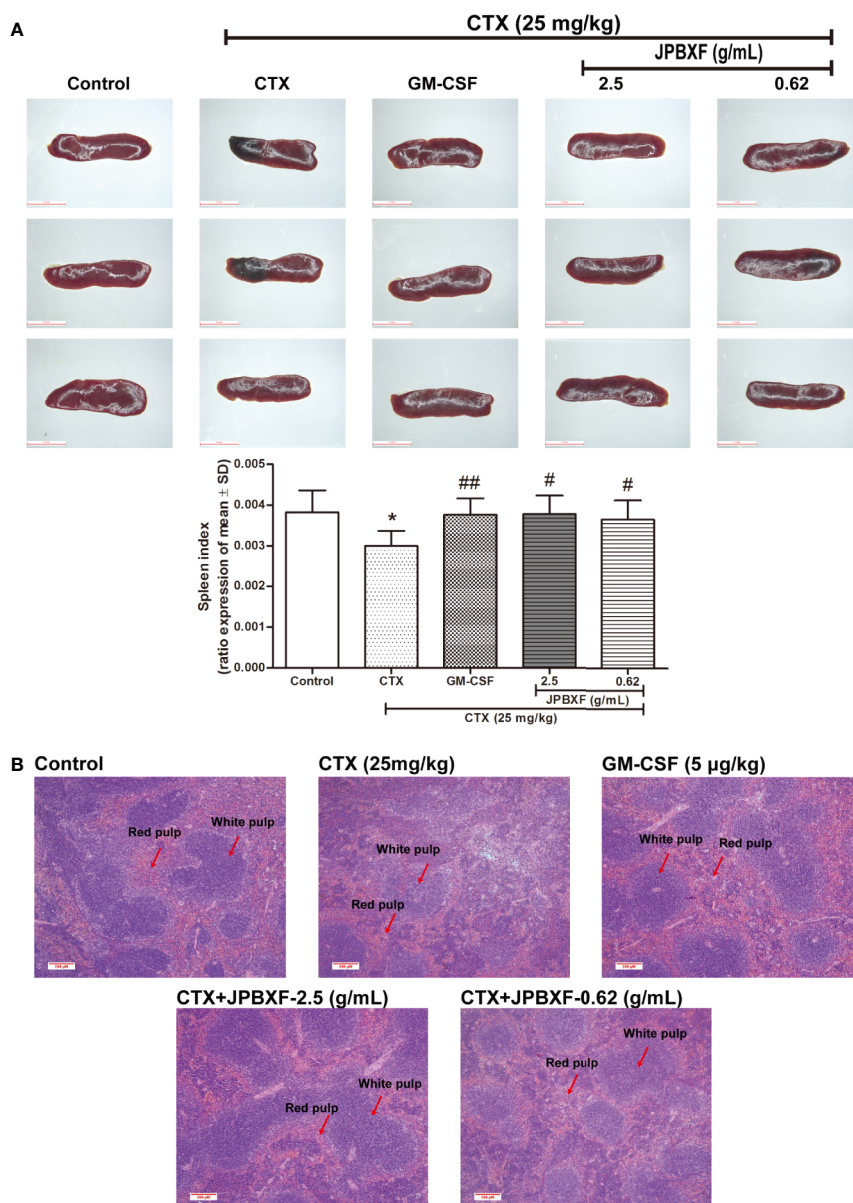

**FIGURE 5 |** Effects of JPBXF on the thymus in CTX-treated mice. **(A)** Sizes and index of thymus in mice (scale = 3 mm). **(B)** Histopathological changes in thymus tissues (stained by H&E,  $\times 200$ ). Data shown are means  $\pm$  SD from day 13. \*\* $P < 0.01$  vs. Control, # $P < 0.05$  vs. CTX.

could increase the number of HSCs and the expression of HSC marker C-kit (**Figure 2**), illustrating that JPBXF could abrogate the myelosuppression induced by CTX. On the other hand, CTX treatment could significantly reduce the number of WBCs and RBCs and the secretion levels of GM-CSF, EPO and TPO in mice, which consistent with the previous reports (Botnick et al., 1981; Jantunen et al., 2003). Expectedly, JPBXF treatments increased the number of RBCs and WBCs, and the secretion levels of EPO and GM-CSF at different degrees (**Figure 3**). Except for increasing blood function, JPBXF also showed great ability on reducing CTX-induced immunosuppression in C57BL/6 mice. It is reported that CTX treatment could induce

immunosuppression and inhibit the generation and function of T cells (Traverso et al., 2012; Salva et al., 2014). CD3, CD4, and CD8a are the most abundant immunity T cell in the PBMCs (Sedgmen et al., 2013). We found that the expressions of CD3, CD4, and CD8a in PBMCs were decreased by CTX, while JPBXF abrogated the decrease expressions of CD3, CD4 and CD8a (**Figure 4**). Furthermore, thymus and spleen are two main immune organs that play important roles in cellular and humoral immunity. Thymus and spleen functions can be inhibited by CTX treatment (Zhao et al., 2009). In the present study, we found that thymic atrophy and splenatrophy were obvious after CTX treatment. To the contrary, thymus and

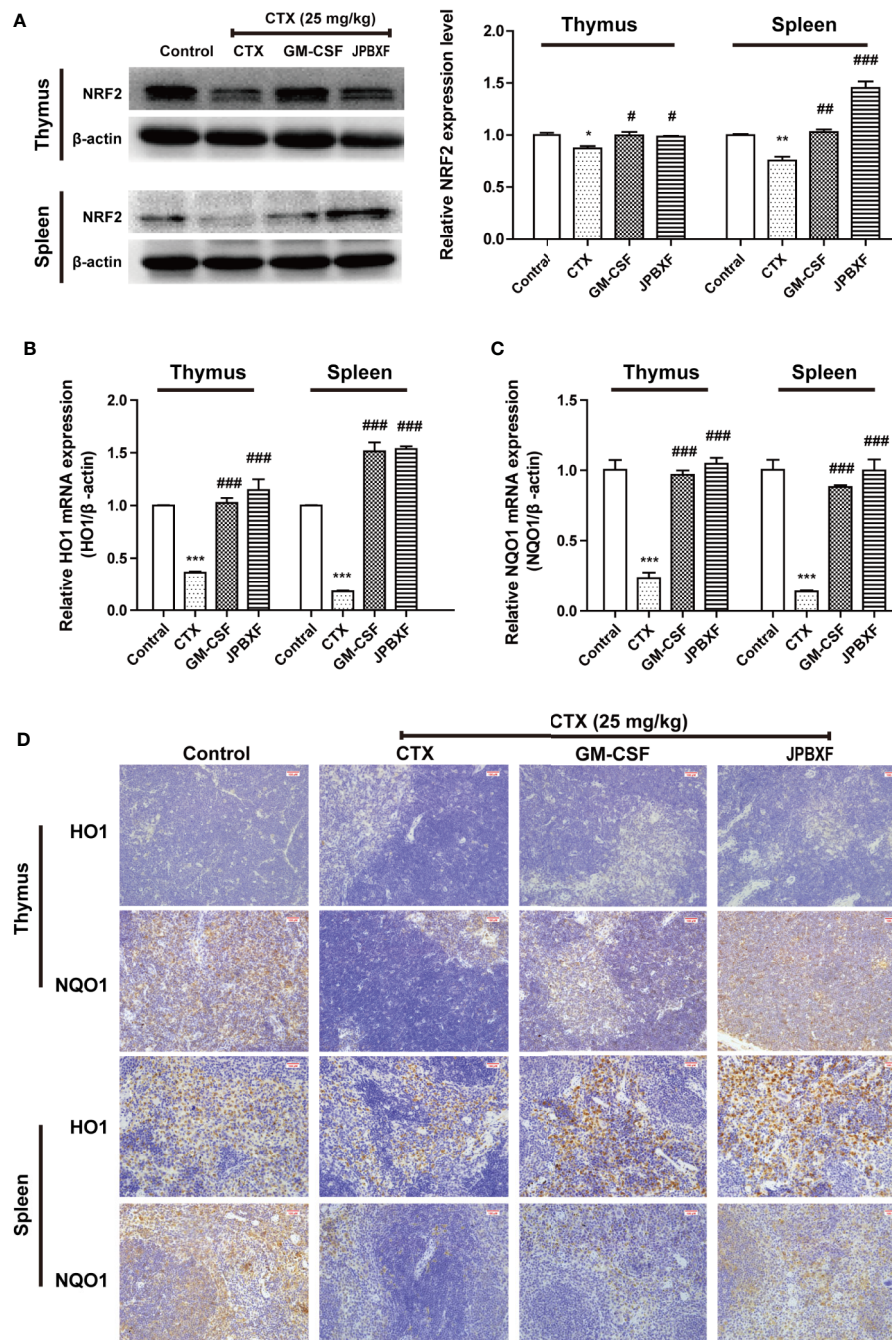

**FIGURE 6 |** Effects of JPBXF on the spleen in CTX-treated mice. **(A)** Sizes and index of spleens in mice (scale=5 mm). **(B)** Histopathological changes in spleens tissues (stained by H&E,  $\times 100$ ). Data shown are means  $\pm$  SD from day 13. \* $P < 0.05$  vs. Control, # $P < 0.05$ , ## $P < 0.01$  vs. CTX.

spleen index increased after JPBXF treatments (**Figures 5A and 6A**). In addition, CTX-induced structure damages, including cortex, medulla and thymic corpuscle in thymus and white pulp atrophy, hemorrhage and necrosis in spleen, were recovered by JPBXF treatments (**Figures 5B and 6B**).

Our data also revealed that JPBXF alleviated CTX-induced myelosuppression through activating NRF2/HO1/NQO1 signaling pathway. It is reported that NRF2 deficiency deteriorated CTX-induced myelosuppression, while activation of NRF2 mitigates CTX-induced myelosuppression (Que et al., 2016). The up-regulation of

HO1 or NQO1 could resist to CTX-induced bone marrow suppression, oxidative stress, inflammation and apoptosis (Chen et al., 2014; HAS et al., 2019). We observed that JPBXF treatment notably reversed CTX-induced NRF2 suppressions both in thymus and spleen, subsequently, recovered the expression of HO1 and NQO1 both in mRNA and protein levels (**Figure 7**), indicating that JPBXF alleviated CTX-induced myelosuppression through activating NRF2/HO1/NQO1 signaling pathway.

In our study, JPBXF aqueous extract showed great ability in alleviating CTX-induced myelosuppression in C57BL/6 mice.

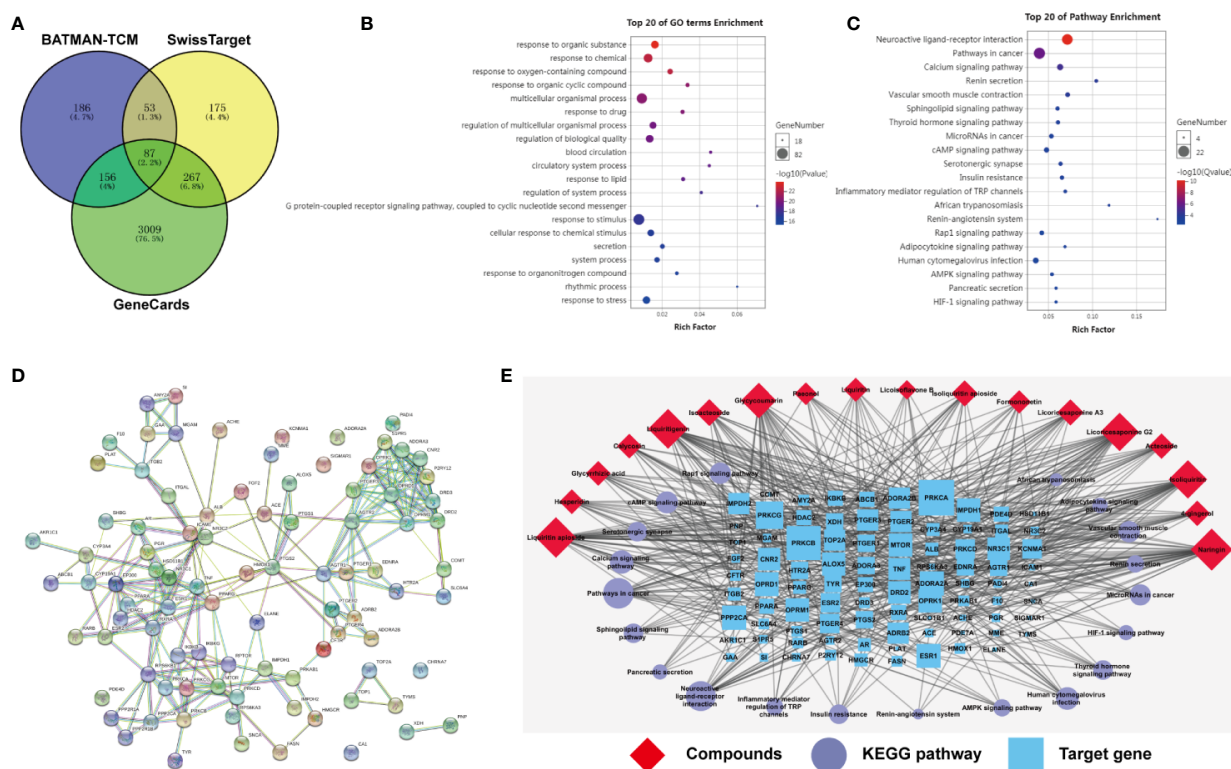

**FIGURE 7 |** JPBXF activated NRF2/HO1/NQO1 pathway. **(A)** Protein expressions of NRF2 in thymus or spleen tissues after treatments as design. mRNA expression levels of HO1**(B)** and NQO1 **(C)** were detected using real-time PCR analysis. **(D)** Images of HO1 and NQO1 protein expressions in thymus or spleen tissues were presented by immunohistochemistry. Data shown are means  $\pm$  SD from day 13. \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$  vs. Control, # $P < 0.05$ , ## $P < 0.01$ , ### $P < 0.001$  vs. CTX.

However, the main chemical constituents in JPBXF aqueous extract and the underline mechanisms of the main compounds on alleviating CTX-induced myelosuppression are still unclear. Herein, we identified main chemical constituents of JPBXF aqueous extract using UHPLC/MS/TOF and

confirmed that the main constituents in JPBXF extracts are paeonol, liquiritin apioside, liquiritin, acteoside, naringin, isoacteoside, hesperidin, isoliquiritin apioside, isoliquiritin, licoricesaponine A3, liquiritigenin, calycosin, licoricesaponine G2, glycyrrhizic acid, formononetin, glycycomarin,

**FIGURE 8 |** Target prediction of eighteen compounds on alleviating myelosuppression. **(A)** The 87 potential target genes of eighteen compounds on myelosuppression were selected using Venny. **(B)** Gene ontology (GO) enrichment analysis of 87 selected genes performed by Database for Annotation, Visualization and Integrated Discovery (DAVID) and visualized by Omicshare. **(C)** KEGG enrichment analysis of 87 selected genes performed by DAVID and visualized by Omicshare. **(D)** The protein-protein interaction (PPI) network of 87 selected genes constructed by the STRING database. **(E)** The compound-target-pathway network was constructed and visualized by Cytoscape.

4-gingerol, and licoisoflavone B (**Figure 1** and **Table 1**). We also try to explain the underline mechanism by which 18 compounds on alleviating CTX-induced myelosuppression using bioinformatics analysis and found that 87 potential targets were primarily associated with the “response to organic substance,” “response to chemical,” “multicellular organismal process,” “regulation of multicellular organismal process,” and “regulation of biological quality” terms by targeting multi-protein network, such as “Neuroactive ligand-receptor interaction,” “Pathways in cancer,” “Calcium signaling pathway” “cAMP signaling pathway,” and “Vascular smooth muscle contraction”. Combining with the PPI network and the three-level network results, 24 identified genes, including AGTR2, PTGS2, MTOR, DRD2, EP300, OPRM1, AGTR1, DRD3, OPRD1, OPRK1, PPARG, PTGER3, RXRA, TNF, PRKCA, PRKCB, IMPDH1, PPP2CA, ESR1, ALOX5, CNR2, IMPDH2, NR3C1, and TOP2A (**Figure 8**), might be the key targets of 18 compounds in alleviating CTX-induced myelosuppression. To confirm these prediction results, more researches will be conducted in the future.

In conclusion, JPBXF can greatly reverse CTX-induced myelosuppression in C57BL/6 mice, especially in improving

the blood and immune function through activating NRF2/HO1/NQO1 signaling pathway, which provides a reliable reference for JPBXF application in clinical. By recognizing 18 compounds in JPBXF aqueous extract and predicting the underline mechanism, our study would provide theoretical guidance for further research of JPBXF.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by International Institute for Translational Chinese Medicine Animal Care and Use Committee, Guangzhou University of Chinese Medicine.

## AUTHOR CONTRIBUTIONS

LL and XL designed the research. QH, LF, HL, and LZ performed the study. QH and LF analyzed the data and wrote the manuscript. ZL and QF revised the manuscript. XQ and YW provided technical support. All authors contributed to the article and approved the submitted version.

**Objective:** The aim of this study was to elucidate the preventive and therapeutic effects and the underlying mechanisms of Huoxue Huatan Decoction (HXHT) on myocardial ischemia/reperfusion (I/R) injury in hyperlipidemic rats.

**Methods:** An I/R model was established in hyperlipidemic Wistar rats. After 4–8 weeks of HXHT treatment, the physical signs of rats were observed. Lipid metabolism, myocardial enzyme spectrum, cardiac function, myocardial histomorphology, and mitochondrial biosynthesis were investigated by a biochemical method, ultrasonography, electron microscopy, pathological examination, real-time PCR, and Western blot.

**Results:** HXHT can affect lipid metabolism at different time points and significantly reduce the levels of cholesterol (CHO), triglyceride (TG), high-density lipid-cholesterol (HDL-C), and low-density lipid-cholesterol (LDL-C) in hyperlipidemic rats ( $P < 0.05$  or  $P < 0.01$ ); it can significantly reduce the levels of creatine kinase-MB (CK-MB) and lactate dehydrogenase (LDH), reduce the myocardial infarct size and myocardial ischemic area, and improve cardiac function. The results of myocardial histomorphology showed that HXHT could protect myocardial cells, relieve swelling, reduce the number of cardiac lipid droplets, and improve myocardial mitochondrial function. HXHT could significantly increase the levels of total superoxide dismutase (T-SOD) and succinate dehydrogenase (SDH) ( $P < 0.05$  or  $P < 0.01$ ), increase CuZn-superoxide dismutase (CuZn-SOD) and glutathione-peroxidase (GSH-Px) levels, and decrease the levels of malondialdehyde (MDA) ( $P < 0.05$ ); it could increase the mRNA and protein expression levels of peroxisome proliferator-activated receptor-gamma coactivator 1 alpha (PGC-1 $\alpha$ ), peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ), nuclear respiratory factor 1 (NRF1), and mitochondrial transcription factor A (mtTFA) ( $P < 0.05$  or  $P < 0.01$ ), and increase the synthesis of mitochondrial DNA (mtDNA) ( $P < 0.01$ ).

**Conclusion:** HXHT can reduce myocardial I/R injury in hyperlipidemic rats. The protective mechanisms may involve a reduction in blood lipids, enhancement of PGC-1 $\alpha$ -PPAR $\alpha$  pathway activity, and, subsequently, an increase in fatty acid  $\beta$ -oxidation, which may provide the required input for mitochondrial energy metabolism. HXHT can additionally enhance PGC-1 $\alpha$ -NRF1-mtTFA pathway activity and, subsequently, increase the antioxidant capacity, promote mtDNA synthesis, and reduce mitochondrial damage. The two pathways use PGC-1 $\alpha$  as the intersection point to protect mitochondrial structure and function, reduce I/R-induced injury, and improve cardiac function.

Coronary heart disease refers to heart disease caused by hypoxia and ischemia of the myocardium due to arterial obstruction or stenosis, which is a common type of disease caused by coronary atherosclerosis (Benjamin et al., 2018). Hyperlipidemia is closely related to the risk of coronary heart disease. At present, 50.0% of patients in China have hypertension, of whom 37.5% have coronary heart disease and more than 30.0% have peripheral arterial disease (Chen et al., 2014). The risk factors of cardiovascular disease can be broadly divided into two categories, i.e., intervenable and non-intervenable. Intervenable factors include lifestyle (smoking, blood pressure, blood sugar, and cholesterol) and medication, non-intervenable factors include age, gender, race, and family history (Derosa et al., 2020).

A high-fat diet, as a common intervenable factor, can lead to lipid accumulation, induce the inflammatory response, promote atherosclerosis, and accelerate the development of cardiovascular diseases (Cao et al., 2018). Specifically, a high-fat diet can increase plasma low-density lipoprotein (LDL) levels. LDL is oxidized and modified into oxidized LDL (Ox-LDL). Monocytes take up Ox-LDL, and the expression of adhesion molecules increases. A high-fat diet promotes the conversion of monocytes into foam cells, which is a key step in the development of atherosclerosis (Henning et al., 2018). Chronic arterial inflammation plays an important role in the pathogenesis of atherosclerosis. The secretion of atherogenic cytokines induces the expression of endothelial adhesion molecules, which mediate the attachment of monocytes and lymphocytes (Ham et al., 2019). Atherosclerosis results in thickening of the vessel wall and a reduction of lumen diameter and blood flow. The current guidelines mainly focus on the treatment of hyperlipidemia, with LDL and cholesterol levels as the main indicators (Okopień et al., 2016), and the ultimate goal is to reduce the risk of atherosclerotic cardiovascular disease. The main ways of lowering lipids are lifestyle regulation and pharmacological lipid-lowering. Studies have shown that reducing LDL-cholesterol (LDL-C) and triglyceride (TG) levels, reducing the intake of saturated fatty acids and refined carbohydrates, and increasing the intake of fruits, vegetables, cereals, and low-fat dairy products can reduce the risk of cardiovascular events and prevent coronary plaque progression. It is important to focus on whole foods and eating habits to successfully reduce the risk of cardiovascular disease (Alissa and Ferns, 2017; Welty, 2020). Pharmacological treatment is still mainly based on statins and targeted at LDL-C (Han et al., 2019).

Traditional Chinese medicine has a rich clinical history of coronary heart disease and dyslipidemia treatment. Coronary heart disease accompanied by elevated blood lipids or obesity is classified as coronary heart disease with phlegm-blood stasis syndrome, and both TG and LDL-C levels are significantly increased in patients with coronary heart disease with phlegm-blood stasis syndrome (Wang et al., 2008). The only patented medicines for the treatment of coronary heart disease with phlegm-blood stasis syndrome in China are Danlou tablets (The cardiovascular disease branch of China Association of Chinese Medicine, 2019). Mitochondria, as semi-autonomous organelles, are known as “enzyme bags” and “power plants.” They are the main sites for the biological oxidation of sugars, proteins, and fats. Myocardial cells have a high demand for energy, and mitochondria account for approximately 40% (m/m) of cardiomyocytes. Abnormal structure and function of mitochondria directly affect myocardial energy metabolism, oxidative stress, ion uptake and release, and apoptosis (Goldenthal, 2016).

Huoxue Huatan Decoction (HXHT) is a commonly prescribed medicine for the treatment of coronary heart disease with phlegm-blood stasis syndrome, and has been used clinically for more than 20 years. It is composed of *Salvia miltiorrhiza* Bunge, *Astragalus mongholicus* Bunge, *Panax notoginseng* (Burkill) F.H. Chen, *Ginkgo biloba* L., *Trichosanthes kirilowii* Maxim., *Allium macrostemon* Bunge, and *Ziziphus jujuba* Mill. HXHT has the effects of invigorating qi and activating blood, resolving phlegm, and removing blood stasis.

The main components of *S. miltiorrhiza* Bunge are tanshinone IIA and *S. miltiorrhiza* polyphenols, which have antioxidant, anti-inflammatory, anticoagulant, anti-atherosclerosis, and vasodilator effects. They can also protect the myocardium and vascular endothelium, reduce adipogenesis, and reduce the proliferation and migration of vascular smooth muscle cells (Ren et al., 2019; Yuan et al., 2020). Astragaloside IV is the main active ingredient of *A. mongholicus* Bunge. It has protective effects on ischemic injury and cardiovascular disease. It has anti-inflammatory, immunomodulatory, and antioxidant effects, and exerts cardioprotective effects through multiple signaling pathways (Li et al., 2017). The main active ingredient of *P. notoginseng* (Burkill) F.H. Chen is *P. notoginseng* saponins, and its pharmaceutical preparations, such as Xueshuantong, Xuesaitong, and Naodesheng, are widely used and have cardiovascular protective effects. *P. notoginseng* saponins can reduce the formation of

atherosclerotic lesions (Liu et al., 2019; Liu et al., 2020). *G. biloba* L. can effectively improve metabolic syndrome, diabetes, hypertension, and dyslipidemia, reduce the risk of cardiovascular disease (Eisvand et al., 2020), and alleviate vascular aging-related dysfunction (Li et al., 2020). *T. kirilowii* Maxim. and *A. macrostemon* Bunge often appear as a pair in commonly used drugs, which are essential for the treatment of angina pectoris, heart failure, and myocardial infarction. *T. kirilowii* Maxim. can protect the myocardium and endothelial cells, eliminates phlegm, and has anti-oxidation, anticoagulation, and anti-inflammatory effects (Yu et al., 2018). *A. macrostemon* Bunge is a potential drug to treat hyperglycemia, hyperlipidemia, and visceral obesity (Xie et al., 2008), and can also reduce myocardial ischemic injury by regulating abnormal energy metabolism (Li et al., 2014). *Z. jujuba* Mill. has sedative and hypnotic effects, and it is clinically used to treat insomnia, forgetfulness, and dizziness. In addition, it also has anti-inflammatory, anti-oxidation, blood pressure-lowering, and blood lipid-lowering effects (He et al., 2020), and it can protect myocardial cells from acute cardiac ischemia/reperfusion (I/R) injury (Gu et al., 2019). The compatibility of the whole prescription is reasonable, it has immune regulatory effects, and it can protect myocardial cells from ischemia and hypoxia. Previous clinical and experimental studies have shown that this prescription can significantly improve the clinical symptoms of patients with coronary heart disease with phlegm–blood stasis syndrome, with good safety (Li, 2016; Zhang et al., 2016).

Therefore, in this study, we analyze the effects of HXHT on myocardial I/R injury in hyperlipidemic rats from the perspectives of lipid metabolism, the myocardial enzyme spectrum, myocardial histomorphology, and myocardial infarct size. In addition, the underlying mechanisms of HXHT in preventing and treating myocardial I/R in hyperlipidemic rats are studied from the perspectives of myocardial mitochondrial function and the expression of genes related to mitochondrial biogenesis.

## MATERIALS AND METHODS

### Preparation of Experimental Drugs

HXHT was provided by the Pharmacology Laboratory of Traditional Chinese Medicine, Guang'anmen Hospital, China Academy of Chinese Medical Science. It is composed of *S. miltiorrhiza* Bunge (17.4%, Specimen ID 33873, product batch

number 140381391), *A. mongholicus* Bunge (7.0%, Specimen ID 106823, product batch number 140581231), *P. notoginseng* (Burkill) F.H. Chen (17.4%, Specimen ID 69689, product batch number 140581091), *G. biloba* L. (11.6%, Specimen ID 4988, product batch number 140581421), *T. kirilowii* Maxim. (17.4%, Specimen ID 15439, product batch number 140281611), *A. macrostemon* Bunge (17.4%, Specimen ID 50154, product batch number 140580301), and *Z. jujuba* Mill. (11.6%, Specimen ID 27570, product batch number 140581941) (**Table 1**). All of the medicinal names have been unified using the Kew Medicinal Plant Names Service. All of the specimens have been deposited in the Chinese National Herbarium, Institute of Botany, Chinese Academy of Sciences (20 Nanxincun, Xiangshan, Beijing 100093, China). All of the medicinal materials were provided by Beijing Kangmei Pharmaceutical Co., Ltd. (Beijing, China).

*S. miltiorrhiza* Bunge was extracted 10 times with 60% ethanol through heating reflux twice, each time for 1.5 h. The ethanol was recovered from the extract and concentrated to thick paste (50°C, density 1.20 g/cm<sup>3</sup>) under reduced pressure, and the concentrated solution was separated twice using an AB-8 macroporous adsorption resin column (Tianjin NANDA Resin Technology Co., Ltd.), where 50% ethanol of the same volume as the column bed was used for elution. The eluate was concentrated into a thick paste (50°C, density 1.20 g/cm<sup>3</sup>), and dried in vacuum at 60°C to obtain the *S. miltiorrhiza* Bunge extract. The leaves of *Ginkgo biloba* L. were extracted 8 times with 60% ethanol through heating reflux twice, each time for 2 h. After vacuum concentration, the concentrated solution was separated three times using an AB-8 macroporous adsorption resin column, where 70% ethanol of the same volume as the column bed was used for elution. The eluate was concentrated into a thick paste (50°C, density 1.20 g/cm<sup>3</sup>), and dried in vacuum at 60°C to obtain the *Ginkgo biloba* L. extract. Then 10 volumes of water were added to the remaining material, and the medicine was extracted twice, concentrated (50°C, density 1.20 g/cm<sup>3</sup>), and dried in vacuum at 60°C. Finally, all the extracts were crushed and mixed to obtain the HXHT extract.

The contents of active ingredients were 12.66% for tanshinone IIA, 9.25% for cryptotanshinone, 34.51% for salvianolic acid B, 5.30% for salvianolic acid A sodium, 1.64% for rosmarinic acid, 0.66% for protocatechuic aldehyde, 1.02% for ginsenoside Rg1, 0.90% for ginsenoside Rb1, 0.20% for

**TABLE 1 |** The composition of traditional Chinese medicine in Huoxue Huatan Decoction (HXHT).

Component	Component (Chinese)	Medicinal parts	Percentage (%)	Active ingredient content (%)
<i>Salvia miltiorrhiza</i> Bunge	Danshen	Dry roots and rhizomes	17.4	tanshinone IIA 0.31%, cryptotanshinone 0.25%, salvianolic acid B 3.44%
<i>Astragalus mongholicus</i> Bunge	Huangqi	Dry roots	7.0	astragaloside IV 0.06%, calycosin glucoside 0.04%
<i>Panax notoginseng</i> (Burkill) F.H. Chen	Sanqi	Dry roots and rhizomes	17.4	ginsenoside Rg1 5.26%, ginsenoside Rb1 4.00%, notoginsenoside R1 1.09%
<i>Ginkgo biloba</i> L.	Yinxingye	Dry leaves	11.6	total flavonols 0.41%, total lactones 0.27%
<i>Trichosanthes kirilowii</i> Maxim.	Gualou	Dry ripe fruit	17.4	–
<i>Allium macrostemon</i> Bunge	Xiebai	Dry bulb	17.4	–
<i>Ziziphus jujuba</i> Mill.	Suanzaoren	Dry mature seeds	11.6	jujuboside A 0.08% spinosin 0.13%

notoginsenoside R1, 0.12% for ginsenoside Re, 25.81% for *G. biloba* total flavonols, 7.01% for *G. biloba* total lactones, 0.29% for the total saponins of *Z. jujuba* Mill., 0.10% for calycosin glucoside, and 0.10% for astragaloside IV (Lin, 2015). All of the components were tested by HPLC (Agilent 1100, Agilent Technologies, Inc., CA, USA). The conditions for the measurement of all of the components and HPLC spectra are shown in **Figures 1–23** in Part 1 of the **Supplementary Materials**. As positive controls, we used a traditional Chinese medicine (Danlou tablets, 0.3 g/tablet, product batch number: 20140605, Jilin Cornell Pharmaceutical Co., Ltd.) and a Western medicine (Atorvastatin calcium tablets, 20 mg/tablet, product batch number: J28283, sub-packaging batch number: J70319, Pfizer Pharmaceuticals LLC, Pfizer Pharmaceutical Co., Ltd., imported sub-packages).

## Wistar Rats

Male SPF Wistar rats ( $N = 168$ , weight  $140 \pm 10$  g) were provided by Beijing Vital River Laboratory Animal Technology Co., Ltd., production license No. SCXK (Beijing) 2012-0001. The research protocol was approved by the Animal Ethics Committee of Guang'anmen Hospital of China Academy of Chinese Medicine (No. 2015EC035-02). In accordance with the Guide for the Care and Use of Laboratory Animals of the National Institutes of Health (Bethesda, MD, USA), they were raised indoors by the Animal Feeding Center of Guang'anmen Hospital, China Academy of Chinese Medical Sciences, at a constant temperature and with good ventilation, and they were fed with standard feed, with free access to food and water.

## Preparation of High-Fat Feed

The high-fat feed contained 78.8% of ordinary feed, 1% of cholesterol, 10% of yolk powder, 10% of lard, and 0.2% of bile salt (People's Republic of China Ministry of Health, 2003). The nutritional composition of high-fat feed, provided by Beijing Huafukang Biotechnology Co., Ltd., is shown in **Table 2**.

## Establishment of the I/R Injury Model in Hyperlipidemic Animals

After 3 days of quarantine, Wistar rats were randomly divided into the following seven groups ( $n = 24$  rats per group): (i) healthy control group (Normal), (ii) hyperlipidemia model group (Model), (iii) Western medicine (Atorvastatin calcium tablets, 3.33 mg/kg) positive control group (Control A), (iv) traditional Chinese medicine (Danlou tablets, 0.75 g/kg) positive control group

(Control B), (v) high-dose HXHT (3.6 g/kg, equivalent to 20.06 g/kg of the original medicinal material) group (HXHT-H), (vi) medium-dose HXHT (1.8 g/kg, equivalent to 10.03 g/kg of the original medicinal material) group (HXHT-M), and (vii) low-dose HXHT (0.9 g/kg, equivalent to 5.02 g/kg of the original medicinal material) group (HXHT-L). The calculation was based on the body surface area of humans and rats. HXHT was suspended in a 0.5% sodium carboxymethylcellulose aqueous solution (carboxymethyl cellulose nanoparticles, size 300–800 mpa-s, batch number: 20081023, manufacturer Sinopharm Chemical Reagent Co., Ltd.).

The Normal group was fed with ordinary feed, and the other groups were fed with high-fat feed. The rats were kept indoors with four animals per cage, at a constant temperature and under good ventilation, and they were fed with standard feed, with free access to food and water. After 4 weeks of feeding, the serum TG and LDL levels in all six high-fat groups were significantly increased compared with the Normal group. The Model group and the five treatment groups were appropriately adjusted according to the statistical results of cholesterol (CHO) and LDL levels, so that the mean values were as similar as possible. After these initial 4 weeks ( $t = 0$ ), rats from the treatment groups were administered once a day a volume of 10 ml/kg for 4 or 8 weeks. The Normal and Model groups were simultaneously treated with an equal amount of 0.5% sodium carboxymethyl cellulose aqueous solution (10 ml/kg). Blood samples were collected from the eyeballs at the 4th, 6th, and 8th weeks to analyze biochemical indicators of blood lipids.

To establish the I/R model, the left anterior descending coronary artery of rats was ligated for 40 min (Liu et al., 2011; Du et al., 2014) and the blood flow was restored for 2 h, at the 4th and 8th weeks. The specific method was as follows.

① After weighing the rats, they were anesthetized with 10% chloral hydrate (330 mg/kg) (product batch number: 20130201, Sinopharm Chemical Reagent Co., Ltd.) by intraperitoneal injection. The rats were fixed on the operating table, the skin was prepared for disinfection, the tracheal tube was inserted, and the physiological signal acquisition system was connected.

② After tracheal intubation, the small animal ventilator was connected with a ventilator frequency of 70 breaths/min, a tidal volume of 8 ml, and a respiratory ratio of 1:3 for assisted respiration.

③ The third rib was cut at 0.5 cm from the left sternal border, the musculature was dissected, the thorax was opened with an eyelid opener to expose the heart, the needle was inserted 2–3 mm from the lower edge of the left atrial appendage with a 3/8 round needle pierced with a 4-0 suture and hooked around the main trunk of the left anterior descending coronary artery, and the needle was withdrawn from the pulmonary conus. A polyethylene tube was cut and placed between the two sutures, the sutures were tightened to form a closed loop, and reperfusion occurred by cutting the sutures 40 min later.

④ Successful criteria of model establishment were the following: the ST segment arch was elevated after ligation; the color of the ligation site was grayish or cyanotic; the ST segment regressed or was elevated after reperfusion; or the color of the ligation site changed from grayish to normal bright red.

**TABLE 2** | Nutrient composition of high-fat feed.

Nutrient composition	Ordinary feed (%)	High-fat feed (%)
Crude protein	20.16	18.89
Crude fat	4.24	19.34
Crude fiber	4.48	3.53
Coarse ash	6.04	4.76
Moisture	10	8.39
Calcium	1.29	1.02
Phosphorus	0.83	0.65

⑤ During the whole process of myocardial I/R, a PowerLab physiological signal acquisition system was used to monitor electrocardiograms (ECGs) intermittently, and ECGs were continuously recorded before and after coronary artery ligation and after reperfusion. ST elevation was closely observed and recorded at the same time.

## Detection of Biochemical Indicators of Blood Lipids in Rats

Blood samples were collected from the retro-orbital venous plexus of the rats before treatment (at  $t = 0$ ) and after 4, 6, and 8 weeks. Blood samples were stored at room temperature for 30 min and centrifuged at 3,000 rpm for 15 min to obtain serum. Four biochemical indicators of blood lipids were measured. The detection of CHO was performed using an enzymatic method (batch number: AUZ1433); the GPO-POD method was used for detection of TG (batch number: OSR61118E); high-density lipoprotein-cholesterol (HDL-C) levels were measured by an enzymatic method (batch number: OSR6287); and LDL-C levels were measured using an LDL-C enzymatic colorimetric assay kit (batch number: OSR6283). These kits were provided by Beckman Coulter Laboratories (Suzhou) Co., Ltd.

## Detection of CK-MB and LDH

Hyperlipidemic rats were anesthetized with 10% chloral hydrate (280 mg/kg) after 4 and 8 weeks, the skin was prepared, the trachea was intubated and connected to a ventilator, the chest was opened, the left coronary artery was ligated with a 4-0 sterile suture for 40 min, and perfusion was restored, while performing ECG monitoring. After 2 h of reperfusion, blood was collected from the intraocular canthus, stored for 30 min at room temperature, and centrifuged at 3,000 rpm for 15 min to obtain serum. The serum was diluted 20 times with purified water, and the creatine kinase-MB (CK-MB) and lactate dehydrogenase (LDH) levels were measured with an AU640 automatic biochemical analyzer. LDH was detected with an LDH lactate substrate assay kit (batch number: AUZ1443, Beckman Coulter Laboratories (Suzhou) Co., Ltd.); CK-MB was detected with a CK-MB enzymatic immunosuppression test kit (batch number: OSR61155, Beckman Coulter Laboratories (Suzhou) Co., Ltd.).

## Cardiac Function

After 4 or 8 weeks, the left coronary artery was ligated for 40 min, and reperfusion was allowed for 2 h. The rats were anesthetized with 10% chloral hydrate (280 mg/kg), prepared for skin disinfection, and fixed on the back. The left ventricular ejection fraction (LVEF), left ventricular end-diastolic inner diameter (LVIDd), left ventricular end-systolic inner diameter (LVIDs), and other cardiac function parameters were measured by DW-350 B-mode echocardiography (Dawei Electronic Equipment Co. Ltd., Xuzhou, JS, CHN).

## Calculation of Infarct Area and Ischemic Area

After 4 or 8 weeks, hyperlipidemic rats were anesthetized with 10% chloral hydrate (280 mg/kg), the left coronary artery was

ligated for 40 min, and reperfusion was allowed for 2 h. The thoracic cavity was opened, the heart was exposed, the left anterior branch of the coronary artery was re-ligated along the suture, and 0.5% Evans blue (Yang et al., 2009) was intravenously injected in the left lung. The heart was stained blue about 2 min later. The heart was removed, rinsed with normal saline, frozen at  $-20^{\circ}\text{C}$ , stained, and photographed using TTC. For statistical analysis, the Evans blue-stained blue area was considered as the normal area, the TTC-stained red area as the ischemic area, and the grayish white area as the infarct area. Photographs were taken with Canon PowerShot A2600 (after 4 weeks) and L2035AW Pioneer (after 8 weeks) cameras, and the myocardial ischemic, infarct, and global areas were analyzed with Image-Pro Plus 6.0 software. The ratio of the ischemic area to the global area and the ratio of the infarct area to the global area were calculated.

## Standard Operating Procedures for Pathological Staining

After 8 weeks, rats in the Normal, Model, Control A, and HXHT-M groups with better pharmacodynamic results were selected for histomorphological and molecular biological mechanism studies based on the previous experimental results. Rats in each group were subjected to myocardial ischemia for 40 min. After 2 h of reperfusion, they were anesthetized with 10% chloral hydrate mixture (280 mg/kg) and thoracotomy was performed. The hearts of the rats were removed and placed on ice, and  $3 \times 3$  mm sized samples from the apical site were rapidly taken and fixed with 3% glutaraldehyde for sectioning. The mitochondrial ultrastructure in the infarct tissue was observed by transmission electron microscopy, with the assistance of the Peking University School. The 0.3 cm of myocardium below the ligature was fixed with 4% paraformaldehyde for He staining (Chen et al., 2018), another  $\sim 0.3$  cm of myocardium was rapidly frozen for Oil Red O staining (Wen et al., 2019), and the rest was stored in a  $-80^{\circ}\text{C}$  freezer.

## Detection of Oxidative Stress Indicators

After 8 weeks, after myocardial ischemia for 40 min and reperfusion for 2 h, and after anesthesia with 10% chloral hydrate (280 mg/kg), about 5 ml of blood was collected from the abdominal aorta. The artery was immediately clamped with the hemostatic forceps. The blood was allowed to stand for 40 min and centrifuged at 3,500 rpm for 10 min, and the serum was separated and stored in a  $-80^{\circ}\text{C}$  freezer until analysis. The myocardial tissue samples were collected as described in the part of Standard Operating Procedures for Pathological Staining. The contents of malondialdehyde (MDA), total superoxide dismutase (T-SOD), CuZn-superoxide dismutase (CuZn-SOD), and glutathione peroxidase (GSH-Px) in rat serum and reactive oxygen species (ROS), succinate dehydrogenase (SDH), and cytochrome c oxidase (COX) in myocardial tissue were measured following the manufacturers' instructions of the respective kits (MDA kit, batch number: 20150118, T-SOD kit, batch number: 20150312, Nanjing Jiancheng Biotechnology Co., Ltd.; CuZn-SOD kit, batch number: 20150204, Shanghai Youniko Co., Ltd.; GSH-Px kit, batch number: 20150206,

Shanghai Youniko Co., Ltd.; ROS kit, batch number: GMS10096.2, Shanghai Jiemei Biological Gene Pharmaceutical Technology Co., Ltd.; SDH kit, batch number: 20150116, Nanjing Jiancheng Biotechnology Co., Ltd.; and COX kit, batch number: GMS10014.3.2, Shanghai Jiemei Biological Gene Pharmaceutical Technology Co., Ltd.).

## Detection of Protein, mRNA, and mtDNA

The protein expression levels of peroxisome proliferator-activated receptor-gamma coactivator 1 alpha (PGC-1 $\alpha$ ), peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ), nuclear respiratory factor 1 (NRF1), and mitochondrial transcription factor A (mtTFA) were measured by Western blot (Chen et al., 2018). The specific methods and steps are shown in Part 2 of the Supplementary Materials. The following antibodies were used: anti-PGC-1 $\alpha$  (batch number: ab54481), anti-PPAR $\alpha$  (batch number: ab8934), anti-NRF1 (batch number: ab175932), and anti-mtTFA (mitochondrial marker, batch number: ab131607) were provided by Abcam (Cambridge, UK); anti- $\beta$ -actin (batch number: TA-09) was supplied by Beijing Zhongshan Jinqiao Biotechnology Co., Ltd. (Beijing, China). The mRNA expression levels of PGC-1 $\alpha$ , PPAR $\alpha$ , NRF1, and mtTFA were measured by real-time PCR (RT-PCR) (Mocker et al., 2019). The specific methods and steps are shown in Part 3 of the Supplementary Materials. Mitochondrial DNA (mtDNA) was detected using the PCR-fluorescent probe method (Liu et al., 2016). The specific methods and steps are shown in Part 4 of the **Supplementary Materials**.

## Statistical Analysis

SPSS 17.0 software was used for statistical analysis. The data are expressed as mean  $\pm$  standard deviation ( $\bar{x} \pm s$ ). One-way analysis of variance (ANOVA) or the Student's *t*-test was used for comparison between groups. Statistical results were considered to be statistically significant at  $P < 0.05$ . The area of myocardial infarction was analyzed with Image-Pro Plus 6.0 software, and the results were statistically analyzed with SPSS 17.0 software.

## RESULTS

### Observation of Physical Signs

The body weight of rats in the Model group and the treatment groups was higher than that of rats in the Normal group, but this difference was not statistically significant. No abnormalities were found in mental status, physical activity, respiration, coat color, facial features, genitalia, food intake, urine, and feces.

### CHO Analysis

After 4 weeks of feeding with the high-fat diet (at  $t = 0$ ), CHO levels were significantly higher in the Model group and the treatment groups than in the Normal group ( $P < 0.01$ ), confirming the hyperlipidemic rat model was established successfully. The CHO serum levels were not significantly reduced in the Control A and B groups compared with the Model group during treatment ( $P > 0.05$ ), although a decreasing

trend was observed. HXHT-H could reduce CHO serum levels to different extents after 4, 6, and 8 weeks; after 6 and 8 weeks, the difference between the HXHT-H group and the Model group was statistically significant ( $P < 0.05$  or  $P < 0.01$ ). After 8 weeks, the HXHT-H, HXHT-M, and HXHT-L groups showed reductions in CHO levels of 30%, 21%, and 16%, respectively (**Figure 1**). In conclusion, HXHT significantly reduced CHO levels compared with Controls A and B.

### TG Analysis

After 4 weeks of high-fat feed (at  $t = 0$ ), the TG serum levels were significantly higher in the Model group than in the Normal group ( $P < 0.01$ ). The TG levels in the treatment groups were lower than in the Model group, but this difference was not statistically significant ( $P > 0.05$ ). After 6 weeks of treatment, TG levels in the treatment groups were significantly lower. TG levels in the Control A and B groups had decreased by 21% and 18%, respectively ( $P < 0.01$ ). TG levels in the HXHT-H, HXHT-M, and HXHT-L groups had decreased by 28% ( $P < 0.01$ ), 20% ( $P < 0.01$ ), and 10% ( $P < 0.05$ ), respectively. In all of the treatment groups except for HXHT-H group, TG levels were lower after 8 weeks than after 6 weeks ( $P < 0.01$ ; **Figure 2**). HXHT significantly reduced TG levels compared with Controls A and B, and there was no significant difference among the three HXHT groups.

### HDL-C Analysis

After 4, 6, and 8 weeks, HDL-C levels were significantly higher in the Model group than in the Normal group ( $P < 0.01$ ). In all three HXHT groups, after 8 weeks, HDL-C levels were significantly lower than in the Model group ( $P < 0.05$ ), and no significant changes were observed among the other groups (**Figure 3**). The

**FIGURE 1** | Effects of Huoxue Huatan Decoction (HXHT) on cholesterol (CHO) serum levels in hyperlipidemic rats ( $\bar{x} \pm s$ ). The number of animals per group at 4 weeks is  $n = 24$ ; the number of animals per group at 8 weeks is  $n = 16$ . <sup>b</sup> $P < 0.01$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group. HXHT, Huoxue Huatan Decoction; CHO, cholesterol.

**FIGURE 2** | Effects of Huoxue Huatan Decoction (HXHT) on triglyceride (TG) serum levels in hyperlipidemic rats ( $\bar{x} \pm s$ ). The number of animals per group at 4 weeks is  $n = 24$ ; the number of animals per group at 8 weeks is  $n = 16$ . <sup>b</sup> $P < 0.01$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group. HXHT, Huoxue Huatan Decoction; TG, triglyceride.

**FIGURE 3** | Effects of Huoxue Huatan Decoction (HXHT) on high-density lipoprotein cholesterol (HDL-C) serum levels in hyperlipidemic rats ( $\bar{x} \pm s$ ). The number of animals per group at 4 weeks is  $n = 24$ ; the number of animals per group at 8 weeks is  $n = 16$ . <sup>b</sup> $P < 0.01$  compared with the Normal group; <sup>c</sup> $P < 0.05$  compared with the Model group. HXHT, Huoxue Huatan Decoction; HDL-C, high-density lipoprotein cholesterol.

reduction of HDL-C levels after 8 weeks of HXHT administration was significantly stronger than that in the Control A and Control B groups.

## LDL-C Analysis

Before treatment (at  $t = 0$ ) and after 4, 6, and 8 weeks, LDL-C levels were increased to different extents in the Model group and

the treatment groups compared with the Normal group ( $P < 0.05$  or  $P < 0.01$ ), confirming the hyperlipidemic rat model was established successfully.

LDL-C levels in all of the treatment groups began to decrease after 4 weeks compared with the Model group. After 8 weeks, LDL-C levels were significantly decreased in the Control A group ( $P < 0.05$ ), while LDL-C levels in the Control B group exhibited no significant change ( $P > 0.05$ ). LDL-C levels in the HXHT-H, HXHT-M, and HXHT-L groups had decreased by 47% ( $P < 0.01$ ), 30% ( $P < 0.01$ ), and 16% ( $P < 0.05$ ), respectively. HXHT and Control A significantly reduced LDL-C levels compared with Control B after 8 weeks of administration (Figure 4).

## CK-MB and LDH Analysis

After 4 and 8 weeks, CK-MB levels after I/R injury were significantly higher in the Model group than in the Normal group ( $P < 0.05$  or  $P < 0.01$ ). CK-MB levels were significantly lower in the Control A, HXHT-H, and HXHT-M groups than in the Model group ( $P < 0.05$  or  $P < 0.01$ ). No significant differences were observed for other groups ( $P > 0.05$ ; Figure 5). After 4 and 8 weeks, LDH serum levels after I/R injury were significantly higher in the Model group than in the Normal group ( $P < 0.01$ ). LDH levels were significantly lower in the Control A, HXHT-H, and HXHT-M groups than in the Model group ( $P < 0.05$  or  $P < 0.01$ ). No significant changes were observed for the remaining groups ( $P > 0.05$ ; Figure 6). HXHT and Control A controlled CK-MB and LDH levels significantly better than Control B after 4 and 8 weeks of administration.

## Analysis of Cardiac Function

After 4 weeks and I/R, no significant changes in LVEF, LVIDd, and LVIDs were observed in any group (Figures 7–10). After 8

**FIGURE 4** | Effects of Huoxue Huatan Decoction (HXHT) on low-density lipoprotein cholesterol (LDL-C) serum levels in hyperlipidemic rats ( $\bar{x} \pm s$ ). The number of animals per group at 4 weeks is  $n = 24$ ; the number of animals per group at 8 weeks is  $n = 16$ . <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group. HXHT, Huoxue Huatan Decoction; LDL-C, low-density lipoprotein cholesterol.

weeks and 2 h of I/R, the LVEF, LVIDd, and LVIDs of rats in the Model group were significantly lower than in the Normal group ( $P < 0.05$ ); the cardiac function of rats in all of the treatment groups was significantly better than in the Model group ( $P < 0.05$  or  $P < 0.01$ ). HXHT, Control A, and Control B significantly improved cardiac function, especially HXHT-M.

## Infarct Size and Ischemic Area Analysis

After 4 weeks, the area of myocardial infarction was larger in the Model group than in the Normal group, and the myocardial infarct size was reduced to different extents in the treatment groups compared with the Model group. The reduction in the area of myocardial infarction was more significantly reduced in the HXHT-M group ( $P = 0.057$ ) than in the Control A and Control B groups. After 8 weeks, the area of myocardial infarction was significantly larger in the Model group than in the Normal group ( $P < 0.05$ ). The area of myocardial infarction was significantly smaller in the treatment groups than in the Model group ( $P < 0.05$  or  $P < 0.01$ ; **Figure 11**).

After 4 weeks, the ischemic area of the Model group was slightly increased compared with the Normal group, but this difference was not statistically significant. The ischemic area in the Control A and HXHT-H groups was significantly smaller than in the Model group ( $P < 0.05$ ), and was larger than that in the Control B group. After 8 weeks, no significant difference was observed between any groups. The results of our analysis of infarct size and ischemic area are presented in **Figure 11**.

## HE Staining Analysis

After 8 weeks and I/R injury, HE staining of myocardial tissue revealed the following.

**Normal group:** Local myocardial cells had small focal necrosis, the arrangement of local myocardial fibers was disordered, wavy, or broken, and granular degeneration and vacuole degeneration could be observed locally. Myocardial capillaries were dilated and hyperemia was observed; inflammatory cell infiltration was observed under the epicardium.

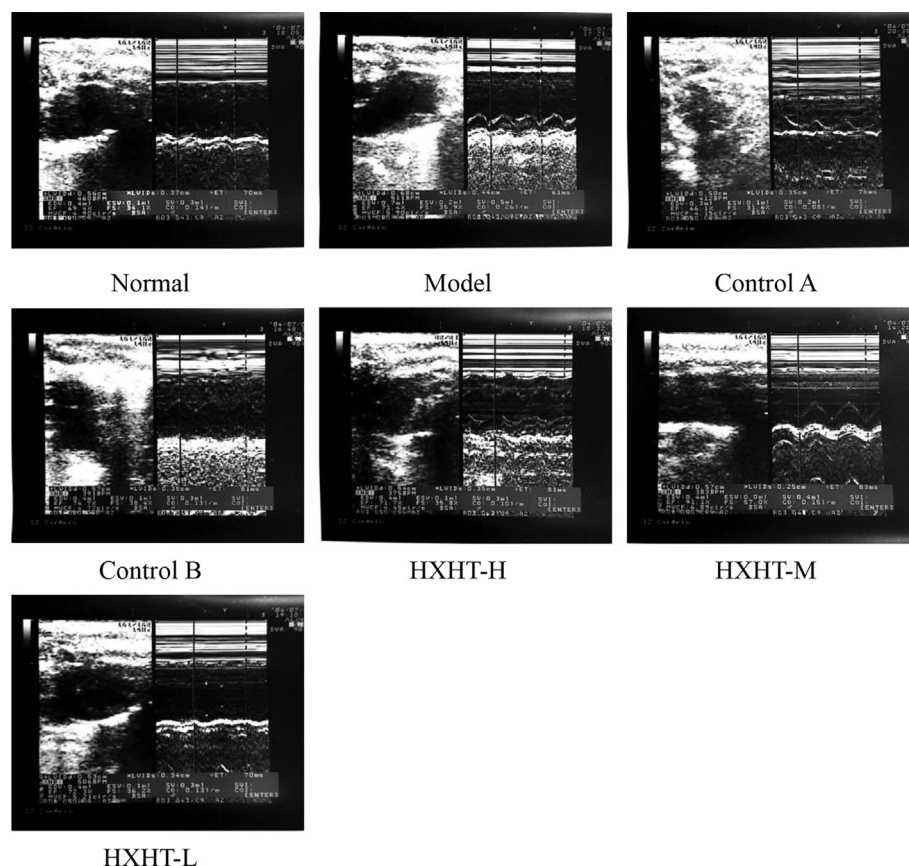

**Model group:** Local myocardial cells had small focal necrosis, and the arrangement of local myocardial fibers was disordered, wavy, or broken, with varying degrees of granular degeneration and vacuolar degeneration. The myocardial interstitium was visibly widened, the myocardial capillaries were dilated, and congestion was obvious. Inflammatory cell infiltration was observed in myocardial interstitium, perivascular, and epicardium, which was more pronounced than in the Normal group.

**Control A group:** Local myocardial cells had small focal necrosis, and the arrangement of local myocardial fibers was disordered, wavy, or broken, with a low degree of cell degeneration and varying degrees of granular degeneration and vacuolar degeneration. Capillary congestion, myocardial interstitial widening, and inflammatory cell infiltration were also observed, but these were milder than in the Model group.

**HXHT-M group:** Mild loose edema of myocardial cells was observed, with local small focal necrosis, occasional wavy myocardial fibers, slight granular degeneration and vacuolar degeneration, and inflammatory cell infiltration, which were milder than in the Model group (**Figure 12**).

## Oil Red O Staining Analysis

After 8 weeks and I/R, the results of Oil Red O staining of myocardial tissue revealed the following:

**FIGURE 7** | B-ultrasound of hyperlipidemic ischemia/reperfusion (I/R) rats.

**FIGURE 8** | Effects of Huoxue Huatan Decoction (HXHT) on left ventricular ejection fraction (LVEF) in hyperlipidemic ischemia/reperfusion (I/R) rats ( $\bar{x} \pm s$ ). The number of animals at 4 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 7$ ;  $n_{\text{Control B}} = 8$ ;  $n_{\text{HXHT-H}} = 7$ ;  $n_{\text{HXHT-M}} = 8$ ;  $n_{\text{HXHT-L}} = 8$ . The number of animals at 8 weeks is  $n_{\text{Normal}} = 16$ ;  $n_{\text{Model}} = 15$ ;  $n_{\text{Control A}} = 16$ ;  $n_{\text{Control B}} = 15$ ;  $n_{\text{HXHT-H}} = 16$ ;  $n_{\text{HXHT-M}} = 16$ ;  $n_{\text{HXHT-L}} = 15$ . <sup>a</sup> $P < 0.05$  compared with the Normal group; <sup>c</sup> $P < 0.05$  compared with the Model group.

**FIGURE 9** | Effects of Huoxue Huatan Decoction (HXHT) on left ventricular end-diastolic inner diameter (LVIDd) in hyperlipidemic ischemia/reperfusion (I/R) rats ( $\bar{x} \pm s$ ). The number of animals at 4 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 7$ ;  $n_{\text{Control B}} = 8$ ;  $n_{\text{HXHT-H}} = 7$ ;  $n_{\text{HXHT-M}} = 8$ ;  $n_{\text{HXHT-L}} = 8$ . The number of animals at 8 weeks is  $n_{\text{Normal}} = 16$ ;  $n_{\text{Model}} = 15$ ;  $n_{\text{Control A}} = 16$ ;  $n_{\text{Control B}} = 15$ ;  $n_{\text{HXHT-H}} = 16$ ;  $n_{\text{HXHT-M}} = 16$ ;  $n_{\text{HXHT-L}} = 15$ . <sup>a</sup> $P < 0.05$  compared with the Normal group; <sup>c</sup> $P < 0.05$  compared with the Model group.

**FIGURE 10** | Effects of Huoxue Huatan Decoction (HXHT) on left ventricular end-systolic inner diameters (LVIDs) in hyperlipidemic ischemia/reperfusion (I/R) rats ( $\bar{x} \pm s$ ). The number of animals at 4 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 7$ ;  $n_{\text{Control B}} = 8$ ;  $n_{\text{HXHT-H}} = 7$ ;  $n_{\text{HXHT-M}} = 8$ ;  $n_{\text{HXHT-L}} = 8$ . The number of animals at 8 weeks is  $n_{\text{Normal}} = 16$ ;  $n_{\text{Model}} = 15$ ;  $n_{\text{Control A}} = 16$ ;  $n_{\text{Control B}} = 15$ ;  $n_{\text{HXHT-H}} = 16$ ;  $n_{\text{HXHT-M}} = 16$ ;  $n_{\text{HXHT-L}} = 15$ . <sup>a</sup> $P < 0.05$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group.

Normal group: Dark red lipid droplets were occasionally observed locally and scattered in cardiomyocytes. Occasionally, the light brown lipid droplets were connected into sheets, and light brown or tan miscellaneous droplets were observed overall.

Model group: Dark red lipid droplets were often observed scattered in cardiomyocytes, which also contained larger lipid

droplets. Light reddish brown lipid droplets at the epicardium were connected into sheets, and brownish red or tan miscellaneous granules were observed overall.

Control A group: Dark red lipid droplets were occasionally scattered in cardiomyocytes, with fewer lipid droplets. The whole body was light brown, but occasionally brown red was found in the folds.

HXHT-M group: Dark red lipid droplets were occasionally scattered in cardiomyocytes, with fewer lipid droplets, and the whole body was light brown. The epicardium was reddish brown, and occasionally brown red was found in the folds.

Oil Red O staining showed that there were more lipid droplets in the Model group, while there were fewer lipid droplets in the Control A and HXHT-M groups (Figure 13).

## Analysis of Mitochondrial Ultrastructure

After 8 weeks and I/R injury, the mitochondrial ultrastructure analysis revealed the following.

Normal group: The mitochondrial ultrastructure was relatively clear and the membrane was relatively intact, but the mitochondrial cristae were vague and disordered, fused, and damaged. Some mitochondrial cristae disappeared or vacuolized, and the ruptured membranes rarely formed vesicles or vacuoles. Occasionally, disordered intercalated discs and poor continuity were observed.

Model group: Mitochondria were significantly swollen, the inner and outer membranes were obviously damaged, or even broken and dissolved, and the contents spilled. Mitochondrial cristae were vague and disordered, and some mitochondrial cristae disappeared or vacuolized. The mitochondrial matrix was blurred, and fragmented mitochondria were observed. Myofibrils were uneven in thickness, the sarcomere structure was unclear, and some myofilaments were damaged and dissolved. Some disordered intercalated discs and

**FIGURE 11** | Effects of Huoxue Huatan Decoction (HXHT) on myocardial infarct size and ischemic area in hyperlipidemic ischemia/reperfusion (I/R) rats ( $\bar{x} \pm s$ ). The number of animals at 4 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 7$ ;  $n_{\text{Control B}} = 8$ ;  $n_{\text{HXHT-H}} = 7$ ;  $n_{\text{HXHT-M}} = 8$ ;  $n_{\text{HXHT-L}} = 8$ . The number of animals at 8 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 8$ ;  $n_{\text{Control A}} = 8$ ;  $n_{\text{Control B}} = 7$ ;  $n_{\text{HXHT-H}} = 8$ ;  $n_{\text{HXHT-M}} = 8$ ;  $n_{\text{HXHT-L}} = 7$ . <sup>a</sup> $P < 0.05$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group. HXHT, Huoxue Huatan Decoction; I/R, ischemia/reperfusion.

**FIGURE 12** | Effects of Huoxue Huatan Decoction (HXHT) on heart histopathology after myocardial ischemia/reperfusion (I/R) injury in hyperlipidemic rats (HE staining, 200×). **(A)** Normal control; **(B)** Model control; **(C)** Control A; **(D)** HXHT-M. The number of animals at 8 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 8$ ;  $n_{\text{HXHT-M}} = 8$ . HXHT, Huoxue Huatan Decoction; I/R, ischemia/reperfusion.

poor continuity were observed. Most of the myofilaments were dissolved, and the Z-line was significantly thickened extending toward the I-band.

**Control A group:** The mitochondrial membrane was thinned or even ruptured. The mitochondrial ridges were reduced and the ridges were blurred. Some mitochondrial cristae disappeared or vacuolized. Mitochondria were swollen, partial rhomboid cristae and longitudinal cristae were observed, and giant myocardial mitochondria, vesicles, or vacuoles formed from ruptured membranes. The intercalated discs were neat and continuous.

**HXHT-M group:** The ultrastructure of rat myocardial mitochondria was clear, the membrane was intact, the mitochondrial cristae were dense, the mitochondrial matrix was clear, and occasional mitochondrial cristae were blurred. The intercalated discs were neat and continuous. Mitochondria were distributed in bands and arranged neatly. The sarcomeres were well arranged.

In the Model group, mitochondria were swollen. The mitochondrial membrane was ruptured. Mitochondrial cristae fused, disappeared, or broke. These phenomena were more serious than in other groups (Figure 14).

### Analysis of Oxidative Stress

After 8 weeks and I/R injury, MDA serum levels were significantly higher in the Model group than in the Normal

group ( $P < 0.01$ ). MDA serum levels were lower in the Control A and HXHT-M groups than in the Model group; for the HXHT-M group, this difference was statistically significant ( $P < 0.05$ ).

T-SOD, CuZn-SOD, and GSH-Px levels were significantly lower in the Model group than in the Normal group ( $P < 0.05$  or  $P < 0.01$ ). T-SOD, CuZn-SOD, and GSH-Px levels were higher in the Control A and HXHT-M groups than in the Model group; for T-SOD in the HXHT-M group, this difference was statistically significant ( $P < 0.01$ ).

The SDH levels in myocardial tissue after myocardial I/R were significantly lower in the Model group than in the Normal group ( $P < 0.05$ ), and the SDH levels in the HXHT-M group were significantly higher than in the Model groups ( $P < 0.05$ ). No significant differences in ROS and COX levels were observed between the groups (Figure 15).

### mRNA and Protein Expression Levels of PGC-1 $\alpha$ , PPAR $\alpha$ , NRF1, and mtTFA

After 8 weeks and I/R injury, the mRNA and protein expression levels of PGC-1 $\alpha$ , PPAR $\alpha$ , NRF1, and mtTFA were significantly lower in the Model group than in the Normal group ( $P < 0.01$ ). The mRNA expression levels of PGC-1 $\alpha$ , PPAR $\alpha$ , NRF1, and mtTFA were significantly increased in the Control A and HXHT-M groups compared with the Model group ( $P < 0.05$ ;

**FIGURE 13** | Effects of Huoxue Huatan Decoction (HXHT) on heart histopathology after myocardial ischemia/reperfusion (I/R) injury in hyperlipidemic rats (Oil Red O staining, 100×). **(A)** Normal control; **(B)** Model control; **(C)** Control A; **(D)** HXHT-M. The number of animals at 8 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 8$ ;  $n_{\text{HXHT-M}} = 8$ . HXHT, Huoxue Huatan Decoction; I/R, ischemia/reperfusion.

**Figure 16**). The protein expression levels of PGC-1 $\alpha$ , NRF1, and mtTFA were significantly increased in the Control A and HXHT-M groups compared with the Model group ( $P < 0.05$  or  $P < 0.01$ ; **Figure 17**). The protein expression levels of PPAR $\alpha$  were significantly increased in the HXHT-M group compared with the Model group ( $P < 0.05$ ; **Figure 17**), but the increase was not significant in the Control A group.

### Analysis of mtDNA Copy Number

After 8 weeks and I/R injury, the mtDNA copy number was significantly lower in the Model group than in the Normal group ( $P < 0.01$ ), and it was significantly increased in the HXHT-M group compared with the Model group, while it was further decreased in the Control A group ( $P < 0.01$ ; **Figure 18**).

## DISCUSSION

Elevated blood lipids are one of the main pathogenic factors of atherosclerosis (Song, 2003). LDL-C has a direct relationship with atherosclerotic cardiovascular disease and is positively correlated with the incidence of the disease. The main goal of preventing and treating atherosclerotic cardiovascular disease is to reduce abnormal blood lipids, especially LDL-C. Therefore,

here we conducted an in-depth study of the dynamic continuous and dose-effect relation of the effects of HXHT on lipid metabolism in hyperlipidemic rats. Our results showed that a high-fat diet could significantly increase the levels of CHO, TG, HDL-C, and LDL-C in Wistar rats. HXHT could significantly reduce blood lipids to different extents after 4, 6, and 8 weeks of administration, and the effects of high-dose HXHT were the most significant. HXHT can significantly reduce CHO, TG, LDL-C, and HDL-C after 4, 6, and 8 weeks of administration. HXHT was superior to the positive control drugs, and it had no significant effect on body weight. *S. multiorrhiza* Bunge, *P. notoginseng* (Burkill) F.H. Chen, *T. kirilowii* Maxim., and *A. macrostemon* Bunge, which are ingredients of HXHT, have previously been reported to have hypolipidemic effects. For example, salvianolic acid B could reduce blood glucose, increase insulin resistance, reduce CHO, LDL-C, free fatty acid, liver glycogen, and muscle glycogen, and increase HDL-C in diabetic model rats (Huang et al., 2015). *P. notoginseng* (Burkill) F.H. Chen could significantly reduce CHO, TG, and LDL-C and increase HDL-C in the treatment of patients with hyperlipidemia (Si, 2015). *T. kirilowii* Maxim. and *A. macrostemon* Bunge could significantly reduce TC, TG, LDL, and arteriosclerosis index ( $P < 0.01$ ). The combination of the two had a synergistic effect and a better lipid-lowering effect (He, 2002).

**FIGURE 14** | Effects of Huoxue Huatan Decoction (HXHT) on myocardial mitochondria after myocardial ischemia/reperfusion (I/R) injury in hyperlipidemic rats (transmission electron microscopy, 40,000 $\times$ ). **(A)** Normal control; **(B)** Model control; **(C)** Control A; **(D)** HXHT-M. The number of animals at 8 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 8$ ;  $n_{\text{HXHT-M}} = 8$ . HXHT, Huoxue Huatan Decoction; I/R, ischemia/reperfusion.

**FIGURE 15** | Effects of Huoxue Huatan Decoction (HXHT) on oxidative stress indicators in hyperlipidemic ischemia/reperfusion (I/R) rats. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  compared with the Normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  compared with the Model group. The number of animals at 8 weeks is  $n_{\text{Normal}} = 8$ ;  $n_{\text{Model}} = 7$ ;  $n_{\text{Control A}} = 8$ ;  $n_{\text{HXHT-M}} = 8$ . HXHT, Huoxue Huatan Decoction; I/R, ischemia/reperfusion.

A high-fat and low-sugar diet did not affect non-ischemic left ventricular function, but it could aggravate myocardial injury and enhance the mortality caused by pump failure and ventricular arrhythmia during myocardial I/R in rats, which might be closely related to myocardial mitochondrial fission

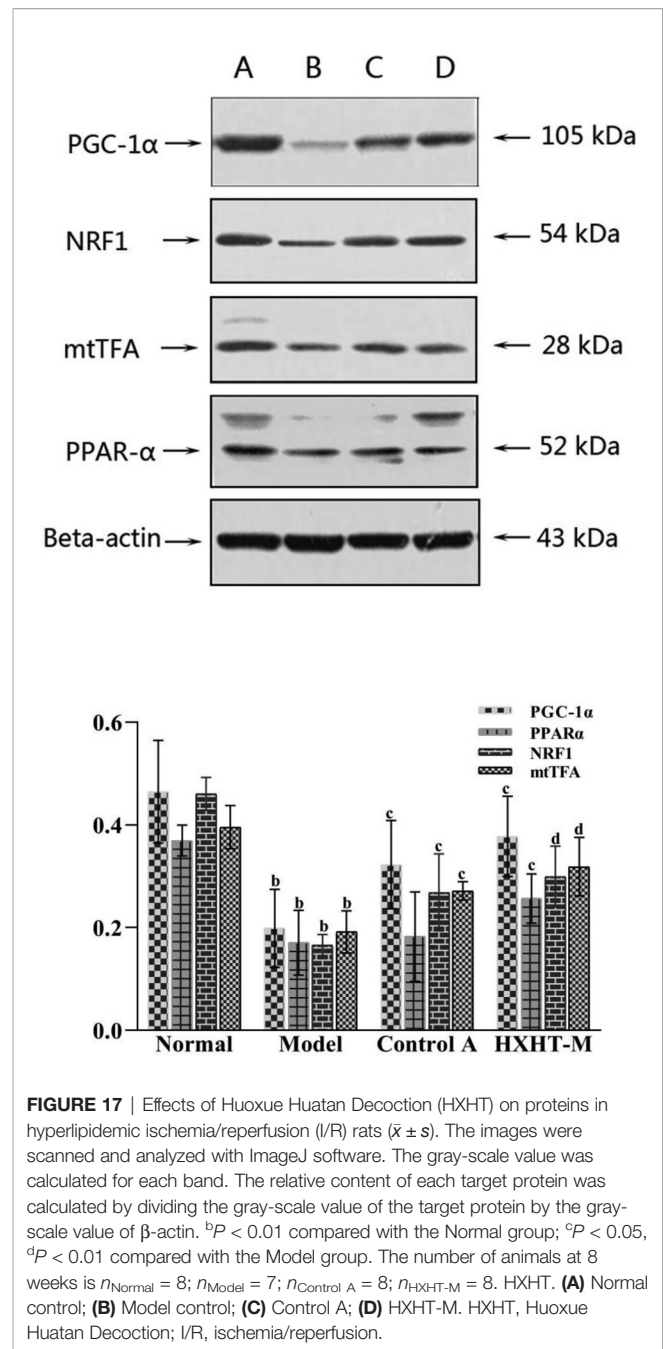

and fusion, calcium channel, and myocardial capacity metabolism (Liu and Lloyd, 2013; Liu et al., 2014). The effect of HXHT on myocardial I/R injury in hyperlipidemic rats was studied. The results showed that after 8 weeks and 12 weeks of feeding, the myocardial enzyme levels, cardiac function, and the

myocardial infarction area of the hyperlipidemia model group were significantly higher, worse, and larger than those of the Normal control group, respectively. A high-fat diet could aggravate myocardial I/R injury in rats. HXHT could prevent myocardial I/R injury in hyperlipidemic rats after 4 weeks of administration, and significantly reduce myocardial enzyme levels. After 8 weeks of administration, HXHT could significantly reduce the myocardial infarction area and improve cardiac function.

The histomorphological study showed that myocardial cell focal necrosis, myocardial vascular congestion, inflammatory cell infiltration, and lipid droplet accumulation were more serious in the hyperlipidemia model than in the other groups, while in the HXHT groups and the Control A group, these were lighter than in the hyperlipidemia model group. On the one hand, HXHT might reduce the infiltration of inflammatory cells due to its lipid-lowering effects; on the other hand, the components of HXHT may have anti-inflammatory effects. Tanshinone and salvianolic acid could promote blood circulation, dilate blood vessels, scavenge free radicals, and protect mitochondria, and they have anticoagulation and anti-inflammatory effects (Adams et al., 2006). Cryptotanshinone, which is also present in HXHT, could downregulate the expression of pro-inflammatory cytokines; cryptotanshinone and 15,16-dihydrotanshinone could inhibit the activities of nuclear transcription factor- $\kappa$ B and activator protein (Jeon et al., 2008). There are many ways to inhibit atherosclerosis. Salvianolic acid B and ginkgolide mainly act on inflammatory cytokines, *P. notoginseng* glycosides act on adhesion factors, and tanshinone acts on growth factors (Li et al., 2007).

Oxygen free radicals, calcium overload, and the inflammatory response are directly or indirectly related to mitochondria, which

function as intracellular effectors and are protected by ischemic preconditioning. Mitochondria, as an important organelle in the regulation of energy metabolism in cells, participate in myocardial I/R injury through various pathways. The results of the present study showed that the mitochondria in the hyperlipidemia model group were swollen and the mitochondrial membrane was ruptured. HXHT could protect the morphology of mitochondria upon I/R. Excessive fat intake increases oxygen free radical levels. Free radicals cause lipid peroxidation of cell membranes, causing mitochondrial dysfunction, which in turn affects the tricarboxylic acid cycle and results in dysfunction of the myocardium. The results of this study showed that the activities of MDA, T-SOD, CuZn-SOD, and GSH-

PX in serum were significantly changed after myocardial I/R in the hyperlipidemia model group, and SDH levels in myocardial tissue were significantly decreased. HXHT could reduce the activity of MDA in serum, increase the activity of T-SOD, and increase the activity of SDH in myocardial tissue. It was speculated that HXHT might: (i) enhance the ability of rats to resist oxygen free radicals, (ii) prevent oxygen free radicals from invading mitochondrial membranes, and (iii) protect mitochondrial membranes, thereby protecting the function of mitochondria (Liu et al., 2014).

The results of this experimental study showed that HXHT may protect the myocardium through the PGC-1 $\alpha$ -PPAR $\alpha$  pathway and regulate mitochondrial biosynthesis through the PGC-1 $\alpha$ -NRF1-mtTFA pathway. The two pathways coordinate to protect myocardial mitochondria during myocardial I/R. In the PGC-1 $\alpha$ -PPAR $\alpha$  pathway, PPAR $\alpha$  could regulate myocardial energy and fat metabolism, participate in every step of myocardial utilization of fatty acids, and play a decisive role in myocardial energy generation (Barroso et al., 2013).

HXHT could increase the gene and protein expression levels of PGC-1 $\alpha$  and downstream PPAR $\alpha$ ; these results were consistent with the lipid-lowering effects of HXHT. PPAR $\alpha$  is mainly expressed in the liver and participates in lipid regulation, adipogenesis, and blood glucose control. PPAR $\alpha$  affects lipid metabolism by regulating fatty acid oxidation. In addition, PPAR $\alpha$  is expressed in various cells constituting the blood vessel wall, such as monocyte-macrophages, smooth muscle cells, and vascular endothelial cells. HXHT could promote the expression of PPAR $\alpha$ . PPAR $\alpha$  directly acts on the inner wall of the blood vessel, increases the antioxidant effect of the vascular wall, and plays a role in the protection of blood vessels. HXHT might regulate fatty acid  $\beta$ -oxidation to ensure energy supply after I/R and rapidly restore the myocardium. Previous studies on the PGC-1 $\alpha$ -NRF1-mtTFA pathway have shown that high fat intake could reduce the mRNA and protein levels of the mitochondrial biogenesis-related genes PGC-1 $\alpha$ , NRF1, and

mtTFA (Keaney et al., 2003; Liu et al., 2014). HXHT could promote the mRNA and protein expression levels of PGC-1 $\alpha$ , NRF1, and mtTFA in the myocardium of hyperlipidemic rats in preliminary experiments, and alleviate myocardial I/R injury. On the one hand, HXHT lowered blood lipids and reduced the damage of CHO and LDL-C to the vascular endothelium; on the other hand, it reduced oxygen free radical levels in mitochondria, and acted on other pathways through its effects on NRF1 and mtTFA. HXHT might increase the expression of mtDNA and promote mitochondrial biosynthesis by promoting the mRNA and protein expression of PGC-1 $\alpha$ , NRF1, and mtTFA and increasing PGC-1 $\alpha$ -PPAR $\alpha$  pathway activity.

## CONCLUSIONS

The results of this study demonstrate that a high-fat diet affects myocardial mitochondria through two pathways: PGC-1 $\alpha$ -PPAR $\alpha$  and PGC-1 $\alpha$ -NRF1-mtTFA. Myocardial fatty acid biosynthesis and oxidation affect mitochondrial function and aggravate I/R injury, as revealed by a comprehensive study of lipid metabolism, the myocardial enzyme spectrum, myocardial histomorphology, and mitochondrial biogenesis. HXHT could affect lipid metabolism and reduce the levels of CHO, TG, HDL-C, and LDL-C in hyperlipidemic rats in a dose-dependent manner, affect fatty acid  $\beta$ -oxidation through the PGC-1 $\alpha$ -PPAR $\alpha$  pathway, and protect against disturbances of mitochondrial energy metabolism. At the same time, HXHT could promote the mRNA expression and protein transcription of the mitochondrial biosynthesis-related genes of PGC-1 $\alpha$ -NRF1-mtTFA, promote mtDNA synthesis, increase T-SOD levels, protect the structure and function of mitochondria, and defend against myocardial I/R injury in hyperlipidemic rats.

Influenza infection is a highly contagious, acute febrile respiratory disease caused by the influenza virus. Traditional Chinese Medicine (TCM) has dominated plenty of theoretical and practical approaches in the treatment of influenza. It is, therefore, important to highlight the effects of TCM in the clinical treatment of influenza and their impact on inhibiting the growth of this virus in laboratory experiments. We scrutinized existing evidence on whether TCM is effective in clinical applications. Moreover, we described the potential mechanisms of TCM against the influenza virus. Our findings provide analytical evidence that supports the effectiveness of TCM in treating influenza infections as well as their mechanisms against this virus.

**Keywords:** influenza, Traditional Chinese Medicine, herbal medicine, influenza symptoms, anti-influenza virus, review

## INTRODUCTION

Influenza is an acute viral respiratory infection that was first described in the 4th century BC. At the time, it was estimated to have caused nearly 60,000 mortalities in Venice, Italy. Due to the impact of this disease in Venice, it was understood by folklore to be a punishment from God and was therefore named “Influenza (Devil)” (JJ, 2010). The influenza virus belongs to the Orthomyxoviridae family. It is a single-stranded negative-sense RNA virus exhibiting an eight-segmented genetic material (Brody, 2019). Its genetic material is made up of Polymerase Basic Protein 1 (PB1), Polymerase Basic Protein 2 (PB2), Polymerase Acidic (PA), Hemagglutinin (HA), Nucleoprotein (NP), Neuraminidase (NA), Matrix Protein (M), and Nonstructural Protein (NS) (Lu, 2008). Depending on the composition of its NP and M, this virus is grouped into three types (A, B, and C). Its subtypes are determined by the antigenicity of two surface glycoproteins, the 18 HA and 11 NA (Webster et al., 1992; Kawaoka, 2006; Huang et al., 2008). It is extremely susceptible to mutations because its RNA genome lacks proof-reading ability during replication as is the case with DNA genomes. Moreover, the mutations are also attributed to antigenic drifts. These mutating types propagate this virus, leading to epidemics in certain seasons (Cox

**Abbreviations:** TCM, Traditional Chinese Medicine; PB1, Polymerase Basic Protein 1; PB2, Polymerase Basic Protein 2; PA, Polymerase Acidic; HA, Hemagglutinin; NP, Nucleoprotein; M, Matrix Protein; NS, Nonstructural Protein; NA, Neuraminidase; NAIs, Neuraminidase Inhibitors; WHAFS, Wind-heat affecting Fei syndrome; RCT, Randomized Controlled Trial; HCP, Houttuynia cordata polysaccharide.

and Subbarao, 2000; He et al., 2011; Kamali and Holodniy, 2013) and, notably, they hinder the development of new antiviral drugs. First-line antiviral drugs in the treatment of influenza rely on blocking the action of NP (Gaitonde et al., 2019). However, the side-effects of anti-NA drugs render many patients unavailable to treatment. In China, the broadly prescribed anti-influenza drugs include oseltamivir, zanamivir, and peramivir (Lee et al., 2017). Notably, Oseltamivir has been associated with resistance (Govorkova et al., 2001; Kiso et al., 2004; Moscona, 2004) and leads to immunocompromised conditions (Govorkova et al., 2001; Moscona, 2009; Panning, 2013). Zanamivir is administered through inhalation, and challenges over its use have been described (Shetty and Peek, 2012). Due to its limited bioavailability, peramivir can only be administered intravenously (Birnkranz and Cox, 2009). Therefore, these challenges call for more effort and attention toward developing fresh strategies to combat influenza. Previously, TCM demonstrated a positive anti-viral effect on influenza virus and alleviated the symptoms among patients (He et al., 2019; Nagai et al., 2019). In TCM theory, influenza disease was classified as “YI Disease” and was first reported in Huang Di Nei Jing. During the Han Dynasty, a theory of Shang Han (Treatise of Exogenous Febrile Diseases or Discourse on Cold-Damage Disorders) was written by Zhang Zhongjing to treat influenza. Later, during the Ming and Qing Dynasties, the emergence of “Wen Yi Lun (Analysis of Epidemic Warm Diseases)” revealed that TCM had contributed enormously to the prevention and treatment of influenza for thousands of years. Despite studies showing that TCMs are effective against influenza (Moscona, 2004; Tian et al., 2011), further studies on the development of novel anti-influenza agents are essential (Rajasekaran et al., 2013; Chang et al., 2014; Ding et al., 2014; Li C. et al., 2015). Herein, we summarize the impacts of TCM in treating influenza from basic experiments to clinical applications.

## CONFIRMED IN CLINICAL APPLICATION

In Asia and some countries in Europe, TCM has been proven to be effective and secure for treating influenza (Moscona, 2004). Traditional Chinese Medicine (TCM) subdivides influenza into cold syndrome and heat syndrome. The major symptoms of wind-cold type include severe cold, light heat, lack of sweating, headache, sore limbs, and stuffy nose. On the other hand, high fever, a mild cold, headache, sore throat, cough are the primary symptoms of wind-heat type. By relying on the concept of evidence-based medicine, several clinical trials have been conducted to verify the efficacy and safety of TCM.

### Meta-Analysis

A meta-analysis enrolled 30 studies consisting of 3,444 cases in all to investigate efficacy and safety of TCM in the treatment of influenza infection. Our findings indicated that the mean time fever resolution of the TCM treatment group was statistically significant compared to the control group. Additionally, the synergistic effects of TCM and conventional medicines on viral infections were better compared to the control group (Li J. H.

et al., 2016). Further, a different TCM prescription from Shang Han Lun, ma-huang-tang (5 g of *ephedra equisetina bunge*, 5 g of *prunus armeniaca* L., 4 g of *cinnamomum verum* J.Presl, and 1.5 g of *glycyrrhiza uralensis fisch. ex DC.*) was confirmed that it alleviated fever when singly administered or in combination with neuraminidase inhibitors (NAIs) and might be a well-tolerated treatment as reported by a systematic review and meta-analysis conducted by Japanese scientists (Yoshino et al., 2019). *Andrographis paniculata* was indicated to be beneficial and safe for relieving influenza symptoms and shortening time to symptom resolution (Hu et al., 2017). Conclusively, TCM are validated in lessening influenza symptoms, such as duration for defervescence and cough.

### Randomized Clinical Trial (RCT)

Researchers conducted a randomized trial for comparing the efficacy and safety of oseltamivir and maxingshigan-yinqiaosan [6 g of *honey-fried ephedra equisetina bunge*; 10 g of *anemarrhena asphodeloides bunge*; 15 g of *artemisia annua* L.; 30 g of *gypsum fibrosum*; 15 g of *lonicera japonica thunb.*; 15 g of *scutellaria baicalensis georgi*; 15 g of *stir-baked prunus armeniaca* L.; 15 g of *forsythia suspensa (thunb.) vahl*; 6 g of *mentha canadensis* L.; 15 g of *fritillaria thunbergii* miq.; 15 g of *arctium lappa* L.; and 10 g of *glycyrrhiza uralensis fisch. ex DC.*] originating from Shang Han Lun and Wen Bing Tiao Bian, in treating uncomplicated influenza. Results have shown that singular use or combinations of oseltamivir and maxingshigan-yinqiaosan minimized defervescence time in patients diagnosed with influenza viral infections (Wang et al., 2011). It was, therefore, proposed that maxingshigan-yinqiaosan in combination with oseltamivir be utilized as an alternative medication in the treatment of influenza viral infections. In a multi-centric, randomized, double-blind, and placebo-controlled trial, a total of 480 adults with influenza symptoms were recruited. It was observed that TCM increased recovery by 17% ( $p < 0.001$ ) and lowered disease severity (evaluated through the median symptom score) by 50% ( $p < 0.001$ ) (Wang et al., 2010). Moreover, 136 influenza patients with wind-heat affecting Fei syndrome (WHAFS) were prescribed with Jinhua Qinggan Granules (JHG) that have been developed by experts in recent years. This preparation has been based on findings in a double-blind randomized control trial. In this trial, the duration of defervescence, the defervescence rate, the efficacy of TCM, the alleviation rate of primary symptoms and physical signs of influenza, the absence of viral nucleic acid in pharyngeal secretions, and safety indices were assessed. It was shown that JHG was efficient and safe in treating patients with WHAFS (Li et al., 2013). Japanese doctors have conventionally prescribed TCM to treat influenza. This is based on findings of a randomized controlled trial that compared the efficacy of TCMs with NP inhibitors in treating influenza. It has been established that TCM was effectively tolerated when used to treat influenza. Meanwhile, TCM and NP inhibitors exhibited equivalent clinical efficacies against the influenza virus (Nabeshima et al., 2012). In the US, a randomized, double-blind placebo-controlled study established that *Echinacea angustifolia* DC, a compound used in herbal tea preparations was potent in alleviating influenza symptoms such as stuffiness, scratchy throat and fever (Lindenmuth and Lindenmuth, 2000). In agreement with our meta-analysis, RCTs

demonstrated that TCM abbreviated fever time and showed a satisfactory impact in relieving cough and sore throat. In **Table 1**, we summarized the efficacy of TCMs in treating influenza (**Table 1**).

## Retrospective Analysis

Besides meta-analysis RCT, researchers analyzed the duration of viral shedding in influenza patients admitted and administered with TCM in China. A total of 963 patients diagnosed with influenzavirus infection between May and July 2009 were recruited. The study showed that TCM therapy contributed to viral shedding among patients with a temperature of  $\geq 38^{\circ}\text{C}$  (Wang et al., 2012). Overall, these studies demonstrated that, besides alleviating symptoms of influenza patients, such as fever and cough, TCM have been proved to contribute to viral shedding.

## Use of TCM in Treating Influenza Among Children and During Pregnancy

Treatment of influenza among children and pregnant women is challenging. However, other than effectively alleviating symptoms, TCM can compensate for deficiencies that cannot be bridged by conventional medicines in pregnant women. Children is the major group affected by influenza virus as they are usually vulnerable to complications. Moreover, the response of children to drug-metabolism is profoundly unique from that of adults. Therefore, it is essential to analyze the effects of TCM on children. It is, therefore, essential to analyze the effects of TCM on children. As mentioned above, ma-huang-tang was expansively used in China to manage children diagnosed with influenza. Ma-huang-tang has been widely used in China to manage influenza diagnoses among children. Without exhibiting adverse effects, it has been validated to be

clinically useful in neonates, infants, and children with febrile viral symptoms (Nishimura et al., 2009). Additionally, it has been shown that it might potentially be useful in patients aged  $\leq 5$  who have a low sensitivity to oseltamivir and experience problems when using zanamivir (Toriumi et al., 2012). Comparison of the efficacies of ma-huang-tang and oseltamivir was evaluated among children with type A influenza. Results showed that ma-huang-tang in combination with oseltamivir was capable of abbreviating fever duration when compared to the group administered with oseltamivir only (Kubo and Nishimura, 2007). Elsewhere, a systematic review focusing on the effects of *Andrographis paniculata* (burm.f.) nees on influenza infections among children reported that this herb minimized the duration of cough, sore throat and morbidity time compared to conventional medicines (Hu et al., 2017). The use of TCM aerosols in treating infantile influenza infections showed an effective rate of 99.03% with a cure rate of 65.38% (Ma et al., 2000). An investigation on the clinical efficacy of a sachet of Chinese herbs in preventing influenza among 239 children from Shanghai Baoshan Xubeihong Art Kindergarten revealed that the sachet alleviated symptoms such as fever, rhinocleisis, runny nose, and throat congestions. Equally, the incidence rates of influenza in the treatment group were low compared to the control group (Liu et al., 2010). Reports indicate that TCM is a valuable option during pregnancy. For instance, when influenza outbreaks occurred in the Middle East, the prevalence in the use of TCM varied between 22.3%–82.3% in pregnant women (John and Shantakumari, 2015). Also, Across-sectional study conducted in the Central Appalachian Region showed that *Trigonella foenum-graecum* L. was regularly used in treating Influenza (Alwhaibi et al., 2017). More and more RCTs are focusing on the efficacy and safety of combination use of TCM and

The upward arrow represents the relief of symptoms after treatment.

conventional therapy (He et al., 2019). In summary, there is potential value in using TCM to treat influenza among children and pregnant women; nevertheless, more investigations are necessary for clinical validations.

## BASIC EXPERIMENTS

### Direct Anti-Influenza Virus by Interfering the Invasion Process

In the clinical set-up, we have witnessed the effects of TCM in improving the symptoms of influenza and cutting the course of the disease. However, how TCM act on influenza virus and its effects on the host requires a comprehensive analysis using basic experiments. Recently, researchers have constantly been drawn to investigate the therapeutic effects of TCM. Several types of TCM including, *coptis deltoidea* (C.Y.Cheng & P.K.Hsiao), *Isatis tinctoria* L., *Lonicera japonica thunb.*, *scutellaria baicalensis georgi.*, *cyrtomium fortunei* J.Sm., *Houttuynia cordata thunb.*, *gardenia jasminoides* J.Ellis, and *chrysanthemum indicum* L., and other TCM prescriptions have been proven to effectively suppress influenza virus (Han et al., 2016).

### Single Herbal Medicine

The influenza virus invades the human body in six steps, that is, adsorption, penetration, shelling, biosynthesis, assembly, and release. As its mode of action, TCM targets these six steps. i) The extracts from single herbal medicine: *Lonicera japonica thunb.* HS-encoded atypical microRNA was verified to inhibit influenza viral replication *in vitro* and *in vivo*. Furthermore, HS decoction significantly minimized mice mortalities from influenza virus infection (Zhou et al., 2015). Extracts of *Laggetera crispata* (vahl) (Hepper & J.R.I.Wood), a TCM have been shown to inhibit NA activity. It has also been reported that this compound could suppress NF- $\kappa$ B signaling pathways and viral RNP complexes from the nucleus thereby inhibiting viral replication (Guan et al., 2017). Besides blocking viral replication, TCM enhances the prognosis of mice infected by influenza. Yan et al. evaluated the effects of berberine, a natural isoquinoline alkaloid isolated from *coptis chinensis franch.* on influenza virus. Their results showed that berberine suppressed viral replication in A549 cells and the lungs of mice. Compared to conventional medicines, this compound exhibited significant anti-inflammatory effects on the pulmonary system and reduced necrosis in mice. It was also observed that inflammatory cell infiltrations and pulmonary edemas due to viral infections in mice were reduced (Yan Y. Q. et al., 2018). *Houttuynia cordata Thunb* (HCP), a TCM, plays a pivotal role in the treatment of bacterial and viral respiratory infections. Accompanied by a reduction in virus replication, HCP is reported to increase the overall survival rate of mice infected with influenza. Further studies have proved that it might be associated with the decrease in the concentration of pulmonary proinflammatory cytokines/chemokines and the number of intestinal goblet cells, which resulting in upregulation of sIgA and tight junction protein (ZO-1) in the intestine (Zhu et al., 2018). Researchers at the Kitasato Institute in Japan extracted flavonoids from the roots and leaves of

*Astragalus mongholicus bunge* and confirmed their capacity in preventing the growth of influenza virus. It has been reported that glycyrrhizic acid significantly inhibits influenza virus (Pompei et al., 1983; Baltina et al., 2009). Besides, extracts of *Paeonia delavayi* Franch. and *pogostemon cablin (blanco) benth.* were found to efficiently inhibit NP (Li J. et al., 2016; Liu et al., 2016). The roots of *Bupleurum marginatum* var. *stenophyllum* (H.Wolff) had inhibitory effects on the replication of influenza (Fang et al., 2017). Importantly, it has been confirmed that *Tetradium ruticarpum* (A.Juss.) T.G.Hartley effectively hindered viral attachment and penetration into host cells (Lin et al., 2016). ii) Single components: A study by Li et al. addressed that, Dendrobine, extracted from a traditional Chinese herb (*dendrobium nobile lindl.*), interfered with early viral replication and bound to the viral NP thereby restricting nuclear export of viral NP and its oligomerization (Li et al., 2017). HESA-A is a natural ingredient retrieved from marine herbs. This compound blocks viral penetration into the cell (Mehrbood et al., 2014). *Persicaria chinensis* (L.) h. gross, from Vietnam, was shown to target NP, including oseltamivir-resistant ones (Tran et al., 2017). These results show that single herbal medicines inhibit viral proliferation by targeting multiple sites and pathways during replication. These results are presented in **Figure 1**.

### Traditional Chinese Herbal Prescription

Besides the single Chinese herbal medicine, traditional Chinese herbal prescription has precariously shaped the academic debate on influenza disease management. Huang-Lian-Jie-Du-Tang (composed of *coptis chinensis* Franch., *scutellaria baicalensis georgi*, *phellodendron chinense* C.K.Schneid., and *gardenia jasminoides* J.Ellis at the weight ratio of 3:2:2:3) (HLJDT) is a classical prescription composed of 4 TCM herbs that have been used to treat diverse diseases including influenza. In total, 13 compounds have been isolated from the plasma profile of HLJDT. These compounds include, jatrorrhizine, palmatine, epiberberine, geniposide, oroxylin A, berberine, coptisine, baicalein, wogonoside, phellodendrine, wogonin, oroxylin A-7-O-glucuronide, and baicalin. They have been shown to be potent NA-1 inhibitors (Zhou et al., 2017). Xin-Jia-Xiang-Ru-Yin [(composed of *mosla chinensis* maxim., *lonicera japonica thunb.*, *dolichos lablab* L., *magnolia officinalis rehd. et wils.* and *forsythia suspensa (thunb.) vahl* at the weight ratio of 2:3:3:2:3)], a traditional Chinese prescription used for managing summer influenza in China, has been demonstrated to integrate antiviral therapy and immune modulation effects by lowering the expression of Interferon- $\gamma$  (IFN- $\gamma$ ) and Signal transducer and activator of transcription-1 (STAT1), resulting to reduced inflammation hence harboring key therapeutic benefits against summer influenza (Li et al., 2018). The Re Du Ping intravenous injection, a TCM can adsorb the virus into host cells and inhibit their proliferation. This injection also has a direct viricidal effect (Jing et al., 2010). Studies into the pharmacodynamics and molecular mechanisms of Qingqi Liangying granules have reported that they participate in Wnt signaling pathways by regulating virus invasions on epithelial cell signaling pathway, thereby, inhibiting viral replication (Wang et al., 2017). Chinese

**FIGURE 1** | Multiple targets and multiple pathways to inhibit influenza virus.

classical herbal prescription was also used in the prevention of influenza. It was reported to reduce the vulnerability of cells to the invasion of influenza virus and alleviate viral induced lung lesions (Liu et al., 2013).

### In-Direct Anti-Influenza Virus by Regulating Host Immune System

In addition to the direct effect on the influenza virus, TCM regulates immune activation and signaling pathways that impact on the influenza virus. The host innate immune response to influenza virus occurs as follows: Infection with influenza virus stimulates the body's innate immune response, which involves multiple effector cells, immune molecules, and factors, such as Interleukin-6 (IL-6) and Interferon- $\alpha$  (IFN- $\alpha$ ), to effectively regulate viral replication (Hayden et al., 1998). Several experiments have confirmed that TCM is the most potent anti-inflammatory natural medicine which can modulate all kinds of cytokines and immune molecules.

### Traditional Chinese Herbal Prescription

A study conducted on the mechanisms of TCM prescription in the treatment of influenza deduced that anti-inflammatory effects conferred by TCM protect against inflammatory injuries induced by the influenza virus in mice. These herbal medicines significantly reduce the expression of pro-inflammatory cytokines Tumor Necrosis Factor- $\alpha$  (TNF- $\alpha$ ) and IL-6 in lung tissues of infected mice (Wang et al., 2005; Xu et al., 2014). Sheng Jiang San (SJS), (*rheum officinale* baill.,

*bombyx batryticatus*, *cicadae periostracum*, and *curcuma longa* L. in a ratio of 4:2:1:3), a traditional multi-herb prescription, used to treat influenza infections. Research has shown that SJS down-regulates TNF- $\alpha$  and up-regulates IL-2 in influenza infected mice. Equally, lung indices used to evaluate the level of inflammation and viral loads in SJS treated mice were markedly decreased compared to the controls (Zhang et al., 2018). Currently, Yinhuapinggan granule (YHPG), a Chinese drug with patent that originated from ma-huang-tang is used in the treatment of influenza. A study conducted by Du revealed that YHPG markedly inhibited replication of the influenza virus and significantly up-regulated the levels of IFN- $\beta$  and IFN-stimulated genes (Mx-1, ISG-15, and ISG-56) compared to the control group (Du et al., 2018). The Yinqiao powder [15 g of *forsythia suspensa* (thunb.) vahl, 15 g of *lonicera confusa* DC., 9 g of *platycodon grandiflorus* (jacq.) A.DC., 9 g of *mentha canadensis* L., 6 g of *lophatherum gracile* brongn., 5 g of *glycyrrhiza uralensis* fisch. ex DC., 6 g of *nepeta tenuifolia* benth., 6 g of *glycine max* (L.) merr., 6 g of *arctium lappa* L., 10 g of *phragmites australis* subsp. australis]; The Xinjiaxiangruyin concoction [6 g of *mosla chinensis* maxim., 9 g of *lonicera confusa* DC., 9 g of *lablab purpureus* subsp. *purpureus*, 6 g of *magnolia officinalis* rehder & E.H. Wilson, 6 g of *forsythia suspensa* (thunb.) vahl]; and the Guizhi-and-Mahuang decoction [9 g of *ephedra sinica* stapf, 6 g of *cinnamomum cassia* (L.) J.Presl, 9 g of *prunus armeniaca* L., 6 g of *glycyrrhiza uralensis* fisch. ex DC., 9 g of *paeonia lactiflora* pall., 9 g of *zingiber officinale* roscoe, 3 g of *ziziphus jujuba* mill.]

are widely applied in clinical influenza treatment. These compounds reduce the expression levels of TLR7, MyD88, IRAK4, and NF- $\kappa$ B thereby by regulating the Toll-Like Receptor7/Nuclear Factor Kappa-B (TLR7/NF- $\kappa$ B) signaling pathway (Fu et al., 2018). Yi-Zhi-Hao pellet (CYZH) is a popular Chinese prescription used in influenza treatment. Mechanistically, CYZH lacked an inhibitory effect on viral protein HA and IAV RNA-dependent RNA polymerase but inhibited IAV replication by activating the Nrf2/HO-1 pathway (Yin et al., 2017). Lianhuaqingwen, a TCM prescription alleviates viral-induced gene expressions of IL-6, IL-8, TNF- $\alpha$ , IP-10, and MCP-1 (Ding et al., 2017). Furthermore, Lianhuaqingwen treatment resulted in abnormal particle morphology of virion in cells (Runfeng et al., 2020). San Wu Huangqin (SWHD) decoction (*sophora flavescens*, *scutellaria baicalensis*, and *rehmannia glutinosa* at a ratio of 1:1:2) exhibits its anti-viral effects by regulating the immune system (Ma et al., 2018). The Ge Gen Decoction [12 g of *pueraria montana* var. *lobata* (Willd.) maesen & S.M.Almeida ex *sanjappa* & *predeep*, 9 g of *ephedra sinica* stapf, 6 g of *cinnamomum cassia* (L.) J.Presl, 6 g of *glycyrrhiza uralensis* fisch. ex DC., 6 g of *paeonia lactiflora* pall., 9 g of *zingiber officinale* roscoe, and 22 g of *ziziphus jujuba* mill.] decreased the expression of TNF- $\alpha$  and toll-like receptor 7 signaling pathways in influenza virus infected mice thereby reducing lung inflammation (Geng et al., 2019). Research endorsed that Gui Zhi Ma Huang Ge Ban Tang [9 g of *ephedra sinica* stapf, 6 g of *cinnamomum cassia* (L.) J.Presl, 9 g of *prunus amygdalus* batsch, and 6 g of *glycyrrhiza uralensis* fisch. ex DC., 9 g of *paeonia lactiflora* pall., 9 g of *zingiber officinale* roscoe, and 10 g of *ziziphus jujuba* mill.] exhibit a good ability to reduce the proportion of Helper T cell 1/Helper T cell 2(Th1/Th2) and Helper T cell 1/Regulatory cells (Th17/Treg) cells thus reducing lung inflammation (Qin et al., 2018). *Artemisia scoparia* Waldst. & Kit. is expansively distributed in Xinjiang China and reported to downregulate NF- $\kappa$ B signal pathway thereby inhibiting viral replication (Yan H. et al., 2018). Summarily, TCM regulates signaling pathways like NF- $\kappa$ B and inflammatory factors such as TNF- $\alpha$  and IL-6, that are important in modulating immune responses against the virus.

### Single Herbal Medicine

Besides the TCM prescription, single herbal medicine indirectly plays a crucial role in anti-viral activity. i) The extracts from single herbal medicine: As mentioned above, *laggera pterodonta*, demonstrated a wide spectrum of anti-influenza virus activity via the NF- $\kappa$ B pathway, COX-2, and p38/MAPK pathway (Wang et al., 2017). Moreover, flavonoids extracted from *Scutellaria baicalensis* Georgi (FESR) could inhibit excessive activations of the complement system, thereby, improving acute lung injuries (Zhi et al., 2020). *Houttuynia cordata* thunb polysaccharide (HCP) aids systemic influenza treatment by locally acting on the intestines and balancing the microbiota (Chen et al., 2019). *Bupleurum falcatum* L., extracted from a traditional Chinese herb, was also found to be an immune modulator (Yao et al., 2018). *Isatis tinctoria* L., attenuates viral-induced NF- $\kappa$ B

activation (Li et al., 2015). Research has shown that *Forsythia suspensa* (thunb.) vahl interferes with the budding process of newly formed virions and reduces influenza M1 protein that is necessary for viral spread (Law et al., 2017). ii) Single components: Baicalin, a popularly known herbal medicine ingredient in China for treating Fei-Re syndrome characterized by fever, and cough, can be extracted from *scutellaria baicalensis* georgi, which was reported to induce autophagy so as to inhibit mTOR signaling pathway. Thus, shedding more light on the development of novel anti-influenza drugs (Zhu et al., 2015). Quercetin-7-O-glucoside was discovered in many types of Chinese herb and demonstrated a strong inhibition against influenza A and B viruses by downsizing virus-induced ROS and autophagy formation (Gansukh et al., 2016). The polysaccharides extracted from the roots of *astragalus mongholicus* Bunge species, a famous TCM used for hundreds of years to improve QI with Chinese medicine theory, was ratified to modulate Th1/Th2 balance and secretions of IFN- $\gamma$ , IL-17A, and IgG2a (Yakuboğulları et al., 2019). These studies testify that different types of TCMs possess remarkable potential in immunomodulation against influenza virus.

## SUMMARY

In conclusion, TCM impacts on the prevention and treatment of influenza. It has a potential value in shorting fever durations and alleviating influenza symptoms among children and pregnant women. However, the side effects of TCM in children and pregnant women are still elusive, which needs more clinical trials about the safety and vivo toxicity. These medicines also regulate the immune system. Their modes of action involve inhibiting NA, viral replication, and stopping viral entry into the cell. The synergistic effects of TCM and conventional medicines are encouraging as an avenue for influenza therapy.

Based on the pathological theory of lipid metabolism and using network pharmacology, this study was designed to investigate the protective effect of water extract of *Veratrinella baillonii* (WVBF) on non-alcoholic fatty liver disease (NAFLD) model using LO2 cells and to identify the potential mechanism underlying the effect. The components of *V. baillonii* were identified from the public database of traditional Chinese medicine systems pharmacology database (TCMSP). Cytoscape software was used to construct the related composite target network. Then, Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis were carried out for critical nodes. The BioGPS database was used to determine the distribution of the target in tissues and organs. Moreover, the inhibitory effect of *V. baillonii* was further investigated using an *in vitro* hepatocyte NAFLD model. Fourteen active components were then selected from the 27 known compounds of *V. baillonii*. The targets of gene enrichment analysis were mainly distributed in the lipid catabolism-related signaling pathway. Network analysis revealed that five target genes of TNF, MAPK8, mTOR, NF- $\kappa$ B, and SREBP-1c were key nodes and played important roles in this process. Organ localization analysis indicated that one of the core target site of *V. baillonii* was liver tissue. The results of the *in vitro* study revealed that WVBF can alleviate the inflammatory response and lipid accumulation in LO2 hepatocytes by inhibiting oxidative stress and the adipocytokine signaling pathway. Genes and proteins related to the lipid synthesis, such as SREBP-1C, acetyl-CoA carboxylase (ACC), and fatty acid synthase (FASN), were significantly decreased, and PPAR $\alpha$  expression is significantly increased with WVBF administration. In conclusion, *V. baillonii* may regulate local lipid metabolism and attenuate oxidative stress and inflammatory factors through the PPAR $\alpha$ /SREBP-1c signaling pathway. The present study also indicates that multiple components

of *V. baillonii* regulate multiple targets and pathways in NAFLD. The findings highlight the potential of *V. baillonii* as a promising treatment strategy for nonalcoholic fatty liver injury.

**Keywords:** nonalcoholic fatty liver, lipid metabolism, amarogentin, network pharmacology, *Veratilla baillonii* Franch

## INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD), the most common chronic liver disease, is a metabolic syndrome characterized by hepatocellular steatosis and fat storage without a history of excessive alcohol consumption (Younossi et al., 2016). Globally, NAFLD accounts for 25.2% of global burden of disease epidemics, with approximately 30% of adults having underlying lipid metabolic disorders (Zobair et al., 2016). NAFLD affects nearly one-third of the world's population and the prevalence of this disorder is increasing every year (Hu et al., 2019). Excessive accumulation of triglyceride (TG) due to an imbalance in fatty acid uptake, synthesis, transportation, and oxidation is the leading cause of liver injury (Du et al., 2016). Based on the underlying pathological conditions, NAFLD can further develop into simple fatty liver, non-alcoholic steatohepatitis (NASH), fatty liver fibrosis, or cirrhosis, which significantly increases the associated mortality (Perumpail et al., 2017; Ipsen et al., 2018). Since no pharmacological therapy has been approved for the treatment of NAFLD so far, there is an urgent necessity to define multiple components, multiple targets and pathways of traditional Chinese medicine (TCM) based strategies of future interventions.

*Veratilla baillonii* Franch (*V. baillonii*) belongs to the Gentianaceae family. *V. baillonii*, a traditional folk medicine, has been widely used in the treatment of hepatitis-induced jaundice and drug-induced hepatitis for decades (Olennikov et al., 2015; He et al., 2015). The water extract of *V. baillonii* (WVBF), which contain flavonoids, iridoid glycosides, and other substances (Vaidya et al., 2009; Ge et al., 2016; Yu et al., 2016; Zhang S. R. et al., 2018; Li et al., 2019). WVBF has significant protective effects on oxidative stress-induced liver injury (Dai et al., 2018), diabetic liver injury (Lian et al., 2010), and drug liver toxicity (Huang et al., 2016). However, the effects and underlying mechanism of *V. baillonii* in NAFLD are still unclear.

Therefore, this study explored the main components, key targets, and signaling pathways of *V. baillonii* in NAFLD. Further, the efficacy network and pharmacodynamic mechanism of WVBF were investigated using the network pharmacology method. Additionally, LO2 liver cells were exposed to mixed free fatty acids (FFA), to establish an *in vitro* NAFLD model for investigation of the protective effect of *V. baillonii* on the liver.

## MATERIALS AND METHODS

### Network Pharmacology Study Compound Profiling and Disease Target Identification

The following databases were searched to identify the compounds in *V. baillonii*: traditional Chinese medicine systems pharmacology

database (TCMSP) (<http://lsp.nwu.edu.cn/tcmsp.php>), a unique pharmacology platform that captures the relationships between herbal ingredients, targets, and diseases: SymMap (<http://www.symmap.org/search/>). The components were filtered by integrating oral bioavailability ( $OB \geq 30\%$ ) and drug-likeness ( $DL \geq 0.18$ ), as suggested by the TCMSP and SymMap databases. OB and DL were used for candidate active ingredient screening based on a computer integrated model of absorption, distribution, metabolism, and excretion (ADME) (Xu et al., 2014).

The PubChem (<https://pubchem.ncbi.nlm.nih.gov/>) and HIT (<http://lifecenter.biosino.org/hit/>) databases were utilized to identify the verified targets of each active component (Song et al., 2018). In order to identify the potential targets of *V. baillonii*, the molecular similarity match tool was used based on the simplified molecular input line entry specification (SMILES) in the similarity ensemble approach (SEA) ( $P < 0.05$ ) (<http://sea.bkslab.org/>) and SwissTargetPrediction ( $P < 0.05$ ) (<http://www.swisstargetprediction.ch/>) (Stork et al., 2019). The UniProt (<https://www.uniprot.org/>) database was used to standardize the results. An interaction network of component-targets was constructed and visualized by Cytoscape software.

Non-alcoholic fatty liver-related targets were retrieved from the online human Mendelian genetics (OMIM, <https://omim.org/>), DisGeNET (<http://www.disgenet.org/>), and GeneCards (<https://www.genecards.org/>) databases. "Non-alcoholic fatty liver disease" was used as the keyword and duplicate values were deleted. The Bioconductor package in the software package R was used to standardize the disease gene targets obtained (Zeng et al., 2019). Finally, Cytoscape 3.2.1 was used to perform visual network analysis of the "disease-target."

### Screening of Candidate Targets for the Treatment of Non-Alcoholic Fatty Liver Disease

Based on the previous steps, two sets of target data files were prepared: drug-related component targets and disease-related targets. Cross genes were screened using the Venn Diagram software package in R. Intersecting protein interactions (PPIs) were analyzed using the String 11.0 database and the common targets were counted using R software. Finally, Cytoscape 3.2.1 was used to perform visual network analysis of the "drug-active ingredient-target-disease" network.

### Network Construction and Central Network Topological Analysis

PPIs for each target were generated from a string database that provides experimental and predictive interaction information based on systematic co-expression analysis, shared selection signal detection across genomes, and automated text mining of scientific literature (Liu et al., 2013). The central network analysis was performed according to the topological method. Three

topological parameters, degree centrality (DC), betweenness centrality (BC), and closeness centrality (CC), were calculated to evaluate the central attributes of the nodes in the network (Wang et al., 2015). In the target network of WVBF and NAFLD,  $DC \geq 2 \times$  median DC,  $BC \geq$  median BC, and  $CC \geq$  median CC were used as the screening criteria to obtain the key targets. The key target interaction network was also depicted using Cytoscape 3.2.1.

### Bioinformatics Annotation Analysis

Bioinformatics annotation using Bioconductor R language was used to evaluate genes with high expression patterns. In this study, the PANTHER classification system (<http://www.pantherdb.org/>), Gene Ontology (GO) annotation database website (<http://www.geneontology.org>), Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis (<http://www.genome.jp/kegg/>), and PPIs analysis (<http://string-db.org/>) were used to analyze the effect of potential targets of active ingredients in *V. baillonii* on gene function and signaling pathways.

### Prediction of Target Organ Recognition

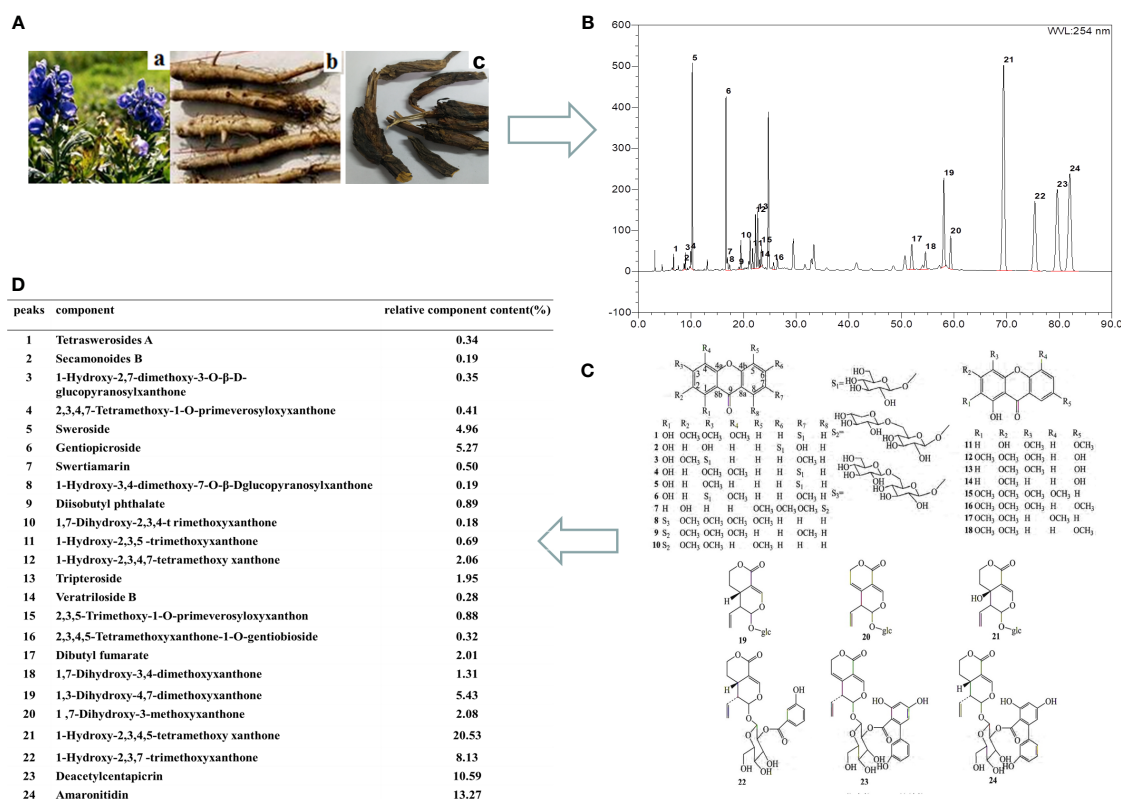

In order to understand the intervention function of *V. baillonii* in NAFLD, the distribution of targets in tissues and organs was analyzed. To gain information about key targets function, the tissue specific probes of the key targets core were identified using

the BioGPS Gene Expression Database (Novartis Research Foundation; <http://biogps.org>). The tissue distribution of targets was determined, specific methods have been described as the following aspects. Firstly, all the core targets collected above were inputted as keywords into BioGPS for screening, and species of human was selected. Secondly, the detailed information of the core targets was queried and click to retrieve the target to show its expression in different tissues. Finally, the obtained distribution and expression of each target in different tissues were imported into the SPSS, and the gene expression in different tissues was plotted (Pritchard et al., 2012; Wang et al., 2017).

### Experimental Cells and Design

#### Extract Preparation

The dried roots of *V. baillonii* (Figure 1A) were bought from Kunming city, Yunnan province in China. The plant materials were authenticated by Dr. Liu Xinqiao, who is affiliated to the School of Pharmaceutical Sciences, South-Central University for Nationalities, China. The voucher specimens (No. S20140710) were deposited at the Herbarium situated in the College of Pharmaceutical Sciences at South-Central University for Nationalities, Wuhan, Hubei, P. R. China. The WVBF was extracted as described previously (Ge et al., 2016; Yu et al., 2016; Li et al., 2019). Briefly, WVBF was prepared by extracting the plant (200 g) crushed into small pieces. The mixture was

**FIGURE 1** | The chemical structures and the typical high-performance liquid chromatographic (HPLC) chromatographic profile of *V. baillonii*. (A) The stems and roots of *Veratrilloside baillonii*. (D) The relative contents of main activate components in *V. baillonii*.

refluxed with water (1:10, w/v) for 2 h. The filtrates were collected and the residues were then refluxed in water (1:10, w/v) for 1.5 h. Two batches of filtrates were combined. Afterwards, the concentrated extract was dried by vacuum concentration to obtain the WVBF extract with a yield of 25.6% (w/w, dried extract/crude herb).

### Analysis of Water Extract of *Veratilla baillonii* by High-Performance Liquid Chromatographic

The multi-components of WVBF were characterized by high-performance liquid chromatographic (HPLC) (Figure 1). The samples were analyzed using Pheceda C18 column (150 mm×2.1 mm, 3 μm) with the detector wave length set at 215 nm, and the mobile phase consisted of water containing acetonitrile (A) and 0.1% (v/v) acetic acid (B). A gradient program was used as follows: 0–10 min, 32–55% A; 10–20 min, 55–100% A. The flow rate was 0.3 ml/min. HPLC fingerprint analysis method was established to obtain the complete fingerprint of WVBF, and the corresponding 24 compounds were identified (Figure 1B). According to the peak area normalization method, the relative contents of WVBF are calculated as follows: gentiopicroside (peak 6, 5.27%), tripteroside (peak 13, 1.95%), 1,3-Dihydroxy-4,7-dimethoxyxanthone (peak 19, 5.43%), 1-Hydroxy-2,3,4,5-tetramethoxy xanthone (peak 21, 20.53%), 1-Hydroxy-2,3,7-trimethoxyxanthone (peak 22, 8.13%), Deacetylcentipicrin (peak 23, 10.59%), Amaronitidin (peak 24, 13.27%) (Figures 1C, D).

### Reagents and Instrument

Fetal bovine serum (FBS) and Dulbecco's modified Eagle's medium (DMEM) were purchased from HyClone. A triglyceride (TG) kit (lot: A110-1-1), lipid peroxides (LPO) kit (lot: A106-1-2), superoxide dismutase (SOD) kit (lot: A001-1-2), and glutathione peroxidase (GSHPx) detection kit (lot: A005), malondialdehyde (MDA) kit (lot: A003-1), alanine aminotransferase (ALT) kit (lot: C009-2-1), aspartate aminotransferase (AST) kit (lot: C010-2-1), reactive oxygen species (ROS) kit (lot: E004) were purchased from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). An Annexin V-FITC Cell Apoptosis Assay Kit (lot: C1062L) and bicinchoninic acid (BCA) protein concentration determination kit (enhanced) (lot: P0010) were purchased from Beyotime Biotechnology (Shanghai, China). Bovine serum albumin (BSA) (98%, Sigma, St. Louis, MO, America), oil red O dye (cell-specific smear), amarogentin (AG) (HPLC≥98%, lot: B20683), gentiopicroside (HPLC≥98%, lot: B20763), sweroside (HPLC≥98%, lot: B21643), and swertiamarin (HPLC≥98%, lot: B21644) were purchased from Shanghai Yuanze Biotechnology Co., LTD. Sodium oleate (OA), palmitic acid sodium (PA), and bezafibrate tablets (BT) (HPLC≥99%) were purchased from Shanghai Macklin Biochemical, China.

A CKX41 inverted microscope (Olympus Corporation, Tokyo, Japan; Spectra Max Plus384), full wavelength marker (Molecular Devices, USA), flow cytometer (BD influx), and an Applied Biosystems 7500 fluorescence quantitative PCR instrument were also used.

### Preparation of Sample Solution

The FFA mixture was prepared as reference described (Zhang et al., 2015). Non-fatty acid BSA was dissolved in DMEM medium to prepare a BSA solution with a concentration of

18.4%. OA (9 mmol·L<sup>-1</sup>) and PA (9 mmol·L<sup>-1</sup>) were each dissolved in medium containing BSA. An FFA/BSA mixture with mixture of (OA: PA, 2:1) was produced. The FFA/BSA mixture was stirred at 37°C for 6 h and the pH of the medium was adjusted to 7.4 with a pH regulator. The medium was filtered aseptically and stored at -20°C for later use.

### Cell Culture and Treatment

Human LO2 cells (obtained from Chinese Academy of Science Committee Type Culture Collection Cell Bank, Shanghai, China) were kept in DMEM containing 10% (v/v) heat-inactivated FBS and 1% (v/v) penicillin/streptomycin (Gibco/BRL, NY) in a 5% CO<sub>2</sub> incubator at 37°C. The cells were exposed to (0.125–2.0 mmol·L<sup>-1</sup>) FFA mixture (OA: PA, 2:1) for 24 or 48 h to induce steatosis. DMEM medium containing 2% FBS without fatty acids was used as the control. Then, cells were divided into eight groups: 1) normal control group (NC), treated with PBS only as vehicle; 2) NC+ high dose of WVBF group (WVBF 5.0), treated with PBS only as vehicle; 3) FFA group (MC), treated with 0.5 mM FFA mixture for 24 h; 4) FFA+ bezafibrate tablets group (BT); 5) FFA+ amarogentin group (AG); 6) FFA+ gentiopicroside: sweroside: swertiamarin: amarogentin, 5:8:6:80 group (PC); 7) FFA+ high dose of WVBF group (WVBF 5.0); and 8) FFA+ low dose of WVBF group (WVBF2.5) treated with ghrelin and FFA mixture described above (as Table 1).

To detect the cell viability, AST and ALT were used as the basis indices for selecting the optimal time and the concentrations of FFA (Mao et al., 2015; Zhang S. R. et al., 2018).

## EFFECT OF WATER EXTRACT OF *VERATRILLA BAILLONII* ON NON-ALCOHOLIC FATTY LIVER DISEASE CELL MODEL

### Assessment of Cell Viability

Cell viability was evaluated by the methylcyclopentadienyl manganese tricarbonyl (MTT) method. After the indicated treatment, MTT was added at a working concentration of 5 mg·ml<sup>-1</sup> and the solution was incubated for 4 h. Then, the MTT solution was removed and 150 μl well<sup>-1</sup> of dimethyl

TABLE 1 | Experimental protocol and group.

Group	0.5 mmol ml <sup>-1</sup> FFA	Drug concentration
Normal control (NC)	-	-
Model control (MC)	+	-
BT	+	Bezafibrate tablets (5.0 μg·ml <sup>-1</sup> )
AG	+	Amarogentin (5.0 μg·ml <sup>-1</sup> )
PC	+	Sweroside:gentiopicroside: swertiamarin:amarogentin=5:8:6:80 (5.0 μg·ml <sup>-1</sup> )
WVBF2.5	+	WVBF (2.5 μg·ml <sup>-1</sup> )
WVBF5.0	+	WVBF (5.0 μg·ml <sup>-1</sup> )
WVBF5.0	-	WVBF (5.0 μg·ml <sup>-1</sup> )

sulfoxide (DMSO) was added to dissolve the needle-like formazan crystals formed by viable cells. The absorbance was measured at 490 nm, and the percentage of cell viability was calculated.

## Flow Cytometry Analysis of Apoptosis

After treatment, the LO2 cells were collected after centrifugation at  $2,000 \text{ r} \cdot \text{min}^{-1}$  for 5 min. The cells were treated according to the instructions of the Annexin V-FITC Cell Apoptosis Assay Kit. Then, a FACSCalibur flow cytometer (BD Biosciences, San Jose, CA, USA) was used to evaluate cell apoptosis and necrosis.

## Cell Oil Red O Staining

The levels of lipids were assessed by oil red O stains on cells. Firstly, the cells grown in six-well plates were washed with phosphate buffer saline (PBS) three times, then 4% paraformaldehyde was used to fix the cells for 20 min. Secondly, the cells attached to the coverslip were stained with the oil red O (ORO) fixative for 15 min, and soaked with 60% isopropanol for 5 min. Then, hematoxylin stain was added onto the slides for 1 min after the slides were washed with distilled water according to the manufacturer's instructions. The lipid droplets stained with oil red O were visualized with a CKX41 inverted microscope equipped with a DP72 microscope digital camera. Then 100% isopropanol was used to extract intracellular cholesterol. The liquid absorbance was measured at OD490 with spectrophotometer.

## Biochemical Analyses

The cell lysates were homogenized and the total lipids were extracted by a mixture of chloroform and methanol (2:1). The protein concentrations of lysis buffer were measured using an enhanced bicinchoninic acid (BCA) protein assay kit. The concentrations of TG, total cholesterol (TC), total superoxide dismutase (T-SOD), glutathione peroxidase (GSH-Px), MDA, and LPO in cell homogenate were determined with commercial kit. All experimental results were normalized according to total protein levels of the samples. The levels of AST and ALT in cell culture supernatant were also determined using a fully automatic biochemical analyzer (Mindray, BS-600, China), according to the manufacturer's protocol.

## Analysis of Intracellular Reactive Oxygen Species Generation

Fluorescent dye 2,7-dichlorofluorescein-diacetate (DCFH-DA, Beyotime, China) was used to detect intracellular ROS generation. After the cells were exposed to FFA for 24 h, and treatment of BT, AG, PC, and WVBF, the LO2 cells were washed with DMEM and stained with  $10 \mu\text{M}$  of DCFH-DA for 30 min at  $37^\circ\text{C}$ . Subsequently, cells were harvested, rinsed twice with DMEM, and then resuspended in 0.5 ml of DMEM and analyzed for DCF fluorescence by flow cytometry.

## Quantitative Real-Time PCR (qRT-PCR)

Quantitative real-time PCR was used to determine the messenger RNA (mRNA) levels of sterol regulatory element binding

proteins-1c (SREBP-1c), peroxisome proliferators activator receptors alpha (PPAR $\alpha$ ), fatty acid synthase (FASN), acetyl-CoA carboxylase (ACC), nuclear factor-erythroid 2-related factor 2 (Nrf2), nuclear factor kappa-B (NF- $\kappa$ B), and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) in LO2 cells. Total RNA was extracted from the cells using TRIzol Reagent according to the manufacturer's instruction. Then, total RNA was reverse-transcribed to complementary DNA (cDNA) using an SYBR<sup>®</sup> PrimeScript<sup>®</sup> RT-PCR Reagent Kit with genomic DNA (gDNA) Eraser (TaKaRa, Japan). The master mix (10  $\mu\text{l}$ ) included: PrimeScript RT Enzyme Mix I (1.0  $\mu\text{l}$ ), RT Primer Mix\*4 (1.0  $\mu\text{l}$ ), 5 $\times$ PrimeScript Buffer 2 (for real time) (4.0  $\mu\text{l}$ ), and RNase Free dH<sub>2</sub>O (4.0  $\mu\text{l}$ ). PCR amplification was performed as follows: stage 1, preheat denaturation at  $95^\circ\text{C}$  for 40 s, stage 2, circulatory system cycled 40 times at  $95^\circ\text{C}$  for 15 s, and  $58^\circ\text{C}$  for 1 min. The sequence of primers used for this reaction is provided in **Table 2**. Each sample was measured three times. The expression levels of the above genes were normalized to those of glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and measured by the comparative  $2^{-\Delta\Delta\text{Ct}}$  method.

## Western Blotting

Total protein was extracted from frozen LO2 cells by adding protein lysates (Beyotime Biotechnology Co, Ltd, Shanghai, China). Protein was quantified using the Bradford method (Thermo Fisher Scientific Inc, Rockford, IL). Total protein was separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (50  $\mu\text{g}$ ), and was then transferred to Millipore Corp, Billerica, MA membranes and sealed with 5% skim milk powder at  $37^\circ\text{C}$  for 1 h. Subsequently, rabbit anti-mouse monoclonal antibodies against PPAR $\alpha$ , SREBP-1c, FASN, Nrf2, and GAPDH (1:1,000; Abcam, Cambridge, MA) were added to the membrane and it was shaken at  $4^\circ\text{C}$  overnight. The membrane was washed with phosphate buffered saline with Tween (PBST) three times, for 5 min each time. Then, horseradish peroxidase-labeled goat anti-rabbit secondary antibody (1:4,000; Cell Signaling Technology, Danvers, MA) was added to the membrane and it was incubated at room temperature for 2 h. The membrane was washed twice using tris-buffered saline with Tween (TBST) for 10 min and was then treated with

**TABLE 2 |** Primers used for real time PCR (RT-PCR).

electrochemiluminescence (ECL) photoluminescence solution for imaging. ImageJ software was used to analyze the test results. The ratio of the gray value of the target band to the GAPDH reference band was used as the relative expression level of the protein. Each experiment was repeated three times.

## Statistical Analysis

The results are expressed as mean  $\pm$  standard error (SE). Multiple comparisons were performed using one-way analysis of variance (ANOVA) followed by Tukey's *post hoc* test. For all analyses, P values below 0.05 were considered to indicate statistical significance. Analyses were performed using SPSS 18.0 software for Windows.

## RESULTS

### Active Ingredient Targets and Disease Targets

As shown in **Table 3**, 14 active ingredients were collected from *V. baillonii* and 496 target proteins were found. Although the number of targets of each compound was different, the targets of the 14 active ingredients significantly overlapped. Topological analysis of protein-interaction network nodes, including screening of key nodes to eliminate duplicates, revealed a total of 287 target proteins. The constructed “composite target” network was used to evaluate the relationships between 287 targets, which had as many as 2,672 nodes. Targets associated with NAFLD were identified in the OMIM, DisGeNET, and GeneCards databases. In this study, 1,200 target genes of disease were retrieved, and 872 key nodes were obtained through screening.

### Target Network Analysis

All active compound protein targets and disease-related proteins were classified into two independent groups. The set and its relations were expressed in a closed-loop form with a fixed position to obtain a Venn diagram and 31 interacting proteins, as shown in **Figure 2A**. Proteins were obtained using String 11.0 and topological data analysis was conducted through CytoNCA,

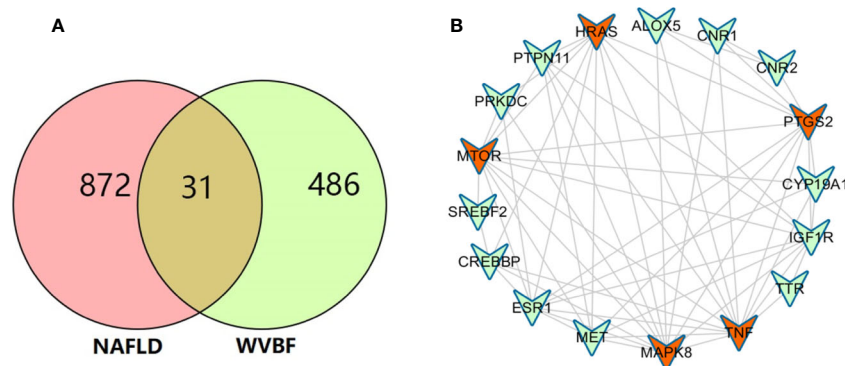

a plugin for Cytoscape, to obtain a network PPI of 17 key targets, as shown in **Figure 2B**. Through network prediction, it was found that TNF, MAPK8, mTOR, HRAS, and PTGS2 were important target genes in the first few degrees.

### Gene Ontology Function, Kyoto Encyclopedia of Genes and Genomes Pathway, and Localization Analysis of Key Targets

The GO functional analysis revealed that *V. baillonii* affected 17 potential key target genes of five main biological processes, including regulation of lipid metabolic process, positive regulation of nitric oxide biosynthetic process, positive regulation of fever generation, regulation of monooxygenase activity, and regulation of fatty acid metabolic process, as shown in **Figures 3A, B**. In addition, a visual analysis was performed on the top 20 signal pathways enriched by KEGG analysis (**Figure 3C**). KEGG enrichment analysis demonstrated that many target genes of *V. baillonii* were closely related to oxidative stress indices, inflammatory factors, the TNF signaling pathway, lipid metabolism, and other signaling pathways such as

**TABLE 3** | Information on 14 compounds of *Veratrilla baillonii*.

**FIGURE 2** | Target network analysis. **(A)** Venn diagram of active ingredient targets and disease proteins. **(B)** Fourteen active ingredients of *Veratrilla baillonii* and cross-critical disease targets. Blue represents the protein at the intersection of the active compound with the disease. Red is the active compound.

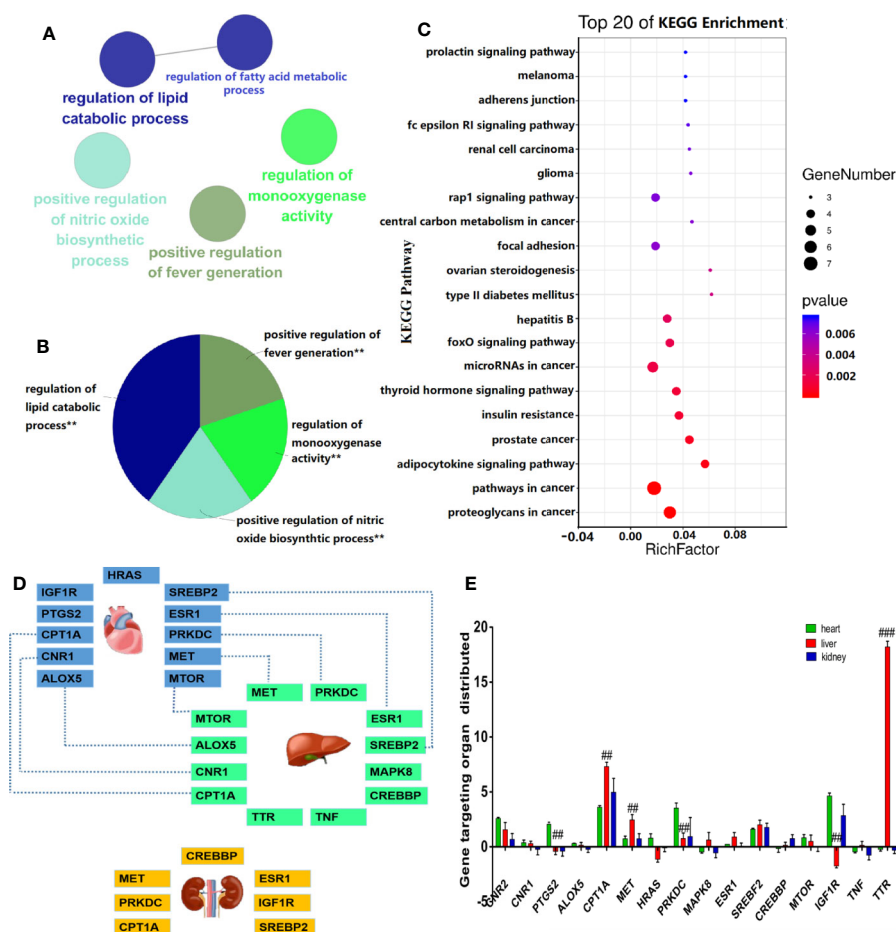

the AMPK signaling pathway and PI3K-Akt signaling pathway, among others.

Moreover, to study the relationship between *V. baillonii* and vital organs, the BioGps database was used. The above mentioned 17 key targets were imported in the BioGps database for organ positioning. The network was divided into several tissue modules, including liver (12 targets), heart (11 targets), and kidney (7 targets) (Figure 3D). The results of this analysis indicated that the targets of the active components of *V. baillonii* were closely related to lipid metabolism disorder. The majority of targets of *V. baillonii* were located in liver tissues (Figure 3E). Lipid metabolic disorders are considered to be one of the vital causes of NAFLD (Ziamajidi et al., 2013). Important target genes of TNF, MAPK8, mTOR, NF- $\kappa$ B, and PPAR $\alpha$  were mainly distributed in the “adipocytokine signaling pathway”. The AMPK pathway and insulin signaling pathway were the other important pathways. These results suggest that the molecular mechanisms of the most active compounds of *V. baillonii* are related to inflammation and lipid metabolism.

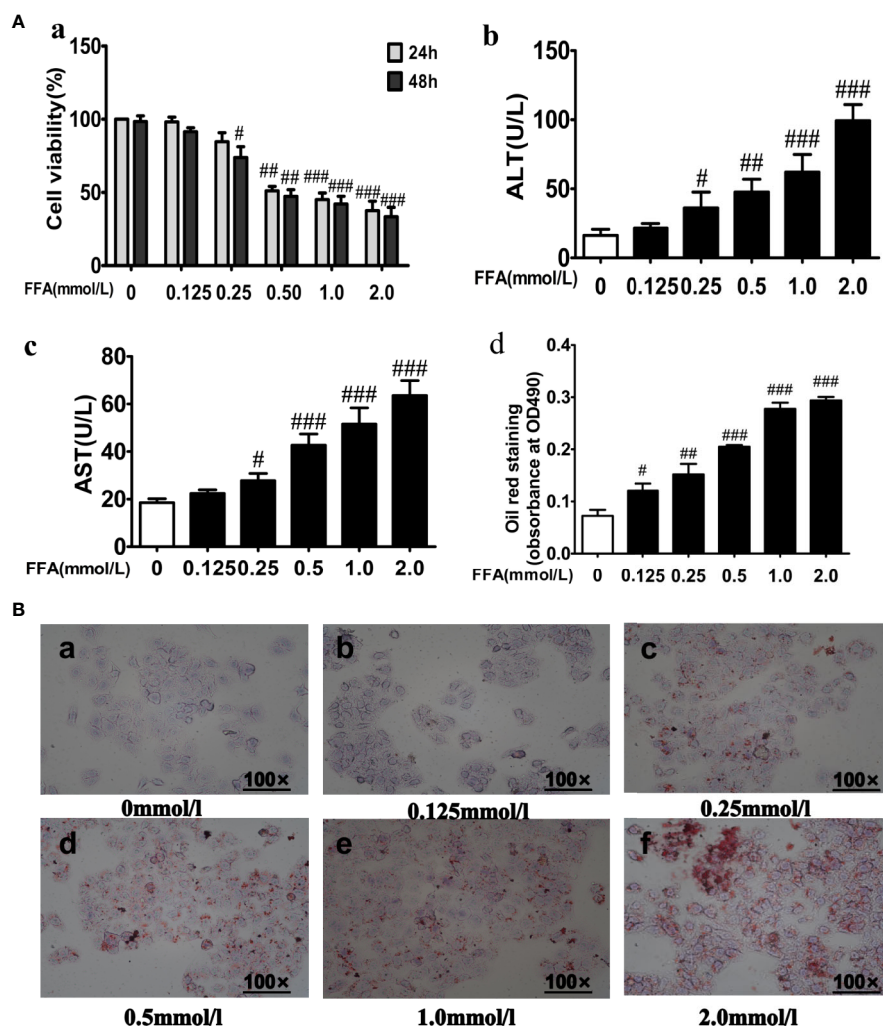

Based on these predictions and the available literature, experiment at the cellular level was conducted then to verified our hypothesis.

## Free Fatty Acids Reduced Cell Viability and Increased Lipid Accumulation in LO2 Cells

As shown in Figure 4Aa, FFA (0.125–2.0 mM) dose-dependently reduced the cell viability of LO2 cells after incubation for 24 or 48 h. A 0.5 mmol·L<sup>-1</sup> dose of FFA inhibited cell growth by more than 50% after 24 or 48 h. Furthermore, ALT and AST leakage were markedly increased in the FFA group compared with the control group (Figures 4Ab, Ac). As the concentration of FFA increased, the accumulation of red-stained lipid droplets in LO2 hepatic cytoplasm increased in a dose-dependent manner (Figures 4Ad, B). Then, a low cytotoxic dose of 0.5 mmol·L<sup>-1</sup> FFA was used and the shorter induction group was exposed for 24 h in the following experiment.

**FIGURE 3** | Bioinformatics analysis and localization analysis of key targets. **(A)** Gene ontology (GO) enrichment analysis of the hierarchical network diagram. **(B)** GO biological process enrichment analysis. **(C)** Enrichment analysis of Kyoto Encyclopedia of Genes and Genomes (KEGG) annotation signaling pathway. **(D)** Targeted organ localization analysis network. **(E)** The key gene expression in different tissues and organs ( $^{##}P < 0.01$ , and  $^{###}P < 0.001$ , liver vs. control heart or kidney.)

**FIGURE 4 |** Effects of free fatty acids (FFA) on cell viability and lipid accumulation in LO2 cells. **(A)** LO2 cells were exposure to the different concentrations of FFA for 24 or 48 h, cell viability (a), ALT (b), AST (c) and quantitative results of graph-B detected by spectrophotometer at OD490nm (d). **(B)** The effect of FFA on the lipid accumulation of LO2 cells.  $n=3$  ( $n$ , the number of experiment), ( $^{\#}P < 0.05$ ,  $^{##}P < 0.01$ , and  $^{###}P < 0.001$  vs. control group).

## Effects of Water Extract of *Veratilla baillonii* on Free Fatty Acids-Induced LO2 Cells

### Water Extract of *Veratilla baillonii* Elevated Cell Viability and Reduced Free Fatty Acids-Induced Cell Apoptosis

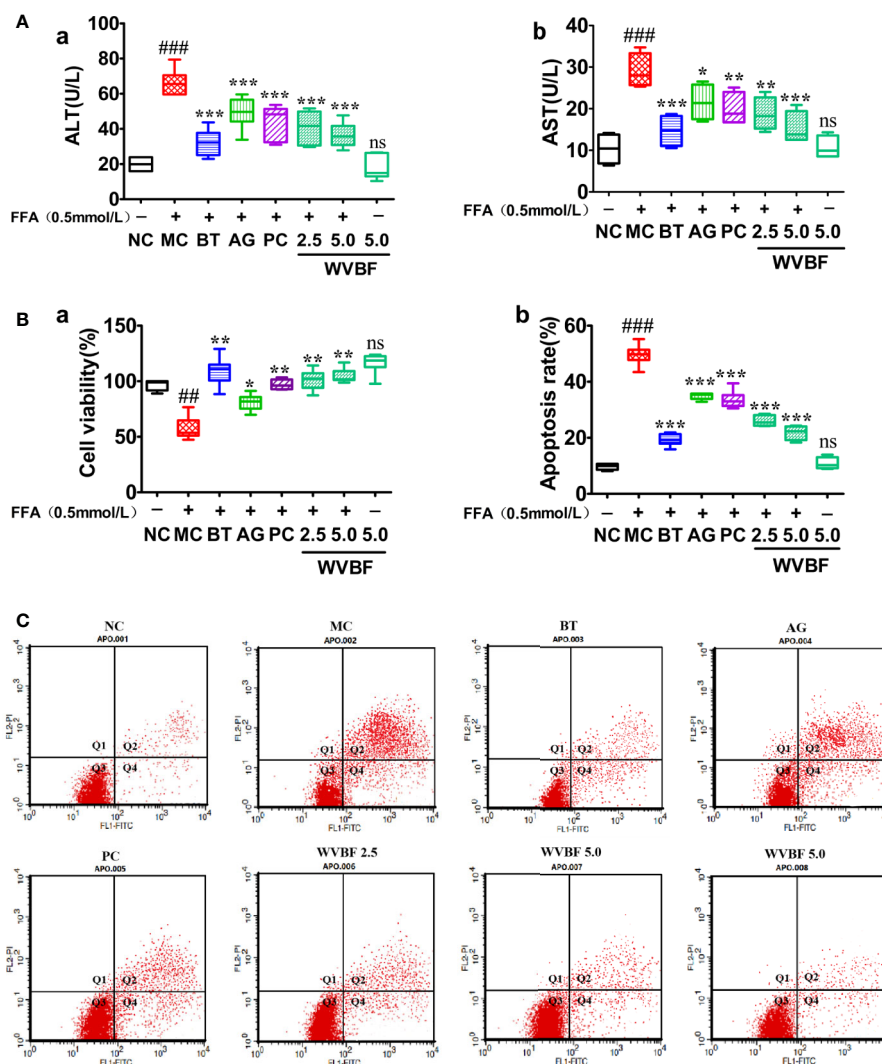

After 24 h of FFA treatment, ALT, AST levels in LO2 cells were significantly elevated, cell viability were significantly decreased. ALT, AST levels significantly decreased, the cell viability rates significantly increased in cells treated with WVBF, BT, AG, and PC (**Figures 5A, B**). Flow cytometry analysis showed that the increased cell apoptosis and cell necrosis rate induced by FFA could be significantly reduced by WVBF treatment in a dose-dependent manner (**Figure 5C**), indicating the protective effect of WVBF treatment on FFA-induced LO2 liver injury.

## Water Extract of *Veratilla baillonii* Attenuates Lipid Metabolic Risk Factors and Accumulation in Cells

FFA resulted in a steady increase in TG, TC levels in liver cells, and increased accumulation of fat droplets in the cytoplasm after incubated for 24 h. And the TG, TC levels could be significantly attenuated by WVBF, BT, AG, and PC (**Figures 6A, B**). Moreover, WVBF significantly reduced the FFA-induced accumulation of fat droplets in the cytoplasm after incubated for 24 h (**Figure 6B**). The high-dose of WVBF group exhibited the best efficacy and showed a specific dose-dependent enhancement. The above results indicate that WVBF regulate the lipids metabolism in cells, thus remission lipotoxicity induced hepatocyte injury.

Effects of Water Extract of *Veratilla baillonii* on Free Fatty Acids-Induced Oxidative Injury in LO2 Cells

**FIGURE 5 |** The effect of water extract of *Veratrum baillonii* (WVBF) on free fatty acids (FFA)-induced apoptosis and injury. **(A)** The cell viability was measured by the methylthiazolyl tetrazolium (MTT) assay, and the levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST). **(B)** Annexin V-FITC/PI and analyzed by flow cytometry (the upper right quadrant represents late apoptosis. The lower right quadrant represents early apoptosis). **(C)** Apoptosis rate (a) and necrotic cell rate (b).  $n = 3$  ( $n$ , the number of experiment), (### $P < 0.01$ , ### $P < 0.001$  vs. control group; \* $P < 0.05$ , \*\* $P < 0.01$ , and \*\*\* $P < 0.001$  vs. FFA group).

The exposure of the cells to FFA resulted in a significant decrease in T-SOD and GSH-PX level, increase in MDA and LPO levels, and produced stronger DCF signals compared to the control group. However, after WVBF, BT, AG, and PC treatment resulted in a marked reduction in DCF fluorescence, indicating an inhibitory effect of WVBF on FFA-induced intracellular ROS production. The above results show that WVBF has certain roles in antioxidation and regulation of oxidation (Figures 7A, B).

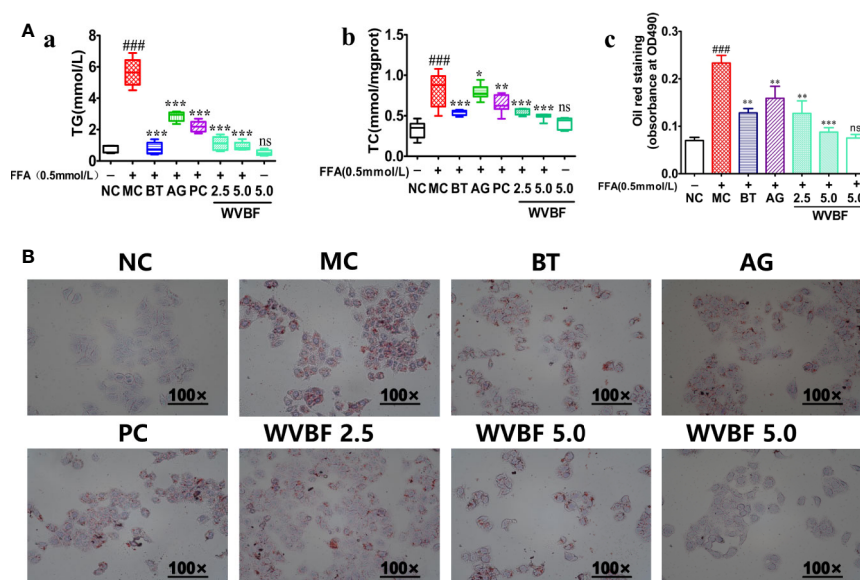

### Water Extract of *Veratrum baillonii* Regulated the PPAR $\alpha$ /SREBP/NF- $\kappa$ B Pathway

The key targets and important signaling pathways, including TNF, MAPK8, mTOR, and NF- $\kappa$ B targets and the adipocytokine signaling pathway, which were obtained from the network pharmacology analysis, were further explored and verified at the

cellular level. As shown in Figure 8A, FFA significantly up-regulated the mRNA levels of SREBP-1c, FASN, ACC, NF- $\kappa$ B, and TNF- $\alpha$  and down-regulated the mRNA levels of Nrf2 and PPAR $\alpha$ . The same trends were observed at the protein level (Figures 8B, C). However, those imbalances were significantly recovered by WVBF in a dose-dependent manner. The results were in accordance with the network analysis to some extent and provide evidence to support the view that activation of oxidative, inflammation, and lipid metabolism stress pathways are involved in a NAFLD cell model.

## DISCUSSION

Research on the efficacy and mechanism of traditional Chinese medicine (TCM) is critical to the modernization of Chinese

**FIGURE 6 |** Effect of water extract of *Veratilla baillonii* (WVBF) on lipid metabolic factors and lipid accumulation in LO2 cells. **(A)** Effect of WVBF on TG (a), TC (b), and quantitative results of graph-B detected by spectrophotometer at OD490nm (c) in LO2 cells. **(B)** Effect of WVBF on lipid accumulation in LO2 cells subjected to free fatty acids (FFA) (the deeper the red oil stain, the more lipid accumulation in the cell). (## $P < 0.01$ , ### $P < 0.001$  vs. control groups; \* $P < 0.05$ , \*\* $P < 0.01$ , and \*\*\* $P < 0.001$  vs. FFA group).

medicine (Hopkins, 2008). Many studies have shown that the effectiveness of TCM in the complex diseases depends on the synergistic effects of multiple compounds and their targets. Network pharmacology and system biology can explain the effects of drugs on biological network destruction from the perspective of macro or global regulation and provide new research ideas and technical means for studying the mechanism of ethnic drug compounds (Muhammad et al., 2018; Zhang Y. et al., 2018). In this study, the complexity of the active ingredients in *V. baillonii* and the diversity of potential regulatory targets in diseases were studied through network pharmacology analysis. The results revealed that the main active ingredients of *V. baillonii*, such as amarogentin, 1-hydroxy-2,3,7-trimethoxyxanthone, and 1,7-dihydroxy-3-methoxyxanthone, possess anti-inflammatory, antioxidant, and liver protection effects, among others. These findings are consistent with those reported in the literature. Clinical and pharmacological studies have found that *V. baillonii* has a variety of anti-inflammatory, antioxidant, antiviral, and liver protective effects in autoimmune diseases. It has remarkable efficacy in the treatment of pulmonary fever, enteritis, cholecystitis, hepatitis, and other diseases of the digestive system (Lian et al., 2010).

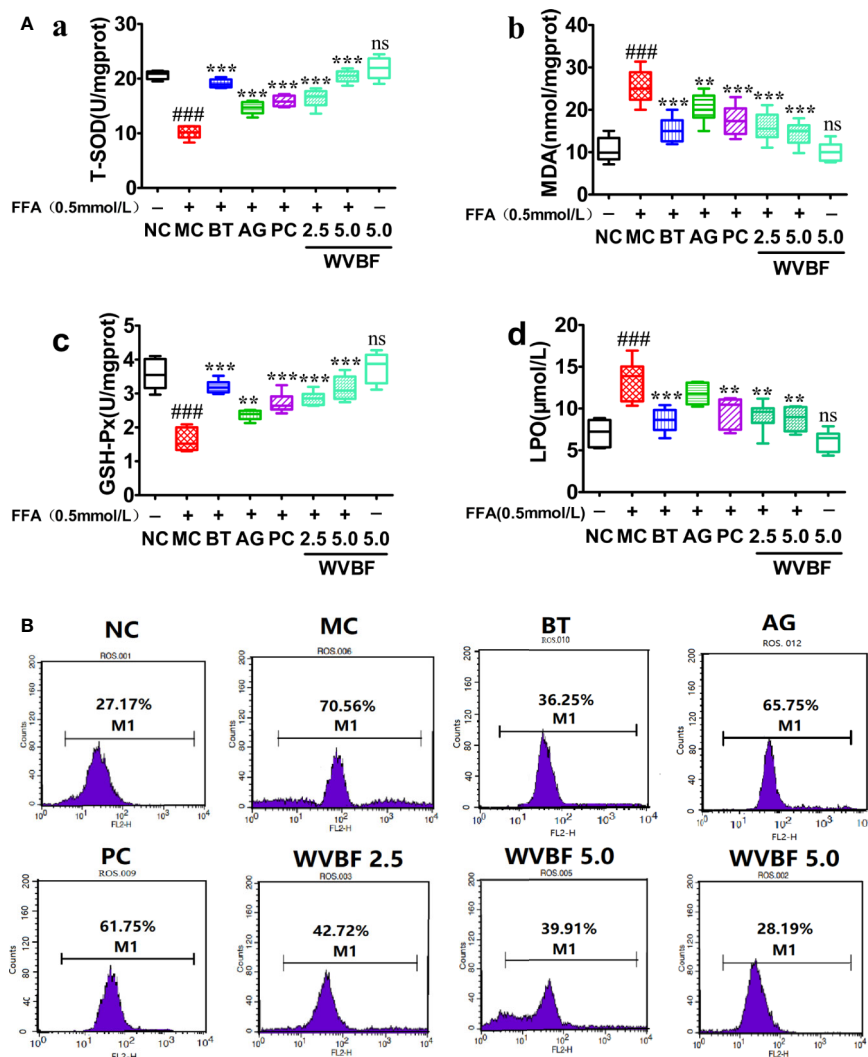

Based on the present results, a NAFLD cell model establishment by FFA-induced LO2 was preliminarily confirmed (Zhang et al., 2015; Zhang Y. et al., 2018; Mao et al., 2015). There are significant increases in ALT and AST levels in patients with fatty liver disease. In NAFLD patients, the levels of TG, and TC, indicators of blood lipids, are significantly increased (Chavez-Tapia et al., 2011). A previous study (Ge et al., 2016) reported that WVBF can decrease *Aconitum brachypodum*-induced acute toxicity in KM mice and

can protect liver tissue by decreasing the release of ALT, AST, and TG in serum. The present study also found that the levels of ALT, AST, TG, and TC in NAFLD model cells were significantly reduced after WVBF treatment, suggesting that WVBF can reduce FFA-induced steatosis injury and the accumulation of lipids in hepatocytes.

Oxidative stress plays an essential role in the regulation of NAFLD from steatosis to steatohepatitis, liver fibrosis, and cirrhosis (Izdebska et al., 2017). Oxidation of fatty acids is considered to be an important source of ROS in fatty liver. ROS can attack a variety of unsaturated fatty acids and induce lipid peroxidation in cells, results in the formation of aldehyde byproducts, such as MDA (Takaki et al., 2013). These molecules can spread inside and outside the cell and accelerating the effects of oxidative stress. Our previous study (Yu et al., 2016) found that WVBF has antioxidant effects which are related to the amarogentin components in WVBF. The current study also confirmed that WVBF has a significant antioxidant effect.

The Nrf2 signaling pathway is an important mechanism of cell resistance to oxidative stress. It can regulate the expression of liver detoxification and antioxidant defense genes (Kathirvel et al., 2010). Preliminary results indicate that WVBF can regulate the NRF2 pathway, WVBF treatment of NAFLD cells increased intracellular Nrf2 expression in a dose-dependent manner, suggesting that the antioxidant potential of WVBF could be an important mechanism for improving liver function of NAFLD cells, which is similar to the results of our previous study (Dai et al., 2018).

PPAR $\alpha$  plays an essential role in fat synthesis (Qiao et al., 2013). The SREBP-1c subtype is a key regulatory element in the

**FIGURE 7 |** Effects of water extract of *Veratrilla baillonii* (WVBF) on free fatty acids (FFA)-induced oxidative stress and intercellular reactive oxygen species (ROS) production in LO2. **(A)** Effects of WVBF pre-treatment on T-SOD (a), MDA (b), GSH-Px (c), LPO (d) product in LO2. **(B)** Flow cytometry analysis of FFA-induced ROS.  $n=3$  ( $n$ , the number of experiments), (### $P < 0.01$ , ### $P < 0.001$  vs. control group; \* $P < 0.05$ , \*\* $P < 0.01$ , and \*\*\* $P < 0.001$  vs. FFA group).

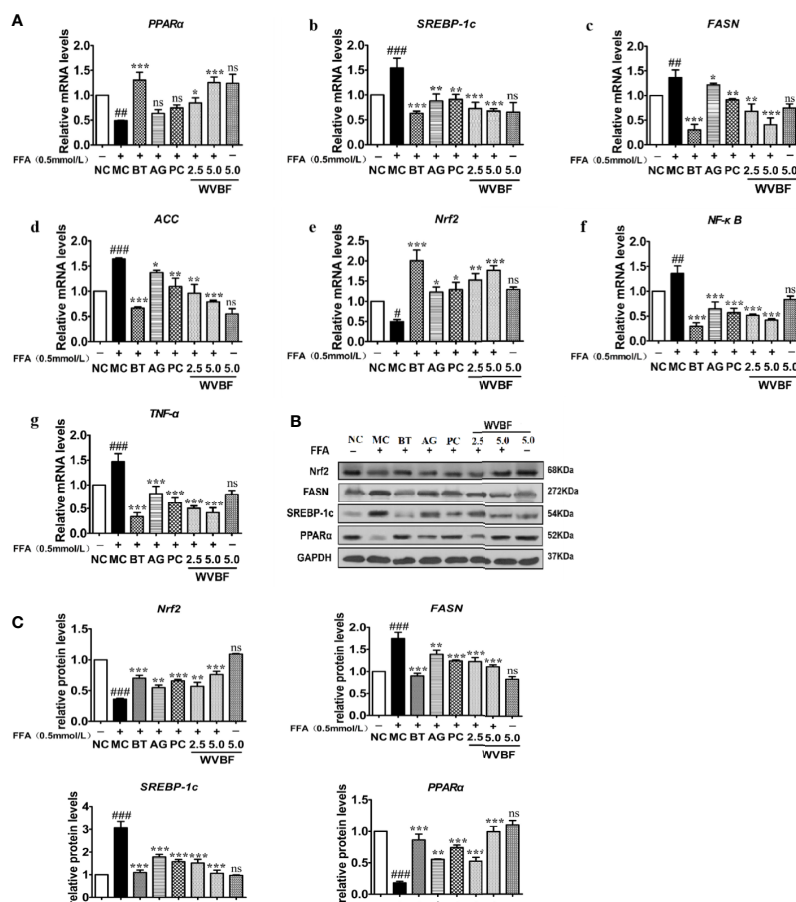

process of lipid synthesis. Its downstream factors include acetyl-CoA carboxylase (ACC) and fatty acid synthase (FAS), which are essential enzymes for fat production (Kanuri and Bergheim, 2013). FFA treatment enhanced the expression of PPAR $\alpha$  and decreased the expression of SREBP-1c in FFA-exposed NAFLD model cells, indicating that WVBF activated the PPAR $\alpha$  pathway and inhibited the expression of the SREBP-1c/ACC/FAS pathway.

Inflammation is another important factor mediating the pathogenesis of NAFLD (Zhou et al., 2018). TNF- $\alpha$ , a pro-inflammatory cytokine, is involved in the pathogenesis of NAFLD (Parafati et al., 2018). Continuous accumulation of fatty acids activates the NF- $\kappa$ B pathway, promoting the release of inflammatory cytokines and causing inflammation (Cheng et al., 2019). In the current study, WVBF inhibited the increased expression of NF- $\kappa$ B and TNF- $\alpha$  induced by FFA, thereby reducing the liver inflammation reaction in the cell.

Together, the above findings indicate that WVBF treatment can significantly reduce FFA-induced lipid metabolism disorder, oxidative stress, and the inflammatory response in LO2 cells by activating PPAR $\alpha$  and inhibiting fat synthesis of the SREBP-1c/FASN/ACC pathway. This ameliorates the symptoms of NAFLD and plays a role in protecting the liver (Figure 9). These results are consistent with our predicted target and signaling network analysis.

## CONCLUSION

This study revealed the potential active compounds and the protective action of *V. baillonii* in a NAFLD cell model. WVBF inhibited oxidative stress and the inflammatory response, and reduced lipid metabolism disorder through various signaling pathways, suggesting that *V. baillonii* may be a candidate drug

**FIGURE 8** | Effect of water extract of *Veratilla baillonii* (WVBF) on non-alcoholic fatty liver disease (NAFLD) lipid, oxidative stress, and inflammation of free fatty acids (FFA)-induced cell. **(A)** Effect of WVBF on the expression of PPARα (a), SREBP-1c (b), FASN (c), ACC (d), Nrf2 (e), NF-κB (f), and TNF-α (g) messenger RNA (mRNA). **(B)** Protein expression of PPARα, SREBP-1c, fatty acid synthase (FAS), acetyl-CoA carboxylase (ACC), and Nrf2 in FFA-induced LO2 cell was detected by western blot. **(C)** Effect of WVBF on the expression of Nrf2, ACC, FASN, SREBP-1c, and PPARα protein.  $n = 3$  ( $n$ , the number of experiment), ( $^{##}P < 0.01$ ,  $^{###}P < 0.001$ , vs. control group;  $^{*}P < 0.05$ ,  $^{**}P < 0.01$ , and  $^{***}P < 0.001$  vs. FFA group).

**FIGURE 9** | The protective mechanism of water extract of *Veratilla baillonii* (WVBF) on free fatty acids (FFA)-induced non-alcoholic fatty liver disease (NAFLD) LO2 cells.

for the treatment of NAFLD. Since NAFLD is a very complex condition in which many factors are involved, lipid accumulation in LO2 liver cells induced by fatty acids can only partially represent NAFLD condition. Further studies are needed to determine the regulatory effect and mechanism of WVBF in animal models of NAFLD.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## AUTHOR CONTRIBUTIONS

X-JH and C-JH conceived the study, participated in its design and coordination, and helped draft the manuscript. C-JH and SL

carried out the experiments and drafted the manuscript. JW carried out the network study. JL and G-ZY carried out the chemical analysis of the WVBF, and ZZ participated in the design of the study and performed the statistical analysis. All authors contributed to the article and approved the submitted version.

*Datura metel* Linn is used traditionally for the treatment of various diseases including relaxation of smooth muscles, relief of fever, as well as gastrointestinal disorder. This study deals with the bio-guided isolation of an active, amyrin-type triterpenoid, namely 3-oxo-6- $\beta$ -hydroxy- $\beta$ -amyrin (daturaolone; **1**), from the chloroform fraction of *Datura metel* L. (Angel's trumpet) fruits and its gastrointestinal motility, antipyretic, and muscle relaxation effects in animal models. The chemical structure of daturaolone (**1**) was elucidated by NMR spectroscopy and crystallography techniques. The chloroform fraction and daturaolone (**1**) were assessed for the GIT motility test. Data exhibited in charcoal meal GI transit test show that chloroform fraction and daturaolone (**1**) significantly reduce GIT motility and increased intestinal transit time, comparable to the standard (atropine), a muscarinic receptor blocking agent. Muscle relaxant potency of the extract and daturaolone (**1**) was assessed in various animal paradigms. In the inclined plane screening test, it produced a significant ( $P < 0.05$ ) muscle relaxation potential in a dose-dependent manner after 30, 60, and 90 min. Likewise, the muscle relaxation potential of the extract and daturaolone (**1**) was strongly complemented by the chimney and traction test, representing a dominant effect after 60 min of sample administration. The chloroform fraction showed good antipyretic activity, and while daturaolone (**1**) exhibited significant activity at a higher dose, the maximum effect (84.64%) was at 20 mg/kg i.p. In acute toxicity screening test, the chloroform extract (100, 250, 500, and 1,000 mg/kg) and daturaolone (**1**) (5, 10, 20, and 50 mg/kg) were found safe. In conclusion, the chloroform extract and daturaolone (**1**) exhibited strong gastrointestinal motility, muscle relaxation, and antipyretic activity in different animal models and intestinally, was found safe at higher tested doses.

**Keywords:** *Datura metel*, daturaolone, gastrointestinal motility, antipyretic activity, muscle relaxation activity

## INTRODUCTION

*Datura metel* is a member of the family Solanaceae and is an erect shrub with spreading branches. The plant has a local name in Bengali called Dhutura. *D. metel* grows throughout the year and is commonly known as Devil's Trumpet in English (Duke and Ayensu, 1985; Dabur et al., 2004). It grows in both hot and humid climate. The plant also has an American origin and is widely distributed in Pakistan, India, South America, and Africa (Sangwan and Camefort, 1983). It has long flowers having purple and white colors which scented up to 6" (Okwu and Igara, 2009), while the leaves are broad in shape and dark green in color. *D. metel* is 10–20 cm long and 5–18 cm broad. Its fruits are spiny capsules in nature with a thickness of 4–10 cm. *D. metel* is widely used in Bangladeshi herbal medicine (Monira and Munan, 2012). In Chinese traditional system, its flowers are known as baimantuolu which are used for the treatment of psoriasis and inflammation of the skin (Wang et al., 2008; Monira and Munan, 2012). In Ayurvedic medicinal systems, its seeds are used to cure ulcers, jaundice, diabetes, skin rashes, and bronchitis (Monira and Munan, 2012). Further to these uses, its flowers are involved in cigarette production, while the seeds are used in making tea with potent sedative action in Brazil (Agra et al., 2007). It is also used for the treatment of heart disease, epilepsy, diabetes, insanity, fever, diarrhea, asthmatic anesthetic, hallucinogenic, anti-asthmatic, hypnotic, antitussive, bronchodilator, anodyne narcotic, and skin diseases (Chopra et al., 1956; Chopra et al., 1986; Monira and Munan, 2012). The bioactivities of *D. metel* are due to secondary metabolites present in it. *D. metel* is well documented to contain varieties of potent secondary metabolites including alkaloids, steroids, saponins, flavonoids, triterpenoids, and tannins (Okwu and Igara, 2009). Various types of alkaloids have been detected in different parts of *D. metel*; the numbers of alkaloids increase with the age of the plant (Afsharypuor et al., 1995; Monira and Munan, 2012). The important compounds of *D. metel* are tropane alkaloids including hyoscyne, hyoscyamine, littorine, valtropine, acetoxytropine, fastusine, and various withanolides as well as a number of trigloyl ester of tropine (Afsharypuor et al., 1995; Monira and Munan, 2012). An alkaloid known as scopolamine, a major compound isolated from *D. metel*, has been documented for curing various diseases including bronchitis and asthma (Dabur et al., 2004). Other tropane alkaloids isolated from *D. metel* are used as antispasmodic, mydriatic, and sedative agents (Nuhu, 2002). It is also an important source of withanolides, which is used to cure pain and has hallucinogenic potency (Abubakar et al., 2009; Yang et al., 2014; Arjun et al., 2015). The seeds of *D. metel* are used to relieve dental pain. Also, it has wide applications in ayurvedic medication such as the ability to cure hair fall and other skin-related infectious diseases (Soni et al., 2012). The plant extracts of *D. metel* have been documented for antimicrobial and anti-inflammatory properties (Akharaiyi, 2011; Alabri et al., 2014). In this context, atropine isolated from the title plant has been used to dilate the pupil, and it helps in the surgery of the eyes (Satyavati and Raina, 1977). The current study deals with the isolation of a triterpenoid, namely daturaolone (1), and the *in vivo* gastrointestinal motility, antipyretic, and muscle relaxation as well as acute toxicity study of the chloroform extract and the isolated daturaolone (1).

## MATERIAL AND METHODS

### Plant Material Collection

Fruits of *Datura metel* (Angel's trumpet) were obtained from the ground of Razagram (Khall, Distt; Dir, KPK, Pakistan). The plant specimen was identified by Dr. Muhammad Ilyas, Head of the Department of Botany, University of Swabi, KPK, Pakistan. The voucher specimen no. Bot (UOS-521) was deposited at the herbarium of the Botany Department, University of Swabi.

### Extractions, Fractionation, and Isolation

The fruits (8.2 kg) were dried in a shade at room temperature, ground into powder and then subjected to cold extraction with methanol (×3), which yield 349 g of reddish extract. The extract was suspended in distilled water and then successively extracted with *n*-hexane (52.8 g), chloroform (93.6 g), and ethyl acetate (45.1 g) as per reported methods (Bawazeer et al., 2019). Based on the TLC profile, the chloroform extract (25.0 g) was chromatographed on the silica gel normal phase column. The column was eluted with a mixture of *n*-hexane and ethyl acetate (0:100) of increasing polarity order. One hundred sub-fractions were obtained, which were combined to 12 major sub-fractions (SB-1–SB-12), as per the TLC profile. Based on the TLC profile, SB-7 was subjected to frequent pencil column chromatography (CC), eluting with *n*-hexane and ethyl acetate (14:86), which yielded white crystals. The obtained crystals were washed with *n*-hexane to afford daturaolone (1) (2.7 g; 99.87% pure). The chemical structure of daturaolone (1) was elucidated by advanced spectroscopic technique. The structure was confirmed by crystallography technique (Figure 1), and the spectral data were compared with the reported ones (Wang et al., 2005).

### Animals

Balb/c mice of either sex, weighing 18–22 g were used throughout this work. These animals were placed under standard laboratory conditions. All animals were served with standard laboratory diet and *ad libitum* water. Experiment was performed at the Pharmacy Department University of Swabi as per standard procedure. Studies involving human participants were reviewed and approved by the ethical committee UOS/Pharm-649, Department of Pharmacy, University of Swabi, Swabi, Pakistan.

### Gastrointestinal Motility Test

The chloroform fraction and daturaolone (1) were assessed for gastrointestinal motility screening test. In these tests, mice were divided into six groups ( $n = 6$ ). The 1<sup>st</sup> group received normal saline (10 ml/kg) and acted as a negative control; the 2<sup>nd</sup> group was administered with the reference drug (atropine; 10 mg/kg, i.p.). The remaining groups were treated with chloroform fraction at the doses 10, 25, 50, 100, and 200 mg/kg, i.p. and daturaolone (1) at the doses 2.5, 5, 10, 20, and 40 mg/kg, i.p. After 15 min of treatment, every animal received a 0.3 ml charcoal meal in the form of a suspension in water with 10% vegetable charcoal and 10% gum acacia. Exactly after 30 min of

**FIGURE 1** | Chemical structure and x-rays' crystallographic image of daturaolone (**1**) isolated from *Datura metel*.

the above administration, all animals were sacrificed by cervical dislocation, and the whole small intestine was detached. Experiments were performed in triplicate, and the percent activity was measured from the distance traveled by charcoal in the small intestine as per our previous methods (Rauf et al., 2016a; Ahmad et al., 2018).

## Muscle Relaxation Assay

The muscle relaxation activity of the chloroform fraction and daturaolone (**1**) was performed using the chimney and inclined plane model according to the standard method (Rauf et al., 2018).

### Chimney Model

Muscle relaxation potency of chloroform fractions and daturaolone (**1**) was performed according to our reported procedure (Rauf et al., 2018). In this model, a pyrex tube having a diameter of 3 cm and length of 30 cm was used. The design tube was marked 22 cm from the base, and the treated mice were allowed to muscle relaxant traits after 30, 60, and 90 min. The animals were divided into various groups ( $n = 6$ ). Animals in one group were fed with distilled water (10 ml/kg), one group with diazepam (1 mg/kg) as a standard drug, and the remaining animals with chloroform fractions at the doses 10, 25, 50, 100, and 200 mg/kg, i.p. and daturaolone (**1**) at doses 2.5, 5, 10, 20, and 40 mg/kg, i.p. All groups of treated animals were allowed at the one adjacent of the tube and then permitted to move rising from the base to the marked position at 20 cm. When the animals reached the mark then we directly converted the tube to vertical. Those animals which fail to climb to the 20 cm mark of the glass tube in 30 s were counted as animals with muscle relaxation potential.

### Traction Model

The muscle relaxation effect of chloroform fractions and daturaolone (**1**) was performed according to our reported traction methods (Rauf et al., 2018). These methods were designed by using a metallic wire coated with rubber, and both sides of the wire were connected with a stand around 60 cm upstairs of the laboratory bench. Different groups of animals ( $n = 6$ ) were fed with distilled water (10 ml/kg), diazepam (1 mg/kg), and the chloroform extract and isolated daturaolone (**1**) (2.5, 5,

10, 20 mg/kg i.p.). Then all the animals were open to traction testing after 30, 60, and 90 min. All groups of animals were suspended by back legs to the attached wire then hanging time was recorded for less than 5 s. Failure of each animal to hang to the wire indicated muscle relaxant potency. The activity was performed again and again to calculate the muscle relaxant potency according to reported methods (Rauf et al., 2018).

### Inclined Plane Model

This model was also used to check the muscle relaxation effect of chloroform fractions and daturaolone (**1**) as per the published method (Rauf et al., 2018). The inclined plane used in this method consisted of two plywood boards which were joined in such a pattern that one plywood board was from the base and the other with the base at 65°. Animals were divided into various groups ( $n = 6$ ); each group was administered with distilled water (10 ml/kg), standard drug (1 mg/kg), chloroform fraction at the doses 10, 25, 50, 100, and 200 mg/kg, i.p., and daturaolone (**1**) at the doses 2.5, 5, 10, 20, 40 mg/kg, i.p. After 30, 60, and 90 min of the administration, animals were permitted on the higher portion of the inclined plane for 30 s to hang or fall.

### Yeast Induced Antipyretic Activity

The antipyretic effect of chloroform extract and daturaolone (**1**) isolated from the title plant was evaluated using a standard procedure (Muhammad et al., 2012). Animals were distributed into various groups ( $n = 6$ ). All groups of animals were subjected to fasting and allowed free access to drinking water. Among the divided groups, Group I received saline (control), Group II received the standard drug (Paracetamol), while the remaining groups (III–VII) received the fraction at different doses 10, 25, 50, 100, and 200 mg/kg, and daturaolone (**1**) at 2.5, at 10, 15, and 20 mg/kg. The normal temperature was noted with the help of a numerical thermometer, and then pyrexia was induced in all groups of animals by introducing aqueous suspension (20%) of Brewer's yeast (10 ml/kg, s.c.). After 24 h, the rectal temperature was noted and groups (III–VII) were administered with the above doses. After drug administration, the rectal temperature was once more noted periodically at 1, 2, 3, 4, and 5 h of drug administration. The percent effect was calculated using our previous formula (Muhammad et al., 2013).

## Toxicological Screening

The acute toxic effect of chloroform fraction and daturaolone (**1**) was performed in mice of both sexes as per our standard method (Rauf et al., 2016a). To find the toxicological profile of the extract and daturaolone (**1**), mice were starved for 16 h earlier to the experiment. All animals were divided into various groups ( $n = 6$ ). Group I (Control group) was fed with normal saline (10 ml/kg). The remaining animals were treated with chloroform fraction in various doses (50, 100, 250, 500, and 1,000 mg/kg, (p.o.) and daturaolone (**1**) at (10, 25, 50, 100, 250, 500 mg/kg, (p.o.). Treated mice were then allowed free access to water and food and were noted for gross behavior change as well as mortality for 24 h.

## Statistical Analysis

All results of this biological screening are presented as the mean  $\pm$  standard error of the mean (SEM). To find the level of significant differences ( $p < 0.05$  or  $0.01$ ) among the experimental groups, One-way analysis of variance (ANOVA) was achieved by Dunnett's multiple comparison test.

## RESULTS AND DISCUSSION

### Structure Elucidation

Daturaolone (**1**) was isolated from chloroform fraction and identified as 3-oxo-6 $\beta$ -hydroxy- $\beta$ -amyrin by different spectroscopic techniques.

Daturaolone (**1**) was isolated as white crystals; IR (KBr,  $\text{cm}^{-1}$ )  $\nu_{\text{max}}$  = 1599 (C=C), 1699 (C=O), 2,918 (C-H), 3,650 (OH).  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ ):  $\delta$  0.83 (s, 3H,  $\text{CH}_3$ -28), 0.85 (s, 6H,  $\text{CH}_3$ -29,  $\text{CH}_3$ -30), 1.08 (s, 3H,  $\text{CH}_3$ -27), 1.15 (s, 3H,  $\text{CH}_3$ -23), 1.22 (t, 2H,  $\text{CH}_2$ -22), 1.32 (s, 3H,  $\text{CH}_3$ -26), 1.40 (s, 3H,  $\text{CH}_3$ -24), 1.49 (s, 3H,  $\text{CH}_3$ -25), 1.53 (s, 2H,  $\text{CH}_2$ -7), 1.62 (t, 2H,  $\text{CH}_2$ -15), 1.64 (d, 1H, CH-5), 1.65 (d, 2H,  $\text{CH}_2$ -19), 1.67 (t, 1H, CH-18), 1.76 (m, 2H,  $\text{CH}_2$ -11), 1.98 (t, 2H,  $\text{CH}_2$ -16), 2.06 (t, 1H, CH-5), 2.22 (3, 2H,  $\text{CH}_2$ -1), 2.73 (3, 2H,  $\text{CH}_2$ -2), 4.49 (brs, 1H, CH-6), 5.24 (s, 1H,  $\text{CH}_2$ -12);  $^{13}\text{C}$  NMR (125 Hz,  $\text{CDCl}_3$ ):  $\delta$  16.5 ( $\text{CH}_3$ -19), ( $\text{CH}_3$ -19),

18.6 ( $\text{CH}_3$ -26), 23.6 ( $\text{CH}_3$ -11, 24), 23.9 ( $\text{CH}_3$ -30), 25.8 ( $\text{CH}_3$ -23), 25.9 ( $\text{CH}_3$ -27), 26.1 ( $\text{CH}_2$ -15), 26.9 ( $\text{CH}_2$ -16), 28.3 ( $\text{CH}_3$ -28), 31.0 (C-20), 32.8 (C-17), 33.3 ( $\text{CH}_3$ -29), 34.0 ( $\text{CH}_2$ -21), 34.4 ( $\text{CH}_2$ -2), 36.3 (C-10), 37.0 ( $\text{CH}_2$ -22), 39.0 (C-14), 40.6 ( $\text{CH}_2$ -1), 41.6 ( $\text{CH}_2$ -7), 42.5 (C-8), 46.7 ( $\text{CH}_2$ -19), 47.3 (CH-9, 18), 48.7 (C-4), 56.5 (CH-5), 69.3 (CH-6), 121.2 (CH-12), 144.5 (C-13), 216.6 (C-3), ppm; HRMS (ESI)  $m/z$ : calcd. for  $\text{C}_{30}\text{H}_{48}\text{O}_2$   $[\text{M}]^+$  440.3710, found 440.3700. The spectroscopic data were compared to those published in the literature for the known compound and were found identical (Wang et al., 2005; Rauf et al., 2016b); furthermore, the daturaolone (**1**) was confirmed by X-ray crystallography data (Figure 1).

### Effect on GIT Motility

Results of the GIT motility test of the extract and daturaolone (**1**) are given in Figures 2, 3. A significant movement of the charcoal meal was recorded in the intestine of mice due to chloroform at a dose of 200 mg/kg; similarly, daturaolone (**1**) exhibited excellent movement of the charcoal meal at a dose of 20 mg/kg. The normal saline was used as a positive control. The tested fraction attenuated the movement of charcoal 60% as compared to normal saline, and the positive control demonstrated 24% motility (Figure 2). Multiple comparison screening tests indicated that the extract and daturaolone (**1**) at a dose of 200 and 20 mg/kg significantly reduce the GIT motility (Figure 3).

### Muscle Relaxant Effect

In both muscle relaxant testing paradigms, the chloroform fraction and tested daturaolone (**1**) demonstrated a significant muscle relaxant effect (Tables 1, 2). Dose- and time-dependent effects were noticed. The effect of chloroform fraction was 49.32% in both tested experimental paradigms. The muscle coordination activity of daturaolone (**1**) was greater than that of chloroform fraction. The isolated daturaolone (**1**) also demonstrated a significant dose- and time-dependent effect. However, the effect of daturaolone (**1**) was highly significant from the start of the experiment as compared to the chloroform fraction.

**FIGURE 2** | Bar diagram indicated the GIT motility profile of chloroform extract in a dose-dependent manner of charcoal meals through small intestine of mice.

**FIGURE 3** | Bar diagram indicated the GIT motility screening profile of daturalone (1) in dose-dependent method of charcoal meals through the small intestine of mice.

**TABLE 1** | Effect of chloroform fraction and daturaalone (1) on relaxation of muscles.

The data of muscle relaxant effect represented the % activity of mice ( $n = 6$ ) in both models, at 30, 60, and 90 min after administration of samples. The data is represented as the mean ± SEM ( $n = 6$ ); \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ ; all values as related with control.

## Antipyretic Effect

Post treatment of chloroform fraction and daturaolone (1) showed a significant ( $p < 0.001$ ) antipyretic activity in febrile mice during different assessment times (1–5 h). The promising antihyperthermia activity (66.98% was recorded for chloroform fraction at 200 mg/kg i.p., while for daturaolone (1) was (78.98%) at 20 mg/kg i.p. after 3 h of sample administration (Figures 4, 5).

## Acute Toxicity

The acute toxicity of chloroform fraction was screen in doses, 100, 250, 500, and 1,000 mg/kg. During 24 h assessment no toxicity was observed. Similarly, daturaolone (1) in doses of, 5, 10, 20, and 50 mg/kg showed no mortality during 24 h of assessment. Neither gross behavior changes nor mortality was observed for the extract and daturaolone (1).

Pretreatment with chloroform fractions and daturaolone (1) caused marked ( $P < 0.05$ ) dose-dependent decrease in distance traveled by charcoal meal and showed a remarkable increase in GI transit time. The percent activity exhibited significant effect of extract and daturaolone (1) isolated from the title plant. When

investigated in charcoal meal gastrointestinal transit, the extract and daturaolone (1) caused a dose-dependent decrease in the propulsive association of charcoal and displayed strong GIT motility effects as compared to atropine sulfate, a muscarinic receptor blocking agent. It has been reported that blockage of muscarinic receptors in the GIT has a promising effect on the GIT smooth muscle motility. Normally, tone and propulsive moments are diminished, thus causing an increase in the intestinal transit time (Rauf et al., 2016a). Consequently, it is recommended that anti-GIT motility of chloroform fraction and daturaolone (1) may be due to the blockage of muscarinic receptors in the GIT. In short, the chloroform fraction and daturaolone (1) isolated from title plant provoked a strong decrease in GIT motility with significant safety in initial studies. More studies are required to ascertain clinical utility.

*In vivo* traction test, chimney test, and inclined plane screening test are the most widely used tools for evaluation of muscle relaxant activity (Rauf et al., 2014). Results of the current finding indicated a strong potential of title plant fraction and daturaolone (1) for muscle relaxation. The muscle relaxation

FIGURE 4 | Percent antipyretic effects of chloroform extract in yeast induced test at various doses.

FIGURE 5 | Percent antipyretic effects of daturaolone (1) in yeast-induced test at various doses. All values are represented as the mean  $\pm$  SEM for all groups of six animals.

effect of chloroform fractions and daturaolone (**1**) isolated from the title plant is displayed in **Table 1** and **Figure 1**. The tested fraction and isolated daturaolone (**1**) exhibited marked muscle relaxation in several animal models such as traction test, chimney test, and inclined plane model. Muscle relaxation effect of the extract and isolated daturaolone (**1**) was assessed in several muscle relaxant paradigms including traction test, chimney test, and inclined plane model. In these models, the muscle relaxant efficiency was assessed after 30, 60, and 90 min of treatment of chloroform fractions and daturaolone (**1**). Significant activity was observed after 60 min of chloroform fractions and daturaolone (**1**) administration. In all tested model the maximum muscle relaxation was noted at a higher dose. It is concluded that chloroform extract and daturaolone (**1**) exhibited promising muscle relaxation effects in various *in vivo* protocols. The hypodermic injection of brewer's yeast induced pyrexia by eventually increasing the synthesis of prostaglandin, and this method is considered the most important *in vivo* analysis test for the evaluation of antipyretic activity (Bertram, 2007; Rauf et al., 2014). Yeast-induced pyrexia is known as non-pathogenic fever, the etiology of which is the making of prostaglandin (PG). Inhibition of PG synthesis may be the potential mechanism of antipyretic potency; that of paracetamol the inhibition of prostaglandin can be attained by blocking the cyclooxygenase enzyme effect (Rauf et al., 2014; Barkatullah et al., 2016). The promising antipyretic effect of chloroform fractions and daturaolone (**1**) is associated with numerous mediators based on pyrexia, mainly prostaglandins (Islam et al., 2015; Barkatullah et al., 2016). The intraperitoneal administration of chloroform fractions and daturaolone (**1**) remarkably attenuated the rectal temperature of yeast-induced febrile mice. Therefore, it can be concluded that chloroform fractions and daturaolone (**1**) interface with the synthesis/release of PG at any stage. We recommend chloroform extract and daturaolone (**1**) to researchers for further detailed and careful studies as potential plants for the controlling of various diseases. The promising gastrointestinal motility, muscle relaxation, antipyretic effects of chloroform fractions and isolated daturaolone (**1**) provide a strong scientific background to the traditional uses of *Datura metel* in the treatment of fever and muscle relaxation.

## CONCLUSIONS

Phytochemicals can afford an excellent pharmacophore template for novel drug discovery which is used for the cure of many

diseases. The crude extract/fraction and the isolated compound, daturaolone (**1**) exhibited significant gastrointestinal motility cessation, muscle relaxation, antipyretic effects. The fractions and daturaolone (**1**) were found safe when tested in a wide range of doses for acute toxicity. However, its safety and effect should further be assessed in chronic disease animal models. Thus daturaolone (**1**) could be used as lead compound for new drug development for fever, muscle relaxation, and associated gastrointestinal problems.

Rheumatoid arthritis (RA) is an autoimmune disease mainly characterized by chronic polyarthritis. Many types of cells play pivotal roles in the pathogenicity of RA, such as T cells, B cells, macrophages, dendritic cells (DCs), osteoclasts (OCs), and fibroblast-like synoviocytes (FLS). Tripterygium wilfordii Hook f. (TwHf) and its ingredients are able to control disease activity by regulating the functions of cells mentioned above, and the clinical studies have highlighted the importance of TwHf ingredients in RA treatment. They have been demonstrated to improve the RA symptoms of animal models and patients. In this review, we discussed the effect of TwHf ingredients on pathogenicity cells, including disease/cell phenotypes and molecular mechanisms. Here, we constructed a cell-cell interaction network to visualize the effect of TwHf ingredients. We found that TwHf ingredients could inhibit the differentiation and proliferation of the pathogenicity cells. Besides, the components could decrease the levels of pathogenicity cytokines [i.e., interleukin-6 (IL-6), interleukin-1 $\beta$  (IL-1 $\beta$ ), and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )]. Many signaling pathways are involved in the underlying mechanisms, such as PI3K, NF- $\kappa$ B, and MAPK signaling pathways.

**Keywords:** Tripterygium wilfordii Hook f., rheumatoid arthritis, immune cell, mechanism, review

## INTRODUCTION

Rheumatoid arthritis (RA) is an autoimmune disease mainly characterized by chronic persistent synovitis, which causes the destruction of articular cartilage and bone, eventually leading to joint deformity and finally loss of function. The incidence of RA in mainland China is about 0.42%, and the disability rate of this disease course over 15 years is 61.3%. The clinical studies have shown that the effectiveness of the anchoring drug methotrexate is only 15%–25% (Lopez-Olivo et al., 2014; Chinese Rheumatology Association, 2018). While the addition of Tripterygium wilfordii Hook f. (TwHf) or Tripterygium hypoglaucom (Levl.) Hutch is able to control RA disease activity more effectively by regulating immune cell functions (Jun et al., 2016; Xiao-yue et al., 2019). In the separable components of TwHf and Levl. Hutch, there are many similar but different active component, such as Wilforlide, Celastrol (Cel), and Triptolide (TP) (Xianguang and Li, 2006; Chao, 2015; Chen-qiong et al., 2015). These active components can regulate the pathogenicity immune cells and connective tissue cells of RA. For example, they can reduce the secretion of inflammatory cytokines (such as TNF- $\alpha$ , IL-1 $\beta$ , and IL-6) of macrophages, the proliferation, and differentiation of

pathogenic T cells, and the bone destruction which mediated by the fibroblast-like synoviocytes (FLS) and the osteoclasts (Peng et al., 2014; Wang et al., 2014; Te et al., 2019).

Tripterygium genus alleviates disease activity by regulating RA-related cells by multiple targeting approaches. Up to date, there is no literature review for TwHf or its active ingredients on RA-related cell dysfunction. Meanwhile, there are signal transduction interactions between various immune cells and connective tissue cells in the process of RA, which jointly promote the occurrence and development of RA. Therefore, we conducted a literature review (search strategy is available in **Supplementary Materials 1**) to summarize the effects of Tripterygium genus active ingredients on RA-related cells. Furthermore, we constructed signal pathways and cell-cell interaction networks to summarize their molecular mechanisms and to speculate the potential target cells and proteins.

## THE FUNCTIONS OF TRIPTERYGIUM INGREDIENTS ON T CELLS AND THE MOLECULE MECHANISMS

T cells play a crucial role in various adaptive immune responses. During RA, T cells received antigens will be activated and proliferate (Smolen et al., 2018). Ho et al. (2013) found that PG27, one of the ingredients of TwHf, inhibited the T cell activation *via* targeting NF- $\kappa$ B and AP-1 pathways. PG27 can inhibit IKK $\alpha$ /I $\kappa$ B $\alpha$ /NF- $\kappa$ B and mitogen-activated protein kinase (MAPK)-AP-1 signaling pathways, while IKK $\beta$  activity was less sensitive for the inhibition of PG27. By contrast, the purified component of TwHf, PG490 (triptolide), similarly suppressed the above pathways. Similar results were demonstrated in RA animal models and patients but lacking molecule mechanisms. Triptolide reduced the numbers of CD4<sup>+</sup> cells in the periphery and increased the numbers of CD8<sup>+</sup> cells in Peyer's patch (Zhou et al., 2006). When triptolide was used to treat T cell isolated from peripheral blood of RA patients, the percentage of CD4<sup>+</sup> and CD8<sup>+</sup> T cells secreting IFN- $\gamma$ , IL-2, and IL-4 was decreased, and the percentage of CD4<sup>+</sup> and CD8<sup>+</sup> T cells expressing CD69 and CD25 was also reduced (Ming et al., 2014). Besides, Tripterygium active compounds have been demonstrated *in vivo* and *in vitro* to reduce T cell number by promoting T cell apoptosis as well as suppressing T cell proliferation and cytokine secretion, while the mechanism is unknown (Tao et al., 1991; Cascão et al., 2015b; Wang et al., 2018).

CD4<sup>+</sup> T cells can activate and polarize into various T helper cell subsets, including T helper 1 (Th1), T helper 2 (Th2), regulatory T (Treg), T helper 9 (Th9), T follicular helper cells (Tfh), T helper 17 (Th17), or T helper 22 (Th22) cells. Th17 cell numbers were increased in the peripheral blood, inflamed synovial tissue, and synovial fluid of RA patients (Leipe et al., 2010; van Hamburg et al., 2011; Penatti et al., 2017). Th17 cells promote the development of RA through the secretion of various inflammatory cytokines and chemokines. TGF- $\beta$ /SMADs/ROR $\gamma$ t and IL-6/STAT3 pathways are involved in mediating Th17 cell differentiation and mediating the expression of IL-17A, IL-17F, and IL-21 (Ivanov et al., 2006; Nishihara et al., 2007; Yang et al., 2008). The Cel, one of the Tripterygium ingredients,

has been proved to have anti-arthritis activity by inhibiting IL-6/STAT3 signal and finally reduce the secretion of Th17-related pro-inflammatory cytokines (Venkatesha et al., 2011). Moreover, Cel inhibits the activation of NF- $\kappa$ B, and caspase-1 in macrophages, resulting in the reduced release of IL-1 $\beta$  and TNF- $\alpha$ , and finally decreased the infiltration and proliferation of joint Th17 cells (Cascão et al., 2012) because IL-1 $\beta$  is able to promote the polarization of Th17 cells through inducing the expression of the transcription factors IFR4 and ROR $\gamma$  (Vallières et al., 2019). In addition, TP inhibits the expression of COX2 and the secretion of PGE2 in the co-culture models of RA synovial fibroblasts (RASFs) and RA CD4<sup>+</sup> T cells, blocking the differentiation of Th17 cells *in vitro* (Peng et al., 2014).

Similar to Th17, Tfh cells also promote RA progression by secreting IL-21 (Vinuesa et al., 2016). However, there is less research on the effects of TwHf on Tfh. In patients with RA treated with TwHf, the number of tenderness joints, the number of swollen joints, and the evaluation score of overall RA in the experimental group were lower than those in the control group. Consistently, the levels of Tfh cells and IL-21 were lower than those in the control group, and the levels of Tfh cells and IL-21 were positively correlated with DAS28 score (Sun et al., 2016).

Treg cells act as protective cells during RA. Enhancing the function or improving the number of Treg cells has been proved to alleviate the RA activity in varying degrees (Cooley et al., 2013). So far, research focused on the effects of TwHf on Treg cells in RA were limited. In the co-culture system of bone marrow macrophages and Tregs, TP up-regulated IL-10 and TGF- $\beta$ 1 produced by Treg cells, resulting in the inhibition of osteoclast differentiation and bone resorption (Xu et al., 2016).

The role of tripterygium ingredients for T cells and the molecule mechanisms were summarized in **Table 1**. The molecule mechanisms of CD8<sup>+</sup> cell and Th17 are available in **Figures 1, 2** (Th1, Th2, Treg, and Tfh are not available because insufficient study describes their molecule mechanism).

## THE EFFECTS OF TRIPTERYGIUM INGREDIENTS ON B CELLS

B cells are also critical in the development of RA. B cells can be used as antigen-presenting cells (APC) to provide synergistic stimulation and then activate T cells. In addition, B cells are able to secrete autoantibodies, such as rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA) (Scherer et al., 2018; Smolen et al., 2018). ACPAs, RF, or their immune complexes interact with immune cells such as macrophages, neutrophils, and osteoclasts to promote joint inflammation of RA. The differentiation and activation of B cells could be mediated by BAFF/BAFF-R-ATK-mTOR, and TACI-NF- $\kappa$ B (Niuro and Clark, 2002; Schmidlin et al., 2009; Pieper et al., 2013). Many studies have demonstrated that Tripterygium ingredients could inhibit the proliferation and the antibody production of B cells while the molecular mechanisms remained unknown (Tao et al., 1991; Wang and Wu, 1994; Chang et al., 1997; Cascão et al., 2015b). Only one study revealed the molecular mechanisms. Pan et al. found Xinfeng capsule, a proprietary Chinese medicine mainly

**TABLE 1 |** The effects of Tripterygium ingredients on T cells.

Subtype	Component	Models	Molecular mechanism	Effects	Animal disease phenotype	Ref.
CD4 <sup>+</sup> T cell	TP	CIA rats	NA	Reduce the number of CD4 <sup>+</sup> T cells in periphery blood	Ameliorate	(Zhou et al., 2006)
CD8 <sup>+</sup> T cell	TP	CIA rats	NA	Increase the number of CD8 <sup>+</sup> T cells in Peyer's patch	Ameliorate	(Zhou et al., 2006)
CD4 <sup>+</sup> T cell and CD8 <sup>+</sup> T cell	TP	Peripheral blood T cells in RA patients	NA	Reduce the percentage of CD4 <sup>+</sup> and CD8 <sup>+</sup> T cells. Reduce the levels of IFN- $\gamma$ , IL-2, IL-4. Decrease the expression of CD69 and CD25	NA	(Ming et al., 2014)
Th17	Cel	AIA Lewis rats	Prohibit the phosphorylation of STAT3 and ERK	Inhibit the differentiation of Th17; decrease the levels of cytokines (IL-17, IL-6, and IFN- $\gamma$ ) and antibodies (anti-Bhsp65 and anti-CCP)	Ameliorate	(Venkatesha et al., 2011)
Th17	TP	Synovial fibroblasts from RA patients and Th17 cells co-cultured model	regulating cyclooxygenase-2/prostaglandin E2 axis	Inhibit Th17 differentiation	NA	(Peng et al., 2014)
Th17	Cel	E. coli stimulated THP-1 macrophage-like cell line and AIA Wistar rats	Inhibiting activation of NF- $\kappa$ B and caspase-1	Inhibit the release of IL-1 $\beta$ and TNF from macrophages, reducing joint the infiltration and proliferation of TH17 cells	Ameliorate	(Cascão et al., 2012)
Treg	TP	Co-cultures system of Tregs and BMMS	NA	Up-regulate IL-10 and TGF- $\beta$ 1, secreted by Treg. Inhibit the osteoclast differentiation and bone resorption caused by osteoclast	NA	(Xu et al., 2016)
TfH	Tripterygium glycosides tablets PG27	Peripheral blood in patients with RA	NA	Decrease the numbers of TfH and the levels of IL-21	Ameliorate	(Sun et al., 2016)
T cell	TP	Human peripheral blood T cells	Inhibiting activation of IKK $\alpha$ and AP-1	Inhibit the activation of T cell	NA	(Ho et al., 2013)
T cell	TP	Human peripheral blood T cells	Inhibiting activation of IKK $\alpha$ , AP-1, and IKK $\beta$	Inhibit the activation of T cell	NA	(Ho et al., 2013)
T cell	Cel	AIA rats	NA	Promote T cell apoptosis	Ameliorate	(Cascão et al., 2015b)
T cell	TP	TNF transgenic mice	NA	Promote T cell apoptosis	Ameliorate	(Wang et al., 2018)
T cell	Triptolide ethanol extraction	Human peripheral blood	NA	Inhibit antigen and mitogen stimulated T cell proliferation and the secretion of IL-2	NA	(Tao et al., 1991)

Cel, Celastrol; TP, Triptolide; STAT3, Signal Transduction and Transcription Activator Protein 3; SOCS, Cytokine Signal Negative Regulator; IL, Interleukin; IKK, I $\kappa$ B Kinase; AP-1, Activin 1; TfH, Follicular helper T cells; OC, Osteoclasts; TNF, Tumor necrosis factor.

composed of TwHf, can up-regulate the PTEN level of B cells while down-regulate PDK1 and BAFF/BAFF-R to suppress the activation of PI3K/AKT/mTORC signal pathway and finally inhibit the proliferation and activation of B cells (Pan, 2018). Besides, the levels of related antibodies such as RF, anti-cyclic citrullinated peptide antibody (anti-CCP Ab), IgG, and IgM, were also inhibited. The effects of Tripterygium ingredients on B cells and the molecule mechanisms are summarized in **Table 2**. The molecule mechanisms of B cell are summarized in **Figure 3**.

## THE ROLE OF TRIPTERYGIUM INGREDIENTS ON MACROPHAGE AND THE MOLECULE MECHANISM

Macrophages are mainly divided into classical activated M1 type and selective activated M2 type. The immuno-inflammatory reaction in RA patients directly affects the polarization of macrophages in peripheral blood, synovium, and synovial fluid, resulting in the continuous increase of M1-type macrophages and

disrupting the balance of M1/M2 (Laria et al., 2016). Macrophages also promote RA and participate in the bone destruction of RA through antigen presentation. The degree of synovial macrophage infiltration was positively correlated with the bone destruction and clinical symptoms of RA (Gierut et al., 2010).

Tripterygium ingredients have been reported to inhibit the M1 polarization and promote the polarization of M2 type macrophages, resulting in the rebalance of the pro-inflammatory and anti-inflammatory cytokines (Feng, 2015; Liu, 2018). Besides, tripterygium ingredients could alleviate synovial macrophage infiltration. However, the molecular mechanism was not explained (Bao et al., 2007; Cascão et al., 2015a; Cascão et al., 2015b; Feng, 2015; Gan et al., 2015; Liu, 2018; Tong et al., 2018; Wang et al., 2018). M1 polarization is mediated by JAK-STAT1 signaling stimulated with IFN $\gamma$  and characterized by increased iNOS, IL-1 $\beta$ , and TNF- $\alpha$ . Another M1 activated signaling pathway is the TLR4/NF- $\kappa$ B signaling pathway (Lawrence and Natoli, 2011). In the AIA rat model, Cel exerted the anti-inflammatory properties *via* down-regulating the NF- $\kappa$ B and the caspase-1 activation, leading to a decrease of IL-1 $\beta$  and TNF- $\alpha$  secretion in macrophages.

**FIGURE 1** | Tripterygium ingredients act on the CD8<sup>+</sup> T cell. CD8<sup>+</sup> T cells could be activated through three signals. The first signal of T cell activation comes from the specific binding of its receptor TCR to the antigen. The second signal of T cell activation comes from costimulatory molecules. Cytokines promote the full activation of T cells. Perforin and granzyme B are secreted to exert cellular immunity via the PI3K signaling pathway. In other cell types, tripterygium ingredients act on the PI3K signaling pathway to prohibit the activation of CD8<sup>+</sup> T cells. Note: AKT (also known as PKB), Protein kinase B; PI3K, Phosphoinositide 3-kinase; mTOR, Mechanistic target of rapamycin kinase; S6K, Ribosomal protein S6 kinase; TCR, T-cell receptor; 4EBP, 4E-binding protein.

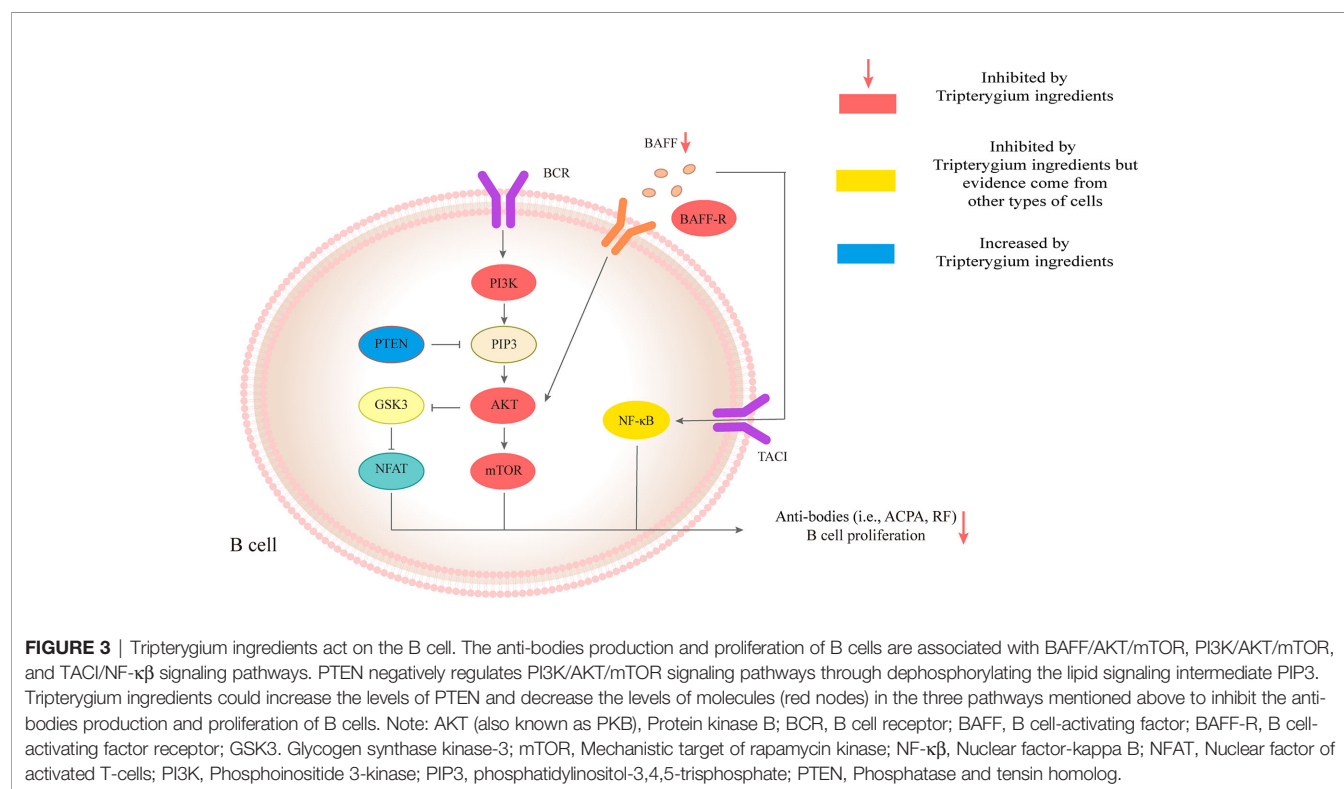

**FIGURE 2** | Tripterygium ingredients act on Th17. TGF-β/SMADs/RORγt, IL-6/STAT3/RORγt, and IL-6/NF-κB signaling pathways are responsible for the differentiation and the secretion of chemokines and cytokines of Th17. The downstream effector cells include B cells, Tfh, FLS, and macrophages. The activation of FLS releases RANKL to promote the secretion of chemokines (i.e., IL-6, IL-1β, and TNF-α) of macrophages, which could target Th17 and further active Th17. Tripterygium ingredients inhibit STAT3 and NF-κB, resulting in the reduction of many cytokines (i.e., IL-6 and IL-21) to negatively regulates Th17 and downstream effector cells. Note: FLS, Fibroblast-like synoviocytes; IFN-γ, Interferon-gamma; IL, Interleukin; NF-κB, Nuclear factor-kappa B; RANKL, Receptor activator of nuclear factor-kappa B ligand; RORγt, Retinoic acid-related orphan receptor gamma t; SMAD, Suppressor of mothers against decapentaplegic; STAT, Signal transducer and activator of transcription; TGF-β, Transforming growth factor-beta; TNF-α, Tumor necrosis factor-alpha.

**TABLE 2** | The effects of Tripterygium ingredients on B cells.

Subtype	Component	Models	Molecular mechanism	Effects	Animal disease phenotype	Ref.
CD19 <sup>+</sup> B cells	Cel	AIA rats	NA	Decrease the numbers of CD19 <sup>+</sup> cells	Ameliorate	(Cascão et al., 2015a)
CD19 <sup>+</sup> CD81 <sup>+</sup> and CD19 <sup>+</sup> CD40 <sup>+</sup> B cells	Xinfeng capsule	RA patients	Inhibit PI3K/AKT/mTOR signaling pathway. Up-regulate PTEN; Down-regulate PDK1 and BAFF/BAFF-R	Inhibit B cells proliferation, and activation; Decrease the levels of antibodies, such as RF, anti-CCP Ab, IgG, and IgM	Ameliorate	(Pan, 2018)
B cells	Tripterygium glycosides	B cells	NA	Inhibit the IgG levels secreted by B cell	NA	(Chang et al., 1997)
B cells	Triptolide ethanol extraction	Human peripheral blood	NA	Inhibit B cell proliferation and decrease immunoglobulin levels	Ameliorate	(Tao et al., 1991)
B cells	TwHf	RA patients	NA	Decrease the percentage of B cells	Ameliorate	(Wang and Wu, 1994)

PTEN, Phosphatase and tensin homolog; PDK1, 3-phosphoinositide-dependent protein kinase 1; BAFF, B cell activating factor; BAFF-R, B cell activating factor receptor; PI3K, Phosphatidylinositol 3-kinase; AKT, Serine protein kinase; mTORC, Rapamycin target protein complex; IL, Interleukin; IgG, Immunoglobulin; TwHf, Tripterygium wilfordii Hook f.

Furthermore, the proliferation of Th17 was also inhibited because of lacking cytokines stimulation (Cascão et al., 2012). In addition, research has indicated that Cel blocked the binding of lipopolysaccharides (LPS) to a myeloid differentiation factor2 (MD2) and then inhibited the M1 activation, which was measured by the expression of inflammatory cytokines including TNF- $\alpha$ , IL-6, and IL-1 $\beta$  (Lee et al., 2015). Some researchers (Lin et al., 2001; Ping et al., 2015) also found that Tripterygium ingredients decreased the production of TNF- $\alpha$ , IL-1 $\beta$ , and IL-6 *via* inhibiting the expression of the TLR4, NF- $\kappa$ B, and prostaglandin E2 (PGE2). Besides, NO production and iNOS expression in macrophages were significantly inhibited by Tripterygium

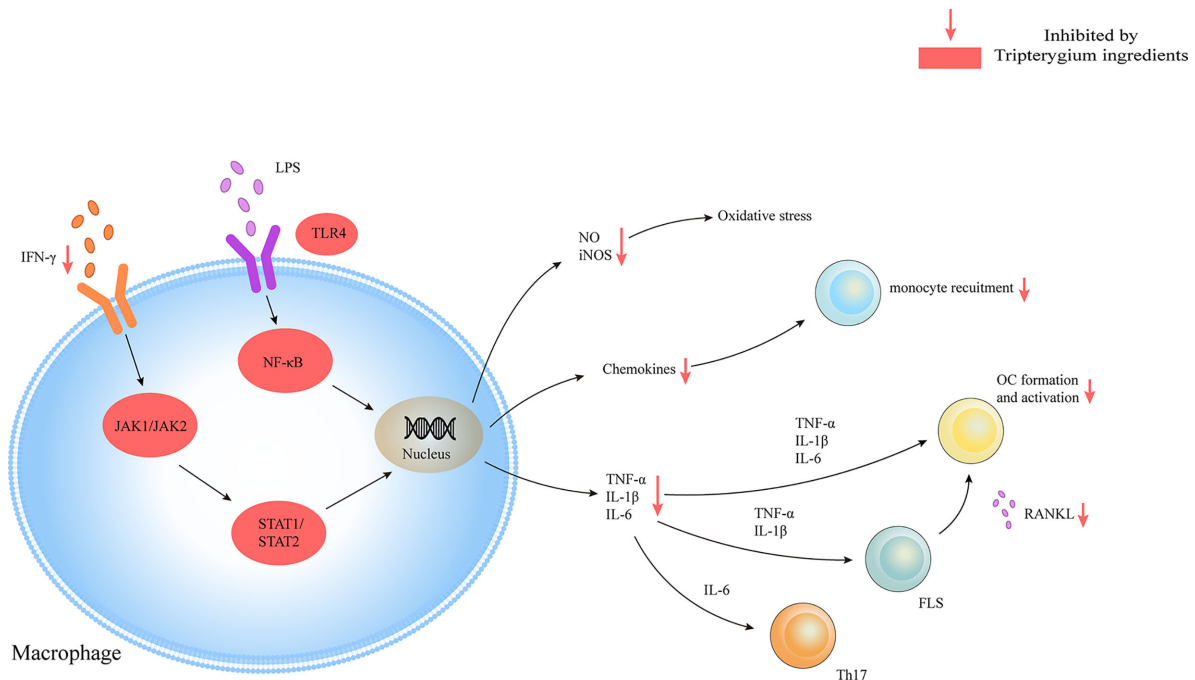

ingredients (Wang et al., 2004; Chen et al., 2018). Furthermore, TP inhibited the promoter activity of the iNOS gene and the inducible activity of iNOS transcriptional regulator Oct-1 (Wang et al., 2004). Pyroptosis is a unique and newly discovered mode of programmed cell death, which is triggered by the activation of Caspase-1 (Bergsbaken et al., 2009). It has been found that Cel can inhibit the pyroptosis induced by LPS and ATP *via* inhibiting the enzyme activities of cleaved-Caspase1 and Caspase-1, and finally blocking the secretion of IL-1 $\beta$  in macrophages (Xin et al., 2018). The effect of tripterygium ingredients on macrophages and the molecule mechanisms are summarized in Table 3. The figure for the molecule mechanism of macrophages is available in Figure 4.

**TABLE 3 |** The role of Tripterygium ingredients on macrophages.

Subtype	Component	Models	Molecular mechanism	Effects	Animal disease phenotype	Ref.
M1, M2 macrophages	Cel	Healthy mice	NA	Inhibit abdominal macrophages to M1 polarization. Promote M2 macrophages polarization	Alleviate	(Liu, 2018)
M1, M2 macrophages	TP	PBMCs, isolated from healthy people, cultured in different pH RPMI-1640	NA	Decrease M1 macrophages level and promote M2 macrophages level	NA	(Feng, 2015)
CD68 <sup>+</sup> CD168 <sup>+</sup> synovial macrophage	Cel	AIA rats	NA	Inhibit the infiltration and proliferation of CD68 <sup>+</sup> CD168 <sup>+</sup> synovial macrophages in the synovial membrane	Alleviate	(Cascão et al., 2015a)
OCP	TP	TNF transgenic mice	NA	Promote the apoptosis of OCP. Inhibit OC proliferation, bone resorption and pro-inflammatory cytokines levels secreted by macrophages	Alleviate	(Wang et al., 2018)
BMDMs	Cel	LPS-induced BMDMs.	Inhibit TLR4 activation via prohibiting the binding of LPS to the TLR4/MD2 complex	Inhibit pro-inflammatory cytokine levels and TLR4 activation in macrophages	NA	(Lee et al., 2015)
Macrophage	Cel	E. coli stimulated THP-1 macrophage-like cell line and AIA Wistar rats	Inhibiting activation of NF- $\kappa$ B and caspase-1	Inhibit the release of IL-1 $\beta$ and TNF from macrophages, reducing joint the infiltration and proliferation of TH17 cells	Alleviate	(Cascão et al., 2012)
Macrophage	TP	RAW 264.7 and U937 macrophage-like cell lines	Induce the degradation of Bcl-2 and the activation of caspase-3	Promote macrophages apoptosis	NA	(Bao et al., 2007)
Macrophage	Cel	CIA DBA/1J mice and RANKL induced RAW264.7 cells	Decrease serum TRAP 5b and the expression of osteoclastic genes (Trap, Ctsk, Ctr, MMP-9) and transcriptional factors (c-Fos, c-Jun and NFATc1); Inhibit NF- $\kappa$ B and MAPK	Decrease the infiltration of osteoclast cells in joints. Decrease serum TRAP 5b and the expression of osteoclastic genes and transcriptional factors	Alleviate	(Gan et al., 2015)
Macrophage	Tripterygium glycosides	CFA-induced arthritis rat and LPS-induced RAW264.7	NA	Ameliorate in paw swelling perimeter, arthritics score, and body weight loss. Reduce the levels of inflammatory cytokine (TNF- $\alpha$ , IL-6, and IL-1 $\beta$ ) secreted by macrophages	Alleviate	(Tong et al., 2018)
Macrophage	Tripterygium glycosides	LPS-induced RAW264.7	down-regulate the expression of TLR4 and NF- $\kappa$ B p65	Decrease the levels of TNF- $\alpha$ and IL-1 $\beta$ secreted by macrophages	NA	(Ping et al., 2015)
Macrophage	TP	LPS induced J774A.1 macrophage and IL-1 $\alpha$ induced human synovial fibroblasts	Inhibit COX-2 in macrophages and pro-MMPs 1 and 3 in synovial fibroblasts. Up-regulate TIMPs 1 and 2 levels in synovial fibroblasts	Decrease PGE2 via inhibiting COX-2. Inhibit pro-MMPs and Up-regulate TIMPs	NA	(Lin et al., 2001)
Macrophage	Tripterygium wilfordii extraction	LPS-induced RAW264.7	NA	Reduce the production of NO and iNOS mRNA in macrophages	NA	(Chen et al., 2018)
Macrophage	TP and TwHf ethyl acetate extraction	Peritoneal macrophages isolated from AIA C57BL/6J mice	Inhibit NO production and iNOS mRNA expression in macrophages. Inhibit the promoter activity of iNOS gene to regulate its transcript factor (Oct-1) activity	Inhibit the production of NO, iNOS, and the activity of Oct-1	Alleviate	(Wang et al., 2004)
Macrophage	Cel	RAW264.7	Decrease the expression of cleaved-caspase-1 and inhibit caspase-1 enzyme activity	Ameliorate cell pyroptosis	NA	(Xin et al., 2018)

## THE EFFECTS OF TRIPTERYGIUM INGREDIENTS ON DENDRITIC CELLS (DCS)

TwHf is reported to inhibit DC development and induce DC apoptosis, finally decreasing the DC number, which resulted in the blocking of the naïve T cell activation and ultimately reduced the differentiation of the autoinflammatory T cells (Wang et al., 2001; Chen et al., 2006; Sun, 2017). Also, TP inhibits DC-related chemokines and reduces the sharing of DCs with MHC molecules and co-stimulatory factors of T and B cells, thereby blockade T and B cell activation. Antigenic peptide on MHC molecules, co-stimulatory molecules (CD80, CD86), and IL-12 of DCs promote the differentiation of Th1 cells, which produce IFN- $\gamma$  and IL-2, required for cell-mediated immunity. Th1 cells directly modulate B cell differentiation into plasma cells. Besides, DCs also mediate the proliferation of these antibody-producing cells by producing BAFF (Khan et al., 2009). Unfortunately, the specific molecule mechanisms were not involved in these studies. Tripterygium ingredients for DCs are summarized in **Table 4**.

## THE FUNCTIONS OF TRIPTERYGIUM INGREDIENTS ON OSTEOCLASTS (OCS) AND THE MOLECULE MECHANISM

OC-mediated bone resorption is one of the typical manifestations of RA. OCs, giant multinucleated cells derived

from the monocyte lineage, are the only cells capable of resorbing bone (Teitelbaum and Ross, 2003). Receptor activator of nuclear factor kappa-B (RANK)/Receptor activator of nuclear factor kappa-B ligand (RANKL)/Osteoprotegerin (OPG) is the most crucial pathway of OC differentiation. Leibbrandt A etc. has demonstrated that RANKL is the critical mediator of OC activation and joint destruction; In a rat model of arthritis, osteoblasts and bone marrow stromal cells produce RANKL, which then triggers local development and activation of OCs. This finding has now become the basis for osteoimmunology (Leibbrandt and Penninger, 2009). Multiple studies have confirmed that Tripterygium ingredients can inhibit the expression of RANK and RANKL, thereby increasing the proportion of OPG, which can antagonize the function of RANK and finally inhibit the differentiation of OCs and reduce bone destruction (Nanjundaiah et al., 2012; Feng et al., 2013; Liu et al., 2013; Wang, 2015). Youn-Kwan Jung et al. (Jung et al., 2019) reviewed the roles of inflammatory signal pathways, including IL-1 $\beta$ /Myd88/TRAF6/NF- $\kappa$ B, TNF- $\alpha$ /TRADD/TRAF2/NF- $\kappa$ B, IL-6/STAT3/MAPK, and RANKL/RANK signal transduction. In these inflammatory pathways, TwHf or its active components impaired the release of cytokines/chemokines, reduced osteoclast differentiation, and activation, then finally blocked bone erosion in mice with collagen-induced arthritis through inhibiting the phosphorylation of NF- $\kappa$ B p65, MAPK (ERK, JNK, and p38) and reducing the expression of

transcription factors c-Fos, c-Jun, and NFATc1 (Gan, 2013; Qian et al., 2015). TwHf or its active components can also promote the apoptosis of OCs and osteoclast precursor (OCP) (Wang et al., 2018; Wang S. et al., 2019). The mechanism may be due to the inhibition of cIAP2 (the positive regulatory protein of TNF and NF- $\kappa$ B signaling pathway). Furthermore, TP has been reported to block OC differentiation by down-regulating the receptor for advanced glycation end-products (RAGE) and the high-mobility

group box chromosomal protein 1 (HMGB1) (Wang et al., 2017). RAGE and its ligands (i.e., HMGB1) are necessary for the skeletal homeostasis and related-disease onset/progression (Plotkin et al., 2019). The elevated levels of RAGE and HMGB1 induce osteoblast apoptosis and OC differentiation/activity. Tripterygium ingredients on OC and the molecule mechanisms are summarized in **Table 5**. The figures for the molecule mechanism of OCs are available in **Figure 5**.

TP, Triptolide; Cel, Celastrol; RANKL, Nuclear factor kappa B ligand receptor activator; RANK, Nuclear factor receptor activator; OPG, Osteoprotegerin; NF- $\kappa$ B, Nuclear factor activated B cell  $\kappa$  light chain enhancer; MAPK, Mitogen activated protein kinase; ERK, Extracellular regulatory protein kinase; JNK, Jun N-terminal kinase; NFATc1, Osteoclast activated T nuclear factor 1; CCL4, C-C motif chemokine ligand 4; HMGB1, High mobility group protein B1; RAGE, Receptor for advanced glycation end products; OC, Osteoclasts.

**FIGURE 5 |** Tripterygium ingredients act on osteoclast. The activation of osteoclast mostly involved IL-1 $\beta$ /MyD88/TRAF6/NF- $\kappa$ B, TNF- $\alpha$ /TRADD/TRAF2/NF- $\kappa$ B, IL-6/STAT3/MAPK, and RANKL/RANK signal transduction. Besides, the anti-bodies released by B cells would promote the activation of osteoclast via PI3K signaling. OPG takes part as a decoy receptor for RANKL and inhibiting RANKL-RANK binding. By rebalancing the RANKL and OPG levels, and inhibiting the pathways mentioned above, tripterygium ingredients negatively regulate the differentiation, bone destruction, cytokines and chemokines expression of osteoclast. ## THE ROLE OF TRIPTERYGIUM INGREDIENTS ON FLS AND THE MOLECULE MECHANISM

Synovial inflammation and synovial cell hyperplasia is a distinctive feature of RA. Synovial cells are composed of two types of cells, including type A and type B. Type A cells have a phagocytic function and are macrophage-like cells; type B cells are fibroblast-like, called FLS (Junqueira and Mescher, 2013). FLS is abundant in the endoplasmic reticulum and can secrete protein complexes (mucin) and hyaluronic acid in synovial fluid. FLS contributes mainly to the exacerbation of RA by attaching to, followed by invading into, and finally degrading cartilage and bone (Lefèvre et al., 2009). FLS are the primary cells leading to joint destruction in RA (Bartok and Firestein, 2010).

The molecular pathologic basis RA-FLS includes the MAPK and NF- $\kappa$ B pathways. These pathways are the most widely studied to mediate the aggressiveness of FLS in RA (Bottini and Firestein, 2013; Ganesan and Rasool, 2017). NF- $\kappa$ B pathway, a significant regulator of pro-inflammatory cytokine production, activates NF- $\kappa$ B kinase (IKK) subunit  $\beta$  (IKK $\beta$ ) in the cytosol through IL-1 $\beta$ , TNF- $\alpha$ , and TLR signaling. The activation of IKK $\beta$  results in the NF- $\kappa$ B family inhibitor proteins (I $\kappa$ B) degradation, promoting NF- $\kappa$ B to migrate freely into the

nucleus and initiate gene transcription (Bottini and Firestein, 2013). Cel inhibited the translocation of NF- $\kappa$ B p65 and reduced the phosphorylation of I $\kappa$ B $\alpha$  and IKK in FLSs from patients with RA, resulting in the decreased expression of several chemokines (i.e., CCR2, CXCR4, CCL2, CXCL10, and CXCL12), cytokines (i.e., IL-6, IL-8, and MCP-1), and matrix metalloproteinase-9 (MMP-9) (Fang et al., 2017). Besides, HIF-1 $\alpha$  binding to the CXCR4 promoter would increase the transcriptional activity of CXCR4, consequently leading to FLS migration and invasion. However, it could be reversed by Cel treatment (Li et al., 2013b). Guo et al. (Li et al., 2012) found that Cel inhibited I $\kappa$ B $\alpha$  phosphorylation and nuclear translocation of NF- $\kappa$ B. Cel also has been found to inhibit the expression of MMP-9 by suppressing the binding activity of NF- $\kappa$ B to the MMP-9 promoter (Li et al., 2012; Li et al., 2013a). Furthermore, MMP-9 suppression was also related to the inhibition of the TLR4/MyD88/NF- $\kappa$ B pathway (Li et al., 2013a). As a result, Cel changes the phenotype of FLS migration and invasion via the molecule mechanism mentioned above. RA-FLS releases important inflammatory cytokines (TNF- $\alpha$ , IL-1 $\beta$ , IL-6, IL-21, IL-22, and IL-32), chemokines (CXCL1, CXCL5, MCP-1, G-CSF, and IL-8) and Inflammatory mediators (TLR-2, TLR-3, TLR-4, iNOS, and COX-2), which promotes the infiltration of monocytes, macrophages, neutrophils, DCs, T cells, and B cells

into joints and results in chronic inflammation and joint destruction (Bottini and Firestein, 2013; Ganesan and Rasool, 2017). Additionally, TP also was found to reduce the FLS migration and invasion by targeting JNK/MAPK signaling pathway (Yang et al., 2016). Moreover, LLDT-8, a Tripterygium derivative, decreased the secretion of chemokines in FLS (Ping et al., 2016; Jia et al., 2017).

Many studies showed the Tripterygium ingredients have the properties to promote FLS apoptosis and cell cycle arrest and inhibit FLS autophagy (Xu, 2013; Xu et al., 2013; Lei et al., 2015; Su et al., 2017; Wong et al., 2019). It may be relevant to the increased expression of Bax/Bcl-2, Caspase-3, Caspase-9, and regulating by Ca<sup>2+</sup>/calmodulin-dependent protein kinases beta (CaMKK)-AMPK-mTOR signaling pathway. Tripterygium

ingredients for FLS and the molecule mechanism are summarized in **Table 6**. The figures for the molecule mechanism of FLS are available in **Figure 6**.

## DISCUSSION

We systematically summarized the role of tripterygium ingredients in the RA treatment as well as explained the therapeutic mechanism (**Figure 7**). The NF- $\kappa$ B pathway is a common pathway involved in TwHf-treated RA. It has been involved in mediating multiple genes, such as the genes of cytokines (i.e., IL-6, IL-17, and TNF- $\alpha$ ), chemokines (i.e., CCL2 and CXCL5), growth factors (i.e., GM-CSF and M-CSF),

**TABLE 6 |** The function of Tripterygium ingredients on FLS.

Component	Models	Molecular mechanism	Effects	Animal disease phenotype	Ref.
Cel	FLSs from patients with RA	Reduce the phosphorylation of IKK and I $\kappa$ B $\alpha$ , and inhibit the translocation of NF- $\kappa$ B p65 from the cytoplasm to the nucleus	Inhibit FLS proliferation and invasion. Reduce the levels of FLS pro-inflammatory cytokines (i.e., IL-6, IL-8, MCP, and MMP9) and chemokines (i.e., CCL2, CXCL10, CXCL12, CCR2, and CXCR4)	NA	(Fang et al., 2017)
Cel	AIA model	Inhibited the transcriptional activity of MMP-9 by suppression of the binding activity of NF- $\kappa$ B in the MMP-9 promoter, and inhibited I $\kappa$ B $\alpha$ phosphorylation and nuclear translocation of NF- $\kappa$ B	Suppressed the IL-17A-induced migration and invasion abilities of FLS	Alleviate	(Li et al., 2012)
Cel	FLSs isolated from the synovium of active RA patients	Inhibit the transcriptional activity of MMP-9 and TLR4/MyD88/NF- $\kappa$ B signaling pathway	Inhibit FLS invasion and migration	NA	(Li et al., 2013a)
TP	FLSs isolated from active RA patients and CIA DBA/1 mice	Inhibit JNK/MAPK signaling pathway	Inhibit FLS invasion and migration	Alleviate	(Yang et al., 2016)
Cel	FLSs isolated from active RA patients	Inhibit the binding activity of HIF-1 $\alpha$ in the CXCR4 promoter to inhibit the transcription activity of CXCR4	Inhibit FLS invasion and migration	NA	(Li et al., 2013b)
TP	MH7A cell line	NA	Promote MH7A cell apoptosis; Decrease the levels of IL-1 $\beta$ , IL-6, and IL-8; Induce membrane ultrastructural changes	NA	(Su et al., 2017)
Cel	Human fibroblast-like synoviocytes-rheumatoid arthritis cells	Increase the expression of Bax/Bcl-2 and promote proteolytic cleavage of Caspase-3, Caspase-9, and PARP	Lead to FLS DNA damage and cycle arrest; Promote FLS apoptosis	NA	(Xu, 2013; Xu et al., 2013)
Cel	Immortalized wild-type and Bax-Bak double-knockout mouse embryonic fibroblasts; RASFs isolated from RA patients; AIA rats	Inhibit SERCA to induce autophagy-dependent cytotoxicity in RASFs/RAFLS via Ca <sup>2+</sup> /calmodulin-dependent kinase kinase- $\beta$ -AMP-activated protein kinase-mTOR pathway	Induce autophagic FLS death in RASFs/RAFLS	Alleviate	(Wong et al., 2019)
TP	MH7A cell line	NA	Inhibit angiogenesis	NA	(Zhang et al., 2008; Mao et al., 2009)
TP	FLSs isolated from RA patients	NA	Lead to FLS cycle arrest and promote FLS apoptosis	NA	(Lei et al., 2015)
LLDT-8	FLSs isolated from RA patients	NA	Inhibit FLS cytokines and chemokines (i.e., IL-6, CCL3, and CCL5)	NA	(Ping et al., 2016; Jia et al., 2017)

TP, Triptolide; Cel, Celastrol; NF- $\kappa$ B, Nuclear factor activated B cell kappa light chain enhancer; Caspase, Aspartic acid protease containing cysteine; TLR4, Toll-like receptor 4; JNK, Jun N-terminal kinase; MAPK, Mitogen activated protein kinase; mTOR, Rapamycin target protein; MMP-9, Matrix metalloproteinase-9; IL, Interleukin; AMPK, AMP-dependent protein kinase.

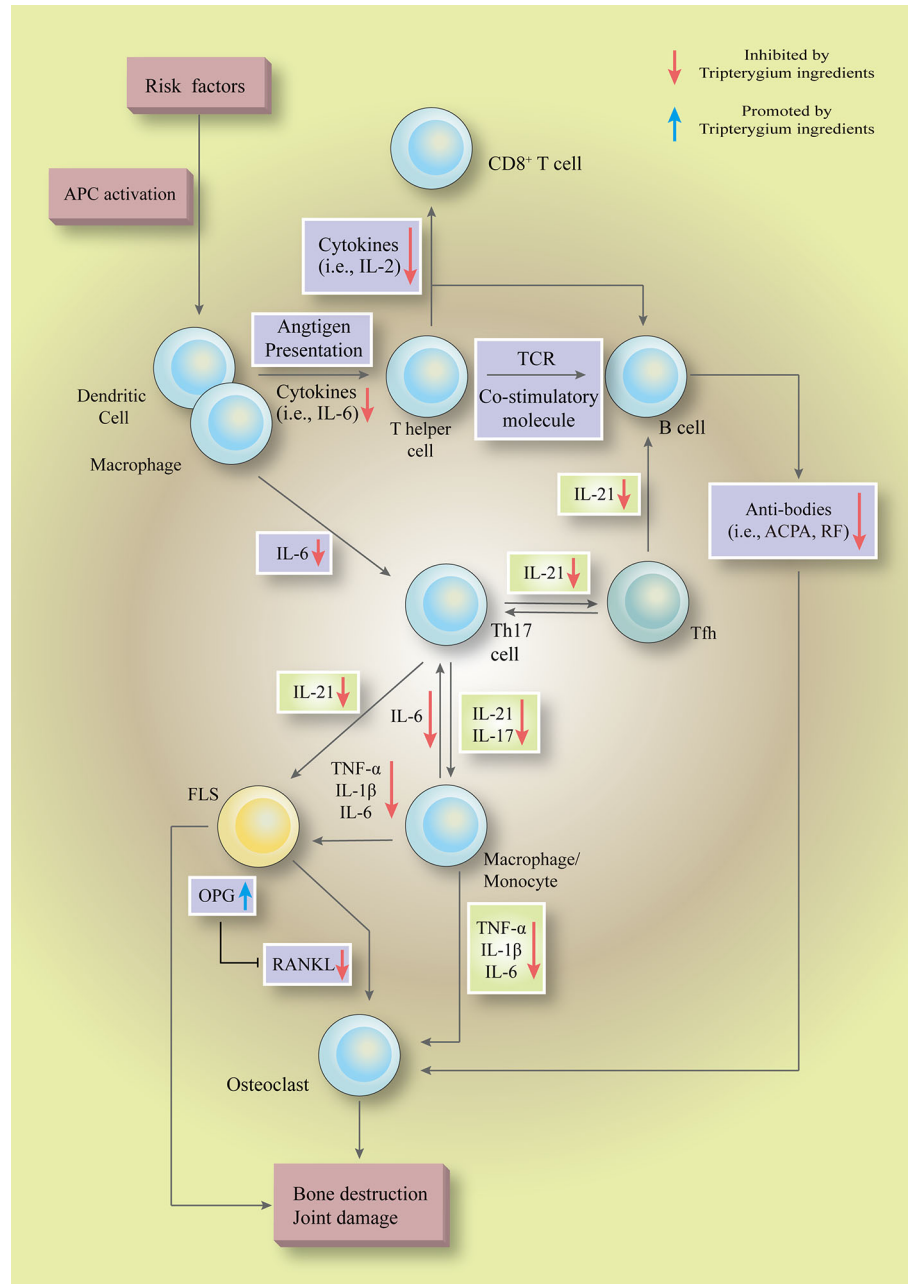

**FIGURE 6 |** Tripterygium ingredients act on FLS. The molecular pathologic basis FLS includes the MAPK and NF-κB pathways. By prohibiting the signal transduction in the pathways, tripterygium ingredients alleviate the proliferation, invasion of FLS, which would promote bone erosion in RA. PTEN and PI3K, which inhibit and promote the activity of IKKβ, respectively, also are related in the networks of FLS. We suppose tripterygium ingredients could increase PTEN and decrease PI3K to alleviate the pathogenicity of FLS. Note: AP-1, Activator protein 1; FLS, Fibroblast-like synoviocytes; JNK, c-Jun N-terminal kinase; IL, Interleukin; IKKβ, IκB Kinase β; MYD88, Myeloid differentiation primary response 88; NF-κB, Nuclear factor-kappa B; PI3K, Phosphoinositide 3-kinase; PTEN, Phosphatase and tensin homolog; TNF-α, Tumor necrosis factor-alpha; TLR, Toll-like receptor; TAK1, Transforming growth factor beta-activated kinase 1.

regulators of apoptosis (i.e., Bcl-2) and transcription factors (i.e., HIF-1α), to regulate cell function, cell death and survival, and proliferation (Mitchell and Carmody, 2018). Experimental inhibitors targeted the IKK kinases to inhibit the activation of NF-κB, but they failed due to toxicity in genetic models (Mitchell and Carmody, 2018). The failure indicated that a broad blockade of NF-κB activation maybe an impracticable approach. Thus, some drugs focus on the non-canonical NF-κB pathway in RA, such as BAFF/NF-κB, RANK/NF-κB signaling (Noort et al., 2015). A phase II trial showed that belimumab [a biologics target B lymphocyte stimulator (BLyS)] was efficacy and well-tolerated in patients with RA (Stohl et al., 2013). Denosumab is a monoclonal antibody neutralizing RANKL. Up to date, many clinical studies have demonstrated that denosumab could inhibit the progression of joint destruction and increase bone mineral density, including a double-blind, placebo-controlled phase 3 trial (Deodhar et al., 2010; Dore et al., 2010; Sharp et al., 2010; Takeuchi et al., 2016; Yue et al., 2017; Takeuchi et al., 2019). However, none of the studies reported there is any benefit in improving disease activity. It is also regrettable that none of the studies test the expression of cytokines, chemokines, and RA-related pathogenicity cells. NF-κB pathways, including canonical and non-canonical pathways, are critical targets of tripterygium ingredients. In the experimental and clinical dimensions, these could explain why tripterygium ingredients could reduce the

levels of many chemokines, cytokines, and growth factors in different cells to improve disease activity as well as inhibit the progression of joint destruction. TwHf and its ingredients could be regarded as one of DMARDs. Thus, they are widely used in treating RA in China. The last 24 weeks, open-label, multicentre, randomized controlled trial demonstrated MTX+TwHF was better than MTX monotherapy (Lv et al., 2015). Furthermore, three meta-analyses (the trial mentioned above included) showed that MTX+TwHF had advantages in improving the laboratory index (CRP, RF, ESR), clinical symptoms, and clinical efficacy, compared with MTX alone (assessed in ACR20, ACR50, and ACR70) (Li et al., 2019; Wang X. et al., 2019; Chen et al., 2020). Another small sample meta-analyses showed that TwHF could decrease bone destruction scores (Zhu et al., 2019).

Our previous research using a bioinformatics approach demonstrated that Kunxian Capsule (a Traditional Chinese Medicine (TCM) patent prescription mainly comprises Levl. Hutch) could target at PI3K/AKT/mTOR signaling pathway (Tang et al., 2020). Therefore, we speculate that some proteins in the PI3K-AKT-mTOR signal pathway are the most likely direct targets of tripterygium ingredients. The signaling pathway is an intracellular signaling pathway and performs multiple physiological functions, such as regulating the cell cycle, survival, and growth (Yap et al., 2008; Ersahin et al., 2015). By far, no clinical study has reported PI3K inhibitors approved by

**FIGURE 7 |** Tripterygium ingredients could inhibit multiple pathways, such as the NF- $\kappa$ B pathway, JAK-STAT pathway, and PI3K-mTOR pathway, to regulate the hyperactive as well as pathogenicity biological functions in a various type of cells (to). In the initial phase, tripterygium ingredients inhibit the immunological recognition functions of APCs to block the pathogenicity signals which are responsible for activating the lymphocytes. In the secondary stage, tripterygium ingredients could inhibit the humoral immunity and cellular immunity of lymphocytes. Meanwhile, the pro-inflammatory signals are amplified by pro-inflammatory cells, such as macrophages. The pro-inflammatory cells release inflammatory cytokines and chemokines to recruit and activate immune cells (i.e., APCs and T cells), connective tissue cells (i.e., macrophages and FLS) and OCs to infiltrate into the joints. Besides, the pro-inflammatory cells lead to a systemic inflammatory response, further promoting the pathogenicity signals of lymphocytes in central and peripheral immune organs. Tripterygium ingredients prohibit the pro-inflammatory signals, alleviate the infiltration and activation of pathogenicity cells in the joint, and finally interrupt the vicious circle which formed by pro-inflammatory cells and immune cells. In the final stage, tripterygium ingredients relieve the joint damage and bone destruction by mediating the expression of OPG and RANKL. Note: APC, Antigen-presenting cell; ACPA, Anti-citrullinated protein antibodies; FLS, Fibroblast-like synoviocytes; IL, Interleukin; OPG, Osteoprotegerin; RANKL, Receptor activator of nuclear factor- $\kappa$ B ligand; RF, Rheumatoid factor; TCR, T-cell receptor; TNF- $\alpha$ , Tumor necrosis factor- $\alpha$ .

the FDA (idelalisib, copanlisib, duvelisib, and alpelisib) in treating RA. Some drugs were demonstrated they were effective in treating RA models *via* PI3K signaling pathway *in vivo* and *in vitro*, including one PI3K inhibitor (Boyle et al., 2014; Feng and Qiu, 2018; Qi et al., 2019).

The two pathways mentioned above have a variety of biological functions. Both of them control cell death, survival, and proliferation. We found that the therapeutic effects of tripterygium ingredients are mostly related to the reduction of the absolute number of cells. At the same time, there are some differences in stimulating signals, signal receptors, and transcription factors required for cascade reactions in different cells, which is related to the multi-target of TwHf. Considering the adverse effects (AEs) of these drugs, a variety of healthy cells in multiple systems (i.e., liver cells) are also be affected. Therefore, the AEs of tripterygium ingredients could be due to the inhibition of NF- $\kappa$ B and PI3K pathways. Ameliorating AEs through drug matching may be a feasible strategy (Tang et al., 2020). For example, some Chinese researchers matched the TwHf with *Cistanche deserticola* Ma or *Cuscuta chinensis* Lam, to reduce the reproductive toxicity of TwHf (Dong et al., 2009; Jing and He, 2013). Nevertheless, whether drug matching would impair the curative effect, still needed to be discovered.

There are many deficiencies in this review. The studies on the drugs/ingredients are all indirect mechanism studies, even with only cell phenotypes but no specific molecular mechanism. Besides, most of them are normal phenotypes in this field, such as inhibition of the apoptosis and differentiation of T cells or impaired proliferation, migration, and invasion of FLS. Moreover, none of the studies analyzed the direct interaction between the drugs and proteins *via* bioinformatics and mass spectrometry approaches. For example, computer simulation and electrospray mass spectrometry (ESI-MS) were used to explore the inhibitory effect of paclitaxel and aryl ether ketone on farpentine diphosphate synthetase by binding to isoprene diphosphate site (Liu et al., 2014), and explain the anticancer and anti-infective drug mechanism of paclitaxel and aryl ether ketone in the direct interaction mechanism. Therefore, we could follow the methods which were used in the study, as mentioned above. For example, we could use bioinformatics to

identify whether TP and Cel could bind to some sites of PI3K, ATK, and NF- $\kappa$ B. Subsequently, we could use ESI-MS to validate it.

## AUTHOR CONTRIBUTIONS

YT: evidence collection, manuscript preparation and write the central part of the manuscript. QL: evidence collection and manuscript editing. FY: evidence collection and write the minor part of the manuscript. YiZ: evidence collection, figures preparation. XZ: gave many professional suggestions and project funding. The treatment of allergic diseases, such as asthma, with both conventional and novel therapies presents a challenge both in terms of optimal effect and cost. On the other hand, traditional therapies utilizing natural products such as onion have been in use for centuries with demonstrated efficacy and safety but without much knowledge of their mechanisms of action. In this study, we investigated if the anti-inflammatory effects of onion bulb extract (OBE) are mediated via the modulation of the EGFR/ERK1/2/AKT signaling pathway, and whether OBE can synergize with steroids to produce greater anti-inflammatory actions. Treatment with OBE inhibited the house dust mite (HDM)-induced increased phosphorylation of EGFR, ERK1/2 and AKT which resulted in the inhibition of HDM-induced increase in airway cellular influx, perivascular and peribronchial inflammation, goblet cell hyper/metaplasia, and also inhibited *ex vivo* eosinophil chemotaxis. Moreover, treatment with a combination of a low dose OBE and low dose dexamethasone resulted in a significant inhibition of the HDM-induced cellular influx, perivascular and peribronchial inflammation, goblet cell hyper/metaplasia, and increased the pERK1/2 levels, whereas neither treatment, when given alone, had any discernible effects. This study therefore shows that inhibition of the EGFR/ERK1/2/AKT-dependent signaling pathway is one of the key mechanisms by which OBE can mediate its anti-inflammatory effects in diseases such as asthma. Importantly, this study also demonstrates that combining OBE with steroids results in significantly enhanced anti-inflammatory effects. This action may have important potential implications for future asthma therapy.

**Keywords:** onion (*Allium cepa* Hysam), asthma, signalling, steroids, synergistic effects

## INTRODUCTION

Natural products have been the cornerstone of therapeutic agents for millennia and more recently an important source of therapeutic drugs with unique structural diversity and pharmacological actions (Newman and Cragg, 2016). Many therapeutic agents currently in use in several therapeutic areas such as cardiovascular, oncology, transplantation are natural products or their derivatives such as digoxin, vincristine, and cyclosporine, respectively. However, their use as pharmaceutical agents has waned over the last few decades in the face of advances in combinatorial chemistry and biopharmaceutical technology, the latter supplying the majority of the top ten block buster drugs in the market in 2018 (Brown et al., 2017). Indeed, more than 70% of the world's population use herb-based medicines for primary healthcare (Newman and Cragg, 2016). A recent study has also reported that approximately 60% of asthma patients in the UK have used herbal remedies for their asthma (Clark et al., 2010). These findings suggest a strong held belief that natural products not only have therapeutic benefit in a wide range conditions, but that they are also safe.

Inflammatory-based diseases, such as asthma, present a global healthcare challenge. Worldwide prevalence of asthma has been estimated to range from 1% to as high as 18% in different populations, affecting up to 300 million people worldwide (Nunes et al., 2017; WHO, 2019) with increasing prevalence particularly among children (GINA, 2019). It is currently the most common chronic respiratory disease in children and costs over a £1 billion per year in some healthcare systems in Europe (Harrison, 2015). There is also good evidence that food allergy and eczema are rising, in parallel to asthma, and have been described as a "second wave" of allergy epidemic particularly in children (Prescott and Allen, 2011). While the mechanisms of asthma still remain unclear, it is well recognized that chronic airway inflammatory disease is central to its pathogenesis and is mediated by inflammatory cells such as mast cells and eosinophils and is driven by specific Th2 and Th17 lymphocytes, cytokines, and chemokines (Massoud et al., 2016; Athari, 2019).

There have been several recent studies demonstrating that pathogenic EGF/EGFR-dependent signaling through EGF and other EGFR ligands, such as amphiregulin, is increased in asthma (Acciani et al., 2016; Ha and Rogers, 2016). EGFR expression has been reported to be weak or absent in healthy individuals but is significantly increased in the airway epithelium of not only asthmatics (Puddicombe et al., 2000; Takeyama et al., 2001a; Takeyama et al., 2001b; Polosa et al., 2002), but also in patients with COPD (de Boer et al., 2006) and cystic fibrosis patients (CF) (Burgel et al., 2007). Furthermore, in a recent clinical study conducted using *ex vivo* lung tissue from patients with COPD, the EGFR inhibitor BIBW 2948 showed some efficacy in inhibiting EGFR phosphorylation and a tendency toward reducing mucous cell metaplasia. More importantly, a positive correlation between EGFR immunoreactivity and MUC5AC mucin staining was noted when bronchial biopsies from healthy volunteers and subjects with mild-to-moderate

asthma were compared, suggesting a causal relationship (Puddicombe et al., 2000). Also, areas of epithelial damage in asthmatic patients exhibited a strong EGFR immunoreactivity suggesting that EGFR activation plays an important role in the epithelial damage/repair process in asthma (Puddicombe et al., 2000). Of interest also is that a positive correlation between mucin and EGFR staining has been shown in the small airway of CF patients (Burgel et al., 2007). Thus, increased EGFR expression is a consistent finding not only in asthma but across several disease states. Moreover, preclinical animal models have also demonstrated a strong role for EGFR in asthma. We and others have shown, using an allergic model of inflammation, that EGFR inhibitors, such as AG1478 or gefitinib, significantly reduce eosinophil recruitment, airway inflammation, airway hyperresponsiveness (AHR), and goblet cell hyper/metaplasia, thus, underscoring the importance of this signaling pathway in asthma pathogenesis (Tamaoka et al., 2008; Le Cras et al., 2011; Song H. N. et al., 2016; El-Hashim et al., 2017). Furthermore, we have also reported that ERK1/2 and AKT are downstream signaling molecules of EGFR activation (El-Hashim et al., 2017). Therefore, both clinical and preclinical studies clearly establish an important role for EGFR-dependent signaling in inflammatory-based diseases.

While the combination of inhaled corticosteroids (ICS) and long-acting beta-agonists (LABA) is a main treatment advocated by most asthma guidelines (O'Byrne et al., 2001; GINA, 2019), a significant number of patients are poorly compliant with inhaled treatments and remain under-controlled (Sherman et al., 2001). Furthermore, severe asthmatics require treatment with moderate to high doses of steroids (Carr and Kraft, 2017). This is associated with a significant side effect profile (Pinto et al., 2013). Therefore, it would be more advantageous if the asthma therapeutic goals can be achieved at lower doses of steroids since the side effects would be minimal. Synergism is a phenomenon whereby combination of drugs produces a greater effect than when each drug is given alone (Jia et al., 2009). This phenomenon is useful when low doses of efficacious drugs are combined as they produce a superior effect but with fewer side effects. Indeed, this has been demonstrated with ICS and several drug classes such as LABA and anti-leukotrienes (Beasley et al., 2019). However, no study has tested if synergism occurs between steroids and natural products within the context of inflammatory based diseases such as asthma.

Novel monoclonal antibody-based therapy, in inflammatory disease management, has made an impact on disease control. For example, the anti-IgE antibody, omalizumab, has been used as a steroid sparing drug in patients with severe asthma, but unfortunately its use is limited (Plosker and Keam, 2008) due to a high frequency of anaphylactic reaction and serum sickness (Harrison et al., 2015) and lack of cost-effectiveness. Similarly, the use of the newly introduced anti-IL5 antibodies such as mepolizumab and benralizumab is limited to severe asthmatics with a high eosinophilic component. However concerns have been raised regarding their cost-effectiveness (Agache et al., 2020). Despite the recent market increase in therapeutic agents that selectively target specific molecules, it is unlikely that the blockade

of individual mediator signaling pathways would result in optimal therapeutic outcomes in asthma, and monoclonal based therapy would certainly be beyond the financial reach of most asthma patients in the developing world due to their high cost.

*Allium cepa* L. (Family Amaryllidaceae) is one of the most commonly consumed vegetables and has also been used for medicinal purposes for numerous ailments such as ulcer wounds, scars, dysentery, inflammation, hypertension and also in respiratory conditions such as cough, asthma, and bronchitis (Lanzotti, 2006; Upadhyay, 2016; Zeng et al., 2017). Onion bulb extract (OBE) has also been shown to effectively reduce airway inflammation, IL4, and IgE levels and induces oxidation in animal models of asthma (Oliveira et al., 2015; Marefati et al., 2018). Thiosulfates (TS) and cepaenes (CS), isolated from onions and/or synthesized, were also shown to have dose-dependent inhibitory effects on both cyclooxygenase and 5-lipoxygenase activity (Dorsch et al., 1990; Wagner et al., 1990) and inhibit *in vitro* chemotaxis of human granulocytes induced by formyl-methionine-leucine-phenylalanine (WKYMvm) (Dorsch et al., 1990). In this regard, it is of interest to note that many of the previous studies that assessed the effects of onion extract have used ovalbumin as the allergenic material to induce airway inflammation. However, the use of ovalbumin has recently been questioned on the basis that it is not clinically relevant, and therefore studies using allergens such as house dust mite or *Alternaria alternata*, that simulate clinical asthma more closely (Gorska, 2018), are necessary in order to better assess the effects of onion extract in animal models.

The EGFR/ERK1/2/AKT signaling pathway has been recently shown to be an important signaling pathway, in both clinical and preclinical studies. However, whether the EGFR/ERK1/2/AKT signaling pathway is a target for OBE in a clinically relevant animal model of allergic asthma, is not known. Also whether OBE synergizes with steroids has not been studied previously. In this study, using a clinically relevant allergen (HDM), we investigated 1) whether the EGFR/ERK1/2/AKT signaling pathway is modulated by OBE, and 2) if OBE synergizes with dexamethasone to result in a greater anti-inflammatory action.

## METHODS

### Acquisition of the Plant Material

Fresh red onion bulbs were bought from the local market. The plant was identified as *Allium cepa*, and a voucher specimen, number KOE-010, was deposited at the herbarium of Kuwait University (KTUH), College of Science, Kuwait.

### Extraction of Onion Bulbs

About 20 kg of fresh red onion was peeled, coarsely cut, and percolated three times, each using 10 L of dichloromethane. The dichloromethane layers of the percolates were separated from the aqueous layer, dried over anhydrous sodium sulphate, and then evaporated *in vacuo* till dryness to obtain brownish syrupy residue. This extraction process was repeated as needed. The treatment stock solution was prepared using the residue and PBS as a vehicle.

## GC-MS Analysis

Dichloromethane extract of onion bulbs (1 µl sample size) was analyzed on a Thermo high resolution gas chromatography-mass spectrometer Double Focusing Sector system (GC-MS DFS) fitted with a DB-5MS capillary column with 0.25 µm film thickness, 30 m length and 0.25 mm inner diameter, using helium as a carrier gas with a flow rate of 0.8 ml/min. The operating conditions were as follows: splitless injector with port temperature 250°C, detector temperature 280°C, and program temperature from 50 to 250°C at the rate of 6°C/min with 10 min hold time, and from 250 to 300°C at the rate of 10°C/min with 6 min hold time. The MS conditions were as follows: electron impact ionization mode, ionization energy 70 eV, ion source temperature 175°C, scan range *m/z* 40–900 Da. The qualitative identification of the compounds was based on computer matching with NIST MS Search 2.0 library and by comparison with data in the literature (Mondy et al., 2001; Gitin et al., 2014; Abdel-Lateef et al., 2018; Fredotovic et al., 2020).

## Animals

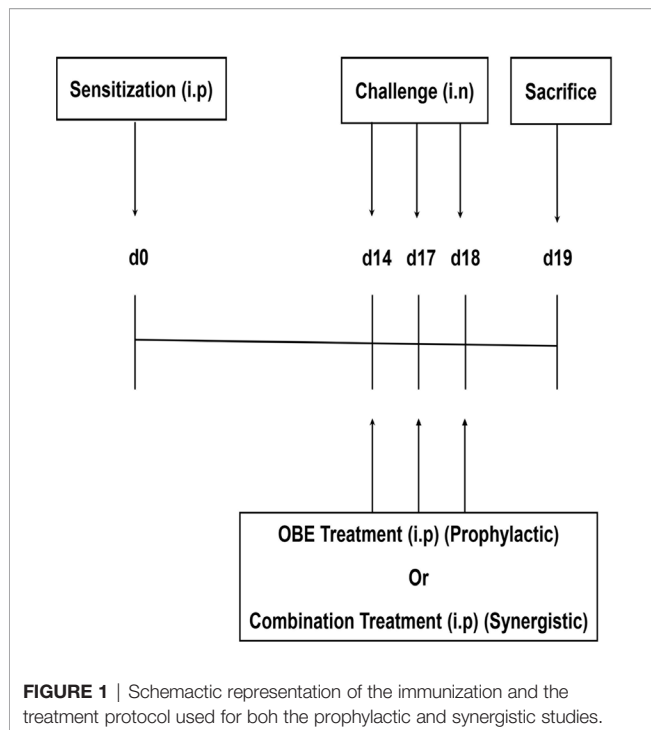

Male BALB/c mice (6–8 weeks old, average weight 25 g) were used in this study. All studies involving animals were in accordance with the ARRIVE guidelines for reporting experiments involving animals. All experimental protocols were approved by the Animal Welfare and Use of Laboratory Animals Committee in the Health Sciences Center, Kuwait University and were carried out in accordance with the EU Directive 2010/63/EU for animal experiments and the National Institutes of Health guide for the care and use of Laboratory animals (NIH Publications No. 8023, revised 1978). Animals were maintained under temperature-controlled conditions with an artificial 12 h light/dark cycle and were allowed standard chow and water *ad libitum*.

## Immunization and Intranasal Challenge and Drug Treatment Protocols

### Protocol for Prophylactic Treatment Experiments

Seven treatment groups (A–G, 9–15 animals per group) were established to determine whether OBE if given prophylactically inhibits the HDM-induced asthma phenotype. All mice were immunized once by intraperitoneal (i.p.) injection of 40 µg HDM in 0.2 ml of alu-Gel-S (Alu-Gel-S; SERVA Electrophoresis GmbH) on day 0. Mice were subsequently challenged for 3 days, days 14, 17, and 18 with HDM or PBS in the case of the control group. Mice in groups A (n = 11) and B (n = 13) were pretreated intraperitoneally with 0.2 ml of the drug vehicle, 1 h before each intranasal challenge with PBS and HDM, respectively. In the same manner, groups C (n = 10), D (n = 9), E (n = 10), and F (n = 15) were pretreated with the same volume of OBE at 10, 30, 60, and 100 mg/kg, respectively, and group G (n = 11) with dexamethasone (3 mg/kg), 1 h before each intranasal challenge with HDM (**Figure 1**).

24 h after the last intranasal challenge, animals were sacrificed with an overdose of halothane; bronchoalveolar lavage (BAL) was performed to obtain BAL fluid, and then the lungs were excised for preparation for histology, Western Blot (WB), and

**FIGURE 1** | Schematic representation of the immunization and the treatment protocol used for both the prophylactic and synergistic studies.

immunofluorescence (IF) studies. In another separate group of animals, airway responsiveness was measured. For the histology/WB/IF studies, the OBE dose of 60 mg/kg was selected to represent the prophylactic approach as it gave an optimum effect.

### Protocol for Synergistic Treatment Experiments

Six treatment groups (A–F, 9–11 animals per group) were established to determine whether combining OBE and dexamethasone would result in synergistic anti-inflammatory actions. Mice in groups A ( $n = 9$ ) and B ( $n = 11$ ) were pretreated intraperitoneally with 0.2 ml of the drug vehicle 1 h before each intranasal challenge with PBS and HDM, respectively. In the same manner, groups C ( $n = 11$ ), D ( $n = 7$ ), E ( $n = 11$ ), and F ( $n = 9$ ) were pretreated with the same volume of OBE at 30 mg/kg (OBE 30), OBE at 30 mg/kg in combination with dexamethasone (DEX) at 0.5 mg/kg (OBE 30 + DEX 0.5), 0.5 mg/kg (DEX 0.5 mg) and 3 mg/kg (DEX 3 mg), respectively, 1 h before each intranasal challenge with HDM. Treatment with OBE and/or dexamethasone was also repeated on days 14, 17, and 18 (Figure 1).

### Bronchoalveolar Lavage Fluid Cell Counts and Lung Histology

BAL fluid was collected by cannulating the trachea and washing the lungs with saline solution (0.3 ml  $\times$  4 each) after sacrificing the animals with an over dose of halothane. The BAL cells were then counted using a particle-size counter (Z1 Single Threshold; Beckman Coulter), and cytospins were prepared for differential count. The cells were stained with Diff-Quik, and a differential count of 200 cells was performed using standard morphologic criteria. Results are expressed as total cell count/ml and as total macrophages, lymphocytes, neutrophils, and eosinophils/ml in

BAL fluid. For histological assessment, segments of the lung tissue were removed and fixed in 10% buffered formalin, embedded in paraffin wax and sectioned into 5- $\mu$ m-thick slices. The sections were processed and stained separately with H&E stain and periodic acid–Schiff (PAS) according to standard methods as previously described (El-Hashim et al., 2017). Sections were examined under light microscope and the severity of pathologic changes scored independently by two experienced histologists unfamiliar with the slides. Score coding was as follows: (1 = normal, 2 = mild, 3 = moderate, 4 = severe and 5 = highly severe).

### Measurement of Airway Responsiveness

Airway responsiveness was measured 24 h after last HDM or PBS challenge, using a separate set of animals using the Buxco FinePointe series RC site (DSI, Wilmington, NC) as described previously (Queto et al., 2010; Ezeamuzie et al., 2014; Correa et al., 2017). Briefly, mice were anesthetized with an intraperitoneal injection of ketamine/xylazine (1:0.1 mg/kg) cocktail and tracheotomized with a steel 18-gauge cannula. Mice were then mechanically ventilated at a rate of 150 breaths/min and a tidal volume of 0.15 ml using a computerized small animal ventilator (FinePointe site). Following a 5 min period of stabilization and administration of PBS, airway resistance was measured by exposing mice to aerosolized methacholine (6.25–50.0 mg/ml, 5  $\mu$ l per delivery) delivered by an aerogen nebulizer and reported as total lung resistance ( $R_L$ ) (cm H<sub>2</sub>O per ml/s).

### Immunofluorescence

Lung tissues were processed as described above. Immunofluorescence was performed as previously described (Khajah et al., 2016). In short, lung sections were incubated in a blocking solution (5% bovine serum albumin (BSA) + 0.3% Triton X-100 in PBS) for 1 h and were subsequently incubated overnight at 4°C with primary antibodies [p-EGFR (Tyr1068) (Rabbit; Cat. No. 3777S), pAKT (Ser 473) (Rabbit; Cat. No. 9271L) and pERK1/2 (Thr202/Tyr204) (Rabbit; Cat. No. 9101L) (1:25–1:800 dilution) or only 1% BSA (for negative control); Cell Signaling, USA], diluted in 1% blocking solution. 24 h later, sections were washed and incubated with secondary antibody conjugated to Alexa Fluor 555 (Goat anti rabbit SFX kit; Life Technologies, USA, 1:400 dilution) for 2 h at room temperature in the dark. Following several washes in PBS, sections were stained with 4', 6 diamidino-2-phenylindole and mounted. Images were then captured on a ZEISS LSM 700 confocal microscope and fluorescence intensity estimated in defined fields using Image J software package. The laser setting and photo processing were equal among the different treatment groups for each protein. 40 $\times$  magnification for the tested molecules was equally modified in terms of sharpness and contrast to show localization of the phospho-proteins in the lung tissue.

### Western Blotting

Appropriate lobes from the dissected lungs of the mice were snap-frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$ . Following

that, the tissue samples were defrosted in ice then transferred to lysis buffer (pH 7.6) containing 50 mM Tris-base, 5 mM EGTA, 150 mM NaCl, 1% Triton 100, 2 mM  $\text{Na}_3\text{VO}_4$ , 50 mM NAF, 1 mM PMSF, 20  $\mu\text{M}$  phenyl arsine, 10 mM sodium molybdate, 10  $\mu\text{g ml}^{-1}$  leupeptin and 8  $\mu\text{g ml}^{-1}$  aprotinin. Using a homogenizer, the tissues were homogenized for 10 s, three times. Samples were allowed to lyse completely by incubation on ice for 30 min. The lysates were then centrifuged at 13,000 rpm for 10 min at 4°C and the supernatants collected, and protein concentrations were estimated by Bio-Rad Bradford Protein Assay (Bio-Rad, Hercules, CA, USA). Aliquots containing equal amounts of protein were subjected to SDS-PAGE and transferred electrophoretically onto nitrocellulose membrane (Schleicher & Schuell, Dassel, Germany). The membranes were blocked with 5% BSA and then incubated with ERK1/2 (137F5) (Rabbit; Cat. No. 4695S), pERK1/2 (Thr202/Tyr204) (Rabbit; Cat. No. 9101L) and  $\beta$ -actin antibody (Cell Signaling Technology, Boston, MA, USA; 1/1,000 dilution) (used as loading control, 1:1,000 in 5% BSA) at 4°C overnight. Membranes were incubated with appropriate secondary antibodies conjugated to horseradish peroxidase (Amersham, Buckinghamshire, UK) to detect phosphorylated form of ERK1/2 (42/44 kDa), or total form of actin (45 kDa). The immunoreactive bands were detected with Super Signal Chemiluminescent Substrate (Immuno Cruz Western blotting luminal reagent SC-20428, Santa Cruz Biotechnology) utilizing a Kodak autoradiography film (Care stream Biomax Xarfil 1660760). Images were then analyzed and quantified and the data were normalized to  $\beta$ -actin levels. The experiment was run twice with lung samples from three different mice in each treatment group (pooled) in each run.

## Measurement of Lung Cytokines

Lung tissues from mice were collected and stored at  $-80^\circ\text{C}$ . The amount of total protein was determined by Bradford analysis using the Bio-Rad Protein Assay reagent. The relative changes of different cytokines and chemokines were detected using Proteome Profiler<sup>TM</sup> Mouse Cytokine Array Kit (Catalog # ARY006, R&D Systems, Inc., Minneapolis, USA). The procedure was done in line with the manufacturer's protocols and as recently described (Khajah et al., 2019).

## Isolation of Human Blood Eosinophils

For this experiment, fresh blood was obtained from healthy individuals with no history of allergic disease and had not taken any medication in the last 72 h after receiving their informed consent. The methods and protocol for these experiments were performed in accordance with and approved by the "Ethical Committee of the Faculty of Medicine, Kuwait University". Granulocytes were isolated from heparinized (10 IU/ml) blood by erythrocyte sedimentation, followed by percoll gradient centrifugation as reported recently (Ezeamuzie et al., 2014). Eosinophils were separated using negative selection with the immunomagnetic method as previously described (Hansel et al., 1991). The eosinophil purity was checked by differential count of a Wright-Giemsa stained cytosmeared and was routinely >98%.

Viability was determined by Trypan blue exclusion and exceeded 98%.

## Boyden Chamber Assay for Eosinophil Chemotaxis

Peripheral blood derived eosinophils were used for chemotaxis assay utilizing a Boyden chamber as previously described (Gomez-Cambronero et al., 2003). Purified naïve eosinophils ( $2 \times 10^5$ ) were then placed in the upper wells, and 500  $\mu\text{l}$  of BAL fluid derived from mice challenged with PBS (vehicle) or with HDM, pretreated *ex-vivo* with either vehicle or OBE (100 and 1,000 ng/ml), were placed in the lower wells ( $37^\circ\text{C}/5\%\text{CO}_2$ ) and eosinophils allowed to migrate for 1 h. The transmigrated eosinophils were determined by counting under the microscope by using a hemocytometer.

## Statistical Analyses

All numerical values were expressed as means  $\pm$  SEM. Total cell counts represent the number of cells/ml of BAL fluid. Differential cell counts represent the absolute number of each cell type/ml of BAL fluid. Absolute  $R_L$  values were computed and were used as an index of airway responsiveness. For the histopathological assessment, a semi-quantitative 5-level lung pathology score was used to grade the degree of inflammation in each microscopic field at  $20\times$ . All data were initially assessed for normality. One-way analysis of variance (ANOVA) test followed by Bonferroni *post hoc* was used to compare differences between individual groups for both total and differential cell count as well as histopathological data and the immunofluorescence data for both the prophylactic and the synergistic studies. A two-way repeated measure analysis of variance followed by a Bonferroni *post hoc* test was used for the airway responsiveness data. The mean difference was considered as significant at a probability level of less than 0.05. All analyses were performed using GraphPad Prism.

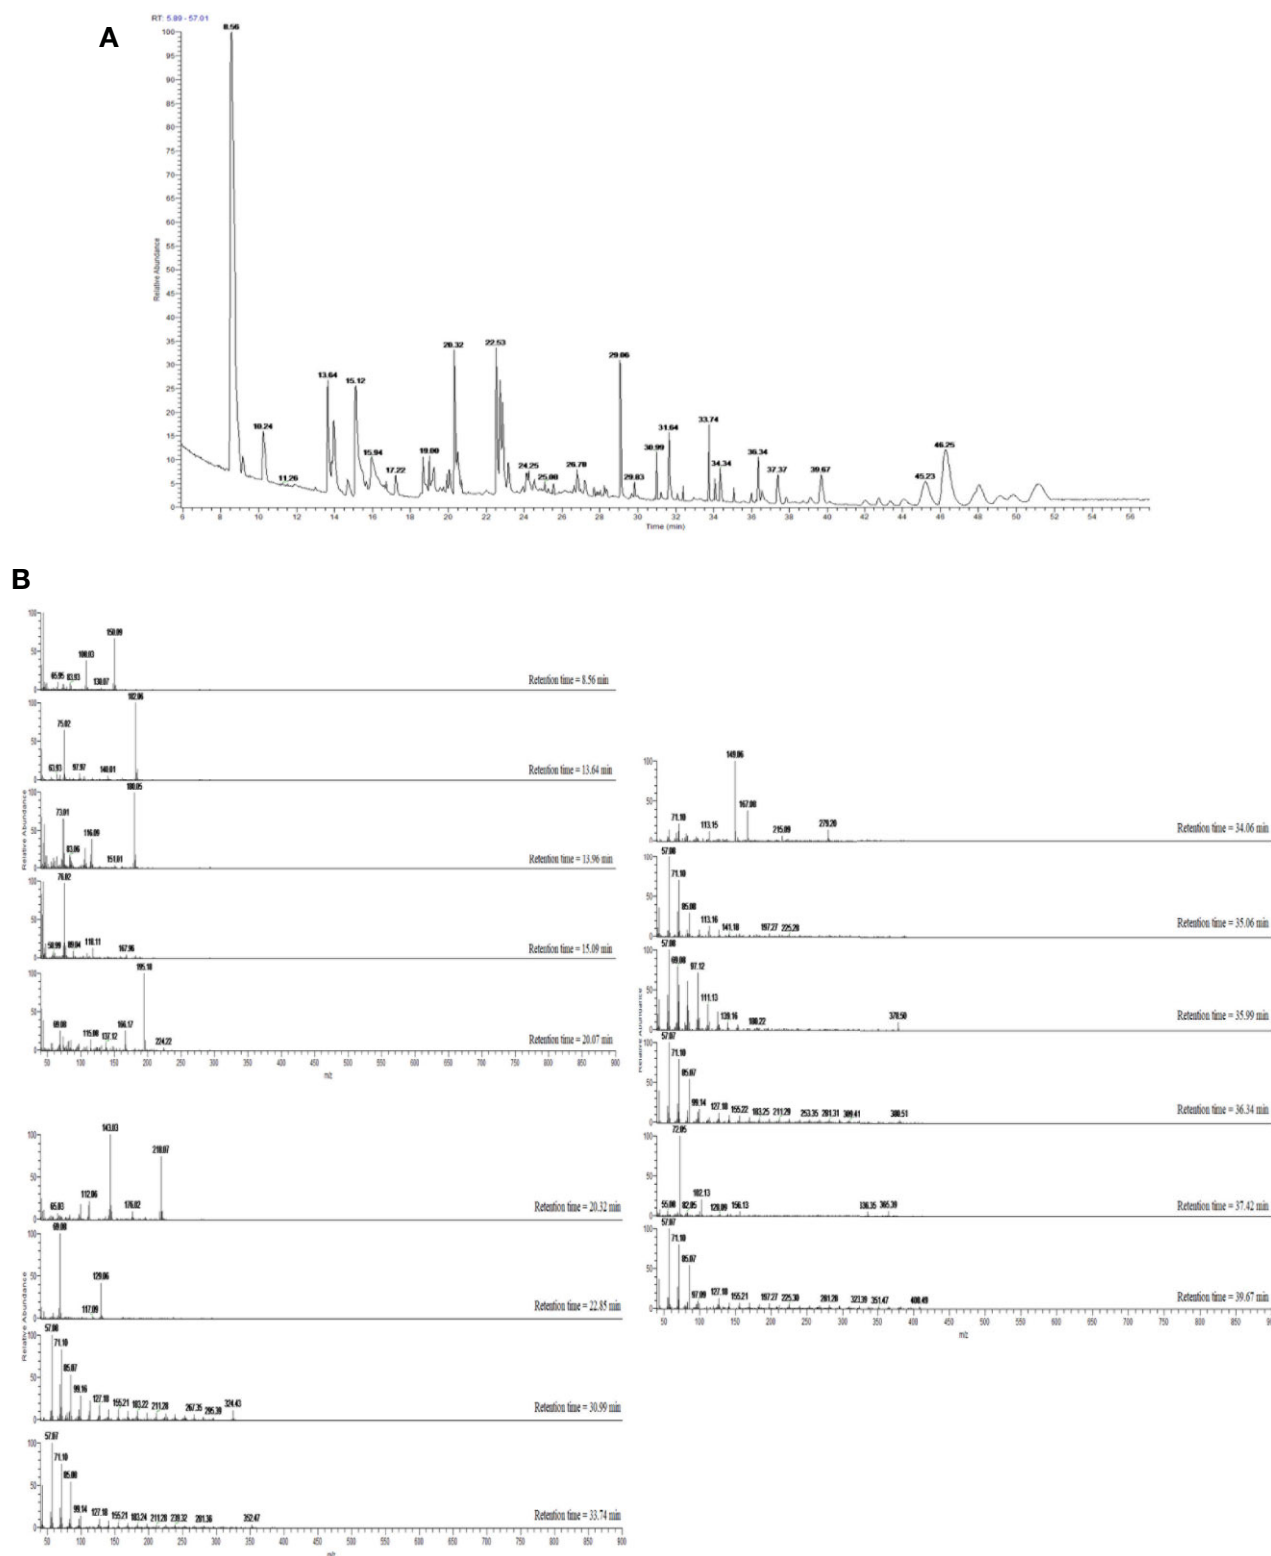

## RESULTS

### Extraction of Onion Bulbs

The extraction process was repeated four times to afford 7.5 g (0.038% yield) of brownish syrupy residue (Figure 2).

### GC-MS Analysis of OBE

Dichloromethane extract of *Allium cepa* bulb (OBE) was analyzed to identify different compounds and confirm the identity of the plant. The identified compounds and their mass spectral data are listed in Table 1. The major compound identified in the extract was shown to be the sulfur-containing compounds dipropyl disulfide, dipropyl trisulfide, and propylpropane thiosulfonate. Other sulfur compounds were also identified but at lesser quantities. Figure 2A shows the TIC of OBE where different 28 peaks are shown. Furthermore, Figure 2B shows the fragmentation patterns of some of these compounds. The identity of these compounds was confirmed *via*

**FIGURE 2 | (A)** GC-MS total ion chromatogram (TIC) of OBE. Peaks were identified through comparison with mass spectral data in the NIST MS Search 2.0 library stored in the GC-MS system and are represented in **Table 1**. **(B)** Mass spectra of compounds eluted with retention times 8.56–46.25 min and presented in **Table 1**.

**TABLE 1** | Compounds identified in *Allium cepa* bulb extract.

Identified Compounds <sup>a</sup>	Retention time, (min)	Area (%)
Dipropyl disulfide	8.56	45.93
Dipropyl trisulfide	13.64	3.16
3,5-Diethyl-1,2,4-trithiolane	13.96	1.88

a direct comparison and matching with the stored spectra in the GC-MS system.

### Effect of OBE on HDM-Induced Inflammatory Cell Influx

In these experiments, we evaluated the effect of OBE on HDM-induced total and differential cell influx. Our findings show that HDM-sensitized and challenged animals (HDM group) developed a significant increase in total cell count ( $1.3 \pm 0.3$  vs  $11.0 \pm 2.0 \times 10^5$  cells/ml) as well as in lymphocytes ( $0.03 \pm 0.01$  vs  $1.9 \pm 0.6 \times 10^5$  cells/ml) and eosinophils ( $0.04 \pm 0.02$  vs  $4.9 \pm 0.6 \times 10^5$  cells/ml), ( $P < 0.05$ ; **Figures 3A, B**,  $n = 9-15$ ), 24 h after the last HDM challenge compared to the control group. Prophylactic treatment with OBE (10, 30, 60, and 100 mg/kg) dose-dependently inhibited the HDM-induced increase in the total cells and was significant at the doses of 60 and 100 mg/kg ( $3.3 \pm 0.7$  and  $2.2 \pm 0.4$  vs  $11.0 \pm 2.0 \times 10^5$ , respectively,  $P < 0.05$ ; **Figure 3A**,  $n = 9-15$ ) and were comparable to the dexamethasone (DEX) group (used as a positive control). Moreover, OBE treatment also inhibited the HDM-induced increase in lymphocytes ( $0.4 \pm 0.2$  vs  $1.9 \pm 0.6 \times 10^5$  cells/ml,  $P < 0.05$ ; **Figure 3B**,  $n = 9-15$ ) and eosinophils ( $0.6 \pm 0.2$  vs  $4.9 \pm 0.6 \times 10^5$  cells/ml,  $P < 0.05$ ; **Figure 3B**,  $n = 9-15$ ).

### Effect of OBE on HDM-Induced Histopathological Changes

H&E and PAS stained lung sections from control mice (PBS group) showed normal histology (**Figures 4A, B**). In contrast, lung sections from mice challenged with HDM showed consistently marked and severe perivascular and peribronchial inflammatory cell infiltration (cellular infiltration score, HDM vs PBS,  $4.2 \pm 0.2$  vs  $1.0 \pm 0.07$ ) and increase in bronchial mucus production and goblet cell hyper/metaplasia (mucous intensity score, HDM vs PBS,  $4.1 \pm 0.3$  vs  $1.0 \pm 0.02$ ) demonstrating a marked degree in airway remodeling ( $P < 0.05$ ; **Figures 4A–D**,  $n = 3-6$ ). However, lung sections from OBE-treated mice (60 mg/kg) showed a significantly lower score of the histopathological parameters that were assessed (cellular infiltration score;  $2.7 \pm 0.3$  vs  $4.2 \pm 0.2$ , and

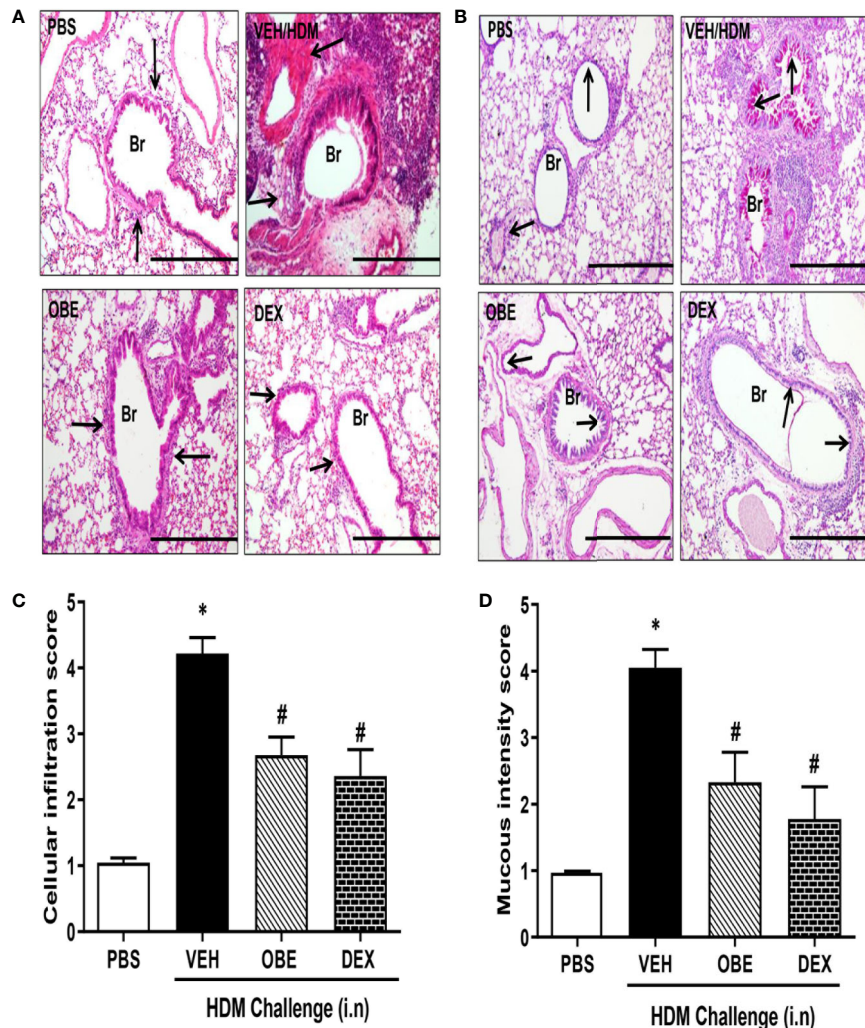

**FIGURE 3** | Effect of OBE, 10, 30, 60, and 100 mg/kg (i.p.) on HDM-induced increase in (A) total cell and (B) differential cell count. OBE treatment resulted in a dose-dependent inhibition of total and eosinophil numbers. Data are expressed as mean  $\pm$  SEM ( $n = 9-15$ ). \* $P < 0.05$  vs PBS group, # $P < 0.05$  vs HDM group.

mucous intensity score;  $2.3 \pm 0.5$  vs  $4.1 \pm 0.3$ ), achieving almost normal histological appearance that was very similar to the dexamethasone treatment group ( $P < 0.05$ ; **Figures 4A–D**,  $n = 3-6$ ).

### Effect of OBE on HDM-Induced Phosphorylation of EGFR, ERK1/2, and AKT as Determined by Immunofluorescence

Our findings show that HDM challenge induced a significant increase of about 3.0, 2.3 and 2.4-fold in the phosphorylation of EGFR, ERK1/2, and AKT, respectively, compared to PBS control as detected by immunofluorescence ( $P < 0.05$ ; **Figures 5A–C**,  $n =$

**FIGURE 4 |** Effect of OBE (60 mg/kg; i.p.) on HDM-induced histopathological changes: **(A)** representative low-magnification light photomicrographs displaying **(A)** H&E and **(B)** PAS staining of whole lung samples from control PBS-challenged mice (PBS), HDM-challenged mice (HDM), HDM-challenged mice pretreated with OBE (60 mg/kg; i.p.) (OBE) and HDM-challenged mice pretreated with dexamethasone (3 mg/kg; i.p.) (DEX), scale bar = 200 $\mu$ m. Graphs shows **(C)** cellular infiltration and **(D)** mucous intensity score for H&E and PAS staining, respectively. OBE treatment resulted in a significant decrease in both peribronchial and perivascular inflammatory cell infiltrations and bronchial mucus production and goblet cell hyper/metaplasia compared with HDM-challenged vehicle treated mice. Data are expressed as mean  $\pm$  SEM ( $n = 3-6$ ). \* $P < 0.05$  vs PBS group, # $P < 0.05$  vs HDM group.

3–5). Negative control shows no non-specific staining (data not shown). Treatment with OBE (60 mg/kg) significantly inhibited the HDM-induced phosphorylation of all proteins ( $P < 0.05$ ) and was comparable to the inhibition obtained in the dexamethasone treatment group ( $P < 0.05$ , **Figures 5A–C**,  $n = 3-5$ ).

### Effect of OBE on HDM-Induced Phosphorylation of ERK1/2 as Determined by Western Blotting

In this experiment, we assessed the levels of p-ERK1/2 and total ERK1/2 by Western blotting in order to confirm and validate the immunofluorescence data. Western blotting analysis of lung homogenate (**Figure 6A**) confirmed the modulated levels of p-ERK1/2 as seen in the immunofluorescence. HDM challenge

resulted in a marked increase in p-ERK1/2 levels compared to PBS-challenged mice (**Figures 6A, B**). Treatment with OBE resulted in a clear inhibition of the p-ERK1/2 and was similar to the dexamethasone-treated group (**Figures 6A, B**,  $n = 3$  for each blot). The effect on HDM and OBE on total ERK1/2 was relatively unchanged.

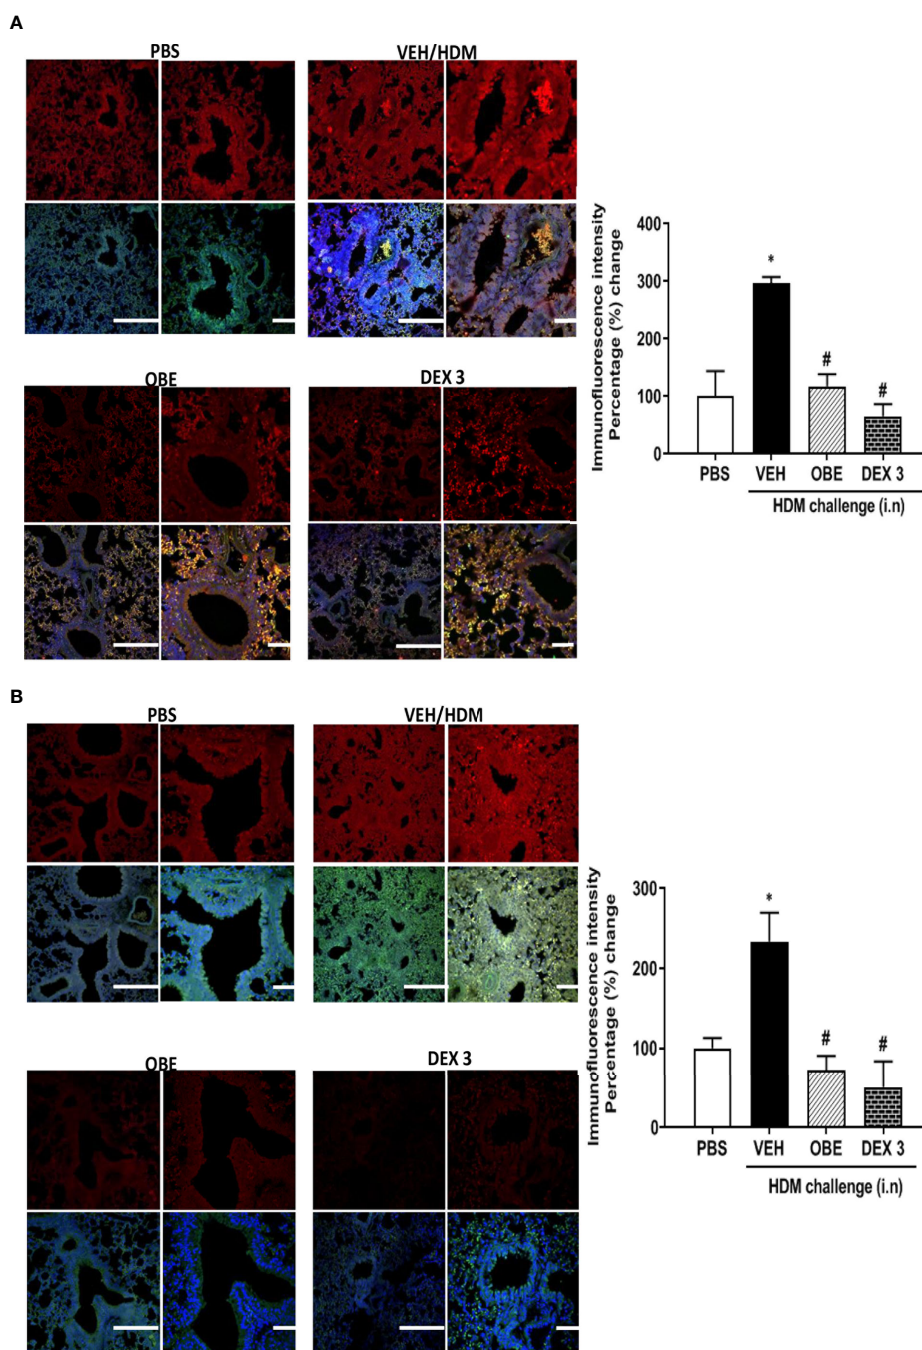

### Effect of OBE on Airway Levels of Various Cytokines Using a Proteome Profiling-Based Technique

The effect of OBE treatment (60 mg/kg) on the airway expression levels of various pro-inflammatory cytokines was determined. HDM challenge significantly enhanced the expression of the following interleukins (IL) by: IL-3 (147.4%), IL-4 (104.6%), IL-5 (5400%), IL-

10 (152.0%), and tumor necrosis factor (TNF- $\alpha$ ) (17,200%) ( $P < 0.05$ ; **Figure 7A**,  $n = 4$ ) compared to PBS-challenged mice. Treatment with OBE significantly reduced the expression of all of the above molecules by approximately 98.2–99.5%, except IL-10 (anti-inflammatory cytokine) which was significantly increased (78.6%) above the HDM levels ( $P < 0.05$ ; **Figure 7A**,  $n = 4$ ).

## Effect of OBE on Eosinophil Chemotaxis *Ex Vivo*

In this experiment, eosinophils showed significant migration towards BAL fluid derived from HDM-challenged mice compared to BAL fluid from PBS-challenged mice ( $16.5 \pm 2.4$  vs  $4.2 \pm 0.6 \times 10^4/\text{ml}$ ,  $P < 0.05$ ; **Figure 7B**). In contrast, pretreatment

**FIGURES 5 |** Continued

**FIGURES 5** | Immunofluorescent (Alexa Fluor) detection of pEGFR (A) pERK1/2 (B) and pAKT (C) shown in the upper panels overlaid with DAPI stain on the lower panel to show lung tissue architecture. Lung sections were taken from different treatment groups: PBS-challenged mice (PBS), HDM-challenged mice pretreated with vehicle (HDM), HDM-challenged mice pretreated with OBE (60 mg/kg; i.p.) (OBE), and HDM-challenged mice pretreated with dexamethasone (DEX) and immunostained for pEGFR, pERK, and pAKT. PBS-treated mice showed minimal pEGFR, pERK1/2, and pAKT expression. HDM challenge resulted in a significant increase in pEGFR, pERK, and pAKT expression, and this was inhibited following treatment with OBE (60 mg/kg; i.p.) and was comparable to the dexamethasone-treated animals, scale bar = 50  $\mu$ m. Graphs show quantitative assessment of fluorescence intensity of pEGFR, pERK1/2, and pAKT (arbitrary units). Data are expressed as mean  $\pm$  SEM ( $n = 3-5$ ). \* $P < 0.05$  vs PBS group, # $P < 0.05$  vs HDM group.

**FIGURE 6** | (A) Western blot analysis of pERK1/2 and total ERK1/2 protein levels from lungs of PBS-challenged mice pretreated with vehicle (PBS), HDM-challenged mice pretreated with vehicle (HDM), HDM-challenged mice pretreated with OBE (60 mg/kg; i.p.) (OBE) and HDM-challenged mice pretreated with dexamethasone (DEX). The blots are of two pooled lung sample ( $n = 3$ , for each). (B) Graph b shows relative densitometric quantification levels of pERK1/2 (relative to total ERK1/2, both normalized to  $\beta$ -actin).

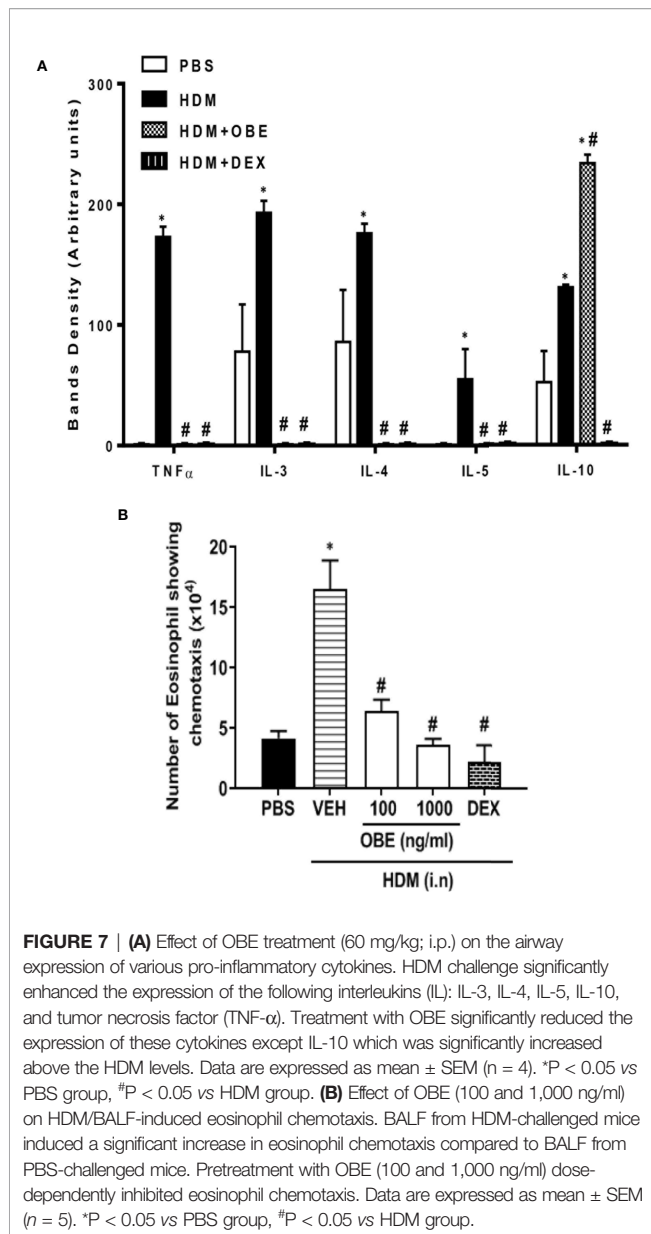

with OBE (100 and 1,000 ng/ml) dose-dependently inhibited the HDM/BAL fluid-induced eosinophil chemotaxis ( $6.4 \pm 1.0$  and  $3.7 \pm 0.5$  vs  $16.5 \pm 2.4 \times 10^4/\text{ml}$ , respectively,  $P < 0.05$ ; **Figure 7B**,  $n = 5$ ).

### Effect of OBE on HDM-Induced Airway Hyperresponsiveness

In this experiment, we evaluated the effect of OBE treatment on the HDM-induced AHR ( $n = 6-13$ ). Our data show that there

was a significant increase in airway responsiveness 24 h after the last intranasal HDM challenge as demonstrated by a significant increase in lung resistance ( $R_L$ ) to methacholine in the HDM-challenged mice as compared to the PBS-treated control mice at a dose of 25 mg/ml ( $5.2 \pm 0.2$  vs  $3.9 \pm 0.2$  cm  $\text{H}_2\text{O}$  per ml/s) and 50 mg/ml ( $7.9 \pm 0.5$  vs  $4.6 \pm 0.3$  cm  $\text{H}_2\text{O}$  per ml/s) (**Figure 8**;  $P < 0.05$ ). However, treatment with OBE did not significantly reduce the average  $R_L$  in comparison with the HDM-challenged/vehicle-

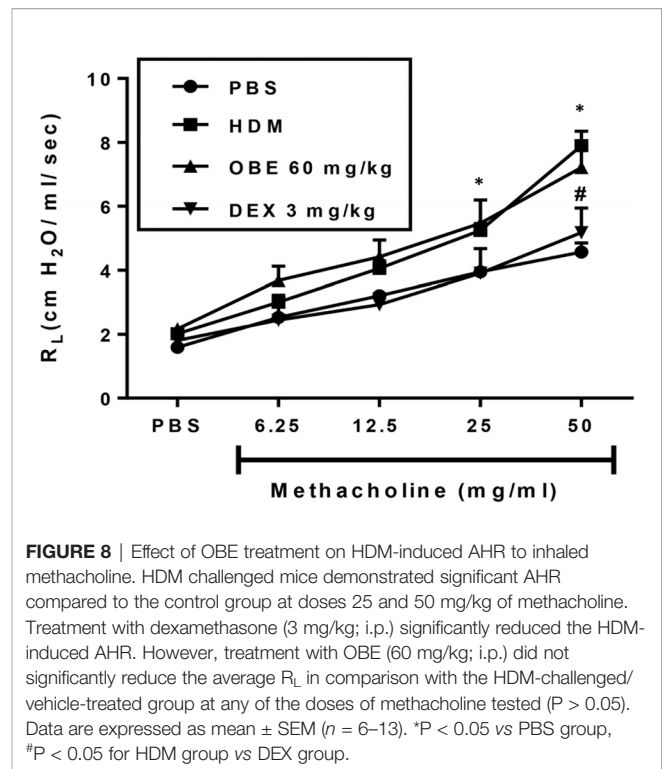

treated group at any of the tested doses of methacholine (Figure 8;  $P > 0.05$ ). Treatment with dexamethasone (3 mg/kg) nonetheless resulted in a significant reduction ( $7.9 \pm 0.5$  vs  $5.2 \pm 0.8$  cm H<sub>2</sub>O per ml/s) ( $P < 0.05$ ; Figure 8) of the HDM-induced AHR at the 50 mg/ml of methacholine.

### Synergism Between OBE and Dexamethasone on Airway Inflammatory Cell Influx

In this experiment, we evaluated the effect of combining OBE with dexamethasone on the HDM-induced total and differential cell influx. Treatment with either OBE 30 mg/kg or 0.5 mg/kg of dexamethasone had minimal to modest effects on the HDM-induced increase in the total cell count ( $5.2 \pm 0.6$  and  $4.3 \pm 0.2$  vs  $6.4 \pm 0.5 \times 10^5$ , respectively, Figure 9A,  $n = 7-11$ ). Furthermore,

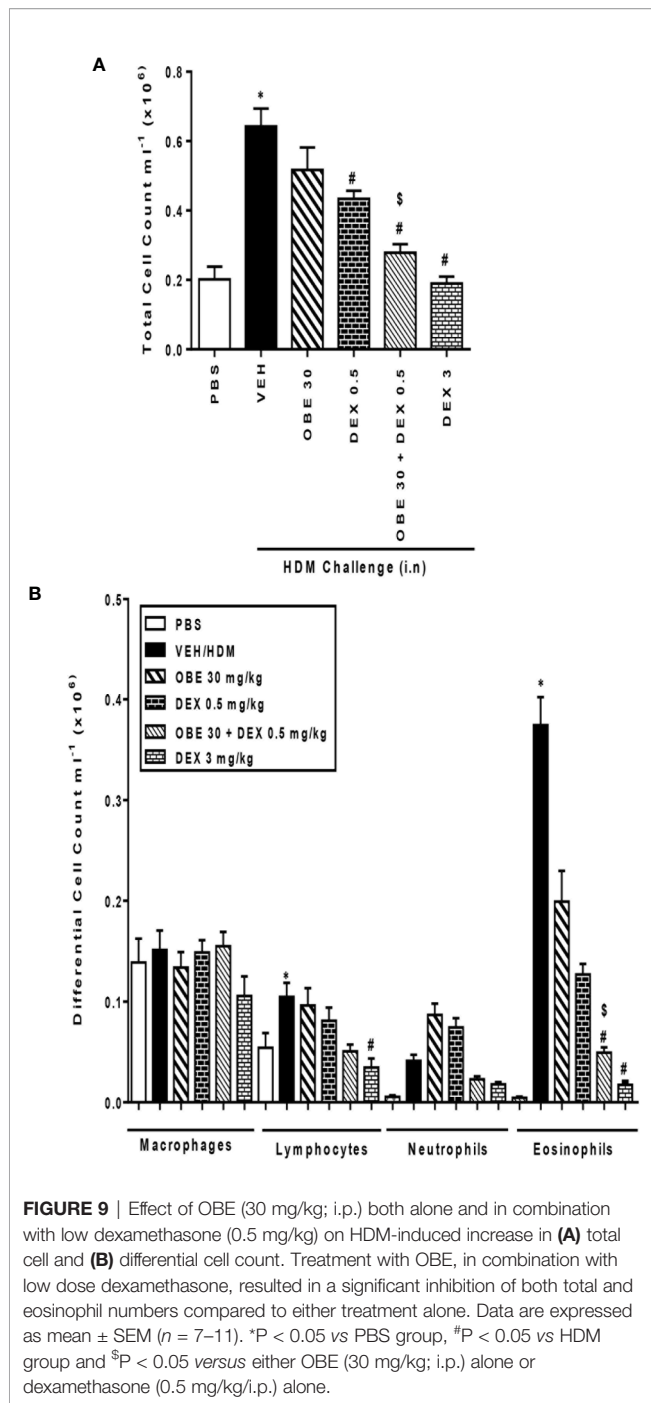

**FIGURE 8 |** Effect of OBE treatment on HDM-induced AHR to inhaled methacholine. HDM challenged mice demonstrated significant AHR compared to the control group at doses 25 and 50 mg/kg of methacholine. Treatment with dexamethasone (3 mg/kg; i.p.) significantly reduced the HDM-induced AHR. However, treatment with OBE (60 mg/kg; i.p.) did not significantly reduce the average  $R_L$  in comparison with the HDM-challenged/vehicle-treated group at any of the doses of methacholine tested ( $P > 0.05$ ). Data are expressed as mean  $\pm$  SEM ( $n = 6-13$ ). \* $P < 0.05$  vs PBS group, # $P < 0.05$  for HDM group vs DEX group.

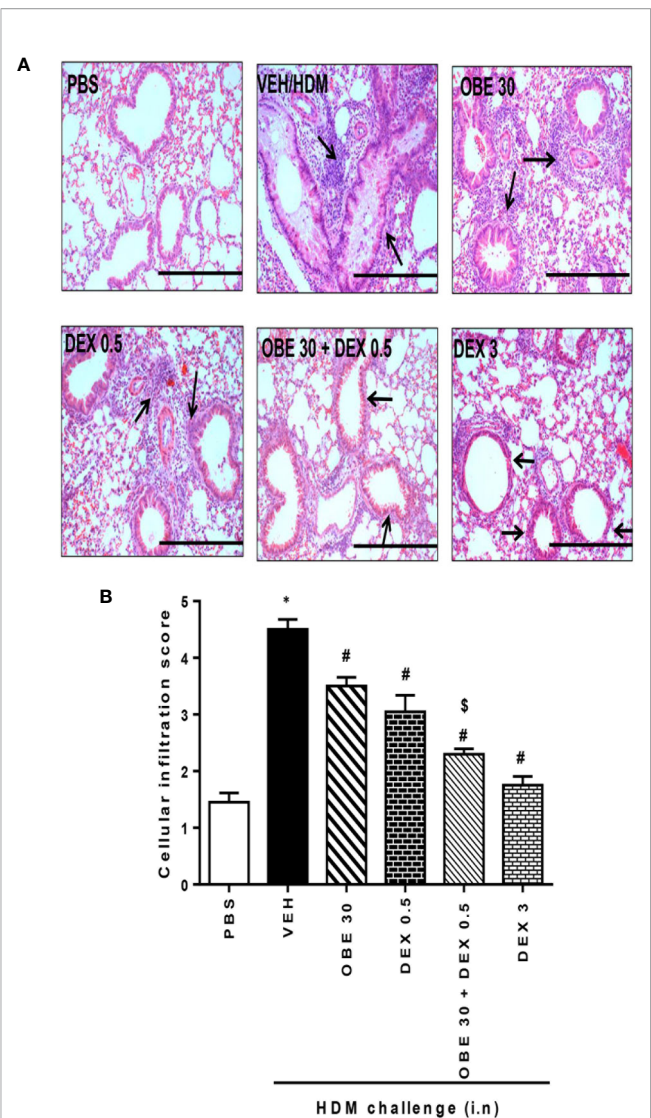

while treatment with either OBE at 30 mg/kg or dexamethasone at 0.5 mg/kg alone reduced the eosinophil influx, this did not reach statistical significance (OBE 30 and 0.5 mg/kg dexamethasone alone vs HDM,  $1.9 \pm 0.3$  and  $1.3 \pm 0.1$  vs  $3.7 \pm 0.3 \times 10^5$ , respectively,  $P > 0.05$ ; Figure 9B). However, when OBE, at 30 mg/kg, was combined with dexamethasone [0.5 mg/kg], the inhibitory effect of this combination was significantly greater compared to either treatment when given alone ( $2.7 \pm 0.2$  vs  $5.2 \pm 0.6$ ,  $4.3 \pm 0.2$ ,  $6.4 \pm 0.5 \times 10^5$ , respectively,  $P < 0.05$ , Figure 9A) and was indeed comparable to the high dose dexamethasone (3 mg/kg). Similarly, the combined treatment of both OBE (30 mg/kg) and dexamethasone (0.5 mg/kg), resulted in a significant reduction in the HDM-induced airways eosinophilia ( $0.4 \pm 0.1$  vs  $1.9 \pm 0.3$ ,  $1.3 \pm 0.1$ ,  $3.7 \pm 0.3 \times 10^5$ , respectively,  $P < 0.05$ ; Figure 9B) compared to either treatment when given alone and was comparable to the high dose dexamethasone treatment (3 mg/kg).

### Synergism Between OBE and Dexamethasone on HDM-Induced Histopathological Changes

In this experiment, our data show that treatment with either OBE (30 mg/kg) or dexamethasone (0.5 mg/kg) alone resulted in modest but significant reduction in the HDM-induced perivascular and peribronchial inflammation (cellular infiltration score;  $3.5 \pm 0.2$  and  $3.1 \pm 0.3$  vs  $4.5 \pm 0.2$ , respectively,  $P < 0.05$ ; Figures 10A, B,  $n = 5$ ). However, when OBE (30 mg/kg) was combined with dexamethasone (0.5 mg/kg), the inhibitory effect on the HDM-induced inflammation was now more marked and significantly greater than each treatment given alone (cellular infiltration score,  $2.3 \pm 0.1$  vs  $3.5 \pm 0.2$ ,  $3.1 \pm$

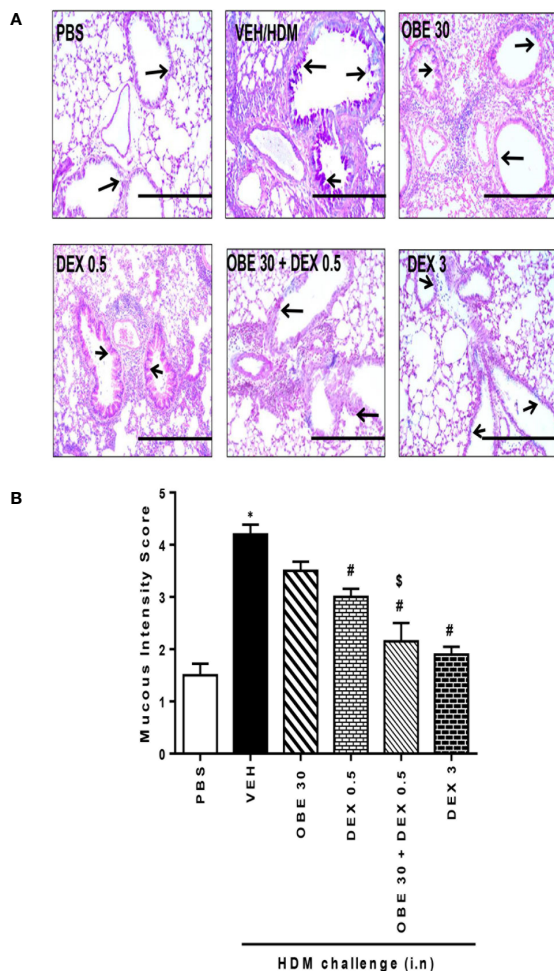

0.3,  $4.5 \pm 0.2$ , respectively,  $P < 0.05$ ; **Figures 10A, B**) and was similar to the high dose dexamethasone (3 mg/kg) treatment. Similarly, treatment with either OBE (30 mg/kg) or dexamethasone (0.5 mg/kg) alone resulted in a modest reduction in the HDM-induced goblet cell hyper/metaplasia and increase in bronchial mucus production (mucous intensity score;  $3.5 \pm 0.2$  and  $3.0 \pm 0.2$  vs  $4.2 \pm 0.2$ , respectively,  $P < 0.05$ ; **Figures 11A, B**,  $n = 5$ ). However, the combination treatment of OBE (30 mg/kg) with dexamethasone (0.5 mg) significantly inhibited the HDM-induced goblet cell hyper/metaplasia and increase in bronchial mucus production airway

**FIGURE 10 |** Effect of OBE (30 mg/kg; i.p.) alone and in combination with low dexamethasone (0.5 mg/kg) on HDM-induced peribronchial and perivascular inflammatory cell infiltrations. (A) Representative low-magnification light photomicrographs displaying H&E staining of whole lung samples from control PBS-challenged mice (PBS), HDM-challenged mice (HDM), HDM-challenged mice pretreated with OBE (30 mg/kg; i.p.) (OBE 30), HDM-challenged mice pretreated with low dexamethasone treated (0.5 mg/kg; i.p.) (DEX 0.5), HDM-challenged mice pretreated with a combination of OBE (30 mg/kg; i.p.) and low dexamethasone treated (0.5 mg/kg; i.p.) (DEX 30 + DEX 0.5), HDM-challenged mice pretreated with high dose dexamethasone (3 mg/kg; i.p.) (DEX 3), scale bar = 200  $\mu$ m. Graphs shows (B) cellular infiltration score for H&E. OBE treatment in combination with low dose dexamethasone resulted in a significant decrease in both peribronchial and perivascular inflammatory compared to either treatment when give alone. Data are expressed as mean  $\pm$  SEM ( $n = 5$ ). \* $P < 0.05$  vs PBS, # $P < 0.05$  vs HDM and \$ $P < 0.05$  versus either OBE (30 mg/kg; i.p.) alone group or dexamethasone (0.5 mg/kg/i.p.) alone group.

when compared to either OBE (30 mg/kg) or dexamethasone (0.5 mg/kg) given alone (mucous intensity score;  $2.2 \pm 0.4$  vs  $3.5 \pm 0.2$ ,  $3.0 \pm 0.2$ ,  $4.2 \pm 0.2$ , respectively,  $P < 0.05$ ; **Figures 11A, B**) and was almost as effective as dexamethasone at 3 mg/kg.

**FIGURE 11** | Effect of OBE (30 mg/kg; i.p.) both alone and in combination with low dexamethasone (0.5 mg/kg) on HDM-induced bronchial mucous production and goblet cell hyper/metaplasia. **(A)** Representative low-magnification light photomicrographs displaying PAS staining of whole lung samples from control PBS-challenged mice (PBS), HDM-challenged mice (HDM), HDM-challenged mice pretreated with OBE (30 mg/kg; i.p.) (OBE 30), HDM-challenged mice pretreated with low dose dexamethasone (0.5 mg/kg; i.p.) (DEX 0.5), HDM-challenged mice pretreated with a combination of OBE (30 mg/kg; i.p.) and low dose dexamethasone (0.5 mg/kg; i.p.) (OBE 30 + DEX 0.5), HDM-challenged mice pretreated with high dose dexamethasone (3 mg/kg; i.p.) (DEX 3), scale bar = 200μm. Graphs show **(B)** mucous intensity score. OBE treatment in combination with low dose dexamethasone resulted in a significant decrease in bronchial mucus production and goblet cell hyper/metaplasia compared to either treatment when give alone. Data are expressed as mean ± SEM (*n* = 5). \**P* < 0.05 vs PBS and #*P* < 0.05 vs HDM and \$*P* < 0.05 versus either OBE (30 mg/kg; i.p.) alone group or dexamethasone (0.5 mg/kg/i.p.) alone group.

## Synergism Between OBE and Dexamethasone on HDM-Induced pERK1/2 Levels

In this experiment, our data show that treatment with either OBE (30 mg/kg) or the low dose dexamethasone (0.5 mg/kg) did not result in marked inhibition of the HDM-induced phosphorylation of ERK1/2 ( $267.0 \pm 13.8$  and  $264.8 \pm 4.9$  vs  $319.0 \pm 10.4\%$ ,

respectively, *P* < 0.05; **Figure 12**, *n* = 4–5). However, when OBE (30 mg/kg) was combined with the low dexamethasone (0.5 mg/kg), there was now a marked and significant reduction in pERK1/2 levels compared to either OBE (30 mg/kg) or the low dose dexamethasone (0.5 mg/kg) alone ( $80.0 \pm 16.0$  vs  $267.0 \pm 13.8$  and  $264.8 \pm 4.9$ , respectively, *P* < 0.05; **Figure 12**). Of interest, the degree of inhibitory effect on pERK1/2, in the combination treatment, was twofold greater than that were obtained with the high dexamethasone dose (3 mg/kg) (*P* < 0.05; **Figure 12**).

## DISCUSSION

The major finding of this study is that OBE produces anti-inflammatory actions in an established asthma model, partly, *via* inhibition of the EGFR/ERK1/2/AKT pathway. Furthermore, our data show that combined treatment with OBE and a classical steroid (dexamethasone) at sub-maximal doses resulted in an enhanced anti-inflammatory effect at the cellular, histopathological, and molecular levels.

The use of natural products as therapeutic agents has been on the rise, not only due to their demonstrated efficacy (both in humans and in preclinical models of disease) but possibly due to their perceived, and in many instances, real lack of adverse effects, even when consumed in large quantities (Bohlin et al., 2010; Atanasov et al., 2015). Based on this, many studies have been conducted over the past decades in an attempt to understand the scientific basis for the use of many natural products, elucidate their actions, and identify their mechanisms of action in animal models of disease (Fang et al., 2017). To this point, several studies have reported that OBE, or its constituents, have many pharmacological actions in many conditions and diseases such as wounds, scars, dysentery, inflammation, hypertension, and also asthma.

Our data show that OBE dose-dependently decreased the total and differential cell influx into the airways, at both 60 and 100 mg/kg dose, confirming data from recent studies reporting its inhibitory effect on BAL fluid cellularity (Ghorani et al., 2018). In line with this, we found that 60 mg/kg dose of OBE resulted in significant reduction of the HDM-induced perivascular and peribronchial inflammatory cell infiltration and goblet cell hyper/metaplasia. These anti-inflammatory actions were comparable to the action of dexamethasone (3 mg/kg) which indicates that the anti-inflammatory action of OBE is, at least, as effective as that of steroids. Our findings are in agreement with studies showing anti-inflammatory action of OBE in asthma-like models and more recently in a mouse model of colitis (Ghorani et al., 2018; Khajah et al., 2019). It is of interest to note that many of the documented activities for onion extract have been attributed to its polar constituents, particularly the known flavonoid quercetin, where polar solvents were mainly used to prepare the tested extracts (Oliveira et al., 2015). However, in this study, the anti-inflammatory action noted are most likely due to non-polar fat-soluble constituents, such as sulfur-containing compounds, mainly dipropyl disulfide and dipropyl trisulfide, which were found in abundance in the essential oil of onion since dichloromethane was used for the extraction method.

**FIGURE 12 |** Immunofluorescence (Alexa Fluor) detection of phosphorylated ERK1/2 are shown in the upper panels overlaid with DAPI stain on the lower panel to show lung tissue architecture. Lung sections were taken from different treatment groups, control PBS-challenged mice (PBS), HDM-challenged mice (HDM), HDM-challenged mice pretreated with OBE (30 mg/kg; i.p.) (OBE 30), HDM-challenged mice pretreated with low dose dexamethasone (0.5 mg/kg; i.p.) (DEX 0.5), HDM-challenged mice pretreated with a combination of OBE (30 mg/kg; i.p.) and low dose dexamethasone (0.5 mg/kg; i.p.) (OBE 30 + DEX 0.5), HDM-challenged mice pretreated with high dose dexamethasone (3 mg/kg; i.p.) (DEX 3), scale bar = 50 μm. Graph shows quantitative assessment of fluorescence intensity of ERK (arbitrary units). Data are expressed as mean ± SEM ( $n = 4-5$ ). \* $P < 0.05$  vs PBS and \* $P < 0.05$  vs HDM and \* $P < 0.05$  versus either OBE (30 mg/kg; i.p.) alone group or dexamethasone (0.5 mg/kg/i.p.) alone group.

The EGF/EGFR is a critical signaling pathway in the pathogenesis of asthma, and both EGF and EGFR levels have been shown to be consistently increased in both human asthma and in animal models of asthma (Amishima et al., 1998; Puddicombe et al., 2000; Song L. et al., 2016). However, other ligands such as heparin-binding EGF-like growth factor (HB-EGF), amphiregulin, and betacellulin can also bind to and activate EGFR (Acciani et al., 2016; Ha and Rogers, 2016). In

addition, ERK1/2 and AKT are not only key signaling molecules in asthma but have also been recently shown to be downstream of EGFR activation (El-Hashim et al., 2017). Our data show that treatment with OBE not only inhibited the development of asthma but also reduced pEGFR levels. Of interest and relevance is data from a recent study from our group, and that of others, using a similar model of asthma, has shown that treatment with selective EGFR inhibitors inhibited the EGFR-

dependent signaling pathway and also reduced eosinophil recruitment, airway inflammation, AHR, and goblet cell hyper/metaplasia (Song L. et al., 2016; El-Hashim, 2017). Therefore, our findings would imply that the inhibitory effects of OBE on the asthmatic phenotype may be, at least partly, *via* inhibition of EGFR-dependent signaling perturbation. However, it is also likely that in addition to the EGFR pathway, OBE may inhibit other pro-inflammatory signaling pathways.

Our data also show that HDM-induced increase in pERK1/2 and pAKT were both inhibited following OBE treatment. While it is plausible that the effect of OBE on these signaling molecules represents independent and separate effects, since both ERK1/2 and AKT are ubiquitous signaling molecules, we have previously reported that AG1478, a selective EGFR receptor inhibitor, inhibited not only EGFR activation but also decreased pERK1/2 and pAKT levels, suggesting that both molecules are downstream of EGFR activation (El-Hashim et al., 2017). Therefore, it is very likely that the inhibitory effect of OBE on these two molecules is primarily due to upstream inhibition of EGFR-dependent signaling. This notion is further confirmed by our recent study showing that the effects of the anti-inflammatory endogenous molecule, Ang-(1-7), in asthma, are mediated *via* inhibition of the EGFR/ERK1/2 dependent signaling (El-Hashim et al., 2019). That OBE can inhibit the EGFR-triggered signaling perturbations suggests that it can inhibit a central signaling pathway in asthma.

It is well recognized that asthma is an immune response driven by Th2 and Th17 cells with cytokines such as IL-4, IL-5, IL-9, IL-10, IL-13, and IL-7 playing important roles (Saeki et al., 2019). Moreover, Th1 cytokines such as TNF- $\alpha$  and IFN- $\gamma$  are also involved in asthma, with pro- and anti-asthma effects, respectively. Our findings show that OBE treatment resulted in a significant reduction of IL-4 and IL-5 consistent with other studies and effects of drugs that mediate an anti-allergic/anti-asthma action (Seo et al., 2019). In addition, OBE treatment decreased the pro-asthma TNF- $\alpha$  but increased the Th2 anti-inflammatory cytokine, IL-10. It is therefore plausible that the OBE-induced increase in IL-10 levels may, in part, explain the anti-inflammatory action of OBE in general and/or the specific decrease in the levels of IL-4 and IL-5, as these cytokines are known to have a reciprocal relationship (Oliveira et al., 2015).

The recent introduction of monoclonal antibodies targeting the eosinophil chemoattractant underscores the importance of eosinophils in asthma (Agache et al., 2020). Our data show that treatment with OBE significantly reduced eosinophil numbers not only in the tissue but also their *ex vivo* chemotaxis towards BAL fluid from HDM challenged mice. Studies have shown that onion constituents, such as thiosulfonates and cypenes, dose-dependently inhibit both cyclooxygenase and 5-lipoxygenase enzyme activity (Werz, 2007). Furthermore, products of 5-lipoxygenase, namely the cysteinyl leukotrienes LTC<sub>4</sub>, LTD<sub>4</sub>, and LTE<sub>4</sub>, are known to be potent inducers of eosinophil chemotaxis (Werz, 2007). Therefore, inhibition of 5-lipoxygenase may represent one possible mechanism by which OBE inhibits eosinophil chemotaxis.

Our data also show that HDM challenge resulted in the induction of AHR, a characteristic feature of both clinical and

preclinical asthma that is not easily amenable to asthma therapy (Busse, 2010; Ezeamuzie et al., 2014). Our findings show that treatment with OBE had no effect on this parameter. Although many studies have reported a causal link between airway inflammation and AHR, others have not been able to confirm this relationship, at least not for all types of AHR (Gozzard et al., 1996; Spina et al., 1998; El-Hashim et al., 1999; Spina and Page, 2009). Indeed, there may be a separation between the two phenomena, as not all agents that inhibit airway inflammation reduce AHR and *vice versa* (Riccio et al., 1997; El-Hashim et al., 2004). Recent studies have also provided good evidence that airway sensory hyper-excitability may also underlie AHR, and hyperactivity of airway nerves is less susceptible to anti-inflammatory agents (Spina and Page, 2009; Delescluse et al., 2012; Lommatzsch, 2012).

Although ICS have been the mainstay treatment for asthma, being effective anti-inflammatory agents, their major limitation is their high side effect profile, particularly with moderate-to-high doses (Hosny et al., 2016). In addition, the high cost of ICS is a real problem in poorer regions of the world (Watson and Lewis, 1997). To test whether OBE and steroids have a synergistic effect, we combined a low dose of OBE, 30 mg/kg and a low dose of dexamethasone, 0.5 mg/kg both of which produced minimal to mild anti-inflammatory effect when given alone. An important and novel finding in this study is that when OBE is combined with a low dose dexamethasone, a more powerful and effective anti-inflammatory effect was produced. Our data also show that the combination treatment resulted in a marked and significant enhancement of the anti-inflammatory effects on the total cell, eosinophil influx, histopathological changes (both perivascular and peribronchial inflammation and goblet cell hyper/metaplasia) when compared to either treatment alone. This combination was at least as effective as the high dose (3 mg/kg) steroid. To determine whether this was being mediated *via* enhanced suppression of the EGFR/ERK1/2/AKT signaling pathway, we assessed p-ERK1/2 expression level as a marker of activation of this signaling pathway. Our results clearly show that whilst neither 0.5 mg/kg dexamethasone nor 30 mg/kg alone had any effect on p-ERK1/2 levels, when both agents are combined, a significant and dramatic decrease in p-ERK1/2 levels was detected. This clearly indicates that the enhanced suppressive effects are being mediated *via* synergistic actions at the molecular level.

In conclusion, our data clearly show that OBE inhibits the asthma phenotype in a clinically relevant murine model of asthma, at least in part, *via* inhibition of Th2 cytokine profile, *via* inhibition of the EGFR/ERK1/2/AKT signaling pathway. In addition, our data also show that combining OBE with steroids resulted in an enhanced anti-inflammatory effect *via* a synergistic action at the molecular signaling level. Therefore, this study not only identifies an important molecular signaling pathway that is targeted by OBE to inhibit the asthma phenotype, but also shows that OBE synergizes with steroids resulting in a greater anti-inflammatory action. This finding may have important implication for the treatment of asthma as it provides a potential to reduce steroid toxicity while maintaining efficacy.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## ETHICS STATEMENT

The animal study was reviewed and approved by Animal Welfare and Use of Laboratory Animals Committee in the Health Sciences Center.

## AUTHOR CONTRIBUTIONS

Conceived and designed the experiments: AE-H, MK, and KO. Performed the experiments: SB, AA and HS. Analyzed the data: SB, AA, HS, AE-H, KO, and MK. Wrote the paper: AE-H. Edited the paper: KO and MK. All authors contributed to the article and approved the submitted version.

of *B. paniculatum* Aqueous Bulb  
Extract on the Human Hepatocellular  
Carcinoma Cell Line BEL-7404.  
Front. Pharmacol. 11:01261.  
doi: 10.3389/fphar.2020.01261

The herb *Bolbostemma paniculatum* (Maxim) Franquet (Cucurbitaceae family), also known as Tu-Bei-Mu (TBM) in Chinese, has shown curative effects to treat several types of cancer as an adjunctive therapy. Thereby we intend to find its effect on the human hepatocellular carcinoma (HCC) and to understand the pharmacological mechanism behind it. In this study, an integrative serum pharmacology-based approach linking serum pharmacology and bioinformatics prediction was employed. Firstly, we used the serum taken introgastrically from the rats administered by TBM aqueous bulb extract to culture the HCC cell line BEL-7404 and detect its anti-tumor effects. Secondly, the TBM putative targets were predicted using the ETCM database and known therapeutic targets of NPC were collected from the OMIM database. Then, a TBM-HCC putative targets network was constructed using the DAVID and STRING databases. Thirdly, key gene targets were obtained based on topological analysis and pathway enrichment analysis. The expression of 4 representative key targets were validated by Western blotting. As a result, 36 TBM targets and 26 known therapeutic targets of HCC were identified. These key targets were found to be frequently involved in 13 KEGG pathways and 4 biological processes. The expression of four representative key targets: TP53, CASP3, BCL2 and BAX further supports the suppression of TBM on HCC. In general, our study shows the curative effects of TBM against HCC. By using this integrative approach, we may find novel potential therapeutic targets to suppress HCC using TBM as an adjunctive therapy. And it could also help us understand the mechanism of HCC treatments in response to TBM.

**Keywords:** traditional Chinese medicine, *Bolbostemma paniculatum*, Tu Bei Mu, hepatocellular carcinoma, network pharmacology

## INTRODUCTION

Hepatocellular carcinoma (HCC) is a globally increased malignant cancer with high death occurrence (Jorge et al.; Elserag, 2011). The major management of HCC includes resection and chemotherapy (Baer et al., 1998; Whittaker et al., 2010). However, many drugs for HCC still have toxic side effects, which limit their usage in the clinic (Cheung et al., 2007; Sak, 2012; Chen et al., 2020; Zingales et al., 2020), and drug resistance of HCC hampers the treatment effects (Xiong et al.; Folmer et al., 2007; Tan et al., 2019; Li et al., 2020; Xu et al., 2020; Yang et al., 2020). Hence, it is urgent to discover new curative compounds with less adverse effects to treat this disease.

Traditional Chinese medicine (TCM) has been used to treat many diseases for more than 2500 years with its comprehensive active compounds and curative therapeutic effects. It has been reported that many herbs show suppressing effects on tumor cells (Wu and Yao; He, 2004; Dorsher and Peng, 2010). People have summarized Chinese herbal medicine's advantages in reducing the side effects of chemo- and radiotherapy (Qi et al., 2010). Several formulas including astragalus, Turmeric (curcumin), and Ginseng have been used to reduce the toxicity as adjunctive therapies. For liver cancer treatment, formulations such as Bojungikki-tang, Kang-Fu-Zhi-Tong, PHY906, Xiao-Chai-Hu-Tang, Huang-Lian-Jie-Du-Tang, and Yin-Chen-Wu-Ling-San, have been reported to protect liver function, reduce cancer-related pain, improve respiratory tract infections and gastrointestinal side effects (Ling et al., 2007; Jeong et al., 2010; M. et al., 2010; Liu et al., 2011). *Bolbostemma paniculatum* (Maxim.) Franquet (Cucurbitaceae family), whose tuber named "Tu-Bei-Mu (TBM)" in Traditional Chinese Medicine, is one such herb (the name of the herb is verified in The Plant List ([www.theplantlist.org](http://www.theplantlist.org)) and Kew Medicinal Plant Names Services (<https://mpns.science.kew.org/mpns-portal/>)). Several groups reported the suppressing effects of TBM on several types of cancer (Islam et al.; Yu et al., 1992; Cheng et al., 2010; Xu, 2010; Chao et al., 2019). Thereby, we intend to study the effects of TBM on hepatocellular carcinoma and to decode the pharmacological mechanism of TBM's action on HCC.

In 1987, a Japanese scientist Hiroko used the serum obtained from mice orally treated with the herbs to culture the cells. And the herb-contained serum effectively increased the mitogenic activity of lipopolysaccharide of murine splenic cells (Hiroko et al., 1987). Since then, many groups have been using herb-contained serum to treat the cells in order to study the herbs' effect on diseases (Zhang et al., 2007; Rui et al., 2011). Cells directly treated by the herbs are easily disturbed by the chemical and physical properties of the herbs itself. Using serum from the rats orally treated or introgastrially administered with herbs can mimic the *in vivo* environment of the cell (Wang et al., 1999; Chen X. Z. et al., 2013). A serum complex containing the herb compounds, serum proteins, genes and other molecules takes its effect as a whole to the disease. The curative effects were obvious when cells were cultured with serum, orally treated or introgastrially administered with herbs (Yun-Ming, 2007; Chen L. et al., 2013). Thereby, we used the serum from rats

introgastrially administered by TBM aqueous bulb extract to decipher its anti-tumor activity on the HCC cells.

As an alternative medicine remedy, TCM is characterized as multi-compound and multi-target, which hinders our understand the mechanism of the action. To address this problem, network pharmacology has been considered as a promising strategy. It combines experiments with bioinformatics, system biology and pharmacology to reveal the interactions among compounds, genes, proteins and metabolites (Lee; Hopkins, 2007; Da and Pei, 2014). This integrative approach helps us to more deeply understand the drug's action on certain diseases and find potential curative compounds. In recent years, our group has been using this approach to decipher the pharmacological mechanism of the herb *Radix Ophiopogonis* in the treatment of Nasopharyngeal Carcinoma (Feng et al., 2019).

In this study, an integrative pharmacology-based approach was employed to understand the TBM's effects on HCC by integrating experiments with bioinformatics predictions. Our study was implemented in three steps: (1) Lab experiments: Studying the effects of a TBM-contained serum on HCC; (2) Bioinformatics: TBM and HCC target prediction, network analysis and identification of key targets; (3) Validation of representative key targets of TBM against HCC. The workflow was elucidated in **Figure 1**.

## MATERIAL AND METHODS

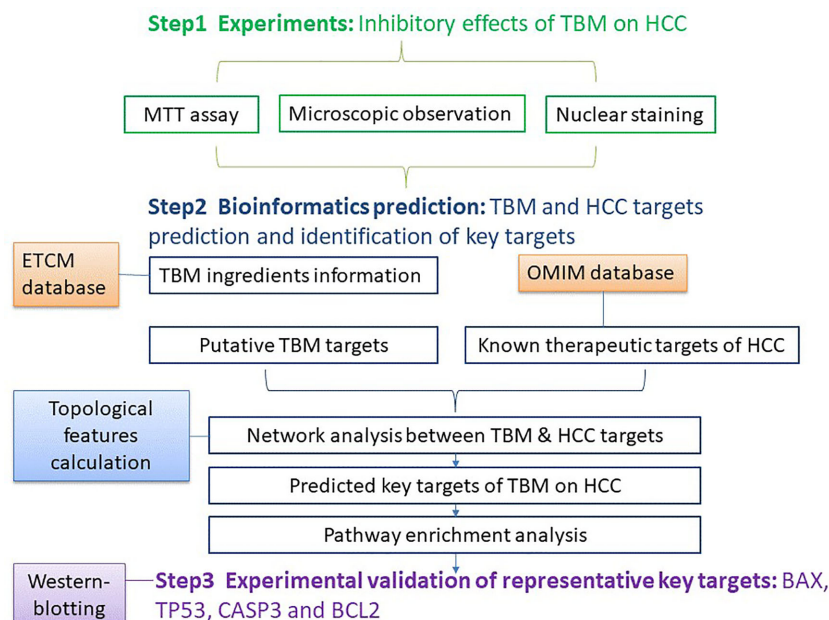

### Step 1: Effects of TBM on HCC

#### Chemicals

RPMT-1640, 3-[4, 5-Dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) powder, dimethyl sulfoxide (DMSO) (purity  $\geq 99.7\%$ ), anti-Bax, Bcl-2, p53, caspase-3 and  $\beta$ -actin primary antibodies were manufactured by Sigma-Aldrich Chemical Co., Ltd.

#### Preparation of the Fraction

The bulb of the *B. paniculatum* (TBM) was bought from the hospital of Shaanxi University of Chinese Medicine (Voucher number: 20181001). The TBM was cultivated and picked in Shaanxi province of China. The herbs were examined under the protocol of Chinese Pharmacopoeia (2015 vision). The TBM was characterized by Thin-layer chromatography (1.5% impurity, 11.9% H<sub>2</sub>O, 13mg/kg CO<sub>2</sub> residue and 1.1% Tubeimusi I). The characterization and inspection were provided by Xing Sheng De pharmaceutical Co., Ltd (Report number: C201810070). The herb was further identified by Dr Bo Li (Shaanxi Collaborative Innovation Center of Chinese Medicinal Resources Industrialization, Shaanxi University of Chinese Medicine, China). 200 ml distilled water was added to 60 g of coarsely powdered bulbs in a beaker. The mixture was kept in a water bath for 30min and boiled for 1h. The aqueous extract was then filtered and collected. The remaining powder was mixed with 200ml distilled water, boiled for 40min, filtered, and added to the prior filtrate. After evaporation, the raw concentration of the TBM was 2.5g/ml. The TBM mixture was

**FIGURE 1** | The work flow of studying the TBM's inhibitory effects on HCC using an integrative pharmacology-based approach.

stored at 4°C in labelled sample bottles. We heated the mixture to 37°C when it was needed to feed the rats.

### Animals and Treatments

30 adult female Wistar rats (200–220 g) were purchased from the Experimental Animal Center of Xi'an Jiaotong University (license number: SCXK 2017-003). The animals were housed (5 rats/cage) in the standard rats plexiglass cages in a room maintained under standard conditions of temperature and humidity with an alternating 12-hr light/dark cycle and we provided regular commercial pellet diet and water to the rats. Female Wistar rats were randomly divided into two groups: the control group and the TBM group. Control group (n = 15) received 2ml tap water twice per day for 14 days by intragastric administration. TBM group (n = 15) received the aqueous fraction of TBM with the same frequency. One hour after the last time intragastric administration, all rats were anesthetized with 2% halothane in 100% O<sub>2</sub> blown over the nose through a face mask. Then the blood was collected from the abdominal aorta of the rats. The serum was collected after centrifuging the blood for 10min at 3000r/min and stored at -20°C for use. To ensure the biosecurity, we all follow the standard protocols in each step. All experiments were conducted in accordance with the ethical guidelines of the Declaration of Helsinki, and all experimental procedures were approved and performed in accordance with the guidelines of the local Institutional Animal Experimentation Ethics Committee.

### Cell Culture

The human hepatocellular carcinoma cell line BEL-7404 and the human liver cell line L-02 were purchased from the Cell Bank of the

Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China) and cultured in the RPMI-1640 containing 10% (v/v) heat-inactivated fetal bovine serum (FBS), 100 µg/ml streptomycin and 100 U/ml penicillin at 37°C in a 5% CO<sub>2</sub> incubator. After the cells were grown into confluency, the HCC BEL-7404 cell line was divided into the following 4 groups: 10% fetal bovine serum (Contro), 25% TBM serum, 12.5% TBM serum and 6.25% TBM serum respectively prior to MTT assay and nuclear staining (The original serum obtained from rats containing TBM was considered as 100% TBM serum). The human liver cell line L-02 were regrouped into 4 groups with the same serum accordingly (Control, 25% TBM, 12.5% TBM and 6.25% TBM respectively.)

### MTT Assay

The MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay was performed with  $1 \times 10^4$  cells/well in 96-well plates. After culture for 12h, the cells were incubated with serum containing TBM. Then, 20 µl MTT (5 mg/ml) was added for 4 h. After removal of the medium, the formazan crystals were dissolved in 150 µl DMSO. Absorbance was obtained at 570 nm with an ELx-800 Universal Microplate Reader (BioTek, Winooski, VT). Cell Inhibition Ratio (%) (IR) was determined as follows:

$$\text{Inhibition Ratio (\%)} = \frac{(\text{OD}_{\text{control}} - \text{OD}_{\text{treated}})}{(\text{OD}_{\text{control}} - \text{OD}_{\text{blank}})} \times 100\%$$
(The control was 10% FBS serum; the treated cells are HCC cell line BEL-7404 and the human liver cell line L-02 treated by different concentrations of TBM; the blank was DMSO)

### Nuclear Staining

BEL-7404 cells treated with the serum containing TBM were fixed with paraformaldehyde at room temperature for 10 min. Then the

cells were incubated with 20  $\mu$ l DAPI at a concentration of 10  $\mu$ g/ml (10 min, room temperature). Nuclear morphology was observed using a fluorescence microscope (Olympus FV1000).

### Statistical Analysis

We display the data as Mean  $\pm$  SD from 3 independent experiments. A student's t-test was employed to test the deviation between different batches. Values were only considered to be statistically significant when p-values were less than 0.05.

## Step 2: TBM and HCC Target Prediction, Network Analysis and Identification of Key Targets

### Compositive Compounds of TBM

The chemical compounds of TBM were obtained from The Encyclopedia of Traditional Chinese Medicine (ETCM) database (Huang et al., 2015; Haiyu et al., 2016; Yu et al., 2017; Xu et al., 2018) (<http://www.nrc.ac.cn:9090/ETCM/index.php/Home/>, updated on 2018). The chemical compounds contained in the TBM aqueous bulb extract were selected by the criteria "Tanimoto scores > 0.8." This score represents the similarity degree of the certain chemical components to that of known drugs. Tanimoto score ranges from "0–1", where "0" means the completely different structures between ingredients and known drugs, and "1" means the same structures of two compounds. This Tanimoto score is the criteria to remove redundant compounds. The known compounds with high structural similarity (the structural similarity score is higher than 0.8) were identified as the putative compounds of TBM. The compounds with a similarity score lower than 0.8 were seen as redundant compounds. Under the criteria above, 10 chemical compounds were obtained from TBM. Detailed information of the chemical compounds contained in TBM is provided in **Supplementary Table S1**.

### TBM Putative Targets Prediction

The known putative targets of TBM were identified from the ETCM database as described above (Xue et al., 2013). As described above, putative targets of certain chemical components were predicted by comparing the structure of the certain chemical components to that of known drugs. The targets of known drugs with high structural similarity (the structural similarity score is higher than 0.8) were identified as the putative targets of the certain chemical components. After removing redundancy, we found 155 TBM putative gene targets. These targets are also provided in **Supplementary Table S1**.

### Known Therapeutic Targets of HCC

Known therapeutic targets for the treatment of HCC were collected from the OMIM database ([www.omim.org](http://www.omim.org), last updated October 31, 2013) (Hamosh et al., 2005). Only Food and Drug Administration (FDA) approved drugs used in humans were chosen. In total, 282 therapeutic targets were selected as HCC-related targets. Detailed information on the collected known therapeutic targets is provided in **Supplementary Table S2**.

## Pathway Enrichment Analysis of TBM and HCC Putative Targets

Both TBM putative targets and known therapeutic targets of HCC treatments were analyzed through pathway enrichment analysis. We used the Database for Annotation, Visualization and Integrated Discovery (DAVID, <http://david.abcc.ncifcrf.gov/home.jsp>, version 6.8) and Kyoto Encyclopedia of Genes and Genomes database (KEGG, <http://www.genome.jp/kegg/>, updated on April 18, 2016) (Kanehisa and Goto, 2000; Dennis et al., 2003) to analyze those targets and involved pathways.

## Network Analysis Between TBM Putative Targets and HCC Known Therapeutic Targets

We use the STRING (Search Tool for the Retrieval of Interacting Genes/Proteins, <https://string-db.org/>, vision 10.5) database to analyze the interaction between TBM putative targets and HCC known therapeutic targets. Interaction confidence of proteins were indicated by scores. We collected the targets when the combined score of those were higher than the medium value. Targets with the combined score lower than the medium value were discarded. Detailed information obtained is provided in **Supplementary Table S3**. Then we use Cytoscape (Vision 3.5.1, Boston, MA, USA) to visualize the networks.

## Identification of Key Predicted Targets Based on TBM-HCC Interaction Network

Based on the above network, we further identified the major nodes in the direct protein-protein interactions. We employ the three topological features: "degree", "betweenness" and "closeness" as criteria to screen the putative targets due to their topological importance. "Degree" was defined as the number of links to one node. "Node betweenness" was defined as the number of the shortest paths between pairs of nodes that ran through one node. "Closeness" was defined as the inverse of the farness, which was the sum of the node distances to all other nodes. The closeness centrality can be regarded as a measure of how long it will take to sequentially spread information from the node to all the other nodes. Degree, node betweenness and closeness centralities can be used to measure a protein's topological importance in the network. A larger value of a certain protein's degree/node betweenness/closeness centrality indicates that this protein is more important in the network (Wang et al., 2012). Only nodes with topological features higher than the corresponding median values were identified as the major targets. After screening with the above criteria, 66 candidates were identified as key targets, provided in **Supplementary Table S4**.

## Step 3: Validation of Representative Key Targets of TBM Against HCC

### Western-Blotting of Key Targets

On the spectrum of key targets' biological and topological significance, we chose caspase-3, p53, Bcl-2 and Bax to detect their expression in TBM-treated cells. As described previously, the HCC cell line BEL-7404 was treated with 10% fetal bovine serum (Contro), 25% TBM serum, 12.5% TBM serum and 6.25%

TBM serum respectively. When the cells were grown into  $1 \times 10^6$  per plate, we treated the cell line with 2, 4 or 6  $\mu\text{g/ml}$  of peiminine for 24 h. Cell lysates were prepared in RIPA buffer (50 mmol/L Tris-HCl buffer, pH 7.4, 150 mmol/L NaCl, 1% Triton X-100, 1% sodium deoxycholate, and 0.1% sodium dodecyl sulfate) supplemented with a protease inhibitor to prevent the protein degradation. Cell lysates were centrifuged at  $12,000 \times g$  for 15 min at  $4^\circ\text{C}$ . Total protein was extracted from the resulting supernatant and the concentration was quantified by the BCA assay. Proteins were separated on 10–12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred to PVDF membranes. The membranes were firstly treated overnight at  $4^\circ\text{C}$  with rabbit monoclonal anti-human  $\beta$ -actin, caspase-3, p53, Bcl-2 and Bax primary antibodies. And then the membranes were washed with PBS incubated with appropriate horseradish peroxidase (HRP)-conjugated secondary antibodies for 1 hour at room temperature. The chemiluminescence of proteins transferred to PVDF membranes was detected with ECL kit (GE Healthcare Amersham, Piscataway, NJ).

## RESULTS

The work-flow of studying the TBM's inhibitory effects on HCC using an integrative pharmacology-based approach was elucidated in **Figure 1**.

### Step I: Inhibitory Effects of TBM on HCC Cytotoxicity of TBM on HCC

The cytotoxicity of the serum containing the TBM aqueous bulb extract upon HCC cell line BEL-7404 and the human liver cell line L-02 was assessed by the MTT assay. We considered the

original serum from the rats treated with TCM as 100% TBM serum. We observed the cell viability after 24h and 48hrs. We chose 25%, 12.5% and 6.25% TBM serum to treat the cells. 10% FBS was used as the control medium. As shown in **Table 1A**, the OD values were significantly decreased after the HCC cells were treated with the TBM serum. The 25% TBM serum inhibited the HCC cells with the inhibition ratio 22.8%, indicating that TBM can significantly inhibit the growth of the HCC cells. Meanwhile, the TBM serum has much fewer inhibitory effects on the human liver cell line L-02 as shown in **Table 1B**. The total inhibitory effects were shown in **Figure 2**.

**TABLE 1A |** The inhibitory effects of the TBM serum on the HCC cell line BEL-7404.

	OD	Inhibition Ratio
Control	$0.5891 \pm 0.0061$	0
25% TBM serum	$0.4550 \pm 0.0089$	22.8%
12.5% TBM serum	$0.5278 \pm 0.0162$	10.4%
6.25% TBM serum	$0.5596 \pm 0.0158$	5.5%

The control was 10% FBS serum. Data are presented as the mean  $\pm$  SD from three independent experiments ( $p < 0.05$ ).

**TABLE 1B |** The inhibitory effects of the TBM serum on the human liver cell line L-02.

	OD	Inhibition Ratio
Control	$0.4891 \pm 0.0055$	0
25% TBM serum	$0.4633 \pm 0.0146$	5.4%
12.5% TBM serum	$0.4775 \pm 0.0127$	2.5%
6.25% TBM serum	$0.4823 \pm 0.0166$	1.9%

The control was 10% FBS serum. Data are presented as the mean  $\pm$  SD from three independent experiments ( $p < 0.05$ ).

**FIGURE 2 |** Inhibition of the TBM serum on the HCC cell line BEL-7404 and the human liver cell line L-02. The Inhibition ratio was calculated as follows: Inhibition Ratio (%) =  $[(\text{OD}_{\text{control}} - \text{OD}_{\text{treated}}) / (\text{OD}_{\text{control}} - \text{OD}_{\text{blank}})] \times 100\%$ . The control was 10% FBS serum. The blue bar shows the inhibition ratio of the TBM serum with different concentrations upon HCC BEL-7404 cells and the yellow bar shows the inhibition ratio of the TBM serum upon the human liver cell line L-02.

### Microscopic Observation Showing TBM's Inhibition on HCC Cell Line BEL-7404 With Less Cytotoxicity Towards the Human Liver Cell Line L-02

Representative images of the morphological changes observed after 48h are shown in **Figures 3A, B**. Compared to the control (FBS-treated cells), the HCC cell line BEL-7404 exposed to the TBM serum was significantly inhibited (**Figure 3A**). And the human liver cell line L-02 showed no obvious difference when they were treated with the TBM serum (**Figure 3B**).

### Nuclear Morphology of the HCC Cell Line BEL-7404 Treated With the TBM Serum

The results of nuclear staining further confirmed that TBM could inhibit the growth of HCC cells. After culturing the HCC cell line BEL-7404 with 10% FBS serum (control), 25% TBM, 12.5% TBM and 6.25% TBM respectively for 48h, the cells show different nuclear morphology as elucidated in **Figure 4**. Compared with the control, the nuclear morphology of the cells treated with TBM were damaged obviously. A higher concentration of TBM culture resulted in more cell damage.

## Step 2: Bioinformatics Prediction

### Chemical Compounds of TBM and Its Potential Gene Targets Prediction

The ETCM database was employed to obtain the chemical compounds of TBM as described previously. As a result, we collected 10 chemical compounds contained in TBM under the criteria "Tanimoto score > 0.8" as described previously in **Supplementary Table S1**. In total, 155 putative TBM gene targets were collected, also shown in **Supplementary Table S1**.

### TBM Compositive Compound-Putative Target Network

A TBM compositive compound-putative target network was built to understand the interaction between the TBM's ingredients with its putative targets as indicated in **Figure 5**. The network consists of 166 nodes (1 herb, 10 compositive compounds and 155 putative targets) and 165 edges. 91 genes with a combined score higher than the medium value were selected as the major TBM putative targets. By pathway enrichment analysis, we found these TBM putative targets were frequently involved in 8 pathways and biological processes including the p53 signaling pathway, Adipocytokine signaling pathway, PPAR signaling pathway, AMPK signaling pathway, FoxO signaling pathway, cyclooxygenase pathway, intrinsic apoptotic signaling pathway in response to endoplasmic reticulum stress and regulation of protein heterodimerization activity.

### TBM Compositive Compound-Putative Known HCC Target Network

We analyzed the interaction between the TBM compositive compounds' targets and putative known HCC targets to evaluate the effects of TBM on HCC. The interaction data of TBM putative targets and HCC known therapeutic targets was acquired as previously described in the materials and methods section. As

shown in **Figure 6**, the network consists of 307 nodes (containing 1 ingredient, 10 compositive compounds of TBM, 155 TBM putative targets, and 282 known therapeutics of HCC) and 1086 edges. As mentioned in material and methods section, three topological features "degree", "betweenness" and "closeness" were employed as criteria to screen the putative targets for topological importance. Only nodes with topological features higher than the corresponding median values were identified as major nodes. As a result, we identified 66 major nodes containing 1 ingredient, 3 compositive compounds in HCC, 36 TBM's putative targets and 26 known therapeutic targets for the treatments of HCC. Details concerning the topological features of the 66 major nodes in this network was shown in **Supplementary Table S4**. Except the ingredient TBM and its three compounds, 62 gene targets (36 TBM's targets and 26 known therapeutic targets of HCC) were considered as the key TBM-HCC predicted targets. According to the pathway enrichment analysis based on the GO annotation system and the KEGG pathway, the key TBM-HCC targets were frequently involved in 4 biological processes and 13 KEGG pathways as shown in **Table 2**. Based on the number of the edges between key targets and pathways, TBM's key targets were found to be strongly connected with Adipocytokine signaling pathway, AMPK signaling pathway, FoxO signaling pathway, Rap1 signaling pathway, mROT signaling pathway, p53 signaling pathway, VEGF signaling pathway, intrinsic apoptotic signaling pathway in response to endoplasmic reticulum stress, PI3K-AKT signaling pathway, TNF signaling pathway, activation of cysteine-type endopeptidase activity involved in apoptotic process by cytochrome c and positive regulation of ERK1 and ERK2 cascade. In the meantime, HCC key gene targets indicate that they are frequently involved in focal adhesion, positive regulation of I-kappaB kinase/NF-kappaB signaling, ErbB signaling pathway, MAPK signaling pathway and Hippo signaling pathway.

### Step 3: Expression of Representative Key Targets Validated by Western Blotting

In total, 62 gene targets were selected as key TBM-HCC targets. These targets show an important role potentially during TBM-HCC interactions. Based on the three topological features "degree", "betweenness" and "closeness", the "degree" ranges from 6-61, the "betweenness" ranges from  $4.55 \times 10^{-4}$  to 0.1279, the "closeness" ranges from 0.3252 to 0.4287, we chose four key targets averagely distributed on the spectrum of their topological significance to validate their expression by Western blotting. The topological values of these four key targets were as follows: TP53 degree 61, betweenness 0.1278, closeness 0.4129; CASP3 degree 24, betweenness 0.0246, closeness 0.3711; BCL2 degree 12, betweenness 0.0028, closeness 0.3333; BAX degree 8, betweenness  $4.55 \times 10^{-4}$ , closeness 0.3271; The detailed information of the key targets is provided in **Supplementary Table S4**. As shown in **Figure 7**, the expression of TP53, CASP3, and BAX were significantly increased when HCC cells were treated with the aqueous extract of TBM. BCL2 was down-regulated when cells were treated by 12%TBM and 25% TBM. The tumor suppressor TP53, CASP3 and BAX genes were mostly down-regulated in many types of tumors including liver cancer, while BCL2 gene suppresses the apoptosis. The up-

**FIGURE 3 | (A)** Morphological changes by different serum treatments on the HCC cell line BEL-7404 after 48h. (1) cells were cultured with 10% FBS at a concentration of  $5.1 \times 10^7$  cfu/ml. (2) Cells were cultured with 25% TBM serum at the same concentration. (3) Cells were cultured with 12.5% TBM serum at the same concentration. (4). Cells were cultured with 6.25% TBM serum at the same concentration. **(B)** Morphological changes by different serum treatment on the human liver cell line L-02 after 48h. (1) cells were cultured with 10% FBS at a concentration of  $5.1 \times 10^7$  cfu/ml. (2) Cells were cultured with 25% TBM serum at the same concentration. (3) Cells were cultured with the 12.5% TBM serum at the same concentration. (4). Cells were cultured with 6.25% TBM serum at the same concentration.

regulation of TP53, CASP3 and BAX and down-regulation of BCL2 supports the TBM's suppression effect on HCC cells. This result further confirms that the TBM's aqueous bulb extract is effective to suppress the growth of HCC cells by regulating these key targets.

## DISCUSSION

Traditional Chinese medicine has been proved to treat cancer effectively with its multi-target therapeutics. TBM, characterized

**FIGURE 4 |** The Morphology of the HCC cell line BEL-7404 by nuclear staining. The HCC BEL-7404 cells were stained using DAPI solution and observed by fluorescence microscopy (x400). (1) The HCC cells cultured with 10% FBS serum for 48h (Control). (2) The HCC cells cultured with 25% TBM. (3) The HCC cells cultured with 12.5% TBM. (4) The HCC cells cultured with 6.25% TBM.

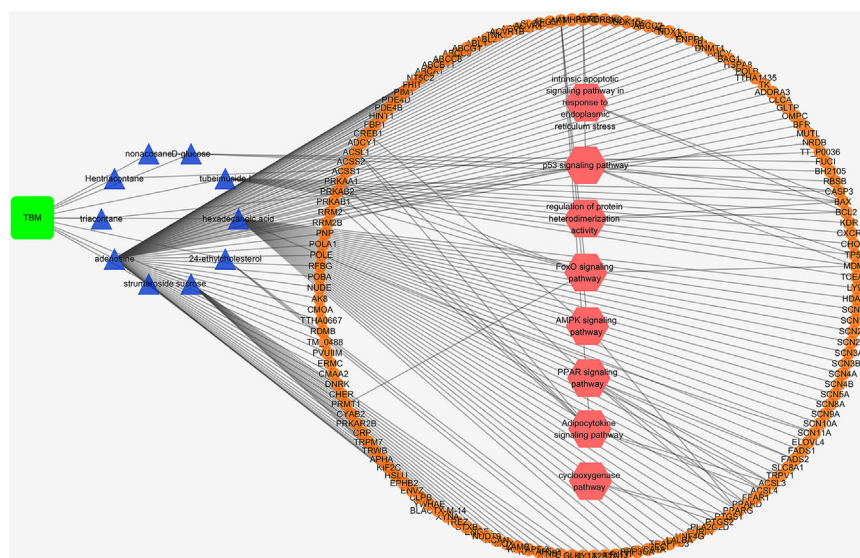

with multi-components and multi-targets, have been used to suppress liver cancer as an adjunctive therapy in recent years. In this study, we develop an integrative pharmacology-based strategy to decipher the mechanism of the TBM's aqueous bulb extract in suppressing HCC. By integrating experiments, bioinformatics prediction and validation, 62 key targets (36 TBM's targets and 26

known therapeutic targets of HCC) were identified after analyzing TBM-HCC interactions. These key targets were frequently involved in 13 KEGG pathways and 4 biological processes. The integrative analysis bridging experiments with bioinformatics prediction provides us novel potential therapeutic targets to treat HCC using TBM. And it could also help us understand the mechanism of HCC treatments in response to TBM.

All 62 key targets have shown their topological and biological significance (**Table 2**). On the topological spectrum of these key targets, we choose 4 representative targets because they are averagely distributed on the topological table (**Supplementary Table S4**). The degree score of TP53, CASP3, BAX and BCL2 are 61, 24, 8 and 12 respectively (the total degree ranges from 6 to 61).

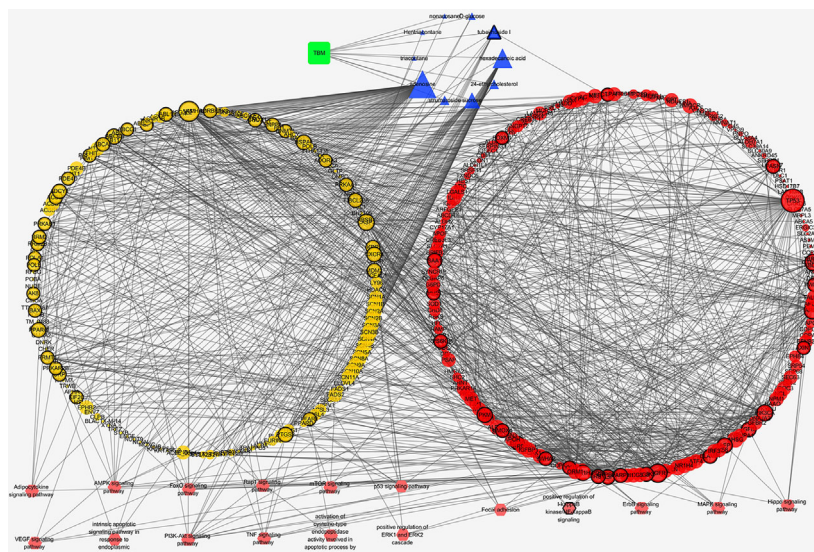

Tumor suppressor protein p53 (TP53) is a suppressor of tumor cells by inducing growth arrest or apoptosis (Moshe et al., 2002). This study revealed that TP53 were frequently involved in the p53 signaling pathway, PI3K-Akt signaling pathway and MAPK signaling pathway in hepatocellular carcinoma. TP53 takes important roles in the signaling pathways of HCC (Sia and Villanueva; Villanueva et al.; Whittaker et al., 2010). Repressed by MDM2, TP53 takes effects on cell survival in PI3K-Akt signaling pathway (Luo et al., 2003; Vara et al., 2004; Gang et al., 2005). the crosstalk between p53 protein and the MKK3/MKK6/p38 MAPK Signaling Pathway in Cancer has also been reported (Lorenzo et al.). The up-regulation of TP53 in the TCM-treated cells indicates TCM's inhibitory effects on tumor cells. And the p53 signaling pathway could act as a significant route when the curative effect of TCM takes place on HCC.

CASP3 encodes a cysteine-aspartic acid protease that plays a central role in the execution-phase of cell apoptosis. We found CASP3 was frequently involved in p53 signaling pathway, TNF

signaling pathway and MAPK signaling pathway in this study. This gene has been recognized for its importance in regulating hepatocellular carcinoma (Aquino et al.; Lu et al.). Our study shows the TBM's action on HCC cells lead to the down-

regulation of CASP3, suggesting CASP3's critical role during treating HCC with TBM.

BAX encodes Bax protein which forms a heterodimer with BCL2, and functions as an apoptotic activator. The association

**FIGURE 7** | Expression of Bcl-2, Bax, p53 and Caspase-3 in TBM-treated HCC cells validated by Western blotting. The Control group is the expression of representative key targets when cells are cultured with 10% FBS. The other three groups are the expression of these targets when cells are cultured with 6.25%, 12.5% and 25% TBM serum respectively ( $p < 0.05$ ).

and the ratio of BAX to BCL2 also determines survival or death of a cell following an apoptotic stimulus. Compared with normal cells, the tumor cells always show a decreased expression of the Bax/BCL2 ratio (Sakinah et al., 2007; Wei et al., 2008). Our study shows an up-regulation of BAX and a down-regulation of BCL2 after the HCC cells were cultured with the aqueous extract of TBM. This result suggests TBM might take its inhibitory effect on HCC *via* regulating the Bax/BCL2 ratio. Furthermore, the result of Western blotting indicates higher concentration of TBM (12% and 25% TBM) is more effective to increase the expression of BAX and to decrease the expression of BCL2.

## CONCLUSION

This study, for the first time, reports that TBM-containing serum could suppress the growth of HCC cells. And we employ an integrative pharmacology-based strategy combining experiments and TCM-HCC network analysis to decipher the mechanism behind. From the results, the inhibitory effects of TBM might be related to its regulation on 62 key targets *via* 13 KEGG pathways and 4 biological processes. Our findings could help us consider novel potential gene targets when treating the hepatocellular carcinoma and understanding the mechanism of curative effect of TBM.

Post-menopausal osteoporosis (PMOP) is associated with estrogen deficiency and worldwide, is becoming increasingly more prevalent in aging women. Various anti-PMOP drugs have been developed to reduce the burden of PMOP; generally, these drugs are efficacious, but with some adverse side effects. Tubson-2 decoction (TBD), a popular traditional Mongolian medicine, has been used to treat PMOP for centuries. However, the precise mechanisms underlying the action of TBD on PMOP have yet to be fully elucidated. Herein, we combined network pharmacology with untargeted metabolomics to identify the key targets and metabolic pathways associated with the interventional effects of TBD on ovariectomized (OVX) rats. Furthermore, we investigated the bone histomorphometry of eight different groups of rats to evaluate the therapeutic effect of TBD. First, we established a TBD-target/PMOP network *via* network pharmacology; this network identified three key protein targets—vitamin D receptor (VDR), cytochrome P450 19A1 (CYP19A1), and 11 $\beta$ -hydroxysteroid dehydrogenase type 1 (HSD11B1). Morphological analysis showed that severe impairment of the bone micro-architecture in OVX rats could be improved by TBD administration. The TBD-treated rats had a significantly lower bone surface-to-tissue volume (BS/TV) and a significantly smaller trabecular separation (Tb·Sp.) ( $P < 0.05$ ) than the OVX rats; in contrast, bone volume fraction (BVF), trabecular thickness (Tb·Th.), trabecular number (Tb·N.), and bone mineral density (BMD) were significantly higher in the TBD-treated rats ( $P < 0.05$ ). Multivariate and univariate analysis showed that OVX resulted in significant alterations in the concentrations of 105 metabolites and 11 metabolic pathways ( $P < 0.05$ ); in addition, 26 potential biomarkers were identified to investigate the progression of PMOP. Network pharmacology showed that major alterations in vitamin B6 metabolism were associated with the VDR target. Next, we validated the three crucial targets (VDR [ $P < 0.01$ ], HSD11B1 [ $P < 0.01$ ], and CYP19A1 [ $P < 0.05$ ]) by enzyme-linked immunosorbent assays (ELISAs) and demonstrated that the levels of these targets were elevated in the

OVX group but reduced in the TBD-treatment group. Collectively, our results suggest that the interventional effects of TBD on OVX rats are likely to be associated with the down regulation of VDR. Our findings enhance our molecular understanding of the interventional effects of TBD on PMOP and will allow us to develop further TBD studies.

**Keywords:** network pharmacology, metabolomics, post-menopausal osteoporosis, ovariectomized, Tubson-2

## INTRODUCTION

Osteoporosis is a systemic bone disease that results in alterations in the microscopic architecture of the bone and a reduction in bone mass (Zou et al., 2020); collectively, these effects result in an impairment of bone quality. Post-menopausal osteoporosis (PMOP) is a global public health issue and has become a significant cause for concern for middle-aged and elderly women (Alexandre and Vico, 2011). Estrogen deficiency is known to be one of the most important mechanisms underlying PMOP and usually occurs 5 to 10 years after menopause (Li et al., 2020). Research studies have also shown that osteoclastic activity exceeds osteoblastic activity after menopause, thus leading to an increase in bone resorption. In turn, these events cause an overall reduction in bone mass reduction and a concomitant increase in skeletal fragility (Gambacciani et al., 2019). Over the last few decades, a considerable body of evidence has accumulated in support of the fact that estrogen prevents bone loss by blocking the production of proinflammatory cytokines by the bone marrow and bone cells. Thus, estrogen replacement therapy remains the gold standard for treating PMOP (Jiang, 2018). However, over the long-term, estrogen replacement therapy is associated with a range of side effects, including pain in the ovaries and endometrium and invasive breast cancer (Komm et al., 2015). Consequently, there is an urgent need to identify novel treatment modalities that are effective but with fewer side effects than existing therapies. Traditional Chinese medicine (TCM), along with other forms of ethnic medicines, has emerged as promising candidates for the treatment of complex disease because these forms of medicine contain multiple components that act on multiple targets. Many researchers have highlighted the fact that many herbs, and prescriptions created from these herbs, can exert an estrogen-like action, including *Eucommia ulmoides* Oliver (EC) (Zhang et al., 2012), *Epimedium brevicornu* Maxim (Liu H. et al., 2018), *Achyranthes bidentata* (Zhang M. et al., 2018), and *Echinops latifolius* Tausch (ELT) (Wang et al., 2020). Considering that these herbs, and their prescriptions, are known to have good anti-osteoporosis effects, it follows that TCM (Li et al., 2018), and other ethnic medicines, may represent a natural drug resource for screening new drugs for the treatment of PMOP.

Tubson-2 (TBD), also known as Erwei Duzhong Decoction, is composed of ELT and EC. This is the basic prescription of Mongolian medicine for treating osteoporosis, recorded in Golden Cabinet of Mongolian Medicine (Zhan, 1977). In a previous study, researchers (Liu, 2016) applied this prescription to 60 patients with PMOP and reported a total

effective rate of 90%. In addition, the ameliorating effect of TBD on estrogen receptors, inorganic elements, bone density, bone biomechanics, and bone metabolism, in ovariectomized (OVX) rats have also been investigated in previous research studies (Liu, 2016). Interestingly, ELT was shown to be able to prevent PMOP by activating the estrogen receptor (ER)/protein kinase B (AKT)/extracellular-signal regulated kinase (ERK) pathway in bone marrow derived mesenchymal stem cells (BMSCs) (Liu Y. et al., 2018), and that the main components of ELT (such as chlorogenic acid and its derivatives) were closely related to oxidative balance in femoral tissue (Han et al., 2017). Moreover, the active compound in EC is known to be a powerful inhibitor of adipogenesis and an enhancer of osteoblastogenesis (Tan et al., 2014). Although the substances that make up ELT and EC have been shown to exert good effects against osteoporosis, the specific mechanisms that underlie the effect of TBD on PMOP have yet to be fully elucidated. However, the complexity of TBD makes it very challenging to investigate its specific mechanism of action. Unlike traditional western medicine, it is not possible to use monomers to perform pharmacodynamic tests with TBD.

Network pharmacology is a new discipline that allows researchers to discover the mechanisms underlying the effects of drug combinations based on multidisciplinary theories such as systems biology and multidirectional pharmacology (Hao and Xiao, 2014). Furthermore, network pharmacology allows us to construct a ‘disease-targets-drug’ network in order to elucidate the mechanisms of action for specific drugs. Metabolomics is considered the latest “omics” science and involves the comprehensive and systematic analysis of small molecular metabolites from tissues, cells, or biological fluids (Johnson et al., 2016). The composition and concentration of metabolites may change with disease progression; this, in turn, will help us to screen potential biomarkers or targeted therapeutic pathways that are closely related to the disease (Lv et al., 2016). Currently, the overall concept of network pharmacology and metabolomics concurs with the ‘multi-component and multi-target’ theory of traditional herbal medicines that is used widely to discover the mechanisms underlying the action of traditional herbal medicines (Zhang et al., 2020).

In the present study, we used a combination of network pharmacology and non-targeted metabolomics to identify and characterize the key targets and metabolic pathways associated with the interventional effects of TBD on PMOP. To verify the efficacy of TBD on PMOP, we created an OVX rat model to mimic the physiological characteristics of menopausal women. First, we established a TBD-target/PMOP network *via* network pharmacology; this network was then used to identify key

protein targets. Next, we analyzed relevant metabolites and metabolic pathways by performing ultra-high performance liquid chromatography mass spectrometry (UHPLC-MS) on serum samples acquired from treated and non-treated rats. Finally, we validated the crucial targets of shared pathways identified by network pharmacology and metabolomics to identify the main interventional effects of TBD on OVX rats. We believe that this approach could significantly enhance our understanding of the mechanisms underlying the effect of TBD on PMOP and thus help to promote its clinical application.

## MATERIALS AND METHODS

### Chemicals and Reagents

*Echinops latifolius* Tausch (ELT) was collected from Wu Chuan (Hohhot, China) and *Eucommia ulmoides* Oliv. (EC) was purchased from Bozhou Pharmaceutical Co. Ltd. (Anhui, China). Chloral hydrate, combined estrogen tablets, Gushukang granules, and saline, were purchased from Ze Sheng Biotechnology Company (Hohhot, China). Methanol and formic acid (MS grade) were acquired from Fisher Scientific Corporation (Loughborough, UK). Ultra-high purity water (18.2 MΩ) was obtained from an ALH-600-U purification system (Chongqing, China). Enzyme-linked immunosorbent assay (ELISA) kits for the vitamin D receptor (VDR), cytochrome P450 19A1 (CYP19A1), 11β-hydroxysteroid dehydrogenase type 1 (HSD11B1) were obtained from Hua Lian Biotechnology Institute (Wuhan, China).

### Instrumentation

The research described herein utilized the following equipment: a high resolution *in-vivo* X-ray microtomograph (SkyScan 1176, Bruker, Germany), a digital microscope (MOTICBA210, Motic, China), an ultrapure water system (ALH-600-U, China), a Thermo Scientific Q Exactive Quadrupole-Orbitrap Mass Spectrometer System (Thermo Fisher Scientific Inc, Grand Island, NY, USA), a rotary evaporator (EYELA n-1100, Shanghai Alang Instruments Co., China), and a microplate reader (Beijing Prolong New Technology Co., China).

### Plant Materials and Preparation of Tubson-2 Decoction

Herbal materials of ELT were collected from Wu Chuan (Hohhot, China, GPS co-ordinates of the plant collection site is 41.1206962700, 111.4084477500) in early autumn 2019 and identified by Professor PX (Department of Natural Medicinal Chemistry, Inner Mongolia Medical University) with the voucher specimen (#20190715) collected in the herbarium of Inner Mongolia Medical University. EC herbal materials were purchased from Bozhou Pharmaceutical Co. Ltd. (Anhui, China) and morphologically authenticated by PX. The voucher specimens were also deposited in the herbarium of Inner Mongolia Medical University (#20190822).

The final preparation of TBD was carried out as described in our previous paper. In brief, two herbal materials were ground

into powder and screened over 50 mm sieve before use. Equal amounts of ELT and EC powders were mixed and then were soaked with ultrapure water at a material-liquid ratio of 1:10 (g/ml) for half an hour before being hot reflux extraction. Subsequently, these powders were refluxed at 100°C twice (for 30 min each time), and then filtered through 180 mm sieve. Following filtration, the filtrate was collected, concentrated, and freeze-dried to obtain a lyophilized TBD powder. Powders were stored in a refrigerator at 4°C and dissolved in an appropriate amount of distilled water prior to use. The chemical profile of TBD was achieved by UPLC-MS/MS (Supporting Information **Figure S1**). The content of sixteen active ingredients in TBD sample was list as **Supporting Information Table S1**.

### Establishment of an OVX Rat Model

Twelve-week-old female Wistar rats, 250–270 g in weight, were purchased from the Laboratory Animal Institute of Inner Mongolia Medical University (Hohhot, China). All animal procedures were approved by the Animal Ethics Committee of Inner Mongolia Medical University (Reference: SCXK2015-0001). Rats were kept in a barrier system with controlled temperature (25–28°C) and humidity (50%–60%) and a light-dark cycle of 12 h per day. After 7-day of acclimatization, 48 rats were equally randomized to 8 groups (6 rats per group), including a blank group, a sham group, an OVX group, a positive control drug group (Gushukang-treated group and an estrogen-treated group), a TBD high dose group, a TBD middle dose group, and a TBD low dose group. All rats except those in the blank group were injected with 10% chloral hydrate solution (0.5 ml/100 g body weight) prior to surgery. Bilateral laparotomy was conducted in the sham group (n=6) while bilateral ovariectomy was carried out in the model group (n=36, six rats were regarded as the OVX group, while the remaining rats were allocated to drug-treatment groups). Seven days after surgery, all rats were subjected to keratinization experiments involving the vaginal epithelium; vaginal smears were then performed once a day for 5 consecutive days. The morphology and staining of the cells contained within vaginal smears were observed by optical microscopy at a magnification of 100×. Results showed that the estrus cycle appeared alternately in the blank group (**Figures 1A–C**), while an estrus interval appeared in the model group (**Figure 1D**) five consecutive days of vaginal smear to tips for successful modeling.

The low dose group was given 237.5 mg·kg<sup>-1</sup>·d<sup>-1</sup> of lyophilized TBD (equivalent to 1.05 g·kg<sup>-1</sup>·d<sup>-1</sup> of raw medicine), the middle dose group was given 475 mg·kg<sup>-1</sup>·d<sup>-1</sup> (equivalent to 2.1 g·kg<sup>-1</sup>·d<sup>-1</sup> of raw medicine), and the high dose was given 950 mg·kg<sup>-1</sup>·d<sup>-1</sup> (equivalent to 4.2 g·kg<sup>-1</sup>·d<sup>-1</sup> of raw medicine). The Gushukang-treated group was given Gushukang granules (105.1 mg·kg<sup>-1</sup>·d<sup>-1</sup>) while estrogen-treated group was given combined estrogen tablets (0.065 mg·kg<sup>-1</sup>·d<sup>-1</sup>). During the same period, the blank group, sham group, and OVX group, were given the same volume of 0.9% saline daily. After 8 weeks of gavage treatment, we anesthetized all animals with 10% chloral hydrate solution and acquired cardiac blood samples. Serum was separated by centrifugation at 3,500 rpm for 10 min at 4°C and frozen at -80°C to await metabolomics analysis. We also removed the left tibia

**FIGURE 1** | Vaginal morphology in sham-operated (A–C) rats and ovariectomized (OVX) rats (D). Methylene blue for 10 min,  $\times 100$ . Sham group rats had an estrous cycle in general, (A): nucleated epithelial cells, keratinized epithelial cells, and leukocytes appear evenly to show a state of the estrous, (B): a large number of nucleated epithelial cells show the a state of proestrus period, (C): a lot of keratinized epithelial cells show the a state of estrus period, (D): a large number of non-nucleated leukocytes show the a state of diestrus period.

from each animal and fixed these samples in formalin to await analysis.

## Analysis of Bone Mineral Density and Trabecular Micro-Architecture

X-ray microtomography was used to analyze bone mineral density and trabecular micro-architecture. All tibias were fixed with 70% ethanol and subjected to X-ray microtomography with an isotropic voxel size of 10  $\mu\text{m}$ . Tomographic images were acquired at an integration time of 250 ms with 500 projections over the full 360° rotation. Three dimensional reconstructions were generated with the following parameters: smoothing was set as 3; ring artifacts reduction was set to 5; and beam hardening correction was set to 30%. Bone volume fraction (BVf), bone surface to tissue volume (BS/TV), trabecular thickness (Tb.Th.), trabecular number (Tb.N.), trabecular separation (Tb.Sp.), and bone mineral density (BMD), were all determined by analyzing a specific region of interest (ROI) that was chosen by setting the same coordinates in the tibial growth plate for each sample.

## Network Pharmacology Analysis Compound Data Acquisition

Details relating to the compounds identified in ELT and EC were obtained by searching the Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform (TCMSP; <http://tcmssp.com/tcmssp.php>) (Ru et al., 2014), the Encyclopedia of Traditional Chinese Medicine (ETCM; <http://www.nrc.ac.cn:9090/ETCM/>) (Xu et al., 2019), and existing literature (Wang et al., 2020). We also added some additional compounds, as determined by the fingerprint we created for TBD in a previous study (Guo et al., 2020).

cn:9090/ETCM/) (Xu et al., 2019), and existing literature (Wang et al., 2020). We also added some additional compounds, as determined by the fingerprint we created for TBD in a previous study (Guo et al., 2020).

## Target Fishing

We used a systemic approach that was based on information integration and text-mining to identify the targets of TBD. Targets were retrieved from Swiss Target Prediction (<http://www.swisstargetprediction.ch>) (Gfeller et al., 2014) and Superpred Webserver (<http://prediction.charite.de/>) (Nickel et al., 2014) software. The SMILE structure of each component was then introduced into Swiss Target Prediction with a probability threshold of 0.6–1. All known and predicted targets were then selected from the Superpred Webserver. Next, the targets that were related to PMOP were acquired from Drugbank (<http://www.drugbank.ca/atc>) (Wishart et al., 2018). We then constructed a compound-target network and then removed the components of TBD that were not connected with PMOP targets.

## Construction of a Protein-Protein Interactions (PPI) Network Related to PMOP

The String database ([https://string-db.org/Version 10.5](https://string-db.org/Version%2010.5)) is a database that is commonly used to analyze known and predicted protein-protein interactions. The common targets of PMOP, along with the active ingredients of TBD, were introduced into the database for protein-protein interaction

(PPI) analysis and the species set to “human.” We then imported node 1, node 2, and comprehensive scoring information, into Cytoscape 3.0 software to create a PPI network map.

### Determination of Key Targets

By filtering common targets, it was possible to identify the specific pathways of the targets *via* the DAVID database (<https://david.ncicrf.gov/>). Next, using the potential targets of TBD for PMOP, we performed enrichment analysis of biological processes using the CLUE GO plugin in Cytoscape software. We then considered this data along with the rankings for biological functions and pathways and identified important pathways. Next, we ranked the genes associated with the identified pathways in terms of frequency and integrated the target data into the PPI network diagram. Finally, we defined the key targets of TBD in PMOP that would be subsequently assayed quantitatively by enzyme-linked immunosorbent assays (ELISAs).

## Metabolomics Analysis

### Preparation of Serum Samples and Quality Control (QC) Samples

Serum samples were thawed at 4°C prior to analysis. Then, 200 µl of each serum sample was mixed with 600 µl of methanol and vortexed for 3 min. Subsequently, the samples were centrifuged at 15,000 rpm for 10 min at 4°C. Supernatants were then transferred to new microcentrifuge tubes and dried in a vacuum dryer. Finally, the samples were dissolved in 200 µl of methanol for analysis.

Quality control (QC) samples were created by pooling serum samples from each analysis sequence. QC samples were analyzed after every 10 samples. This practice ensured that our analysis was accurate and consistent.

### UHPLC-MS Conditions

UHPLC-MS analysis was performed on a Thermo Q-Exactive-MS (Thermo, USA). Chromatographic separations were performed on a Waters ACQUITY UPLC HSS T3 column (2.1×50 mm, 1.8 µm) at 35°C, and the flow rate was set to 0.4 ml/min. The mobile phase was formed by MS-grade methanol (A) and water containing 0.1% formic acid (B). The gradient program was set to the following parameters: 0–1.7 min, 5%–10% A; 1.7–3.0 min, 15%–17% A; 3.0–3.3 min, 17% A; 3.3–8.0 min, 17%–25% A; 8.0–9.7 min, 25%–30% A; 9.7–10.6 min, 30%–35% A; 10.6–14.1 min, 35%–55% A; 14.1–14.6 min, 55% A; 14.6–15.1 min, 55%–100% A; 15.1–17.0 min, 100% A; 17.0–18.1 min, 100%–5% A; 18.1–20 min, 5% A. For each sample, we injected 5 µl for analysis.

Q-Exactive-MS analysis was performed in full scan/dd ms<sup>2</sup> mode. Spray voltage was set to 4 kV for positive ion mode and 3.2 kV for negative ion mode. The sheath gas flow rate was 40 L/min for positive ion mode and 35 L/min for negative ion mode. The auxiliary gas flow was 2 L/min for both of the ion mode at 350°C. The capillary temperature was 300 V for both two ion modes. Data were collected in centroid mode and the mass range was 100–1,100 m/z.

### Data Processing and Statistical Analysis

Original data files were independently processed by Compound Discoverer (CD)<sup>TM</sup> 2.0 software for peak alignment, peak filter,

peak extraction, and automatic integration. The minimum peak intensity for component extraction was  $2 \times 10^6$  and the mass tolerance was 10 ppm. The retention time window was 1 min and the signal-to-noise ratio was 3. CD software was then used for spectral comparison, grouping, compound detection, and metabolite identification. We were then able to create multi-dimensional peak tables containing prediction formulas, accurate mass data, retention times, peak areas, and mzCloud results. The multi-dimensional peak tables acquired in positive and negative ion mode were processed separately and transferred into a Microsoft Excel file which was subsequently imported into SIMCA-P (version 14.1, Umetrics, Sweden). Performed principal component analysis (PCA) was then performed to identify the overall metabolic profile for each group of samples. Supervised partial least squares discriminant analysis (PLS-DA) was then applied to compare distinguishing markers between the OVX group and the sham group. The fitness and predictive ability of the model were then verified according to R<sup>2</sup> and Q<sup>2</sup> values in cross-validation and permutation tests, respectively. We then identified potential biomarkers as metabolites with  $P < 0.05$  and variable importance plot (VIP) > 1.

Potential biomarkers were then matched with structural data acquired from the Human Metabolome Database (HMDB) (<http://www.hmdb.ca/>) and mzCloud (<https://www.mzcloud.org/>). Pathway enrichment analysis was then performed for the identified biomarkers using MetaboAnalyst (<http://www.metaboanalyst.ca/>).

## Analysis of Biochemical Indicators

Blood samples were collected from all rats at sacrifice, as described earlier. The serum levels of VDR, HSD11B1, and CYP19A1, were then determined by enzyme-linked immunosorbent assays (ELISAs) in accordance with the manufacturer's instructions.

## Statistical Analysis

Data relating to BVF, BS/TV, Tb-N., Tb-Sp., Tb-Th., BMD, CYP19A1, VDR, and HSD11B1, are described as the mean ± standard deviation (SD). The student's unpaired t test was performed with SPSS 19.0 software and a P value ≤ 0.05 was regarded as statistically significant.

## RESULTS

### TBD Improved Ovariectomy-Induced Bone Loss and Deleterious Changes in the Trabecular Micro-Architecture

Analysis of vaginal smears from our experimental rats proved that the PMOP model had been successfully established by ovariectomy. Three dimensional microtomographic analyses allowed us to gather additional architectural, cortical, and trabecular, information from the tibias of experimental rats. We found that the OVX group showed significant changes in both BMD and trabecular micro-architecture. As shown in **Figure 2C**, the bone microstructure of the tibia in the OVX group exhibited severe damage. Moreover, the trabecular region in the OVX rats appeared to be small, thin and

sparse. Analysis also revealed that there was a significant reduction in Tb-N. ( $P=0.003$ ), BVF ( $P=0.011$ ), BMD ( $P=0.008$ ), and BS/TV ( $P=0.001$ ), along with a significant increase in Tb-Sp. ( $P=0.000$ ) in the OVX group (**Figures 3A–F**).

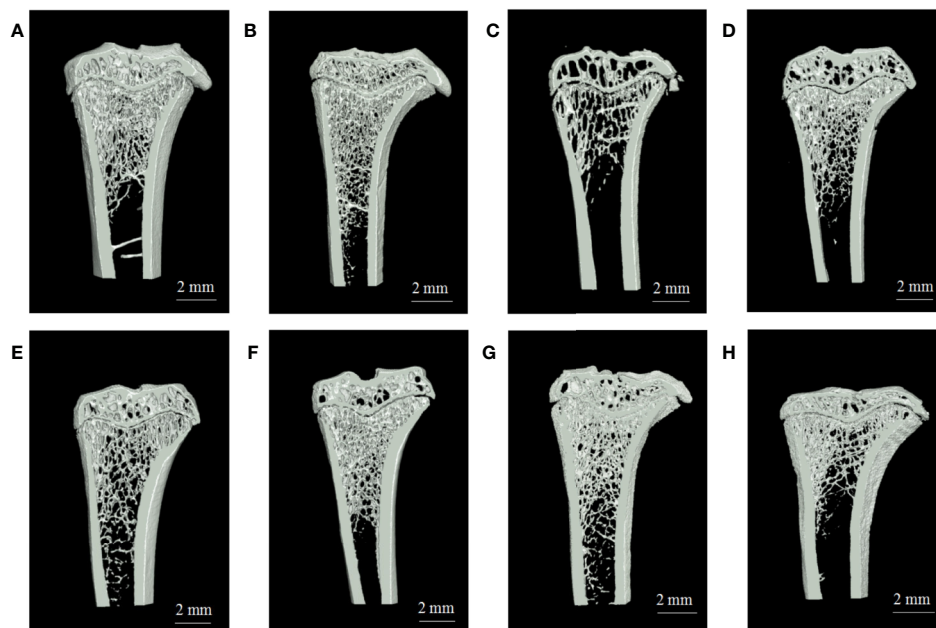

One striking observation arising from our analysis of bone mineral density and trabecular micro-architecture was the existence of a severe reversion in bone loss in the treatment groups (**Figures 2A–H**). All treatment groups showed a remarkable improvement in trabecular micro-architecture, with a slightly dilated medullary cavity and a slightly disordered trabecular arrangement (**Figures 2D–H**). The trabecular morphological parameters were turned over in these drug-treated groups as shown in **Figures 3A–F**. Compared with the OVX group, the drug-treatment groups showed significant elevations of Tb-N. ( $P<0.05$ ), BVF ( $P<0.05$ ), BMD ( $P<0.05$ ), and BS/TV ( $P<0.05$ ), and a reduction of Tb-Sp. ( $P<0.05$ ). There was only a marginal and non-significant difference in the estimated trabecular morphological parameters when compared between different drug-treatment groups. This data demonstrated that TBD has similar effects in OVX rats as the positive drug. However, the effect of TBD on these indicators did not show a dose-dependent effect.

### VDR, HSD11B1, and CYP19A1 Were Crucial Targets in the Interventional Effects of TBD on OVX Rats

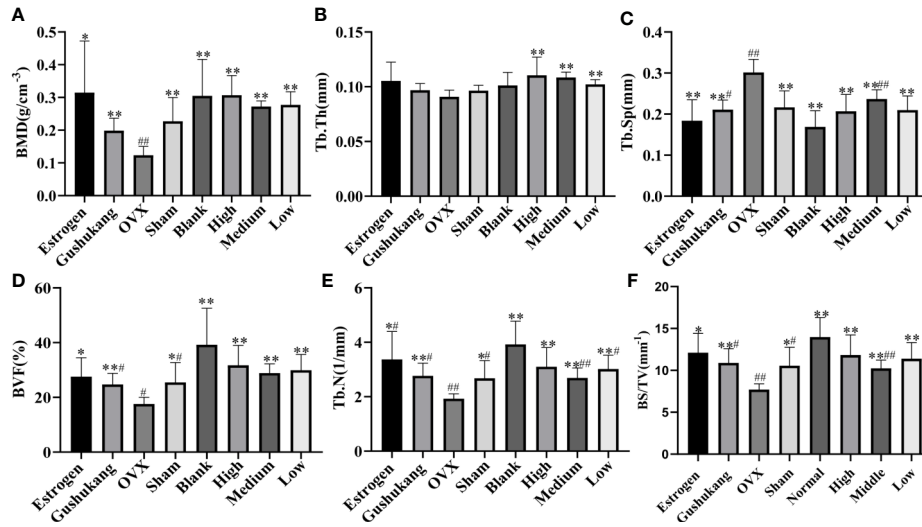

Following the screening of compound data, we identified 195 compounds in TBD, of which 28 were unique to ELT, 163 were

unique to EC, and 4 were common to both herbs. Because the oral bioavailability (OB) and drug-likeness (DL) values for most compounds in EC and ELT were low or unknown, we were not able to apply these values for compound screening. We therefore considered all compounds with known targets as the active ingredients of EC and ELT. In total, 62 compounds had known targets; these were considered as the active ingredients of TBD.

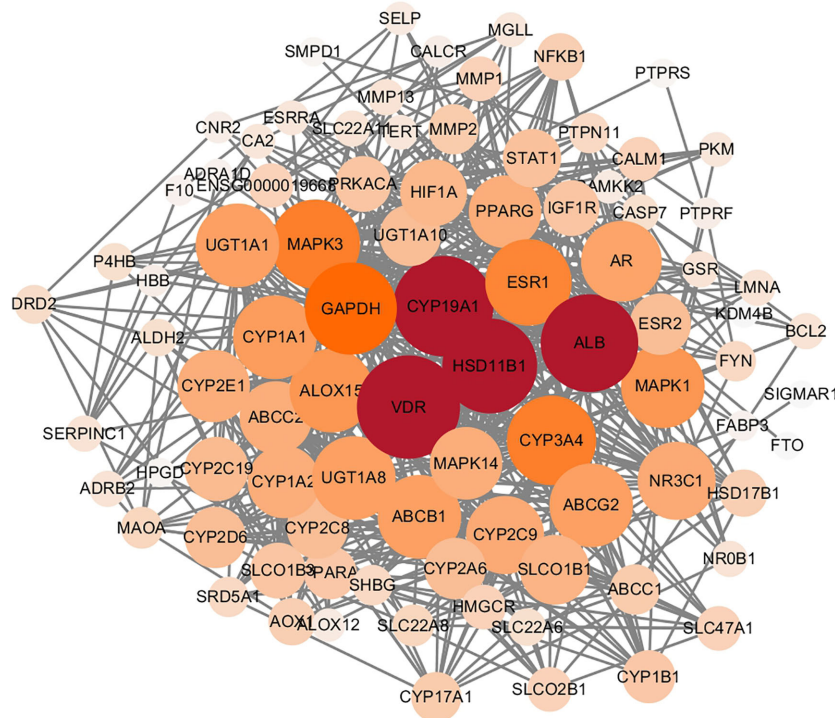

Following the removal of duplicates, we identified a total of 2,251 targets for TBD. In total, we identified 1,412 targets for the active ingredients of EC, 509 targets for the active ingredients of ELT, and 330 targets for the targets shared by EC and ELT. All compound targets were retrieved from Swiss Target Prediction software and the Superpred Webserver. We also identified 581 gene targets that were associated with PMOP *via* the use of Drugbank. After comparing the targets that were associated with both TBD and PMOP, we identified 89 potential targets for TBD against PMOP. These potential targets were entered into the String database (set to human and a high confidence level of 0.7). Node1 and node 2 were then imported into Cytoscape software to allow us to create an interaction network (**Figure 4**). The nodes shown in **Figure 4** graph represent the targets while the edges represent associations between different proteins. The color and size of the nodes reflect the degree value for each protein target: the larger and darker the node, the greater the degree value. As shown in **Figure 4**, the target interaction network featured 89 nodes and 626 edges. According to degree

**FIGURE 4 |** Protein interaction network of Tubson-2 decoction (TBD) against post-menopausal osteoporosis (PMOP). The nodes in the graph represent targets, while the edges represent the association between proteins. And the node size represented degree value. The larger the node, the larger the degree value.

values, the key targets for TBD against PMOP were CYP19A1, HSD11B1, VDR, and albumin (ALB).

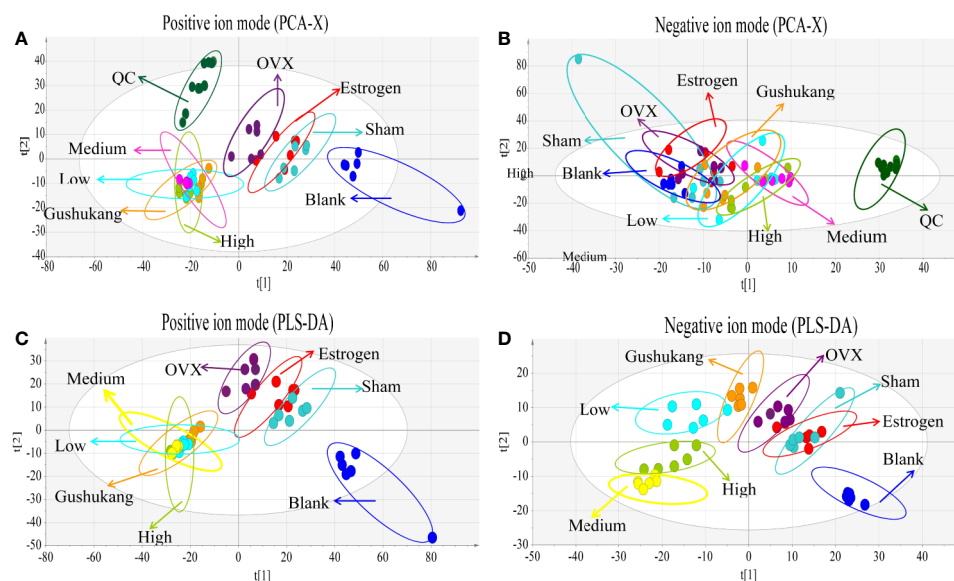

GLUE GO analysis identified the top biological features of our interaction network as hormone metabolic process, steroid metabolic process, and oxidoreductase process. We then calculated the gene frequencies for the key target genes in these three biological pathways. Analysis showed that VDR, CYP19A1 and beta-2 adrenergic receptor (ADRB2) appeared eight times; tyrosine-protein phosphatase non-receptor type (PTPN), estradiol 17-beta-dehydrogenase 1 (HSD17B1), and ethylene-responsive transcription factor ESR1 (ESR1) appeared seven times; and HSD11B1 appeared six times. By combining these results with the PPI data, we found that CYP19A1, HSD11B1, and VDR were the most important potential targets for TBD when used to treat PMOP.

## Metabolomics Analysis Showed That 26 Potential Biomarkers Were Involved in OVX-Induced Osteoporosis and Regulated by TBD

As shown in the PCA score plot (Figures 5A, B), the analysis of QC samples showed good reproducibility and reliability. PCA showed that the dataset derived from the OVX group was separated from the data derived from the other groups. The widespread distribution of data following PCA was likely to be caused by individual differences in rats and/or the timing of sampling. To exclude the effect of potential confounding variables that were not related to the group differences, and to evaluate the statistical significance of these effects, we applied

PLS-DA analysis (Figures 5C, D). The results of this analysis were highly encouraging as the discrimination model could readily differentiate between the eight groups. Although the distribution of pre-cachexia overlapped with the OVX and estrogen groups, these models showed appropriate goodness-of-fit values with high cross-validation predictability, with cumulative R<sup>2</sup>Y values of 1.000 and cumulative Q<sup>2</sup> values of 0.977 in the positive mode, and R<sup>2</sup>Y value of 0.959 and a cumulative Q<sup>2</sup> value of 0.541 in the negative mode (Table 1), indicating reliable differentiation between the groups.

In order to identify distinct biomarkers that may be associated with TBD treat OVX-induced osteoporosis among a dataset featuring thousands of variables, we conducted pairwise comparisons between the OVX and TBD medium-treated groups (Figures 6A, B). Validation analysis was satisfactory with regards to group classification, with a cumulative R<sup>2</sup>Y value of 0.999 and a cumulative Q<sup>2</sup> value of 0.978 in the positive mode, and a cumulative R<sup>2</sup>Y value of 0.997 and a cumulative Q<sup>2</sup> value of 0.935 in the negative mode (Table 1). Permutation tests for the TBD medium-treated groups and OVX group are shown in Figures 6C, D. After filtering with VIP values, and results arising from the Student's t test, we identified 105 metabolites as potential biomarkers (82 metabolites from the positive ion mode and 23 metabolites from the negative ion mode). Next, we used HMDB and the mzCloud online database to identify these potential biomarkers. By considering the metabolites that overlapped each pairwise comparison, we identified a total of 26 putative biomarkers (Table 2). The potential differential metabolites were identified by standard,

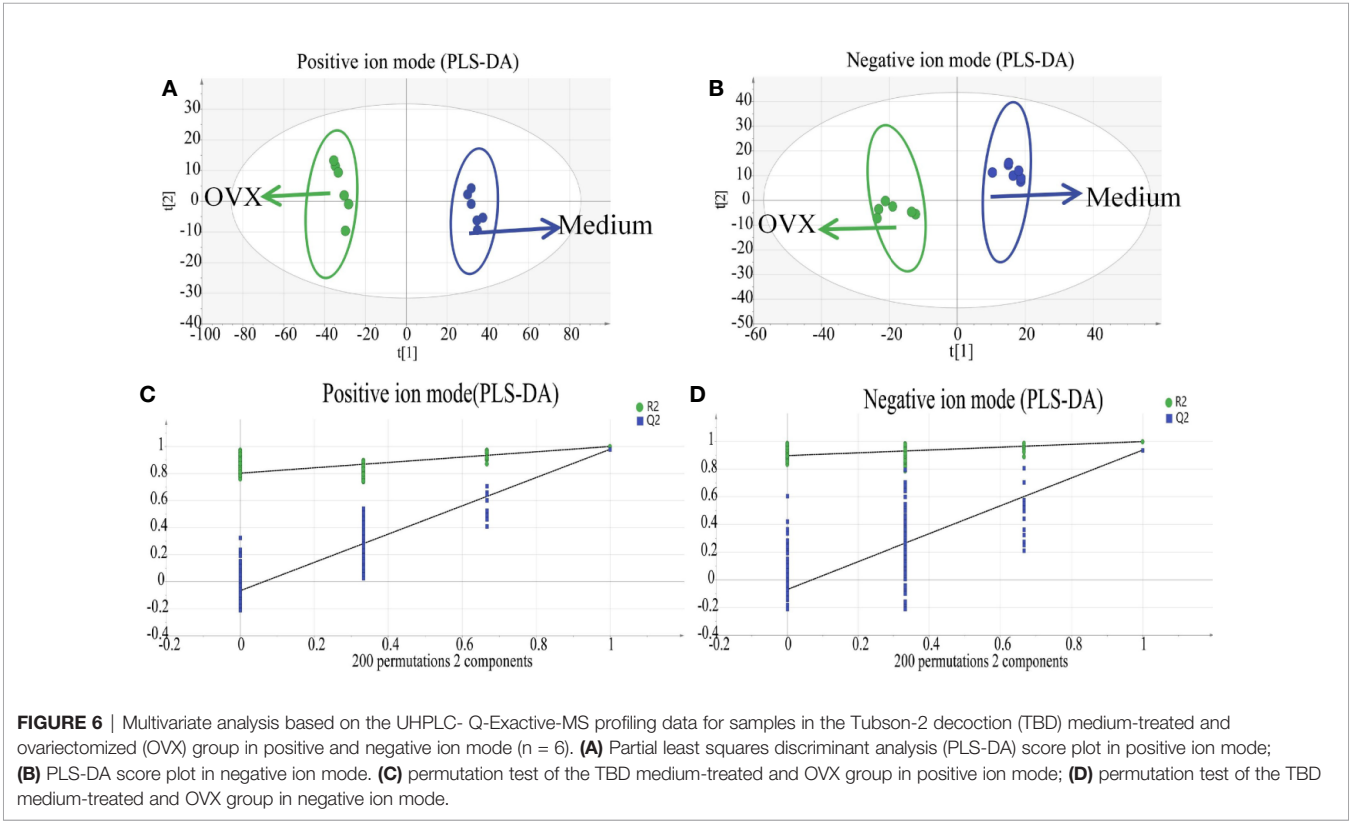

**FIGURE 5** | Multivariate analysis based on the UHPLC-Q-Exactive-MS profiling data for samples in the blank, sham, ovariectomized (OVX), low dose treated group, medium dose treated group, high dose treated group, estrogen treated group, and gushukang treated group in positive and negative ion mode ( $n = 6$ ). ferulic acid, 350 its parent ion is [M-H]<sup>-</sup>: 193.005063, the main product ion fragments are (m/z): 134.03546, 351 149.06041, 178.00696, and the retention time is 11.45 min. This is consistent with our results and 352 further confirms the reliability of the ferulic acid test results.

### Metabolomic Analysis Identified Vitamin B6 Metabolism as the Key Pathway in OVX-Induced Osteoporosis and Could Be Regulated by Tubson-2

Next, we pooled the metabolites that showed alterations in rat serum and identified a total of 26 putative metabolites for analysis. The fold-changes of these metabolites in the OVX, sham, and medium-dose-treated groups are shown in **Table 2**. Pathway analysis, carried out using MetaboAnalyst ([\[metaboanalyst.ca/\]\(http://www.metaboanalyst.ca/\)\), revealed the detailed impacts of OVX-related alterations in metabolic networks \(\*\*Figure 7A\*\*\). To investigate the most influential metabolic pathway, we set the following threshold values: -log \(P\) values >1.5 and pathway impact >0.1. Three metabolic pathways were defined as being disturbed in the serum profiles of rats with TBD treated OVX-induced osteoporosis: vitamin B6 metabolism, phenylalanine metabolism, phenylalanine, and tyrosine and tryptophan biosynthesis. Based on the biomarkers that were potentially responsible for TBD treatment, we then used the Kyoto Gene and Genome Encyclopedia database \(KEGG \(<http://www.genome.ad.jp/kegg/>\), and the human metabolism database \(<http://www.hmdb.ca/>\), to create a metabolic network for metabolic pathways that were altered by TBD treated OVX \(\*\*Figure 7B\*\*\).](http://www.</a></p></div><div data-bbox=)

## Target Validation Was Performed by ELISA Assay

We used network pharmacology and metabolomics to identify the crucial targets for TBD in the treatment of PMOP; the most important targets were VDR, HSD11B1, and CYP19A1. We then used ELISA kits to validate the levels of these crucial targets in

samples of rat sera. As shown in **Figure 8**, the concentrations of VDR, HSD11B1, and CYP19A1 were elevated in the OVX group, thus presenting the inhibition of these cytokines. The serum levels of VDR and CYP19A1 were reduced following the administration of TBD, suggesting that TBD is able to treat OVX-induced osteoporosis by ameliorating the levels of VDR and CYP19A1.

**FIGURE 8** | Three targets levels of serum in eight groups: **(A)** HSD11B1; **(B)** CYP19A1; **(C)** VDR. Values were expressed as the mean  $\pm$  SD;  $n = 6$ . # $p < 0.05$ , ## $p < 0.01$  compared with blank group. \* $p < 0.05$ , \*\* $p < 0.01$  compared with OVX group.

## DISCUSSION

Previous research (Li et al., 2016) has demonstrated that PMOP is related to estrogen withdrawal and represents the most common metabolic bone disease in females. The use of bilateral ovariectomies in female rats is now well established as the method of choice with which to create an experimental model of osteoporosis (Thompson et al., 1995). Ovariectomy simulates menopause and osteopenia in experimental rats. Although it is well known that ovariectomy induces a menopausal status and ‘osteoporotic’ bone changes (Saleh et al., 2020), we analyzed vaginal smears and performed X-ray microtomography on each of our ovariectomized rats in order to confirm that the OVX-induced model of osteoporosis had been successfully created (Yousefzadeh et al., 2020). We selected Gushukang granules, as a traditional Chinese medicine (TCM) (Li et al., 2019), for osteoporosis, and estrogen tablets, a common supplement for PMOP patients, as positive control drugs with which to evaluate the efficacy of TBD on PMOP. As illustrated in previous, there was only a marginal and non-significant difference between different drug-treatment groups with respect to several trabecular morphological parameters. This implies that TBD exerts the same effect on OVX rats as the positive control drugs. We also investigated the relative effects of different TBD doses on OVX rats; doses were selected according to the guiding principles laid down by non-clinical pharmacokinetic drug research. The “low-dose” of TBD was the clinical equivalent dose, the “medium-dose” of TBD was double the clinical equivalent dose, and the “high-dose” of TBD was four times the clinical equivalent dose. However, we observed no dose-dependent relationship with regards to the relative effects of TBD on trabecular morphological parameters. It is likely that this observation was related to individual differences among the rats.

Metabolomics analysis revealed that 26 putative metabolites and 11 metabolic pathways were associated with the progression of TBD-treated-PMOP, including vitamin B6 (Hellmann and Mooney, 2010) metabolism, phenylalanine metabolism, phenylalanine, and the biosynthesis of both tyrosine and tryptophan. The metabolites involved in these metabolic pathways were shown to interact with each other to form a complex network. The derivatives of pyridoxal and pyridoxamine are able to form vitamin B6; consequently, these are key

metabolites in the vitamin B6 metabolism pathway and were previously reported to be reduced in OVX results. Over recent years, an increasing body of research studies have demonstrated that a low dietary intake of vitamin B6, or low levels of vitamin B6 in the blood, might represent a novel and potentially modifiable risk factor for osteoporosis (Wang et al., 2019). Phenylalanine and hippuric acid are known to be the key biomarkers associated with the metabolic pathway of phenylalanine. Phenylalanine is an essential amino acid in the human body and belongs to the family of aromatic amino acids (Lopansri et al., 2006). Phenylalanine is oxidized by phenylalanine hydroxylase to form tyrosine and a range of brain chemicals, including levodopa, epinephrine, norepinephrine, and thyroid hormones (Fernstrom and Fernstrom, 2007). Therefore, the metabolic status of phenylalanine is closely related to normal physiological function in the body. Previous researchers (Tao et al., 2017) have highlighted that the regulation of metabolic disorders associated with phenylalanine can prevent the occurrence of osteoporosis. Hippuric acid, a glycine conjugate of benzoic acid, is expressed in many disorders associated with enzymatic metabolism, including diabetes, obesity, and osteoporosis. Hippuric acid is mainly excreted *via* glomerular filtration and by an active secretion mechanism in the renal tubules. However, when the kidney is damaged, the content of hippuric acid in the urine decreases; consequently, there is an increase in the serum levels of hippuric acid (Wang and Bao, 2013). Vitamin D needs to be catalyzed by  $1\alpha$ -hydroxylase in the kidney and is then hydroxylated again to become the more active  $1,25\text{-(OH)}_2\text{D}_3$ . A reduction in  $1,25\text{-(OH)}_2\text{D}_3$  content will inevitably lead to the loss of bone mass and induce osteoporosis in the bones (Lin et al., 2008).

CYP19A1, an aromatase-encoding gene, is known to be related to osteoporosis and can influence BMD by altering the levels of estrogen (Sowers et al., 2006). HSD11B1 is known to be expressed by human osteoblasts *in vivo* and could reduce the proliferation of osteoblasts and induce the differentiation of osteoblasts *in vitro*. Gene polymorphism can result in direct changes in the mass of bone and can help to convert androgens and glucocorticoids to estrogen (Hwang et al., 2009). A previous study showed significant associations between a range of HSD11B1 alleles and haplotypes and bone fracture density and BMD in postmenopausal women. VDR is the target receptor that regulates the transcription of vitamin D. Previously, researchers

have focused on the relationship between VDR and PMOP and demonstrated that changes in the VDR genotype were evident in patients with PMOP (Zhang L. et al., 2018). We found that the levels of these indices in the OVX group were much higher than those in the sham group, but were down regulated in the drug-treatment groups, thus suggesting that TBD can treat PMOP by regulating the specific levels of these targets.

Previous literature has reported a clear relationship between vitamin B6 levels, vitamin D, and parathyroid hormone (PTH) (Khundmiri et al., 2016), and a positive correlation between VDR, PTH, and vitamin D. This view makes the results of network pharmacology and metabolomics organically combined. Phylloxerone and pyridoxal are two forms of vitamin B6, which are important different metabolites in the vitamin B6 metabolic pathway (Saito, 2006). In other words, there is a close connection between the gene VDR and the differential metabolites compound phylloxerone, pyridoxal, and the vitamin B6 metabolic pathway. We used network pharmacology and metabolomics to integrate the crucial targets, differential metabolite and metabolic pathways to explore the mechanism of TBD to treat PMOP. Our analysis showed that VDR and vitamin B6 metabolism were critical mechanisms underlying the effect of TBD on PMOP. However, we have not been able to identify the specific components of TBD that combine with the target VDR. In our future research, we aim to use online docking software in an attempt to identify the specific compounds in TBD that bind to VDR; such work should provide us with stronger evidence for the wider application of TBD in the clinical treatment of PMOP.

## CONCLUSION

By integrating the results derived from network pharmacology and metabolomics, we identified VDR and vitamin B6 metabolism as the key indicator and pathway, respectively, for the action of TBD against PMOP. ELISAs further showed that several crucial targets (VDR, HSD11B1, and CYP19A1) were elevated in the OVX group but were reduced following TBD treatment. From a mechanistic point of view, TBD appears to regulate vitamin B6 metabolism by altering VDR content, thus mitigating the process of PMOP. Our findings enhance our understanding of how TBD could be used to treat PMOP and will help to facilitate the wider clinical use of TBD treatments.

The increase of the prevalence of anxiety greatly impacts the quality of life in China and globally. As the most popular traditional Chinese medicinal ingredient for nourishing health and tranquilizing mind, Jujube seed (*Ziziphus jujuba* Mill., Rhamnaceae) (SZJ) has been proved to exert anxiolytic effects in previous reports. In this study, a system biology method assisted by UPLC-Q-TOF/MS and RT-qPCR was developed to systematically demonstrate the anxiolytic mechanisms of SZJ. A total of 35 phytochemicals were identified from SZJ extract (*Ziziphus jujuba* Mill. var. *spinosa* [Bunge] Hu ex H.F. Chow), which interact with 71 anxiolytic targets. Protein-protein interaction, genes cluster, Gene Ontology, and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways analysis were subsequently conducted, and results demonstrated that regulation of serotonergic and GABAergic synapse pathways were dominantly involved in the anxiolytic mechanisms of SZJ extract. The effects of SZJ extract on mRNA expressions of multiple GABA<sub>A</sub> (gamma-aminobutyric acid type A) and 5-HT (serotonin) receptors subtypes were further validated in human neuroblastoma SH-SY5Y cells using RT-qPCR. Results showed that SZJ extract (250 µg/mL) significantly up-regulated the mRNA level of GABRA1 and GABRA3 as well as HTR1A, HTR2A, and HTR2B in non-H<sub>2</sub>O<sub>2</sub> treated SH-SY5Y cells. However, it exerted an inhibitive effect on the overexpressed mRNA of GABRA1, GABRA2, HTR1A, and HTR2A in H<sub>2</sub>O<sub>2</sub> treated SH-SY5Y cells. Taken together, our findings suggest that anxiolytic mechanisms of SZJ mostly involve the regulation of GABAergic and serotonergic synapse pathways, especially a two-way modulation of GABRA1, HTR1A, and HTR2A. Our current results provide potential direction for future investigation of SZJ as an anxiolytic agent.

**Keywords:** anxiety, jujube seed, anxiolytic mechanism, system biology, 5-HT receptors, GABA<sub>A</sub> receptors

## INTRODUCTION

Anxiety is characterized as excessive and persistent worry about the future, which in turn can impact one's ability to carry out activities of daily living. Anxiety can be divided into generalized anxiety disorder, panic disorder, obsessive-compulsive disorder, social anxiety disorder, and posttraumatic stress disorder (Möhler, 2012; Cohen et al., 2015). Physiological anxiety symptoms include pounding heart, difficulty breathing, upset stomach, muscle tension, sweating, and feeling faint or shaky (Teychenne et al., 2015). The global prevalence of anxiety is estimated at 16.6% across the life span, and it becomes a burden of healthcare and quality of life (Somers et al., 2006); therefore, it is important to develop effective and safe solutions for treatment (Starcevic, 2006). Tricyclic antidepressants, serotonin-specific reuptake inhibitors, and benzodiazepines have been developed to mitigate anxiety. While effective, these classes of drugs come with many side effects, such as insomnia, sexual dysfunction, suicidal ideation, and/or drug-dependency (Lakhan and Vieira, 2010). Therefore, the use of complementary and alternative medicines to improve anxiety has received increased attention. Traditional medicinal materials, such as Jujube seed (*Ziziphus jujuba* Mill., Rhamnaceae) (SZJ) (Huang et al., 2008; Wang Y. et al., 2008), saffron (*Crocus sativus* L.) (Lopresti et al., 2018; Milajerdi et al., 2018), valerian root (*Valeriana officinalis* L.), and passion flower (*Passiflora incarnata* L.) (Müller et al., 2003; Cass, 2004; Benke et al., 2009) have shown anti-anxiety benefits.

SZJ, also known as *Suanzaoren* in Chinese, was first recorded in *Shennong Bencao Jing*, the earliest classic treatise of Chinese Materia Medica. SZJ has a long history of use in China as a vital food and/or medicine that traditionally is considered to sustain human health by calming the mind and improving the quality of sleep. In recent years, accumulated evidences have shown that SZJ and/or its preparations exert positive outcome on insomnia (Jiang et al., 2007; Chen et al., 2011; Ni et al., 2015; Shergis et al., 2017; Xiao et al., 2018), anxiety (Peng et al., 2000; Liu et al., 2015), and depression (Liu et al., 2012; Liang et al., 2016), mainly through regulating GABAergic (Chen et al., 2007; Chen, 2008; Shergis et al., 2017) and serotonergic systems (Wang L.-E. et al., 2008; Wang et al., 2010; Liu et al., 2015). Jujubosides (e.g., jujuboside A, B), C-glycoside flavonoid (e.g., spinosin), and pentacyclic triterpenic acid (e.g., betulinic acid) have been identified from SZJ (Liu et al., 2007; Zhang et al., 2008; Lee et al., 2016) as the potential active phytochemicals contributing to these healthy benefits.

Although previous studies have shown promising anxiolytic effects of SZJ, the underlying mechanism has not been systematically and comprehensively investigated. In our current work, we developed an integrated strategy of system biology assisted by ultra-performance liquid chromatography quadrupole-time of flight mass spectrometer (UPLC-Q-TOF/MS) and real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR) to uncover the active phytochemicals and anxiolytic mechanism of SZJ extract. This approach provides a modern and practical way to study complicated chemical systems with multiple pathways and connected targets, which is otherwise a difficult challenge in mechanistic research of traditional Chinese medicine ingredients.

## MATERIAL AND METHOD

### Phytochemical Analysis of SZJ Extract Using Ultra-Performance Liquid Chromatography Quadrupole-Time of Flight Mass Spectrometer (UPLC-Q-TOF/MS)

#### Characteristics of the SZJ Extract

Commercial SZJ extract (batch number HS-180651) was purchased from Honsea Sunshine (Guangzhou, China). Dried seed of *Ziziphus jujuba* Mill. var. *spinosa* (Bunge) Hu ex H.F. Chow was used for SZJ extract production in Guangzhou, China. SZJ was extracted by supercritical fluid CO<sub>2</sub> to remove lipid fraction, and the residue was further extracted by 50% ethanol, followed by vacuum concentration and vacuum drying. The final extraction ratio is 5:1, and total content of jujuboside A and B was quantitatively detected as 0.20% using HPLC method. A voucher of the batch used has been deposited at -16° refrigerator, sampler chamber of Amway (China) R&D Center (Shanghai, China).

#### Sample Preparation

Thirty mg of SZJ extract powder was precisely weighted and then transferred to a centrifugal tube, with 1.5 mL of methanol (Mass Pure Grade from MERCK), ultrasonicated for 30 min (KQ-300DB, 300W, 40kHz) at ambient temperature, followed by centrifuge (12000 rpm, 5 min, SIGMA 3K15, SIGMA). The obtained supernatant is filtered through 0.22 µm filter member prior to UPLC-Q-TOF/MS analysis.

#### UPLC-Q-TOF/MS Conditions

Chemical profiling was performed on an Agilent 1290 UPLC system (Agilent Technologies, Palo Alto, USA) coupled with Sciex TripleTOF 4600® quadrupole-time of flight mass spectrometer (AB Sciex, Darmstadt, Germany) equipped with a DuoSpray source (electrospray ionization, ESI). Agilent SB C18 column (2.1×100 mm i.d., 1.8 µm; Agilent) was used for components separation. The mobile phase consisted of water containing 0.1% formic acid (A) and acetonitrile (B). The following gradient condition was used: 0–2.0 min, 5%–5% B; 2.0–10.0 min, 5%–30% B; 10.0–15.0 min 30%–50% B; 15.0–25.0 min, 50%–95% B; 25.0–27.0 min, 95%–95% B, with the flow rate of 0.3 mL/min. The injection volume was 1 µL, while column oven temperatures was set at 25°C. The mass spectrometer was operated in full-scan TOF-MS at m/z 100–1500 and information-dependent acquisition (IDA) MS/MS modes, with both positive and negative ion modes. The collision energy was -40 ± 20 eV, ion source gas 1 and 2 were set 50 psi, curtain gas was 35 psi. The temperature and ion spray voltage floating were 500°C and 5000/-4500 V, respectively.

#### Data Analysis

Data recording and processing was performed by Analyst software (Version 1.6, AB Sciex, USA). The compounds were tentatively characterized based on their retention time, mass accuracy of precursor ions, MS/MS spectra, and fragmentation

pathways, referring to the SCIEX natural products HR-MS/MS Spectral Library, standard references, and previous literatures.

## System Biology Analysis of SZJ Extract With Anxiolytic Effects

### Construction of Anxiety-Related Targets Database

A text mining of National Center for Biotechnology Information (NCBI) (<https://www.ncbi.nlm.nih.gov/gene/>), Integrative Pharmacology-based Research Platform of Traditional Chinese Medicine (TCMIP, <http://www.tcmip.cn/TCMIP/index.php/Home/>) (Xu et al., 2019), and Comparative Toxicogenomics Database (CTD, <http://www.ctdbase.org/>) (Davis et al., 2019) was conducted to retrieve anxiety-related targets with the keywords “anxiety.” TCMIP integrates the diseases related genes data of Therapeutic Targets Database (<https://db.idrblab.org/ttd/>), Human Phenotype Ontology database (HPO, <https://hpo.jax.org/app/>), and DisGeNET database (<https://www.disgenet.org/>). The search results of targets from NCBI, TCMIP, and CTD were filtered with “Homo sapiens,” and only the targets with direct evidence supported by CTD were selected. All acquired targets were combined and then mapped to UniProt (<https://www.uniprot.org/>) for normalization and removal of duplicate and erroneous targets (Liu J. et al., 2018). The remaining satisfactory targets constitute the anxiety-related gene targets database.

### Acquisition of Potential Targets Regarding Anxiolytic Benefits for Identified Phytochemicals

The targets of identified phytochemicals and their potential metabolisms were acquired from multiple databases. In addition to retrieving candidate targets from TCMIP and CTD platforms, PharmMapper Server (<http://www.lilab-ecust.cn/pharmmapper/>) (Wang et al., 2017) was employed to fish the potential targets for those phytochemicals of which no available candidate targets were found in TCMIP and CTD. Those targets were excluded if their reliable score was lower than 0.8 from TCMIP, interaction counts less than 5 from CTD, and/or their normalized fit score lower than 0.8 from PharmMapper. After removal of the duplicates, erroneous, and non-Homo sapiens targets, the rest were then mapped to an anxiety-related gene targets database to screen out the intersecting targets.

### Protein-Protein-Interaction (PPI) and Clusters Analysis.

The selective target genes of SZJ extract were imported to STRING (Version 11.0, <https://string-db.org/>) (Szklarczyk et al., 2019) to obtain PPI results. The interaction score set as high confidence (>0.7). The STRING analysed results were then imported into Cytoscape (Version 3.6.1) (Su et al., 2014), and cluster analysis of target genes was conducted using a Molecular Complex Detection (MCODE) plug-in according to the method in the literature (Wang et al., 2020).

### Enrichments Analysis Along With Network Construction.

The target genes contained in the MCODE enriched clusters were imported into the database for annotation, visualization,

and integrated discovery (DAVID, version 6.8) (<https://david.ncicrf.gov/tools.jsp>) (Huang et al., 2009) to conduct Gene Ontology (GO) terms enrichment including biological processes, cell component, and molecular function. ClueGo plug-in (Version 2.5.7) (Bindea et al., 2009) was further employed to analyze and demonstrate their participated biologic process and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways, respectively. The latest databases of GO-Biologic Process annotation EB1-Uniport and KEGG pathway were selected. Visual style was set as “groups,” minimum gene number, and percentage contained in a term set as 5 and 5%. Statistical method of two-sided hypergeometric test and Bonferroni step down p-value correction was used. Cut-off value of kappa score of GO term/pathway network connectivity was set as 0.5, and only term/pathway with p-value < 0.05 was shown.

## RT-qPCR Test

### Samples Preparation

Gamma-amino butyric acid (GABA) was kindly provided by Toong Yeuan International Group (Shanghai, China). GABA was considered as positive control in this test. SZJ extract and GABA ingredients were dissolved in deionized water and diluted in culture solution before use.

### Cell Culture

Human neuroblastoma SH-SY5Y cells were kindly provided by Stem Cell Bank, Chinese Academy of Sciences, and cultured in MEM/F12 (Gibco) supplemented with 10% (v/v) inactivated fetal bovine serum (Gibco), 1% Gluta-max (Gibco), 1% Sodium pyruvate (Gibco), 1% NEAA (Gibco), and 100 U/mL penicillin/streptomycin. The cells were maintained at 37° in 5% CO<sub>2</sub> and 95% humidified air incubator for the indicated time. All experiments were carried out 24 h after cells were seeded.

### Samples Concentration Determination

CellTiter-Glo assay was used to evaluate the available concentration of test samples according to the method described in literature (Fallahi-Sichani et al., 2013). The inhibition on SH-SY5Y cell viability of a series of concentrations of SZJ extract and GABA samples, from 3 mg/mL-0.46 µg/mL, were respectively evaluated. The nonlinear fitting curve of logarithm concentration response to cells viability was then simulated by GraphPad Prism 7.0 (GraphPad Software Inc., San Diego, CA, USA). The concentration of SZJ extract for further test referred to the correspondence value of 90% cells viability.

### Samples Stimulation and Grouping

A total of 6 group samples were simultaneously tested: control group (deionized water), 250 µg/mL SZJ extract group, 100 µg/mL GABA group, 100 µM H<sub>2</sub>O<sub>2</sub> group, 250 µg/mL SZJ extract with 100 µM H<sub>2</sub>O<sub>2</sub> group, and 100 µg/mL GABA with 100 µM H<sub>2</sub>O<sub>2</sub> group. Stimulation duration of all group samples was 48 h. Duplicates for each group were set as 3.

### RNA Isolation and Reverse Transcription

RNA isolation and reverse transcription were conducted following the method reported in the literature (Fuchsova

et al., 2016). Briefly, RNAprep Pure Cell/Bacteria kit (Tiangen, China) was used to extract total RNA according to the manufacturer's instructions. NanoDrop One<sup>C</sup> (ThermoFisher, USA) was used to determine RNA yield and purity by absorbance ratios A260/A280 and A260/A230. OD260/OD280 ratios of the RNA of all samples were in the range of 1.8–2.0. 2 µg of total RNA used to synthesize the first strand complementary DNA (cDNA) using high-capacity cDNA reverse transcription kit (ThermoFisher, USA) according to manufacturer's directions. All reverse transcription products were 10-fold dilution.

### Oligonucleotide Primers

PrimerBank was applied to search primers for the amplification of human GABRA1, GABRA2, GABRA3, HTR1A, HTR1B, HTR2A, HTR2B, and internal reference genes (GAPDH and ACTB). Nucleotide sequence of primers are listed in **Table 1**.

### Real-Time PCR (qPCR).

Levels of mRNA were quantified by conducting qPCR reactions with SsoAdvanced Universal SYBR Green Supermix (Bio-Rad, USA) according to the manufacturer's directions. CFX equipped with software (Bio-Rad, USA) was used to perform measurements. PCR was in the 20 µL reaction system containing 0.5 µM primer, 10 µL Mix, 5 µL cDNA, and 3 µL RNase-free ddH<sub>2</sub>O, and the amplification and dissolution curve condition was shown in **Table 2**. qPCR amplification of ACTB (β-actin) and GAPDH (glyceraldehyde-3-phosphate dehydrogenase) transcription were used as the internal control to verify that equal amounts of RNA were used in each reaction. Fold expression was defined as the fold change relative to control cells.

### Statistical Analysis

Bio-Rad CFX Manager software (Bio-Rad, USA) was employed to analyze raw expression data (CT values). For further statistical

analysis we used values normalized to the normalization factor calculated as a geometric mean of the expression of two reference genes. All data were expressed as the mean ± SD, and a two-way ANOVA followed by Tukey test was applied for statistical analysis using GraphPad Prism 7.0.

## RESULTS

### Phytochemicals Identification of SZJ Extract

Thirty-five phytochemicals were identified from SZJ by using the UPLC-Q-TOF/MS method. The MS chromatogram in negative ion model of SZJ extract is shown in **Figure 1**. The chemical information of identified phytochemicals is seen in **Table 3**. Among them, 11 phytochemicals were identified by comparison with standard references. The rest of the compounds were identified through comparison with literature data. These phytochemicals are mainly classified into four subcategories: (1) saponins including jujuboside A and jujuboside B; (2) flavones and their C-glycosides including catechin, epicatechin, vicenin-2, swertisin, nicotiflorin, isovitexin and its analogues, and spinosin and its analogues; (3) organic acids including triterpenic acid (e.g., aliphatic acid), fatty acid (e.g., linoleic acid), and glycosylated organic acids (pseudolaroside B and oleuropein); and (4) alkaloids including indoleacetic acid derivatives (e.g., N-glc-indoleacetic acid) and isoquinoline alkaloids (zizyphusine).

### Potential Metabolic Products by Gut Microbes of C-Glycoside and Jujubosides Phytochemicals

Gut microbes are known to deglycosylize and cleavage ester bond of flavone C-glycosides and their derivatives (Kim et al., 2015; Vollmer et al., 2018; Zheng et al., 2019). Similarly, jujuboside A is metabolized to jujubogenin in gastrointestinal to exhibit effects on the expression and activation of gamma amino-butyric acid A (GABA<sub>A</sub>) receptors (Song et al., 2017). Based on the metabolic patterns reported in those literatures, we deduced the metabolic products by gut microbe of flavone C-glycosides and jujubosides of SZJ extracts. As a result, 11 metabolites of these flavone C-glycosides and jujubosides are concluded for further system biology analysis. To be specific, ferulic acid is metabolized from 6'''-feruloylspinosin and 6'''-O-feruloylspinosin, para-coumaric acid is from 6'''-para-coumaroylspinosin, phaseic acid is from 6'''-(E)-phaseolspinosin, para-hydroxybenzoic acid is from 6'''-para-hydroxyl-benzoylspinosin, sinapic acid is from 6'''-sinapoylspinosin, vanillic acid is from 6'''-vanilloylspinosin,

**FIGURE 1** | Chromatographic profile of SZJ extract using UPLC-Q-TOF/MS in negative ion mode.

kaempferol is from kaempferol-3-O-rutinoside, genkwanin is from swertisin, naringenin is from 5,7-Dihydroxy-2-(4-hydroxyphenyl)6,8-bis[3,4,5-trihydroxy-6(hydroxymethyl)oxan-2-yl]-2,3dihydrochromen-4-one, apigenin is from spinosin and its analogues, and isovitexin and vicenin-2, jujubogenin is from jujuboside A and jujuboside B.

## Anxiolytic Effect-Related Targets of Phytochemicals in SZJ Extract and Their Metabolites

In an integrated search of multiple databases, a total of 476 targets were found to be relevant with anxiety related disorders or diseases, of which 455 targets were acquired for 35 phytochemicals and 11 metabolites. All the interactions among the phytochemicals and targets are listed in **Supplementary Table 1**. After the two clusters were compared and analyzed, 71 target intersects were further determined and are listed in **Table 4**. Among the interactions of phytochemicals and metabolites on those 71 targets (data is not shown), (epi) catechin had the most interactions (degree =22), followed by kaempferol (degree =19), palmitic acid (degree =17), oleic acid (degree =15), betulinic acid (degree =14), apigenin (degree =14), zizyphusine (degree =12), and naringenin (degree =11), etc.

To screen out the core targets, PPI and MCODE cluster analysis was performed on 71 identified targets. As shown in **Figure 2**, 67 nodes plus 260 edges were obtained, in which the clustering coefficient is 0.564 and average number of neighbors is 7.761. With that, MCODE cluster analysis indicated 5 clusters. Specific data of target clusters were exported and are presented in **Table 5**. As a result, 35 core targets were obtained from these 5 clusters, suggesting the core anxiolytic effect targets of SZJ extract. Notably, most of these targets are neuroactive ligand

receptors including serotonin (5-HT) receptors (e.g., HTR1A, HTR1B, HTR2A, HTR2B, HTR2C, and HTR1D), GABA<sub>A</sub> receptors (e.g., GABRA1, GABRA2, GABRA3, GABRA6, and GABRG2), dopamine receptors (e.g., DRD2, DRD3, and DRD4), cannabinoid signaling (CNR1 and CNR2), and adrenergic (ADRA2A) and glutamate receptor (GRIN2A).

## GO and KEGG Pathway Enrichment and Analysis

GO enrichment analysis was conducted on the 35 core targets by using DAVID. All the enriched GO terms are seen in **Supplementary Table 2**. The top 10 significant terms in biological process, molecular function, and cell component categories are shown in **Figure 3**. The results demonstrated that GO terms were mainly concentrated in neurotransmitter receptors signaling, particularly GABA and serotonin receptor signaling. Functions of activating neurotransmitter receptors and ligand-gated ion channel *via* receptor complex, and regulating synaptic transmission were mainly involved. Cytoscape ClueGo plug-in was further applied to visualize the interaction network of biological process, as shown in **Figure 4**. All statistically significant biological processes were listed in **Supplementary Table 3**.

In addition, 35 identified core targets were imported to ClueGo for KEGG pathway enrichment, resulting in 14 statistically significant pathways. The targets-pathway network is shown in **Figure 5**, demonstrating that neuroactive ligand-receptor interaction is the most significant pathway with involvement of 18 targets, followed by serotonergic synapse pathway (8 targets), taste transduction pathway (7 targets), etc. Other nervous system related pathways including GABAergic synapse and retrograde endocannabinoid signaling, signaling transduction related pathways including TNF signaling

**TABLE 4 |** Information of anxiolytic effects related targets of SZJ extract.

Gene Symbol	Full Name
ACSL4	acyl-CoA synthetase long-chain family member 4
ADIPOQ	adiponectin, C1Q and collagen domain containing
ADRA2A	adrenoceptor alpha 2A
AKR1C1	aldo-keto reductase family 1 member C1
AKT1	AKT serine/threonine kinase 1
ALDH2	aldehyde dehydrogenase 2 family (mitochondrial)
ALDH5A1	aldehyde dehydrogenase 5 family member A1
ANG	angiogenin
APP	amyloid beta precursor protein
ATP1A1	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 1
ATP1A3	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 3
BCAT2	branched chain amino acid transaminase 2
BDNF	brain derived neurotrophic factor
CAT	catalase
CCL3	C-C motif chemokine ligand 3
CHRNA7	cholinergic receptor nicotinic alpha 7 subunit
CNR1	cannabinoid receptor 1
CNR2	cannabinoid receptor 2
COMT	catechol-O-methyltransferase
COX1	cytochrome c oxidase subunit I
COX2	cytochrome c oxidase subunit II
CREB1	cAMP responsive element binding protein 1
CTNNA1	catenin beta 1
CXCL8	C-X-C motif chemokine ligand 8
CYP2E1	cytochrome P450 family 2 subfamily E member 1
DNMT1	DNA methyltransferase 1
DRD2	dopamine receptor D2
DRD3	dopamine receptor D3
DRD4	dopamine receptor D4
EDN1	endothelin 1
ESR1	estrogen receptor 1
ESR2	estrogen receptor 2
GABRA1	gamma-aminobutyric acid type A receptor alpha1 subunit
GABRA2	gamma-aminobutyric acid type A receptor alpha2 subunit
GABRA3	gamma-aminobutyric acid type A receptor alpha3 subunit
GABRA6	gamma-aminobutyric acid type A receptor alpha6 subunit
GABRG2	gamma-aminobutyric acid type A receptor gamma2 subunit
GLO1	glyoxalase I
GM2A	GM2 ganglioside activator
GPB1	G protein-coupled estrogen receptor 1
GRIN2A	glutamate ionotropic receptor NMDA type subunit 2A
GSK3B	glycogen synthase kinase 3 beta
GSTP1	glutathione S-transferase pi 1
HSD11B2	hydroxysteroid 11-beta dehydrogenase 2
HTR1A	5-hydroxytryptamine receptor 1A
HTR1B	5-hydroxytryptamine receptor 1B
HTR1D	5-hydroxytryptamine receptor 1D
HTR2A	5-hydroxytryptamine receptor 2A
HTR2B	5-hydroxytryptamine receptor 2B
HTR2C	5-hydroxytryptamine receptor 2C
HTR3A	5-hydroxytryptamine receptor 3A
ICAM1	intercellular adhesion molecule 1
IL6	interleukin 6
INS	insulin
MAPK1	mitogen-activated protein kinase 1
MIF	macrophage migration inhibitory factor (glycosylation-inhibiting factor)
ND1	NADH dehydrogenase, subunit 1 (complex I)
NOS2	nitric oxide synthase 2
NR1I2	nuclear receptor subfamily 1 group I member 2
NR3C1	nuclear receptor subfamily 3 group C member 1
PAH	phenylalanine hydroxylase

(Continued)

**TABLE 4 |** Continued

Gene Symbol	Full Name
PON1	paraoxonase 1
SCN1A	sodium voltage-gated channel alpha subunit 1
SHBG	sex hormone binding globulin
SIRT1	sirtuin 1
SOD1	superoxide dismutase 1, soluble
SQSTM1	sequestosome 1
TGFB2	transforming growth factor beta receptor 2
TNF	tumor necrosis factor
TP53	tumor protein p53
TRPV1	transient receptor potential cation channel subfamily V member 1

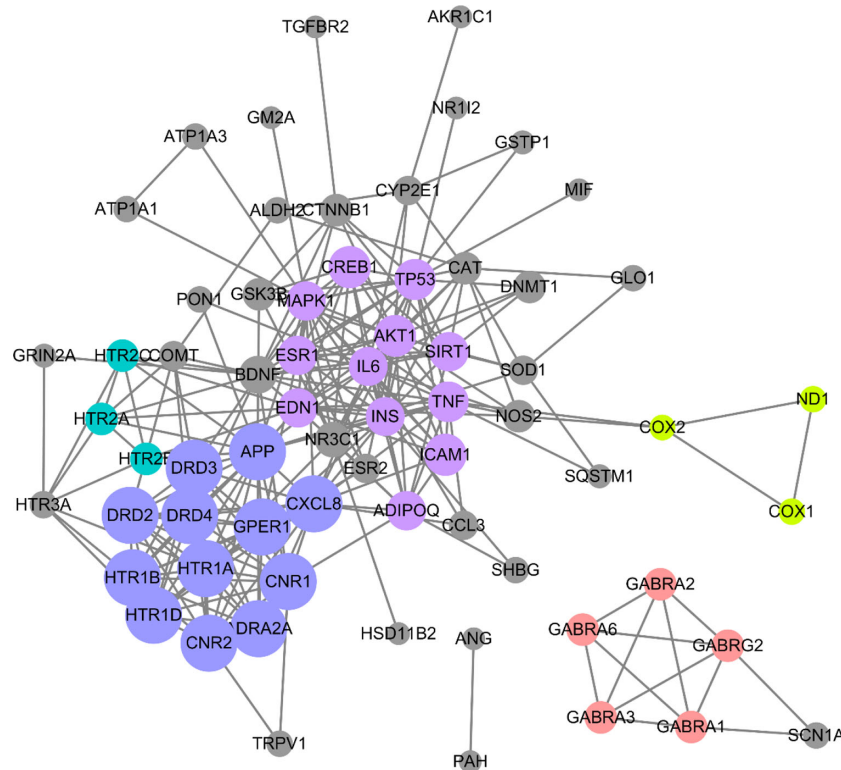

pathway, and longevity regulating pathways were also significantly enriched. These results are consistent with the results from GO enrichment analysis. Taken together, these findings suggest that SZJ extract mainly exerts an anxiolytic effect *via* modulation of serotonergic and GABAergic systems.

GABA<sub>A</sub> receptors in the central nervous system are known as the major targets for the first line treatment of anxiety (Poisbeau et al., 2018). GABA<sub>A</sub> receptors subunits, mainly including GABRA1, GABRA2, and GABRA3, have been reported to mediate anxiolysis (Möhler, 2012). Similarly, preclinical studies have suggested that most 5-HT receptors subtypes participate in anxiety-like processes, and blocking or stimulating individual 5-HT receptor subtypes might cause the anxiolytic-like effect (Żmudzka et al., 2018). HTR1A, HTR1B, HTR2A, and HTR2B were commonly targeted in preclinical studies for the anxiety treatment (Graeff et al., 1996; Clinard et al., 2015; Spicci et al., 2016; Colangeli et al., 2019) as well as the anxiolytic-like studies of SZJ (Wang et al., 2010; Liu et al., 2015). Hence, among the potential targets acted by SZJ, GABRA1, GABRA2, GABRA3, HTR1A, HTR1B, HTR2A, and HTR2B were preferentially selected for further validation.

## Effects of SZJ Extract on mRNA Expression of GABA<sub>A</sub> and 5-HT Receptor Subtypes

Based on the findings from system biology analysis, RT-qPCR was employed to evaluate the effects of SZJ extract on mRNA expression of GABRA1, GABRA2, GABRA3, HTR1A, HTR1B, HTR2A, and HTR2B. As shown in **Figure 6**, in the non-H<sub>2</sub>O<sub>2</sub> treated cells, GABA 100 µg/mL significantly enhanced the expression of GABRA1 ( $p < 0.0001$ ), GABRA2 ( $p < 0.0001$ ), and HTR1A ( $p < 0.001$ ) comparing with the control group, while it significantly decreased the expression of GABRA3 ( $p < 0.01$ ) and HTR2B ( $p < 0.05$ ). Similar as GABA, SZJ extract 250 µg/mL exhibited significant effect on enhancing expression of GABRA1 ( $p < 0.001$ ) and HTR1A ( $p < 0.05$ ). However, contrast to GABA group, obvious expression enhancement of GABRA3 ( $p < 0.01$ ) and HTR2B ( $p < 0.0001$ ) were observed at 250 µg/mL SZJ extract. These differences in regulating GABA<sub>A</sub> receptor subtypes following SZJ and GABA stimulations could help to explain the different mechanisms of anxiolytic effect of the two ingredients.

**FIGURE 2 |** Protein-protein interaction (PPI) network of anxiolytic effects-related targets of SZJ. Cytoscape (Version 3.6.1) was applied to construct the interactions downloaded from the STRING (interaction score set as high confidence >0.7). All the targets are represented by nodes, whereas the interactions between the targets are represented by edges. MCODE plug-in was applied to conduct cluster analysis. Different clusters are noted with different colors. The node size is proportional to its located cluster MCODE score.

**TABLE 5 |** List of genes clusters information analyzed by MOCDE on the base of PPI data downloaded from the STRING.

Cluster	Score (Density*#Nodes)	Nodes	Edges	Node IDs
1	10.154	12	66	GPER1, ADRA2A, DRD2, CNR2, CNR1, HTR1A, HTR1B, APP, DRD4, HTR1D, DRD3, CXCL8
2	8	12	52	CREB1, AKT1, TNF, SIRT1, TP53, MAPK1, EDN1, ICAM1, ADIPOQ, IL6, ESR1, INS
3	3.333	5	10	GABRA2, GABRG2, GABRA6, GABRA3, GABRA1
4	1.5	3	3	HTR2C, HTR2A, HTR2B
5	1.5	3	3	COX1, COX2, ND1

Furthermore, because oxidative stress mechanisms have been well explored in anxiety disorders (Bouayed et al., 2009; Salim, 2017), the effects of SZJ extract on GABA<sub>A</sub> and 5-HT receptors were also evaluated in hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) induced oxidative stress condition. As a result, a remarkable increase (*p* < 0.0001) in GABRA1, GABRA2, HTR1A, HTR1B, and HTR2A expression following 100 μM H<sub>2</sub>O<sub>2</sub> stimulation was observed. Currently, though the alteration of GABA<sub>A</sub> and 5-HT receptors under strong oxidative stimulation is unclear, our result in some extent suggested that overexpression of GABRA1, GABRA2, HTR1A, HTR1B, and HTR2A may be involved in oxidative stress-induced anxiety. Intriguingly, the sharp increase induced by H<sub>2</sub>O<sub>2</sub> in GABRA1, GABRA2, HTR1A, and HTR2A were significantly antagonized by both SZJ extract 250 μg/mL and GABA 100 μg/mL. Hence, inhibition of

GABRA1, GABRA2, HTR1A, and HTR2A overexpression is also possibly involved in anxiolytic-like mechanisms of SZJ.

DISCUSSION

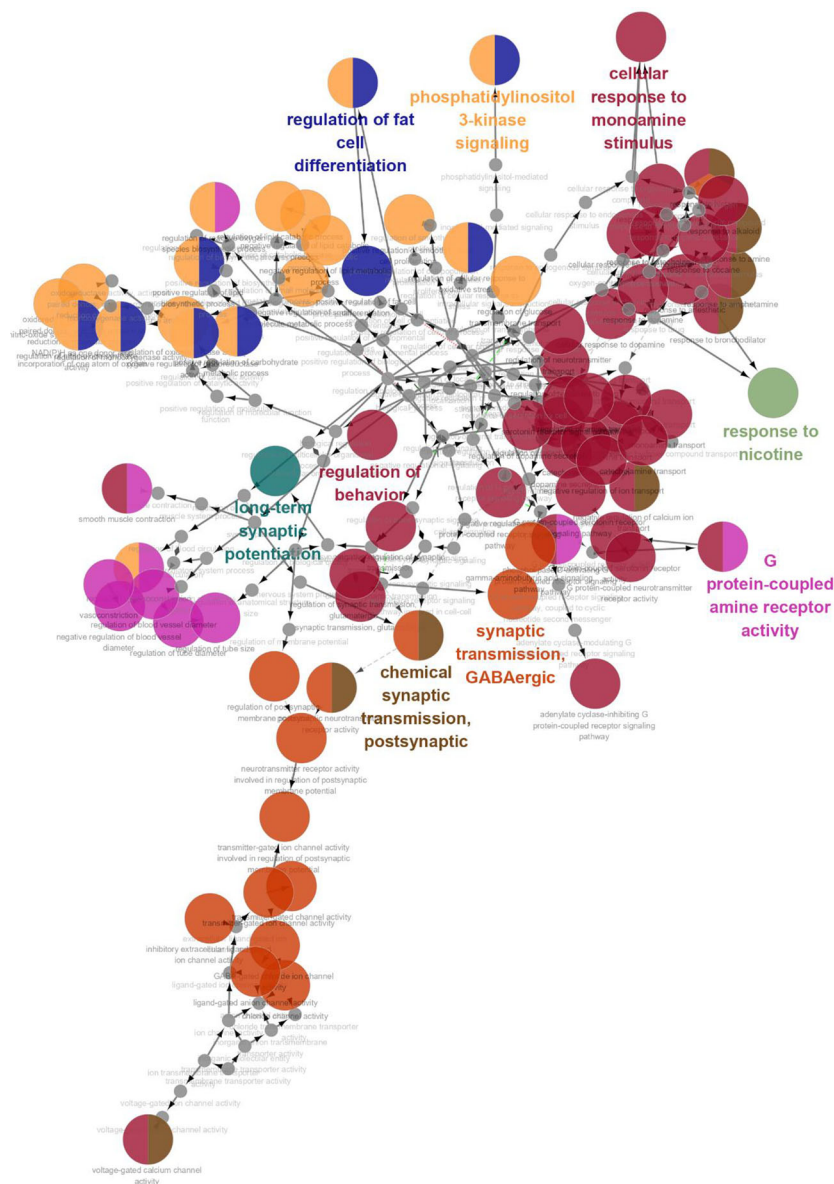

The identification of phytochemicals in herbal materials is a critical step during the process of system biology analysis. Herbal materials are often subjected to extraction, concentration, and/or purification, resulting in the phytochemical compositions alteration. The phytochemical data from current databases (e.g., TCMSP, <http://tcmsp.w.com/tcmsp.php>; TCMID, <http://www.megabionet.org/tcmid/>) may not be used directly for system biology investigation. Additional methods for phytochemical identification, such as UPLC-Q-TOF/MS, should be a complementary tool to obtain

more accurate results of phytochemical compositions (Shen et al., 2013). In current work, a series of flavonoid glycosides and saponins were identified from SZJ extract, in which the spinosin derivatives including 6'''-vanilloylspinosin, 6'''-para-hydroxylbenzoylspinosin, 6'''-sinapoylspinosin, 6'''-para-coumaroylspinosin, 6'''-feruloylspinosin, 6'''-(-)-phaseoylspinosin, and 6''-O-feruloylspinosin are rare in other plant species. The studies on their bioactivities and effective targets have been so poorly reported that there is not enough data for system biology analysis. In addition, their chemical structures are complicated and contain multi-chiral centers that bring a great challenge to obtain the potential targets through reverse virtual fishing technique. Traditional system biology analysis would take ADME (absorption, distribution, metabolism, and excretion) screening strategy that may exclude these glycosides with low oral bioavailability and low drug-likeness (Yue et al., 2017a; Yue et al., 2017b). For instance, ginsenosides are the dominant phytochemicals in ginseng and are thought to be contributed to its multiple bioactivities (Ru et al., 2015; Kim et al., 2017). However, the above analysis strategy, i.e., ADME screening, would exclude the ginsenosides along with their contributions on efficacy when performing systematic research of ginseng. Therefore, such an analytical strategy is incomplete and not systematic. In fact, it has been well demonstrated that the metabolites of the ginsenosides are responsible for the specific bioactivities (Chen et al., 2018; Kim, 2018). Similarly, the chemoinformatics and pharmacoinformatics approach indicated that jujubogenin was the effective GABA<sub>A</sub> agonist, neither jujuboside A nor jujuboside B (Chen, 2009). Gut microbes play an important role in favoring phytochemicals

transformation into metabolites endowed with biological activity (Dey, 2019). As a result, the strategy that involves the metabolites of glycosides in gastrointestinal environment (e.g., gut microbes) will be a more reasonable approach to understand the actual efficacy and mechanism of herbal materials in which the glycosides are considered as the main active components.

The GABA<sub>A</sub> receptors are chloride channels and are composed of several subunit classes ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$ ) (Olsen and Sieghart, 2008). GABAergic neurotransmission plays an important role in anxiety status. Previous studies have shown that deficit of GABA<sub>A</sub> receptors and reduction of GABA transmission were observed in people with anxiety-like symptoms (Horowski and Dorow, 2002; Nutt and Malizia, 2004; Hasler et al., 2008). In contrast, positive modulation of GABA<sub>A</sub> receptors and enhancement of GABA transmission have shown anxiolytic effects. Classic benzodiazepines reduce anxiety by interacting with the GABA<sub>A</sub> receptors *via* the benzodiazepine binding site, which is present at the interface of  $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 3$ , or  $\alpha 5$  subunits and  $\gamma$  subunit of GABA<sub>A</sub> receptors (Möhler, 2012). Other classes of compounds, GABA, barbiturates, and alcohol also could act at different benzodiazepine binding sites to increase the opening of the chloride channel resulting in enhancement of inhibitory synaptic transmission (Harris, 1990; Schousboe and Redburn, 1995). The results of our system biology study suggested the GABA<sub>A</sub> receptors signaling is a significant pathway involving in anxiolytic effect of SZJ. In fact, pharmacologic study has found that spinosin, a major C-glycoside flavonoid in SZJ, exerted anxiolytic-like effects *via* modulation of GABA<sub>A</sub> and 5-HT receptors (Liu et al., 2015). Similarly, 6'''-feruloylspinosin and

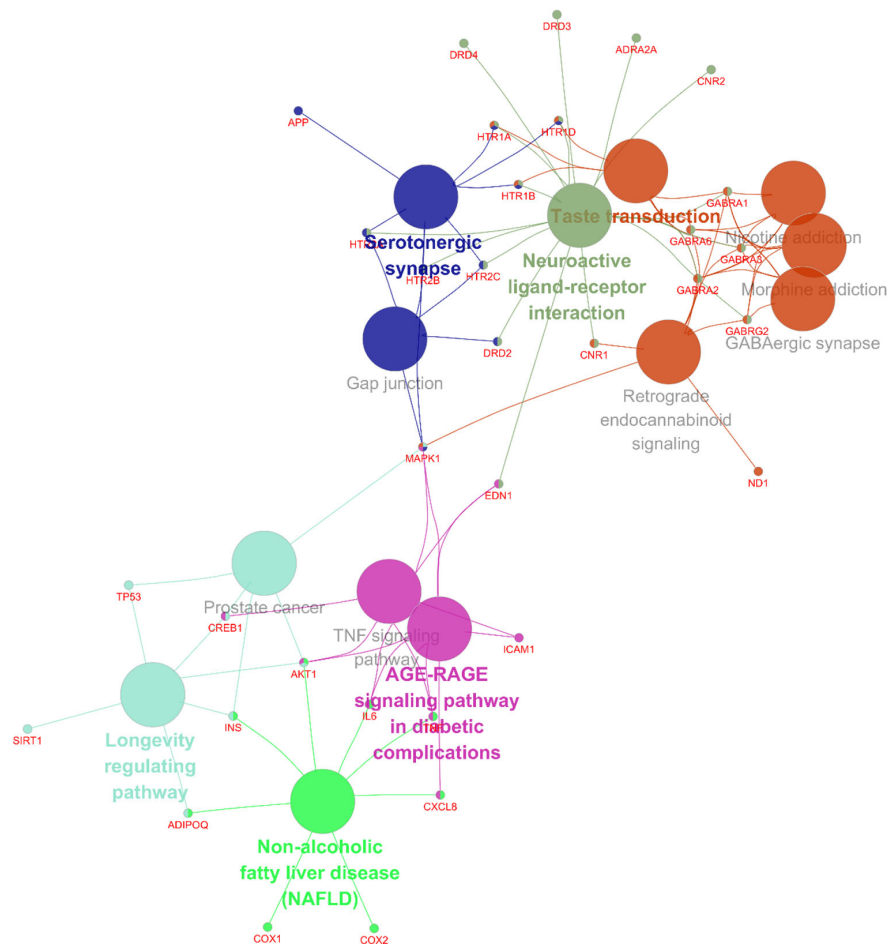

**FIGURE 4** | The interaction networks of enriched biological processes. ClueGO was applied to analysis procedure, and multiple color circles indicate that they are involved in multiple biological processes.

spinosin have been reported to significantly enhance the expression of GABRA1 and GABRA5 mRNA in rat hippocampal neurons (Qiao et al., 2016). In addition, it has been found that stimulation of jujuboside A at 50  $\mu\text{g/mL}$  could increase the mRNA transcription levels of GABRA1, GABRA5, GABRB1, and GABRB2 in hippocampal neurons (You et al., 2010; Wang et al., 2015); however, long time stimulation of jujuboside A at a high dose of 100  $\mu\text{g/mL}$  result in the decrease of GABRA1 and GABRB2 mRNAs expression (You et al., 2010). These results suggested a two-way modulatory effect of SZJ on GABRA1 and other GABA<sub>A</sub> receptors. Such benefits were similar to what we

found in this work, that is, SZJ extract enhanced mRNA level of GABRA1 in non-H<sub>2</sub>O<sub>2</sub> treated SH-SY5Y cells, but inhibited the H<sub>2</sub>O<sub>2</sub>-induced overexpression of GABRA1. Therefore, combining with the results from literatures and our results, it was suggested that SZJ exhibited anxiolytic effects through modulating GABA<sub>A</sub> receptors, in which a two-way modulation of GABRA1 may play an important role.

It was well established that the alteration of various behaviors in anxiety disorders including appetite, mood, sleep, and cognitive function have been linked to the serotonergic system (Liu Y. et al., 2018; Liu et al., 2019). Serotonin receptors are

**FIGURE 5 |** Targets-pathway network associated with anxiolytic effects of SZJ extract. A cytoscape ClueGo plug-in was applied to enrich the pathways and construct the network.

prevalent throughout the nervous system and the periphery, and they potentially control the serotonergic neurotransmission throughout the brain and neuronal activity to alleviate neuropsychiatric disorders (Okazawa et al., 1999). Generally, the activation of HTR1A, HTR2A receptors can produce anxiolytic effects, whereas inactivation of them increases anxiety-like behaviors (Clinard et al., 2015; Spiacci et al., 2016). Involvement of other 5-HT receptors including HTR1B, HTR1B, and HTR2C in the mechanisms of anxiety have also been recognized (Graeff et al., 1996; Griebel et al., 1997; McCorvy and Roth, 2015). Similarly, our system biology analysis found that the serotonergic synapse pathway was dominant in anxiolytic effects mechanism of SZJ extract, in which different subtypes of 5-HT receptors were involved. Notably, as the same effect on GABRA1, SZJ extract also showed a two-way modulation on HTR1A and HTR2A in our RT-qPCR test. Genetic studies in animal models have suggested that anxiety-like behavior can increase when the HTR1A function is eliminated or overexpressed (Overstreet et al., 2003). Hence,

these results suggested the involvement of modulating serotonergic synapse pathway, specifically two-way modulation of HTR1A and HTR2A in anxiolytic effects of SZJ.

In addition, the cannabinoid receptors (CNR) are extensively expressed in areas of the nervous system and have been found closely associated with anxiety behavior (Akirav, 2011). It has been well illustrated that endocannabinoid (eCB) reduces the serotonin release in the central nervous system and increases the expression and function of HTR1A in the hippocampus *via* the activation of CNR1 (Haj-Dahmane and Shen, 2011; Patel et al., 2017). Beyond CNR1, eCB system could exert actions on other targets including CNR2, transient receptor potential vanilloid receptor type 1 (TRPV1), or cyclooxygenase-2 (COX2) to participate in improvement of anxiety (Patel et al., 2017). In addition, cyclic AMP-responsive element-binding protein (CREB) has been suggested to be crucial for the role of HTR1A in modulating anxiety-related behaviors *via* mediating hippocampus structural plasticity (Zhang J. et al., 2016). Intriguingly, this systematic analysis work showed phytochemicals in SZJ extracts potentially

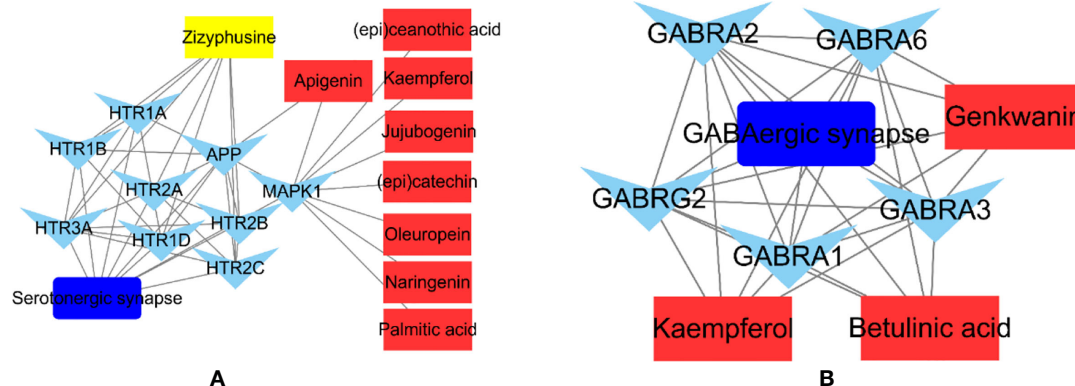

**FIGURE 6** | Effects of SZJ extract on mRNA gene expressions of different subtypes of GABA<sub>A</sub> and 5-HT receptors. GraphPad Prism 7.0 software was applied for statistical analysis and graphing. All data were expressed as mean  $\pm$  SD, and a two-way ANOVA followed by Tukey's test was applied. Two-way ANOVA analysis results presented that, GABRA1,  $F(2, 12) = 57.27$ ;  $p < 0.0001$ ; GABRA2,  $F(2, 12) = 112.50$ ;  $p < 0.0001$ ; GABRA3,  $F(2, 12) = 40.10$ ;  $p < 0.0001$ ; HTR1A,  $F(2, 12) = 677.80$ ;  $p < 0.0001$ ; HTR2A,  $F(2, 12) = 13.07$ ;  $p = 0.0010$ ; HTR1B,  $F(2, 12) = 42.99$ ;  $p < 0.0001$ ; HTR2B,  $F(2, 12) = 151.50$ ;  $p < 0.0001$ . Post hoc Tukey's test results were represented by comparing with non-H<sub>2</sub>O<sub>2</sub> treated control group, \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$  and \*\*\*\* $p < 0.0001$ ; compared with H<sub>2</sub>O<sub>2</sub> treated control group, ### $p < 0.001$  and #### $p < 0.0001$ .

act on the above mentioned targets including CNR1, CNR2, TRPV1, COX2, and CREB. These results, to some extent, suggested that the mechanism of action of SZJ in anti-anxiety may also involve those pathways/targets that indirectly modulate eCB and serotonergic systems. More attention needs to be paid to those targets/pathways in further experimental studies on anxiolytic effects of SZJ.

The phytochemicals in herbal medicines are the substantial basis for their pharmacologic actions. Those phytochemicals with good bioactivity and high content are considered to be the chemical markers in quality control of the herbal medicines. Jujuboside A and spinosin are used to quality markers of SZJ crude drug in Chinese Pharmacopoeia (Edition 2020). Combining the results from literatures reports (Han et al., 2009; Abdoul-Azize, 2016) and our results, the modulations of GABAergic and serotonergic systems seem the major mechanisms of SZJ exerting anxiolytic effects, as well as the traditional efficacy of nourishing heart and calming mind. Based on that, we abstracted the phytochemicals-targets-pathway sub-

networks of GABAergic and serotonergic synapse pathways. As shown in **Figure 7**, it demonstrated that metabolites of C-glycosides (spinosin, etc.) and jujubosides (jujuboside A, etc.) including apigenin, kaempferol, naringenin, genkwanin, and jujubogenin were involved in modulation of GABAergic and serotonergic synapse pathways. The result provides the extra evidence to support that C-glycosides and jujubosides are responsible for the anxiolytic effects of SZJ, and they support jujuboside A and spinosin as chemical markers for quality control of SZJ and its preparations. Beyond the C-glycosides and jujubosides, the involvements of triterpenic acid (e.g., betulinic acid) and alkaloid (zizyphusine) were also observed in modulation of GABAergic and serotonergic synapse pathways. Specifically, betulinic acid is a function of the modulating GABAergic system *via* multiple subtypes of GABA<sub>A</sub> receptors, whereas zizyphusine is a function of the modulating serotonergic system *via* multiple subtypes of 5-HT receptors. Notably, it has been reported that zizyphusine was identified as one of the principal components in SZJ by principal component

**FIGURE 7** | Abstracted phytochemicals-targets-pathway sub-networks of serotonergic synapse (A) and GABAergic pathways (B). Cytoscape (Version 3.6.1) was applied to construct the sub-networks.

analysis (Sun et al., 2014). And according to records in TCMIP, zizyphusine is exclusively derived from *Ziziphus jujube* (fruit or seeds), and its bioavailability and druglikeness is much better than C-glycosides and jujubosides. These findings recommend that the involvement of zizyphusine in quality control of SZJ extract and pharmacologic actions in anxiolytic effect is worth investigating in the future. Because the pharmacologic study of zizyphusine is poor at present, more attention could be paid to research and development of zizyphusine as a potential natural anti-anxiety drug.

There are some limitations of our current research. First, we did not conduct the behavioral test to confirm the anxiolytic-like effect of SZJ. Such benefit of SZJ was concluded on the base of previous pharmacodynamic studies, as well as clinical practice experience of traditional medicine. Our *in vitro* mRNA expression evaluation of GABA<sub>A</sub> and 5-HT receptors only used a single concentration of SZJ extract, which corresponds to approximately 90% cell viability in CellTiter-Glo assay. Leveraging the integrated approach of system biology, UPLC-Q-TOF/MS and RT-qPCR, present work contributed to the illustration of potential mechanism of action involved in the anxiolytic-like effect of SZJ. However, further in-depth preclinical studies are warranted to verify the results obtained from the current analysis.

## CONCLUSIONS

In conclusion, our results systematically demonstrated that anxiolytic mechanisms of SZJ mainly involved the regulation of serotonergic and GABAergic synapse pathways, in which the two-way modulation of GABRA1, HTR1A, and HTR2A may play an important role. In addition to C-glycosides and jujubosides, triterpenic acids and zizyphusine identified in SZJ also contributed to the regulation of serotonergic and GABAergic synapse pathways. This study provides directional predictions of anxiolytic mechanism of SZJ and insights to improve the quality control of standard extraction.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## AUTHOR CONTRIBUTIONS

LC, XZ, and JK designed the study. XZ, YZ, LZ, and BL performed the experiments. LC, CH, and JD prepared the manuscript. All authors contributed to the article and approved the submitted version.

## FUNDING

The Nutrilite Health Institute fully funded this study.

## ACKNOWLEDGMENTS

We would like to thank Dr. Zhou Yang from Shanghai Standard Technology Co., Ltd. for chemical composition analysis and identification in this paper.

Citri Reticulatae Pericarpium (CRP), dried peels of *Citrus reticulata* Blanco and its cultivars, is an important traditional Chinese medicine for the treatment of spleen deficiency-related diseases. To date, the mechanism of CRP alleviating spleen deficiency has not been well investigated. This study aimed to explore corresponding mechanisms with integrating pharmacology and gut microbiota analysis. Firstly, the therapeutic effects of CRP against spleen deficiency were evaluated in reserpine-treated rats. CRP was found to effectively relieve the typical symptoms of spleen deficiency, including poor digestion and absorption capacity, and disorder in gastrointestinal hormones, immune cytokines and oxidative stress. Secondly, high throughput 16S rRNA gene sequencing revealed that CRP could not only up-regulate some short-chain fatty acids producing and anti-inflammatory bacteria but also down-regulate certain spleen deficiency aggravated related bacteria, eventually led to the rebalance of gut microbiota in spleen deficiency rats. In addition, a total of 49 compounds derived from CRP were identified in rat urine using ultra-high performance liquid chromatography-quadrupole-time of flight tandem mass spectrometry. Network pharmacology analysis showed that apigenin, luteolin, naringenin, hesperidin, hesperetin, homoeriodictyol, dihydroxy-tetramethoxyflavone, and monohydroxy-tetramethoxyflavone were the core bioactive components for CRP against spleen deficiency. Further Gene Ontology analysis and pathway enrichment suggested that therapeutic effects of CRP against spleen deficiency involved multiple pathways such as tumor necrosis factor signaling, hypoxia-inducible factor-1 signaling and Toll-like receptor signaling pathway. These results would help to understand the mechanism of CRP alleviating spleen deficiency and provide a reference for further studies.

**Keywords:** Citri Reticulatae Pericarpium, spleen deficiency, gut microbiota, metabolites, network pharmacology

## INTRODUCTION

In the theory of traditional Chinese medicine (TCM), spleen deficiency is a common clinical syndrome and described as symptoms such as emaciation, inappetence, epigastralgia, flatulence, lassitude, wilted complexion, loose stool, *etc.* Modern researches show that the spleen in TCM theory not only refers to the anatomical spleen, but also includes some functions of the pancreas and lymphatic system (Zheng et al., 2014). Spleen deficiency is a comprehensive manifestation of multiple functional declines, involving food digestion, nutrient absorption, energy metabolism, and immune system (Wang et al., 2016). Moreover, recent studies suggested that spleen deficiency is closely related to gut microbiota disorder (Qiu et al., 2017; Lin et al., 2018). Gut microbiota, as the main member of gut microecology, plays an essential role in the host's health and can be deeply influenced by diets (Bibbò et al., 2016), antibiotics (Nogacka et al., 2018) and other environmental factors (Capurso and Lahner, 2017). In turn, the dysbiosis of the gut microbiota will act as a causative factor in gastrointestinal diseases (Feng et al., 2018). Recently, researchers found that some TCMs could exert their therapeutic effects on gastrointestinal diseases through regulating the balance of gut microbiota (Yang et al., 2017).

Citri Reticulatae Pericarpium (CRP), commonly referred to as Chenpi in Chinese, is derived from the pericarp of mature fruits of *Citrus reticulata* Blanco and its cultivars (State Pharmacopoeia Committee of People's Republic of China, 2015). It is an important Chinese medicinal material which has been used for the treatment of respiratory and digestive diseases for thousands of years (Zheng et al., 2018). Long-term and extensive clinical applications have confirmed that CRP could alleviate multiple spleen deficiency related diseases, including indigestion, inappetence, abdominal fullness and distention (Yu et al., 2018). However, the mechanism of CRP alleviating spleen deficiency has not been well investigated. On the one hand, information concerning the bioactive components and potential targets involved in the effects of CRP against spleen deficiency are scarce. On the other hand, given the gut microbiota modulatory potential of CRP (Zeng et al., 2020a), it is meaningful to investigate the role of gut microbiota in the therapeutic efficacy of CRP.

In this study, reserpine-induced spleen deficiency rat model was established and used to evaluate the therapeutic effects of CRP. Reserpine, which was once used in the treatment of hypertension, could inhibit the vesicular monoamine transporter and deplete the brain monoamines such as 5-hydroxytryptamine by interfering with storage capacity, and ultimately lead to similar syndromes of spleen deficiency (Zhao et al., 2011; Maldonado and Maeyama, 2015). Meanwhile, spleen deficiency related disease targets were collected from accessible online databases and then used to explore the bioactive components and potential targets of CRP based on a network pharmacology strategy. Network pharmacology is a new discipline combined systems biology with drug efficacy, which helps to elucidate the inherent multi-component, multi-target, and multi-pathway characteristics of TCM (Ning et al., 2017).

Hereon, the therapeutic efficacy of CRP against spleen deficiency was evaluated in reserpine treated rats based on

body signs and biochemical indexes including digestion, absorption, gastrointestinal hormones, immune regulation and oxidative stress. The gut microbiota modulatory properties of CRP in spleen deficiency rats were investigated with high throughput 16S rRNA gene sequencing. Moreover, CRP derived metabolites were identified using ultra-high performance liquid chromatography-quadrupole-time of flight tandem mass spectrometry (UHPLC-Q-TOF-MS/MS) and were further employed in network pharmacology analysis to capture the bioactive components and potential targets of CRP in treating spleen deficiency. This study would be helpful for further understanding of the pharmacological effects and therapeutic benefits of CRP against spleen deficiency related diseases.

## MATERIALS AND METHODS

### Chemicals and Materials

CRP samples (Batch number: 201712) were acquired from Xinhui Hele Tea Art Co. Ltd. (Jiangmen, China), and were authenticated by Prof. Wenbo Liao from Sun Yat-sen University. Corresponding voucher specimens were kept in our laboratory. Reserpine injection was purchased from Guangdong Bangmin Pharmaceutical Co., Ltd. (Jiangmen, China). The reference standards of hesperidin, naringin, neohesperidin and rutin were obtained from National Institute for Control of Biological and Pharmaceutical Products of China (Beijing, China). Hesperetin, naringenin, nobiletin and mass spectrometry (MS) grade formic acid were purchased from Sigma-Aldrich (St. Louis, MO, United States). MS grade acetonitrile was purchased from Fisher Scientific (Pittsburgh, PA, United States). All water used was distilled and further purified by a Milli-Q system (Millipore, Milford, MA, United States). Other reagents used in the experiment were of analytical grade.

### Preparation of Citri Reticulatae Pericarpium Extract

The CRP sample (20 g) was cut into small pieces, and soaked in boiled distilled water for three times (2, 1.5 and 1.5 L of each bulk, respectively; 20, 15 and 15 min of each time, respectively). After filtration, the whole extracts were evaporated to 500 ml with a rotary evaporator (Eyela, Tokyo, Japan) at 60°C, to obtain the CRP extract with a concentration of 0.04 g mL<sup>-1</sup>.

### Animals and Experimental Design

Thirty male Sprague-Dawley rats (weighting 180–220 g) were purchased from Guangdong Medical Laboratory Animal Center, and maintained in standard temperature conditions (20–23°C) and a 12/12-h light-dark cycle, with food and water supplied *ad libitum*. All experimental procedures were approved by the Animal Ethics Committee of the School of Life Sciences in Sun Yat-sen University and carried out in accordance with the National Institutes of Health guide for the care and use of Laboratory animals (NIH Publications No. 8023, revised 1978).

Rats were randomly divided into three groups (control group, model group and CRP group). Rats in model and CRP group were injected subcutaneously with reserpine injection at 0.5 mg kg<sup>-1</sup> d<sup>-1</sup>

for 14 days to induce spleen deficiency (Wang et al., 2016). Rats in the control group were injected with the same volume of saline. After that, rats in CRP group were intragastrically given CRP extract ( $0.04 \text{ g ml}^{-1}$ ,  $15 \text{ ml kg}^{-1} \text{ d}^{-1}$ ) for 14 days. Rats in control and model groups received distilled water.

After the last administration, rats were housed individually in metabolic cages (Y-3102, Yuyan Instruments Co. Ltd.; Shanghai, China), with fasting and free access to water. Urine samples were collected within 12 h post-dose for metabolite identification. Subsequently, about 1 ml blood was sampled from retro orbital plexus, and then 5 ml 3% D-xylose solution was intragastrically administered to rats. Exactly 1 h later, rats were anesthetized with 10% chloral hydrate ( $3 \text{ ml kg}^{-1}$ ) to collect blood samples from abdominal artery. Serum was obtained after centrifugation. In addition, feces samples for gut microbiota analysis were collected from the rectum, transferred into sterile conical tubes, and then immediately frozen in liquid nitrogen. Obtained samples were stored at  $-80^{\circ}\text{C}$  until analysis.

## Kits Tests

The activities of superoxide dismutase (SOD) and amylase in serum, as well as the concentrations of D-xylose and malondialdehyde, were determined following protocols of corresponding Kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China). The concentrations of gastrin, motilin, cholecystokinin-8 (CCK-8), interleukin 6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) in serum were detected using commercial ELISA kits (Usnlife Sciences & Technology Co., Wuhan, China) according to the manufacturer's instructions.

## Gut Microbiota Analysis Using 16S rRNA Gene Sequencing

Total bacterial DNA were extracted and amplified as previously described (Zheng et al., 2020). After PCR amplification, sequencing was performed on an Illumina HiSeq 2500 platform by Biomarker Technologies Co. Ltd. (Beijing, China). Bioinformatics analysis was performed based on operational taxonomic units, which were clustered based on a 97% sequence similarity according to UCLUST (Edgar, 2010). For alpha diversity analysis, Chao1, ACE, Shannon index, and Simpson index were calculated in the QIIME program (version 1.8) (Caporaso et al., 2010). For beta diversity analysis, principal coordinate analysis (PCoA) was performed under the Gower algorithm. All processes were performed on the BMKCloud platform (www.biocloud.net). The Spearman's rho non-parametric correlations between gut microbiota (the top 60 genera in relative abundance) and spleen deficiency related indexes were then calculated by using SPSS software (version 22.0) and displayed by R software with a heatmap package.

## Identification of Metabolites Derived From Citri Reticulatae Pericarpium

To identify CRP derived metabolites, an aliquot of  $100 \mu\text{L}$  urine sample was vortex-mixed with  $200 \mu\text{L}$  volume acetonitrile for 3 min, and centrifuged at  $15,000 \times g$  for 30 min at  $25^{\circ}\text{C}$ . Finally,

$10 \mu\text{L}$  supernatant was subject to UHPLC-Q-TOF-MS/MS analysis.

Detection of CRP derived metabolites was carried out using an ultra-fast liquid chromatography (Shimadzu Corp., Kyoto, Japan) coupled with quadrupole/time-of-flight mass spectrometry (Triple TOF 5600 plus, AB SCIEX, Foster City, United States). Gradient chromatographic separation was performed on a Kinetex  $\text{C}_{18}$  column ( $2.6 \mu\text{M}$ ,  $150 \text{ mm} \times 3.0 \text{ mm}$ ) and maintained at  $40^{\circ}\text{C}$ . The mobile phase consisted of acetonitrile (A) and water containing 0.1% aqueous formic acid ( $v/v$ ) (B). The elution was carried out following the program: 5–100% A (0–30 min), 100% A (30–34 min) with the flow rate kept at  $0.3 \text{ ml/min}$ . The mass spectrometry detector was equipped with an electrospray ionization source and operated under the same parameters with our reported studies (Zeng et al., 2019).

Data acquisition was carried out using Analyst® TF 1.6 software (AB Sciex, Foster City, United States) in information-dependent acquisition mode. Metabolite identification was based on chromatographic elution time, chemical composition, MS/MS fragmentation pattern, and comparisons with available standards and references.

## Network Pharmacology Analysis Collection of Potential Targets for Citri Reticulatae Pericarpium

With the UHPLC-Q-TOF-MS/MS system, a total of 49 metabolites were characterized in rat urine. The associated proteins of CRP were searched in Comparative Toxicogenomics Database (Davis et al., 2019), Encyclopedia of TCM (Xu et al., 2019) and Swiss Target Prediction Database (Gfeller et al., 2014).

## Collection of Potential Targets for Spleen Deficiency

As there are no therapeutic targets about spleen deficiency that were available directly in the databases, targets of diseases that have similar pathological features with spleen deficiency were collected as alternatives. Diarrhea, dyspepsia, enteritis and gastritis were chosen out, and the corresponding targets were searched in DisGeNET (Pinero et al., 2020).

## Protein-Protein Interaction Analysis

Protein-protein interaction (PPI) data was constructed by inputting official gene symbol to the “Multiple Proteins” search on String website (Szklarczyk et al., 2019), with organism species limited to “Homo sapiens” and a confidence score  $>0.9$ . The interaction results were exported as (.tsv) file for further network analysis by using Cytoscape software. The CRP-related target-spleen deficiency target network (CT-ST network) was constructed based on their PPI data and visualized by Cytoscape 3.7.0 software. The CRP-related targets were mapped to the spleen deficiency-related targets for obtaining the common targets of both. Then a network including the common targets and their first neighbors was extracted from the CT-ST network. In the generated networks, nodes represent targets and components, and edges represent the relationship between them. The targets without interaction were excluded

from the network. Afterward, a plugin of Cytoscape (Network Analyzer) was applied to analyze the topological parameters of each node in the network. Among the topological parameters, degree, betweenness centrality and closeness centrality were used as crucial factors to evaluate the most influential nodes in networks. The nodes with “Degree” value greater than twofold the median value of all the network nodes, “Betweenness centrality” and “Closeness centrality” value greater than the median value of all the network nodes were chosen as the key targets.

### Gene Ontology Enrichment and Pathway Analysis

The Database for Annotation, Visualization and Integrated Discovery was applied for Gene Ontology (GO) enrichment and pathway analysis (Jiao et al., 2012). The specific operation steps were as following, inputting the protein ID and restricting the species to “Homo sapiens,” then utilizing the functional annotation tool to make GO enrichment and pathway analysis.

### Statistical Analysis

Data were expressed as mean  $\pm$  standard deviation ( $n = 10$ ). The significant differences between the groups were assessed by ANOVA test in SPSS software (version 22.0), and  $p$  values less than 0.05 or 0.01 were considered as significant difference. Figures were plotted with GraphPad Prism (Version 7.00).

## RESULTS AND DISCUSSION

### Therapeutic Effects of Citri Reticulatae Pericarpium Against Spleen Deficiency

TCM clinical syndromes are often difficult to quantify with modern analysis methods. How to use animal models to characterize the syndromes is one of the difficulties in the

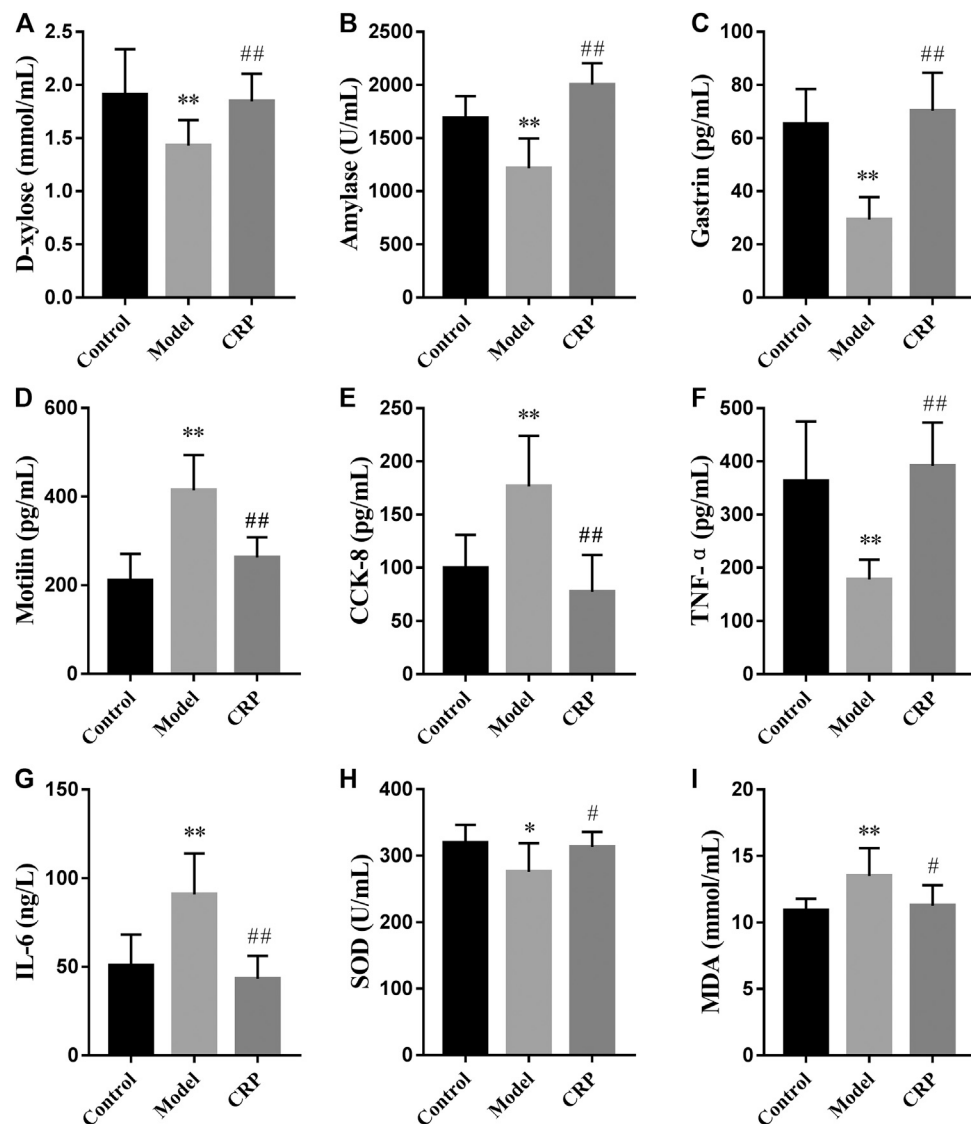

modern researches on TCM (Meng et al., 2013). In this work, a reserpine-induced spleen deficiency rat model was established to evaluate the therapeutic effects of CRP based on body symptoms and biochemical indexes. Three days after the subcutaneous injection of reserpine, rats showed typical symptoms of spleen deficiency, such as anorexia, weight loss, pasty loose stools, inactiveness, and grouping. As presented in **Figure 1**, reserpine treatment significantly reduced the body weight of rats ( $p < 0.01$ ). With the administration of CRP for 14 days, above-mentioned symptoms of spleen deficiency in rats were significantly improved. Rat body weights of CRP group were higher than that of model group, although there was no significant difference. These results preliminarily suggested that CRP administration could relieve the symptoms of spleen deficiency induced by reserpine.

Subsequently, we further investigated the effects of CRP on biochemical indexes in reserpine-induced spleen deficiency rats, including the parameters used to characterize digestion, absorption, gastrointestinal hormones, immune regulation and oxidative stress. Obtained results were illustrated in **Figure 2**. Reported studies have observed that patients with spleen deficiency usually showed the symptoms of poor digestion and absorption (Chung et al., 2016). In this study, the activity of amylase and the concentration of D-xylose in serum were used to reflect the digestion and absorption of nutrients in rats (Gao et al., 2009; Li et al., 2020). As shown in **Figure 2**, the level of D-xylose and the activity of amylase in model group were significantly lower than that in control and CRP group ( $p < 0.01$ ), suggesting that reserpine treatment could significantly reduce the digestion and absorption in rats while CRP administration could effectively reverse these changes.

Gastrointestinal hormones take an important role in regulating secretory and motor functions of the digestive tract (Xie et al., 2006). It has been found that the levels of gastrointestinal

**FIGURE 1 |** Rat body weights comparison between control, model and CRP treated group. ( $n = 10$ , \*\* $p < 0.01$ , vs. control group. Although the body weights of CRP treated group were higher than that of model group after intervention, there existed no significant difference.)

**FIGURE 2 |** Effects of CRP on biochemical parameters in serum, including the concentrations of (A) D-xylose and (I) MDA, the activities of (B) amylase and (H) SOD, the levels of (C) gastrin, (D) motilin, (E) cholecystikinin-8, (F) TNF- $\alpha$  and (G) IL-6 ( $n = 10$ ; \* $p < 0.05$ , vs. control group; \*\* $p < 0.01$ , vs. control group; # $p < 0.05$ , vs. model group; ## $p < 0.01$ , vs. model group).

hormones in patients with gastrointestinal diseases were different from those in normal individuals (Wang et al., 2013). Hereon, three representative gastrointestinal hormones (gastrin, motilin, CCK-8) were employed to evaluate the effects of CRP on neuroendocrine in spleen deficiency rats. Gastrin, released from the G cells in antrum and duodenum, could stimulate the secretion of gastric acid, pepsin, bile and improve gastrointestinal movement (Itoh et al., 2005). Motilin is a peptide synthesized by mucosal endocrine cells in the upper segment of small intestine. It could promote gastrointestinal motility and improve the contractility and tension of the gastrointestinal tract and biliary tract (Itoh et al., 2005). CCK-8, a peptide hormone widely distributed in gastrointestinal tract and brain, is experimentally identified as a transmitter involved in multiple physiological activities, such as acting on feeding center, causing satiety and

inhibiting feeding (Stengel and Tache, 2011). As illustrated in **Figure 2**, compared with control group, the level of gastrin in model group significantly decreased while the levels of motilin and CCK-8 significantly increased ( $p < 0.01$ ), showing that reserpine treatment led to the disorder of gastrointestinal hormones secretion in rats. Changes in these three gastrointestinal hormones caused by reserpine treatment were up to normal after the administration of CRP for 14 days, revealing the efficiency of CRP in improving digestive dysfunction through regulating neuroendocrine.

The dynamic balance between Th1 and Th2 immune response is important for the immune system (Bashyam, 2007; Fischer et al., 2007). Th1 cytokines are with mediation in cell immunity response and mainly include IFN- $\gamma$ , TNF- $\alpha$ , IL-1, IL-2, while Th2 cytokines mediate humoral immunity and include IL-4, IL-5,

**TABLE 1** | The diversity index of gut microbiota in rats in different groups.

Group	Community richness		Community diversity	
	ACE	Chao1	Shannon	Simpson
Control	516.47 ± 24.71	524.54 ± 26.4	4.51 ± 0.23	0.03 ± 0.01
Model	396.41 ± 38.51**	407.74 ± 39.15**	4.06 ± 0.17**	0.04 ± 0.01
CRP	459.20 ± 37.60##	460.2 ± 34.76##	3.68 ± 0.18	0.07 ± 0.01

Note: n = 10, vs. Control: \*\*p < 0.01; vs. Model: ##p < 0.01.

IL-6, IL-10 (Mosmann et al., 1986). In the model group, reserpine treatment significantly decreased the level of TNF- $\alpha$  while promoted that of IL-6 in serum ( $p < 0.01$ ). After the intervention with CRP, the level of TNF- $\alpha$  and IL-6 restored to normal, suggesting that CRP could help maintain the balance of Th1 and Th2 immune response.

In addition, the balance between oxidants and antioxidants is necessary in maintaining health, and corresponding imbalance may result in oxidative stress causing functional disorders and certain diseases (Sharma et al., 2015). In this study, rats in model group had lower activity of SOD and higher level of malondialdehyde ( $p < 0.05$ ) than control group, indicating that reserpine treatment resulted in free radical disorder in spleen deficiency rats. CRP administration could improve the activity of antioxidant enzyme and reduce lipid peroxidation damage ( $p < 0.05$ ).

In summary, CRP administration could effectively alleviate the syndromes of spleen deficiency induced by reserpine treatment in

rats, including poor digestion and absorption capacity, and disorder in gastrointestinal hormones, immune cytokines and oxidative stress.

## Gut Microbiota Modulatory Effects of Citri Reticulatae Pericarpium in Spleen Deficiency Rats

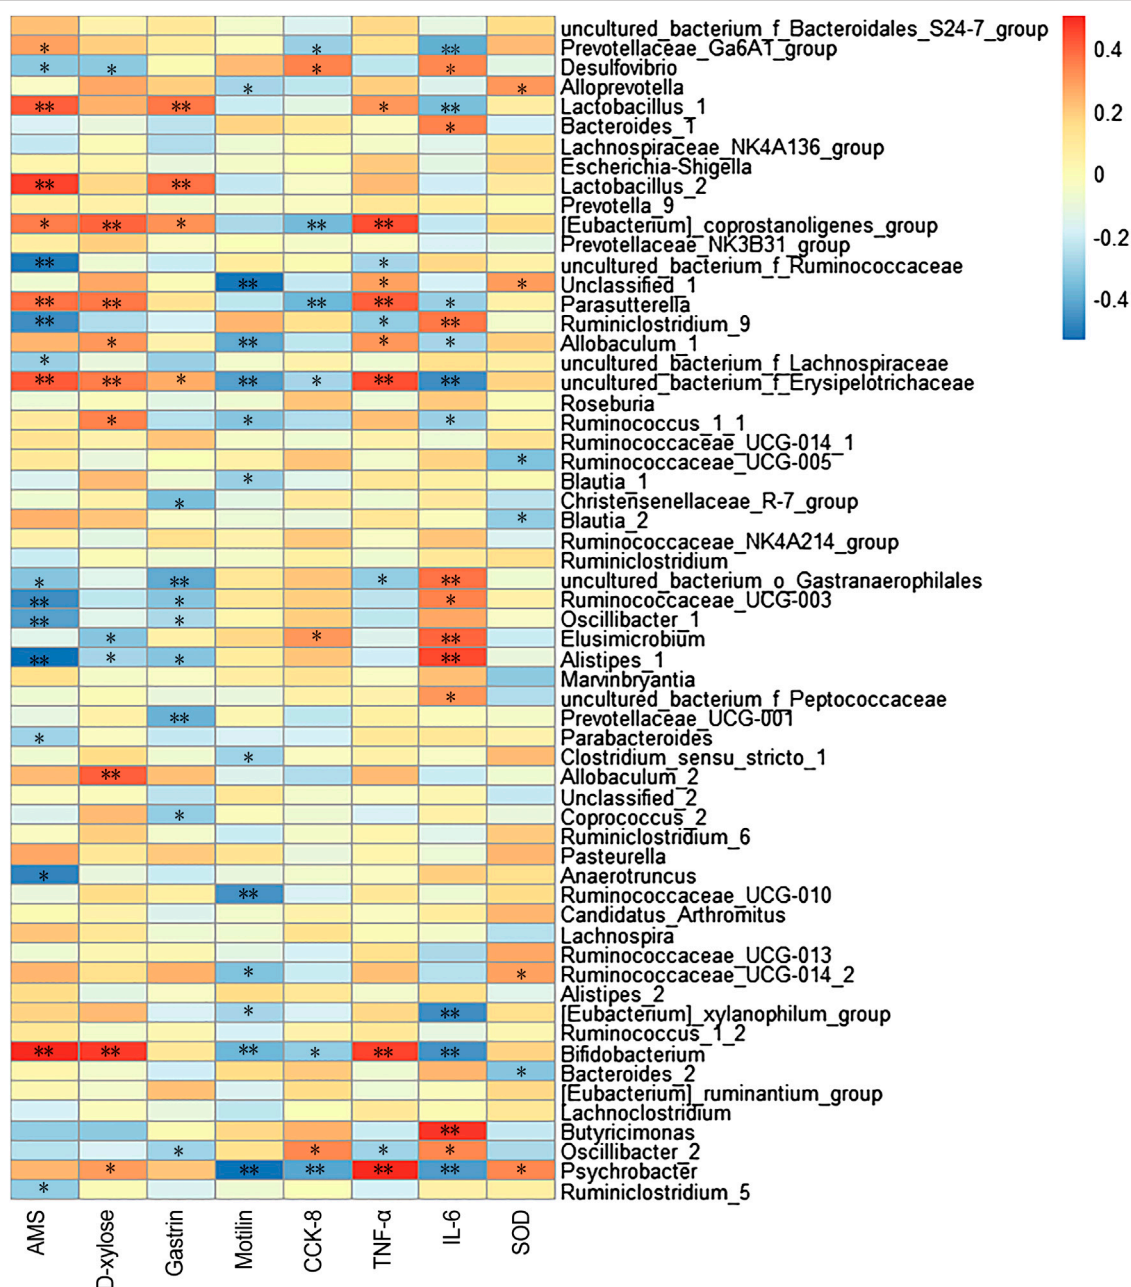

Gut microbiota plays a vital role in maintaining normal intestinal functions, such as food digestion, nutrient absorption, integrity of epithelial barrier, and development of mucosal immunity (Veerappan et al., 2012). Recently, more and more evidence indicated that gut microbiota imbalance is a potential trigger for many diseases such as inflammatory bowel disease (Veerappan et al., 2012), diabetes (Meijnikman et al., 2018) and metabolic syndrome (Zeng et al., 2020a). In this study, the changes of bacterial richness (expressed in ACE and Chao1) and diversity (expressed in Shannon and Simpson index) in response to reserpine treatment and CRP intervention were investigated. As shown in **Table 1**, remarkably lower ACE, Chao1 and Shannon indexes were observed in the model group ( $p < 0.01$ ), which suggested that reserpine treatment disturbed the balance of gut microbiota. By contrast, supplement with CRP gave rise to a higher community richness than that of the model group ( $p < 0.01$ ), indicating that CRP is beneficial to the growth of gut microbiota. Beta diversity analysis among experimental groups was performed with PCoA. As shown in **Figure 3**, the PCoA score plot depicted three clearly

divided groups: samples from the model group gathered in the second quadrant; samples from the control group dispersed in the first, third, and fourth quadrants; and samples from CRP group concentrated in the third quadrant, which were similar to that of control group. These results indicated that CRP intervention could help to restore changes in the richness and diversity of gut microbiota in spleen deficiency rats.

The correlations between gut microbiota (the top 60 genera in relative abundance) and spleen deficiency-related indexes were calculated using Spearman's rho non-parametric correlation

analysis (Figure 4). The heatmap reflected significant positive correlations between the improvement of spleen deficiency related-indexes and some short-chain fatty acids (SCFAs) producing bacteria, such as *Bifidobacterium*, *Lactobacillus*, *Allobaculum*, *Psychrobacter*, *Prevotellaceae\_Ga6A1\_group*, *[Eubacterium]\_coprostanoligenes\_group*, *Parasutterella*, etc. SCFAs (acetate, propionate and butyrate), the end products of gut microbial fermentation of indigestible dietary components, appeared to enhance epithelial barrier function, improve gut permeability, inhibit the inflammation. Among them, *Bifidobacterium* and

**FIGURE 4 |** Heatmap of Spearman's correlation between gut microbiota (the relative abundances of top 60 genus) and spleen deficiency related indexes. The colors range from blue (negative correlation) to red (positive correlation). Significant correlations are noted by \* $p < 0.05$  and \*\* $p < 0.01$ .

*Lactobacillus* are the most widely used probiotics with many health-promoting properties, such as prevention of enteropathogen colonization (barrier effects) (Candela et al., 2008), anti-inflammatory effects on mucosal surfaces, optimization of the composition of gut microbiota (O'Mahony et al., 2005). There has been growing interest in using probiotics as an adjunct to standard anti-inflammatory and immune suppressing therapy (Veerappan et al., 2012). *Allobaculum*, a butyrate-producing genus, has been reported to be an important functional phylotypes in many researches, its reduction was associated with obesity and diabetes (Zhang et al., 2015; Barouei et al., 2017). *Eubacterium coprostanoligenes* group can convert cholesterol to coprostanol which is poorly absorbed in human intestines and would be excreted, leading to blood cholesterol concentration reduction (Li et al., 1998). In addition, *Alloprevotella* was positively correlated with SOD activity, a genus that fermented carbohydrates and produced acetate and butyrate (Downes et al., 2013). Studies have illustrated that its abundance was negatively correlated with various diseases such as obesity, diabetes and cardiovascular diseases (Wei et al., 2018).

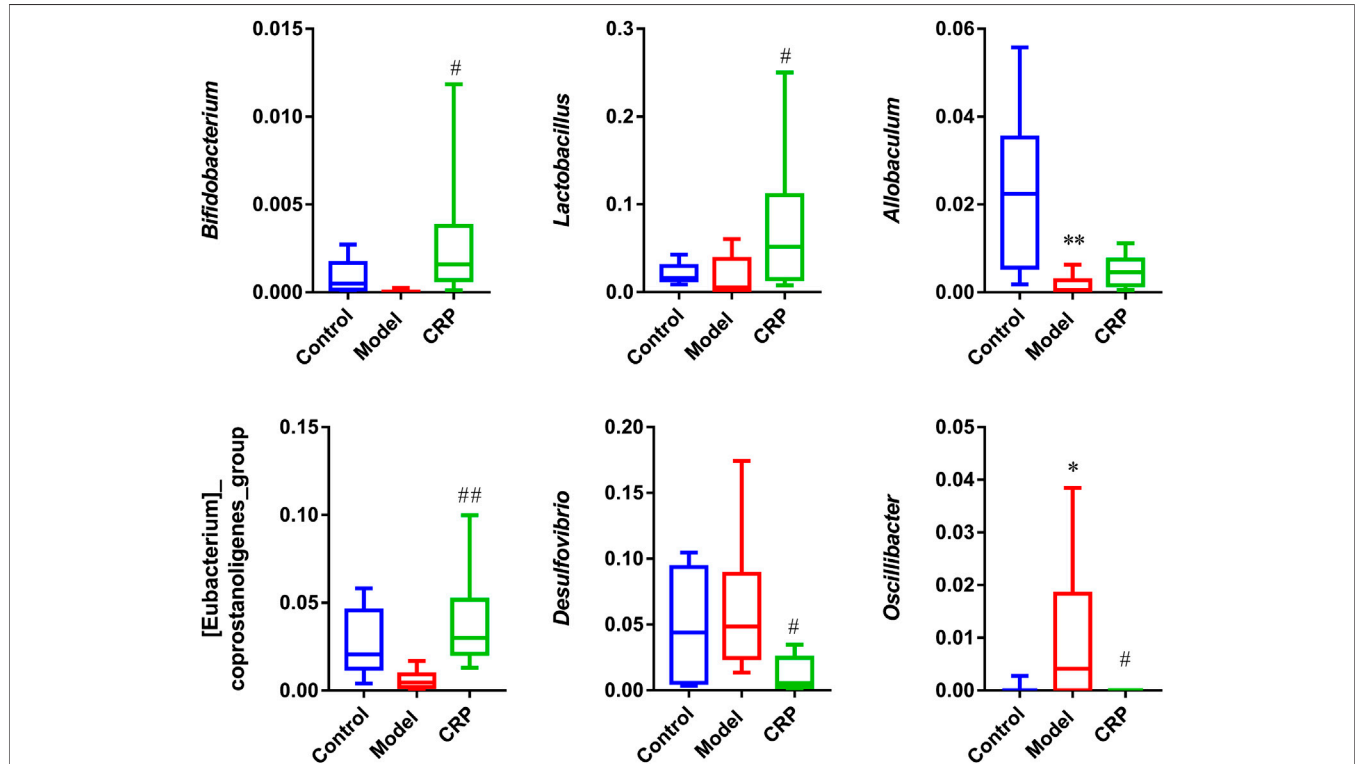

Moreover, significant negative correlations between spleen-deficiency aggravated related indexes and *Alistipes*, *Anaerotruncus*, *Desulfovibrio*, *Oscillibacter*, *Ruminiclostridium\_9*, *Ruminococcaceae\_UCG-003*, *Parabacteroides*, *Ruminiclostridium\_5*, etc. Among them, *Desulfovibrio* is the predominant bacteria in human colon sulfate-reducing bacteria, which can reduce sulfate to produce  $H_2S$ . Since endogenous  $H_2S$  can poison intestinal

epithelial cells, clinical studies have inferred that *Desulfovibrio* was associated with intestinal diseases (Gobert et al., 2016). It is reported that *Oscillibacter* was increased in the diet-induced metabolic dysfunctions, and associated with impaired intestinal barrier integrity (Lam et al., 2012).

As described in our preliminary study, flavonoids are the primary components in CRP (Zheng et al., 2019). Flavonoids, as common dietary polyphenols, have been proven to exert potential modulatory effects on gut microbiota by inhibiting the growth of multiple pathogens and promoting beneficial genera. These modulations in turn promote gut health through maintaining gut immune homeostasis, and improving nutrients absorption (Dueñas et al., 2015; Pei et al., 2020). In this work, CRP exerted a significant effect on improving the composition of gut microbiota, especially for SCFAs producing and anti-inflammatory bacteria (Figure 5), whose metabolites could enhance epithelial barrier function, improve gut permeability, and inhibit inflammation. Based on these results, it is reasonable to propose that the relief of symptoms in spleen deficiency rats was closely associated with the rebalance of gut microbiota.

## Identification of Metabolites Derived From Citri Reticulatae Pericarpium

Generally, ingested exogenous compounds would undergo multi-step *in vivo* biotransformation processes mediated by gut

**FIGURE 5 |** Relative abundances of *Bifidobacterium*, *Lactobacillus*, *Allobaculum*, [*Eubacterium*]*coprostanoligenes\_group*, *Desulfovibrio*, *Oscillibacter*. (n = 10; \*p < 0.05, vs. control group; #p < 0.05, vs. model group; ##p < 0.01, vs. model group.)

microbiota and mammalian metabolic enzymes (Walle, 2004), which mainly comprise phase I and phase II metabolism. Phase I metabolism (hydrolysis, oxidation, demethylation, etc.) would change the skeleton structure of compounds, while phase II metabolism (glucuronidation, sulfation, acetylation, etc.) converts the compound into more water-soluble metabolites for excretion through urine (Gradolatto et al., 2004). Urine is filtered and concentrated from the blood through nephron. Metabolites in the blood are eventually excreted in the urine with higher concentrations, making them easier to be detected in urine by analytical instruments (Gao, 2015; Zhao et al., 2018). In addition, urine can be continuously sampled in a non-invasive way, and will not affect the body's normal physiological processes. Hence, urine is probably a better source for metabolite identification than blood.

In this work, based on our preliminary results of chemical composition analysis (Zheng et al., 2019), a total of 26 prototype compounds and 23 metabolites were detected in rat urine after the ingestion of CRP. Prototype compounds were mainly polymethoxyflavones, as well as hesperetin, naringenin, isoprinosin, luteolin and apigenin. Catalyzed by phase I and phase II metabolic enzymes, ingested prototype compounds underwent hydrolysis, demethylation, glucuronidation and sulfation, giving rise to a mass of metabolites. Compound descriptions, molecular formulas, retention times, and fragment ions of these prototype compounds and metabolites were detailed in **Table 2**.

Nobiletin is a hexamethoxyflavone abundant in CRP and has been documented to possess multiple pharmacological activities, such as anti-inflammatory, bacteriostasis and antioxidant (Li et al., 2014). As shown in **Table 2**, nobiletin gave its quasi-molecular ion  $[M + H]^+$  at  $m/z$  403.1363, yielding the characteristic ions at  $m/z$  388.1176, 373.0916, 358.0858 with successive loss of  $CH_3$ . Compound 26, 27, 28 all possessed the  $[M + H]^+$  ion at  $m/z$  389, which was 14 Da ( $CH_2$ ) less than protonated nobiletin. Herein compound 26, 27, 28 were tentatively assigned as the mono-demethylated metabolite of nobiletin. Using *in vitro* incubation methods, Koga et al. (Koga et al., 2007) investigated the metabolism of nobiletin in rat liver microsomes. As a result, three mono-demethylated metabolites were identified, which were 4'-OH-, 7-OH-, and 6-OH-nobiletin. Based on the retention time, compound 26, 27, 28 were identified as 6-OH-, 7-OH-, and 4'-OH-nobiletin, respectively. These metabolites could be subsequently demethylated into several dihydroxy-tetramethoxyflavone, while the position of the hydroxyl group needs to be further assigned. These hydroxyl-containing polymethoxyflavones could be further combined with glucuronic acid or sulfuric acid to generate corresponding phase II metabolites.

As presented in **Table 2**, retro Diels-Alder reaction was a characteristic pattern of flavanone and flavone derivatives in MS/MS fragmentation (Zeng et al., 2020b). Taking naringenin as an example, in the negative ion mode, the main fragment ions of deprotonated naringenin ( $m/z$  271.0613) were  $m/z$  151.0043, 119.0508, 107.0154, and 93.0381. Among them, product ions  $m/z$  151.0043 ( $^{1,3}A^-$ ) and 119.0508 ( $^{1,3}B^-$ ) were presumed to be produced by retro Diels-Alder reaction on chemical bond 1 and 3,

while  $m/z$  107.0154 was derived from  $^{1,3}A^-$  with the loss of  $CO_2$  (44 Da). The signal at  $m/z$  93.0381 was presumed to be yielded by the breaking of chemical bond 5. Above fragmentation schemes were proposed in **Figure 6**.

Oral ingestion is the most common mode of administration used in herbal medicine. Generally speaking, exogenous compounds could only exert its pharmacological activity if it is absorbed into the blood and maintains a certain concentration. Urine is filtered from the blood and accumulated all changes in the body. It contains all metabolites in the blood, and thus comprehensively reflects the metabolic information. In this work, the concentration of prototype compounds detected in urine was much lower than that of the corresponding metabolites, suggesting that flavonoid metabolites may be the primary substance for pharmacological activity of CRP, rather than its prototype compounds. Therefore, identified metabolites were employed in subsequent network pharmacology analysis so as to discover the bioactive components and potential targets of CRP against spleen deficiency.

## Network Pharmacology Analysis

On the basis of identified metabolites, a total of 583 potential targets for CRP's efficacy were defined. Meanwhile, a total of 520 spleen deficiency-related disease targets were acquired by integrating data on diarrhea, dyspepsia, enteritis and gastritis from disease databases. Detailed information was presented in **Supplementary Table S1**. The CRP's efficacy-related targets were mapped to the spleen deficiency-related targets, and as a result, 98 common targets were obtained. Then a PPI network (**Supplementary Figure S1**) was constructed using the common targets and further used to construct the CT-ST network. **Figure 7** illustrated the CT-ST network which consists of 111 nodes (17 compounds and 94 candidate targets, compounds with multiple isomers are combined and shared one name) and 662 edges. Among them, several flavonoids including apigenin, luteolin, naringenin, hesperidin, hesperetin, dihydroxy-tetramethoxyflavone, monohydroxy-tetramethoxyflavone and homoeriodictyol were considered to be key compounds for CRP to alleviate spleen deficiency. The primary targets of these compounds included STAT3, IL6, TNF, JUN, AKT1, TP53, MAPK1, MMP9, PIK3R1, PTGS2, VEGFA, EGFR, IL1B, CXCL8, IL4, CCL2, IL10, and FOS. That is to say, CRP may interact with these targets to exert its effects in relieving spleen deficiency.

In order to further reveal the molecular mechanism of CRP against spleen deficiency, GO analysis and pathway enrichment of mentioned 94 common targets were performed with KEGG database. The results of GO analysis were described by biological process (BP), cell component (CC), and molecular function (MF) terms. In GO analysis, 330 of 426 BPs, 58 of 72 MFs, and 26 of 33 CCs enriched for these targets were recognized as  $p < 0.05$ . Top 5 enriched terms of BP, MF, CC categories in the GO analysis were presented in **Figure 8A**. Moreover, 97 target-related pathways were found in KEGG, top 15 KEGG signaling pathways were constructed in bubble plot based on  $P$ -Value (**Figure 8B**), and the involved genes were showed in **Supplementary Table S2**. Consistent with the

pharmacological activities, network pharmacology analysis revealed that the interaction between CRP and spleen deficiency involved multiple BPs and pathways, including inflammatory responses, immune system, and oxidative stress, mediating by TNF signaling pathway, hypoxia-inducible factor-1 (HIF-1) signaling pathway, Toll-like receptor signaling pathway, *etc.* Reported studies showed that pro-inflammatory and/or oxidative stress mediators are directly interlinked with the pathogenesis of many gastrointestinal diseases (Chung et al., 2016). Among mentioned pathways, TNF signaling is critical to the maintenance of intestinal barrier and epithelial cell tight junctions (Kolodziej et al., 2011). HIF-1 signaling pathway is closely related to stress-responsive gene expression (Surazynski et al., 2008). Toll-like receptor signaling pathway is important for maintaining tolerance to commensal microbiota and inducing inflammation against pathogens, hence playing an essential role in homeostasis of the intestine (Biswas et al., 2011; Kamdar et al., 2013). However, further mechanism studies are necessary to assign the role of these pathway in CRP against spleen deficiency.

As shown in **Figure 7**, a total of 17 compounds (mainly flavonoids) were assigned as the core bioactive components in CRP by network pharmacology analysis. Our preliminary chemical profile analysis suggested that these compounds were abundant in CRP herbs (Zheng et al., 2019). Besides mentioned targets and

pathways, these compounds could also interact with gut microbiota after oral administration, which probably contribute to the overall therapeutic effects of CRP against spleen deficiency. Take hesperetin as an example, ingestion of an assigned diet (0.5% hesperetin) for three weeks could significantly affect the structure and activity of gut microbiota in rats (Unno et al., 2015). The richness of *Clostridium subcluster XIVa* in feces was significantly reduced, while the cecal SCFA pool was noticeably increased. Therefore, in the follow-up study to clarify the mechanism of action, we should not only pay attention to identified targets and pathways but also focus on gut microbiota.

## CONCLUSION

In this study, the efficacy against spleen deficiency and gut microbiota modulatory properties of CRP were investigated using reserpine treated rats as the animal model. CRP derived metabolites were identified in rat urine and further applied to explore the core bioactive components and potential targets through network pharmacology analysis. As a result, CRP administration could effectively alleviate the typical symptoms of spleen deficiency induced by reserpine treatment, including

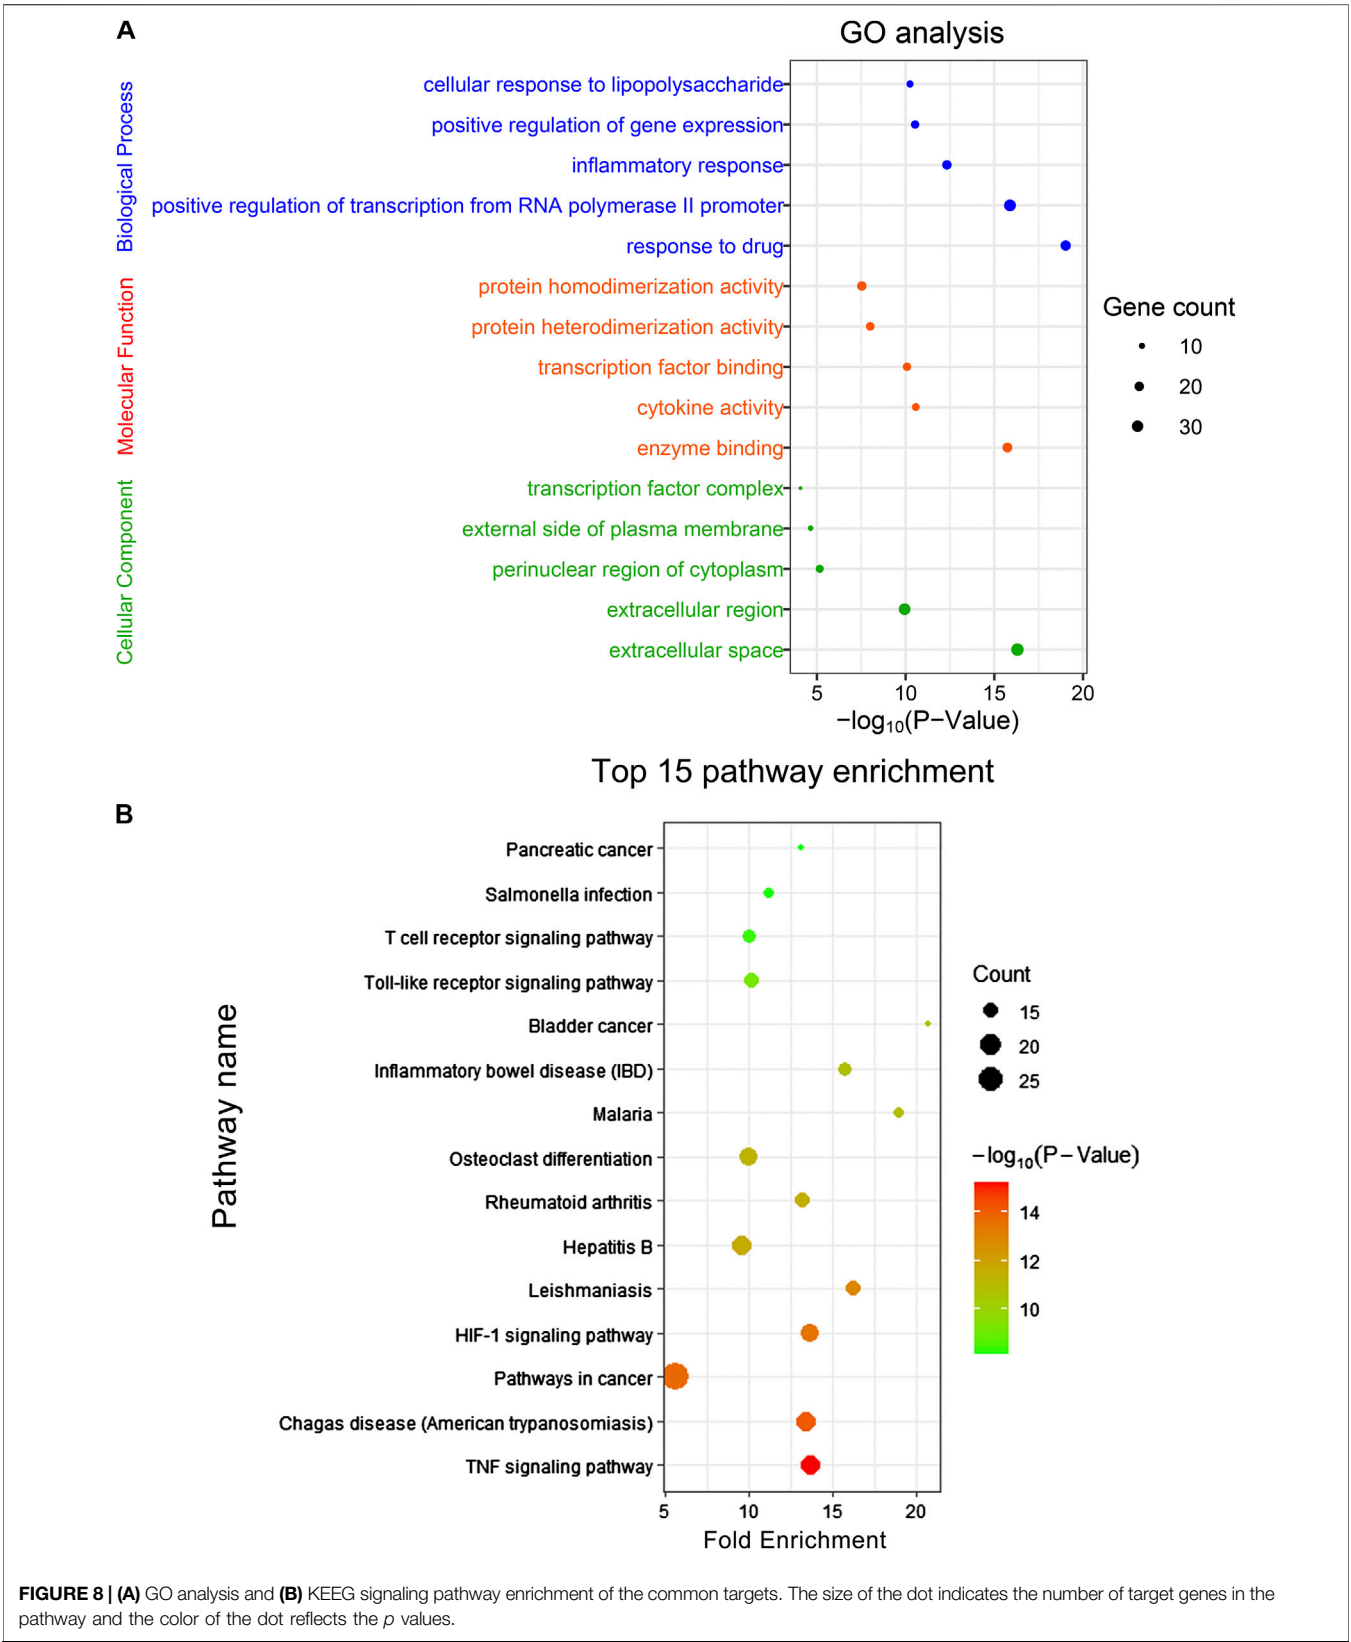

**FIGURE 7 |** The Citri Reticulatae Pericarpium (CRP)-related target-spleen deficiency target network (CT-ST network). Pink circles, purple diamonds represented CRP compounds and the common targets for both compounds and spleen deficiency, respectively. The size of circles and diamonds indicated nodes degree value.

poor digestion and absorption capacity, and disorder in gastrointestinal hormones, immune cytokines and oxidative stress. Meanwhile, CRP was found to improve the diversity and structure of the gut microbiota in spleen deficiency rats. Compared with model group, some SCFAs producing and anti-inflammatory bacteria including *Bifidobacterium*, *Lactobacillus*, *Allobaculum*, *Psychrobacter*, [*Eubacterium*]<sub>coprostanoligenes\_group</sub>, *Prevotellaceae\_Ga6A1\_group*, *Parasutterella* were up-regulated, while some spleen deficiency aggravated related bacteria including *Alistipes*, *Anaerotruncus*, *Desulfovibrio*, *Oscillibacter*, *Ruminiclostridium\_9*, *Ruminococcaceae\_UCG-003*, *Ruminiclostridium\_5*, *Parabacteroides* were down-regulated in CRP group rats. Further Spearman's correlation analysis indicated that there existed a close correlation between the profiles of gut microbiota and the spleen-deficiency related

biochemical indexes. In addition, a total of 26 prototype compounds and 23 metabolites were detected in rat urine after the ingestion of CRP. Through network pharmacology analysis, apigenin, luteolin, naringenin, hesperidin, hesperetin, dihydroxy-tetramethoxyflavone, monohydroxy-tetramethoxyflavone and homoeriodictyol were assigned as the core bioactive components, while STAT3, IL6, TNF, JUN, AKT1, TP53, MAPK1, MMP9, PIK3R1, PTGS2, VEGFA, EGFR, IL1B, CXCL8, IL4, CCL2, IL10, and FOS were defined as the major potential targets. Further GO analysis and pathway enrichment suggested that therapeutic effects of CRP against spleen deficiency involved multiple BPs, including inflammatory responses, immune system and oxidative stress such as TNF signaling pathway, HIF-1 signaling pathway, and Toll-like receptor signaling pathway. Besides these targets and pathways,

identified compounds could also interact with gut microbiota after oral administration, which probably contribute to the overall therapeutic effects of CRP. This work provided systematic insights to understand the mechanism of CRP alleviating spleen deficiency-related diseases.

## DATA AVAILABILITY STATEMENT

The datasets generated for this study can be found in GenBank accession numbers (MW015148–MW015742).

## ETHICS STATEMENT

The animal study was reviewed and approved by Animal Ethics Committee of the School of Life Sciences in Sun Yat-sen University.

Traditional Chinese medicine (TCM) formulas treat complex diseases through combined botanical drugs which follow specific compatibility rules to reduce toxicity and increase efficiency. “Jun, Chen, Zuo and Shi” is one of most used compatibility rules in the combination of botanical drugs. However, due to the deficiency of traditional research methods, the quantified theoretical basis of herbal compatibility including principles of “Jun, Chen, Zuo and Shi” are still unclear. Network pharmacology is a new strategy based on system biology and multi-disciplines, which can systematically and comprehensively observe the intervention of drugs on disease networks, and is especially suitable for the research of TCM in the treatment of complex diseases. In this study, we systematically decoded the “Jun, Chen, Zuo and Shi” rules of Huanglian Jiedu Decoction (HJD) in the treatment of diseases for the first time. This interpretation method considered three levels of data. The data in the first level mainly depicts the characteristics of each component in single botanical drug of HJD, include the physical and chemical properties of component, ADME properties and functional enrichment analysis of component targets. The second level data is the characterization of component-target-protein (C-T-P) network in the whole protein-protein interaction (PPI) network, mainly include the characterization of degree and key communities in C-T-P network. The third level data is the characterization of intervention propagation properties of HJD in the treatment of different complex diseases, mainly include target coverage of pathogenic genes and propagation coefficient of intervention effect between target proteins and pathogenic genes. Finally, our method was validated by metabolic data, which could be used to detect the components absorbed into blood. This research shows the scientific basis of “Jun-Chen-Zuo-Shi” from a multi-dimensional perspective, and provides a good methodological reference for the subsequent interpretation of key components and speculation mechanism of the formula.

**Keywords:** system pharmacology, traditional Chinese medicine, compatibility, Dijkstra model, information graph algorithm

## INTRODUCTION

After thousands of years of experience in the treatment of diseases, the effectiveness of traditional Chinese medicine (TCM) is indisputable (Liang et al., 2015). During this process, TCM has also formed unique medication standards and compatibility theories, such as “Jun (emperor), Chen (minister), Zuo (adjuvant) and Shi (messenger)” (Wang et al., 2008; Lin and Yuhang, 2009). The basic and common feature of TCM is that it is consisted in the form of formula by the guidance of compatibility theory, different botanical drugs are orchestrated to form a multi-botanical drug combination of TCM (Lv et al., 2018). The principle of a formula is not just simply to mix botanical drugs, it is a process to increase efficiency and reduce toxicity. During this process, traditional compatibility rules will affect the changes of effective and toxic components of the formula, thus could reflect the advantages of enhancing synergistic effect and reducing toxicity of the formula (Liu et al., 2018). In TCM formula, botanical drugs are divided into “Jun, Chen, Zuo and Shi” according to the therapeutic characteristics of TCM, which are the basis of compatibility of TCM formula. “Jun” botanical drugs play leading roles in the treatment of diseases in the formula. “Chen” botanical drugs are usually worked as assistants to provide help to Jun botanical drugs in treating diseases; “Zuo” botanical drugs are used in combination with Jun and Chen botanical drugs to treat diseases or inhibit the toxic effects of Jun and Chen botanical drugs; “Shi” botanical drugs are widely used to coordinate the above botanical drugs and enhance their functions. It can be seen from this that the “Jun, Chen, Zuo and Shi” of the botanical drugs in the formula are mainly distinguished according to the primary and secondary roles of the medicine in the formula (Yao et al., 2013; Wu et al., 2014). Although “Jun, Chen, Zuo and Shi” is a widely used principle in the compatibility of TCM, the action pattern and underlying mechanisms of the compatibility rule of “Jun, Chen, Zuo and Shi” is still unclear. How to understand the action pattern and underlying mechanisms of compatibility rule is the basic and key step to decode the functional mechanisms of formulas in the treatment of complex diseases and benefit to secondary development of formulas.

A TCM formula generally contains several botanical drugs, and each botanical drug contains numbers of chemical components (Jia et al., 2004). These components are the material basis of the effect and mechanism of action (MOA) of the TCM formula. Studying the chemical composition and differences in efficacy of formula compatibility are helpful to clarify the pharmacological mechanism of TCM formula (Zhang, 2017). The traditional method to study the pharmacological effects of the single or several components in TCM is cell test or animal verify. These experiment-based research methods are divorced from the characteristics of the overall treatment of TCM, not only unable to tap the effective components of TCM, but also have no ability to effectively reveal the mechanism of TCM.

Network pharmacology has been widely used in the research of TCM in the treatment of complex diseases (Gu and Jianfeng, 2017). With the accumulation of omics data and the progress of network pharmacology technologies, increasing models are

proposed to decode the therapeutic molecular mechanisms of formulas in treating complex diseases. For example, Wang et al. employed network pharmacology model combined with hypergeometric distribution to identify the enriched significant pathways. These pathways affected by a group of differentially expressed genes in pathway enrichment analysis, and further be used to reveal the mechanism of Wuwei-Ganlu-Yaoyu-Keli in treating rheumatoid arthritis (Wang et al., 2017). Gu et al. established a model for predicting signal transduction effects and extracting sub-networks by using EGS for mechanism analysis based on the data of TCM components and diseases (Gu et al., 2014). However, most models are used to decode the mechanism of TCM in treating complex diseases via networks analysis. Few models considered the compatibility rules and formulation principles of TCM, which are closely related to the effect and toxicity of drugs. He et al. studied the effect of compatibility of *Ginseng trifolium* (L.) Alph. Wood and *Aconitum carmichaeli* Debeaux on cardiac toxicity of rats through metabolomics and found that *Ginseng trifolium* (L.) Alph. Wood compatibility of *Aconitum carmichaeli* Debeaux can reduce its cardiac toxicity and increase its pharmacological effects by affecting the content of citric acid, glutathione, phosphatidyl choline and uric acid (He et al., 2015). In the treatment of rheumatoid arthritis, Zhang et al. observed that total glucosides of paeony combined with Tripteryginum wilfordii polyglycoside has better performance in the treatment of RA by increasing efficiency and reducing toxicity at the clinical applications (Zhang et al., 2019). How to utilize system pharmacology to analyze the principle of formulas in TCM at systemic level through mathematical and quantitative methods could be benefit for truly understanding the mechanisms of formula in the treatment of diseases.

Huanglian Jiedu Decoction (HJD) is composed of four botanical drugs, namely, *Coptis chinensis* Franch (Huanglian), *Scutellaria baicalensis* Georgi (Huangqin), *Phellodendron amurense* Rupr (Huangbo) and *Gardenia jasminoides* J. Ellis (Zhizi), with a compatible dosage of 3:2:2:3 (Ma et al., 2009). HJD is widely used in diabetes, cardiovascular and cerebrovascular diseases, inflammation, Alzheimer's disease, etc. in clinical applications (Wang and Xu, 2000; Xin et al., 2011; Zhang et al., 2014). It has a wide range of pharmacological activities such as antibacterial, anti-inflammatory, antioxidant, neuroprotective, etc (Lv et al., 2017). Previous pharmacological studies have shown that HJD could effectively control the weight of diabetic rats and has a good regulating effect on blood lipid and oxygen radical metabolism (Zhang et al., 2011). It has been reported that HJD has a strong lipid-regulating effect on type 2 diabetic rats, which can reduce the increase of pancreatic lipase activity in intestinal tract and inhibit the activity of pancreatic lipase *in vitro* (Zhang et al., 2014). In addition, pharmacological experimental study has found that the inflammatory factors in cerebrospinal fluid of AD rats demonstrated a callback trend after treatment with HJD, indicated that HJD can ameliorate the central inflammatory status of AD rats by regulating the levels of inflammatory factors (Gu et al., 2018). The above experimental results showed that HJD possessed obvious beneficial effects in the treatment of DM and AD.

Four botanical drugs in this formula are used for clearing away heat and toxic materials for thousands of years. In order to compare the effects of HJD and its botanical drugs on *C. albicans* biofilm formation *in vitro*, Wang et al. found that the inhibitory effects of Huangqin, Huangbo on *C. albicans* biofilm were close to that of HJD, and Huanglian was superior to the other agents, Zhizi had no evidently inhibitory effect. Studies have also shown that HJD has obvious protective effect on cerebral ischemia injury (Wang et al., 2008). Wang et al. evaluated the effect of HJD and its botanical drugs on rabbit platelet aggregation and found that the aggregation inhibition rate of HJD was higher than that of each single botanical drug, and in four botanical drugs of HJD the aggregation inhibition rate of Huanglian was higher than that of the other three botanical drugs (Wang et al., 2014). The above applications of “Jun, Chen, Zuo and Shi” of HJD show that the relationship among “Jun, Chen, Zuo and Shi” does exist and has quantitative basis in modern pharmacology and experimental scientific research. How to detect the action pattern and underlying mechanisms of “Jun, Chen, Zuo and Shi” at a systematic and global perspective is the key to understand the mechanisms of formulas in the treatment of complex diseases in TCM.

In this study, the compatibility rules of “Jun, Chen, Zuo and Shi” of HJD in the treatment of diseases are systematically interpreted. Specifically, our new system pharmacology strategy integrated three levels of data including the characteristics of each component in HJD single botanical drug, the characterization of component-target-protein (C-T-P) network in the whole protein-protein interaction (PPI) network and the characterization of intervention propagation properties of HJD in the treatment of different complex diseases. Overall, our study provides a comprehensive systems pharmacology framework to decode the principles of “Jun-Chen-Zuo-Shi” from multi-level perspective, which may give some enlightenment for the subsequent interpretation of key components and hidden mechanism of the formula.

## MATERIALS AND METHODS

### Chemical Components Collection

All chemical components of HJD and seven important pharmacological related descriptors (MW, ALOGP, HDON, HACC, CACO-2, OB (%) and DL) for each component were collected from Traditional Chinese Medicine Systems Pharmacology (TCMSP) database (Ru et al., 2014) (<http://lsp.nwsuaf.edu.cn/tcmsp.php>). The chemical identification and concentration of in HJD were collected from the previous reports (Yang et al., 2019). All chemical structures were prepared and converted into canonical SMILES using Open Babel Toolkit (version 2.4.1). The targets of HJD were predicted by using Similarity Ensemble Approach SEA (Keiser et al., 2007) (<http://sea.bkslab.org/>), hitpick (Liu et al., 2013) (<http://mips.helmholtz-muenchen.de/proj/hitpick>) and Swiss Target Prediction (David et al., 2014) (<http://www.swisstargetprediction.ch/>).

### Active Components Screening

ADME properties of drugs refer to the Absorption, Distribution, Metabolism and Elimination, which are the key properties of whether small molecules of drugs can be used as medicines. It is estimated that due to low intestinal absorption rate and poor metabolic stability, the oral bioavailability of drugs is low, and finally about 50% of drugs fail in clinical trials (Beaumont et al., 2014). Therefore, ADME predictive screening of drugs is particularly important in drug discovery.

Oral bioavailability (OB) refers to the percentage of oral dose of drugs reaching the blood circulation system, which is the most common pharmacokinetic parameter for drug screening (Chiou, 2001). For specific oral drugs, due to poor intestinal absorption, drug metabolism, efflux and other reasons, the number of drugs that eventually reach the circulatory system is greatly reduced, so the oral availability of drugs ranges from 0 to 100%. As the initial absorption rates of intestinal tract and liver are generally about 43 and 44% respectively, components with OB greater than or equal to 30% are selected as active components.

Drug-like (DL) refers to a class of components that have the same functional group or similar physical characteristics as most known drugs (Han et al., 2011). The drug-like index of a new component is calculated based on Tanimoto similarity. According to the drug-like index, molecules with drug-like properties less than 0.14 are eliminated. Finally, the components screened according to OB and drug-like index take intersection as the active component (Wang et al., 2018).

### Network Construction

The C-T-P network of HJD were constructed by using Cytoscape software (Version 3.7.0) (Lopes et al., 2010). The networks and topological parameters were analyzed using NetworkAnalyzer, which is a plugin of Cytoscape (de Jong et al., 2003). The PPI data were derived from public databases BioGRID, STRING, Dip, HPRD, Intact, Mint and Reactome (Guan et al., 2014).

### Detection of Functional Communities Structure in HJD

Community structures in the biomedical network are more important for annotating the biological means. One index *codebook* and *n community codebooks* were defined to character the movements of random walker within and between communities respectively. Community codebook  $x$  has one codeword for each node  $a \in x$  and one exit codeword. The frequency at which random walkers visit each node in the community is the codeword length,  $k_{a \in x}$ , and exits the community,  $s_{x \rightarrow}$ . The was used to denote the sum of these frequencies, the total use of codewords in community  $x$ , and  $K^x$  to denote the normalized probability distribution. Consistent with the above, the index codebook has the community entries of codewords. The codeword lengths are derived from the set of frequencies at which the random walker enters each community. The was used to denote the sum of these frequencies, the total use of codewords to move into communities, and  $S$  to denote the

normalized probability distribution. We want to express average length of codewords from the index codebook and the community codebooks weighted by their rates of use. Therefore, the map equation is

$$L(N) = s_{\sim} H(S) + \sum_{x=1}^n k_{x\cup} H(k_x) \quad (1)$$

Next, we elaborate on the terms of the map equation in detail and illustrate it with Hoffman code examples.

$L(N)$  represents the per-step description length for community partition  $N$ . That is, for community partition  $N$  of  $n$  nodes into  $n$  communities, the lower bound of the average length of the code describing a step of the random walker.

$$s_{\sim} = \sum_{x=1}^n s_{x\sim} \quad (2)$$

The index codebook rate is used. The per-step use rate of the index codebook is given by the total probability that the random walker enters any of them communities. This variable represents the proportion of all codes representing community names in the codes. Where is probability of jumping out of community  $x$ .

$$H(S) = - \sum_{x=1}^n (s_{\sim} / s_{x\sim}) \log(s_{x\sim} / s_{\sim}) \quad (3)$$

This variable represents the average byte length required to encode community names. The frequency-weighted average length of codewords in the index codebook. The entropy of the relative rates to use the motif codebooks measures the smallest average codeword length that is theoretically possible. The heights of individual blocks under *Index codebook* correspond to the relative rates and the codeword lengths approximately correspond to the negative logarithm of the rates in base 2.

$$k_{x\cup} = \sum_{\alpha \in x} k_{\alpha} + s_{x\sim} \quad (4)$$

This variable represents the coding proportion of all nodes (including jump-out nodes) belonging to community  $x$  in the coding. The rate at which the community codebook  $x$  is used, which is given by the total probability that any node in the community is visited, plus the probability that the random walker exits the community and the exit codeword is used.

$$H(k^x) = -(s_{x\sim} / k_{x\cup}) \log(s_{x\sim} / k_{x\cup}) - \sum_{\alpha \in x} (k_{\alpha} / k_{x\cup}) \log(k_{\alpha} / k_{x\cup}) \quad (5)$$

This variable represents the average byte length required to encode all nodes in community  $x$ . The frequency-weighted

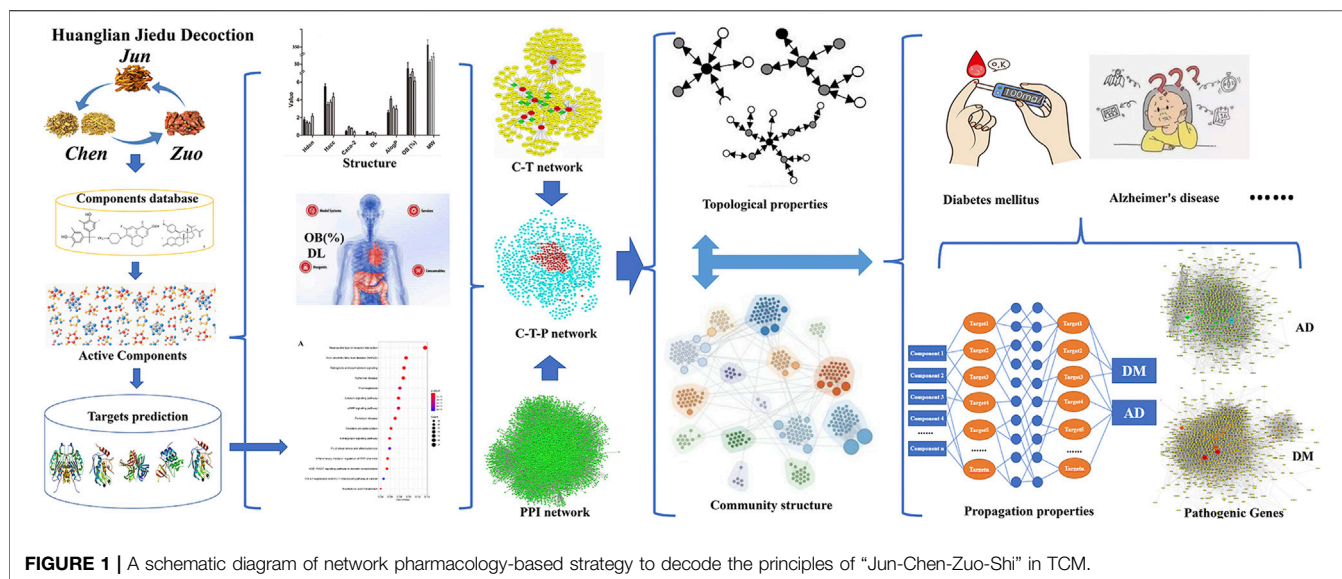

average length of codewords in community codebook  $x$ . The entropy of the relative rates at which the random walker exits community  $x$  and visits each node in community  $x$  measures the smallest average codeword length that is theoretically possible. The heights of individual blocks under community codebooks correspond to the relative rates and the codeword lengths approximately correspond to the negative logarithm of the rates in base 2.

## Propagation Coefficient Calculation

The role of drug response in the body is a complex process involving different proteins or genes. However, these proteins and genes are regulated by different cellular components, which constitute complex network relationships in the process of disease occurrence and development. These network relations could propagate the therapeutic effects through the network and orchestrate the cascade path of drug response. At present, most network pharmacological models just focus on the direct relationships between drugs and targets, and do not consider the propagation mode and propagation effect of drug intervention. In this study, we use Dijkstra model to detect the shortest distance from the direct target to the pathogenic gene based on C-T-P network, and keep the path with less than or equal to three nodes in the shortest distance. We believe that the initial node is the direct target of components, the final node is the pathogenic gene, which is also defined as the number of reached effector proteins, and the intermediate node is defined as the mode of propagation. Components with more modes of propagation and more effector proteins usually have better intervention effects. Based on the number of reached effector proteins and the mode of propagation, we calculated the propagation coefficient of each single botanical drug in HJD.

We defined the C-T-P network as the graph  $G(V, E)$ ,  $V$  and  $E$  represents nodes and edges, respectively  $(u, v)$  represents edge in  $E$ ,  $W_{u,v}$  stand for the weight of the edge.  $V$  is divided into two sets  $S$  and  $T$ , where the distance from the targets in  $S$  to  $U$  has been determined and the distance from the target to  $U$  contained in  $T$  has not been determined. Then, the distance from  $u$  to the target  $x$  in  $T$  is set as  $d_{u,x}$  which is defined as the shortest path length from  $u$  to the target  $x$  in  $T$ . The specific formula is as follows:

- 1) At the beginning,  $S = \{u\}$ ,  $T = V - \{u\}$ . For all targets  $x$  in  $t$ , if there is a path from  $u$  to  $x$ , then  $d_{u,x} = w_{u,v}$ ; Otherwise, set  $d_{u,x} = \infty$ .
- 2) For all targets  $x$  in  $T$ , find the target  $T$  with smallest  $d_{u,x}$  i.e.:  $d_{u,t} = \min\{d_{u,x} | x \in T\}$   
 $d_{u,t}$  is the shortest distance from target  $t$  to effector proteins  $u$ . At the same time, target  $T$  is also the target closest to  $u$  among all targets in set  $T$ . Delete target  $t$  from  $T$  and merge it into  $S$ .
- 3) For all targets  $x$  adjacent to  $t$  in  $T$ , update the values of  $d_{u,x}$  with the following formula:  
 $d_{u,x} = \min\{d_{u,x}, d_{u,t} + w_{t,x}\}$
- 4) Continue the above steps until  $T$  is an empty set.

- 5) During calculation of  $d_{u,x}$  holding paths less than or equal to 3 nodes as the shortest distance  $d_{min}$ , in a path with three nodes, the first node mean components targets, the second node represent propagation modes, the third node represent effector proteins, the formula for calculating the propagation coefficient of each single botanical drug is:

$$PC_{(\text{botanical drug})} = \frac{\sum_i^n d_{min}/n}{\sum_j^m u/m} \quad (6)$$

The propagation coefficient (PC) represents the strength of intervention ability of a botanical drug. The  $n$  represents the number of propagation modes, the  $m$  represents the number of effector proteins.

## KEGG Pathway

To analyze the main function of botanical drugs in HJD, the latest pathway data were obtained from the Kyoto Encyclopedia of Genes and Genomes (KEGG) database (Draghici et al., 2007) were extracted for KEGG pathway enrichment analyses.  $p$ -values were set at 0.05 as the cut-off criterion. The results of analysis were annotated by Pathview (Luo and Brouwer, 2013) in the R Bioconductor package (<https://www.bioconductor.org/>).

## Statistical Analysis

To compare the importance of communities in HJD, SPSS22.0 was used for statistical analysis. One-way analysis of variance followed by a Dunnett post-hoc test was used to compare more than two groups. Obtained  $p$ -values were corrected by Benjamini-Hochberg false discovery rate (FDR). Results were considered as statistically significant if the  $p$ -value was  $<0.05$ .

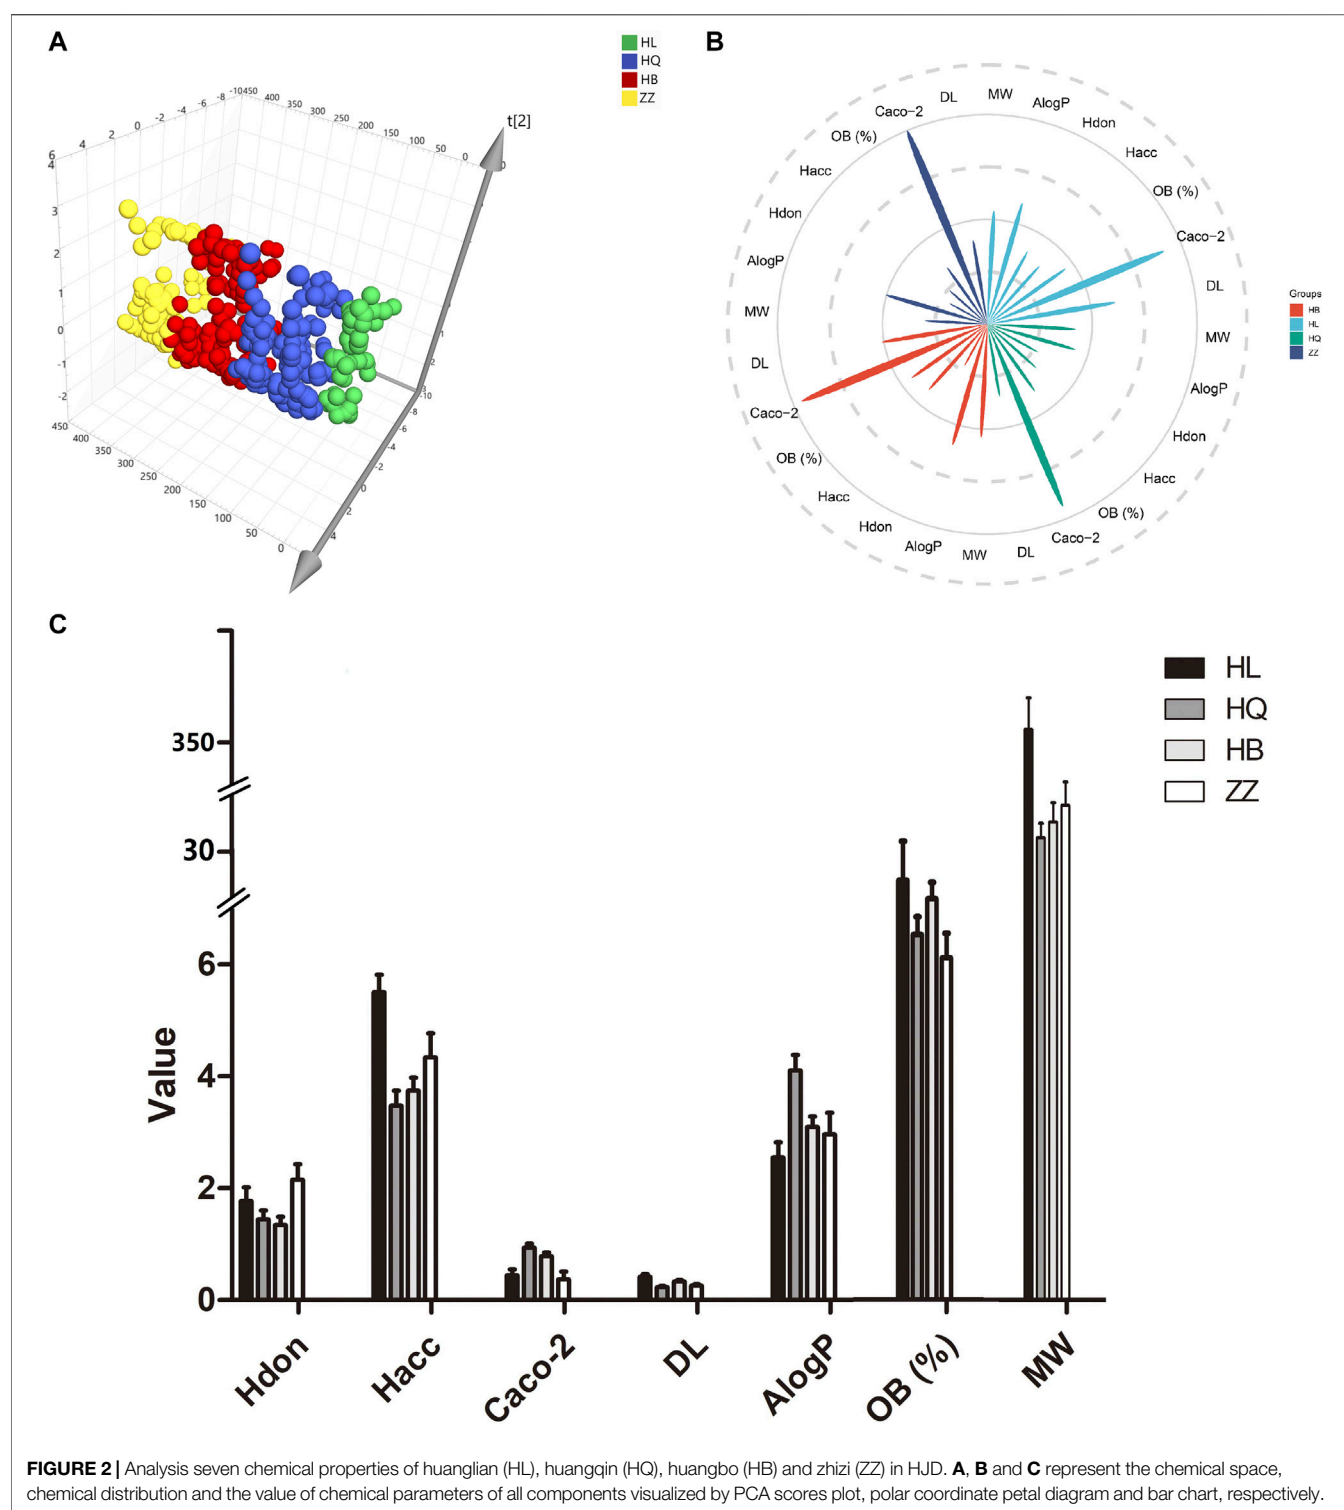

## RESULTS

“Jun-Chen-Zuo-Shi” is one of the widely used compatibility principles of TCM in the treatment of diseases. However, there is still lack researches on the compatibility principle of “Jun-Chen-Zuo-Shi”. In this study, we systematically analyze the compatibility principle and mechanism of HJD based on “Jun-Chen-Zuo-Shi” at three levels: the characteristics of each component in single botanical drug of HJD, including the physical and chemical properties of component, ADME properties and functional enrichment analysis of component targets; the characterization of C-T-P network in the whole PPI network, mainly including the characterization of degree and key communities in C-T-P network; the characterization of intervention propagation properties of HJD in the treatment of different complex diseases, mainly including target coverage of pathogenic genes and propagation coefficient of intervention effect between targets and pathogenic genes (Figure 1).

## Comparison of Chemical Properties of Components

Physical and chemical properties of drugs directly affect the activity of drugs and play important roles in the druggability of TCM. In order to detect the importance of these physical and chemical properties in “Jun-Chen-Zuo-Shi”, seven important pharmacologically related descriptors, MW, ALOGP, HDON, HACC, CACO-2, OB (%) and DL, were analyzed from four botanical drugs in HJD. Principal component analysis (PCA) widely used as a pattern recognition method to reflect the most primitive state of data in an unsupervised state. Here, PCA was applied to detect the distribution of the above physical and chemical properties of four botanical drugs in “Jun-Chen-Zuo-Shi”. The results showed that Huangqin and Huangbo are closest

to Huanglian, indicating that their physical and chemical properties are close to Huanglian. Zhizi is farthest from Huanglian, which indicates that their physical and chemical properties are quite different in PCA scatter plot (Figure 2A). To further describe the specific differences among the four botanical drugs, we have made a detailed analysis of the seven

parameters. As shown in Figures 2B,C, 1) For MW, the average value of all components in huanglian (342.2) is higher than that of huangqin (277.7), huangbo (287) and zhizi (297). 2) For bioavailability, the average OB value (%) of huanglian (36.09) is also higher than that of huangqin (31.42), huangbo (34.51) and zhizi (29.43). (3) For permeability, the average Caco-2 value of

**TABLE 1 |** The information on chemical analysis of the botanical drugs from the literature in HJD.

Formula	Method	Component	Concentration (mg/g)	Ref
Huanglian Jiedu decoction (HJD)	HPLC	Phellodendrine	3.8276 ± 0.1158	(Yang et al., 2019)
		Heriguard	1.0800 ± 0.0261	
		Magnoflorine	6.7489 ± 0.0450	
		Geniposide	72.3830 ± 1.0948	
		Coptisine	14.0580 ± 0.1631	
		Epiberberine	8.9056 ± 0.0864	
		Jatrorrhizine	9.4028 ± 0.0966	
		Berberine	53.0820 ± 0.5443	
		Palmitine	19.6820 ± 0.1452	
		Baicalin	18.5770 ± 0.0927	
		Oroxindin	17.5360 ± 0.2370	
		Wogonin	2.1689 ± 0.3488	
		Oroxylin A	0.2618 ± 0.0212	

huanglian (0.4423) is lower than that of huangqin (0.9371) and huangbo (0.7851). (4) For DL, like MW and OB, huanglian possessed higher average DL value (0.4165), that is very different from that of huangqin (0.2301), huangbo (0.3303) and zhizi (0.258). (5) Compared with the all components of huanglian (2.551), the ALogP value of huangqin (4.101), huangbo (3.096) and zhizi (2.964) exhibited significantly higher average ALogP values, which indicates the majority components in huangqin, huangbo and zhizi are hydrotropic, but that in huanglian are hydrophobic. (6) The values of nHAcc in huanglian (5.5) are all higher than those in others (3.476, 3.743, 4.337, respectively). The above analysis results show that the chemical properties of the four botanical drugs are obviously different. Therefore, we can speculate that each botanical drug plays a different role in the compatibility of this TCM. The Jun botanical drug huanglian is distinguished based on the compatibility principle of “Jun-Chen-Zuo-Shi”, and has good performance in most physical and chemical properties such as OB (%), DL and MW, which indicated that it may play a leading role at the functional level.

## Chemical Analysis in HJD

Chemical analysis plays an important role in the study of the substances basis and mechanism of botanical drugs in the formula. The information on specific chemical identification and concentration of the botanical drugs in HJD were collected by searching from the literature (Yang et al., 2019). The detailed information was shown in **Table 1**. The results suggest that the chemical components of botanical drugs and the concentration of identified components provide an experiment-aided chemical space for the search of active components. This will provide valuable reference for further analysis.

## Comparison of Active Components

TCM formula contains a large number of chemical molecules, the traditional methods of exploring the active components in TCM are mainly based on the separation, purification and structure analysis of mass spectrometry (MS) and high-performance liquid chromatography (HPLC). These methods supplied quantitative concentration of components, however, these experiment-based methods cost a lot of manpower, material and financial

resources to excavate the effective components in TCM. Therefore, it is particularly important to analyze, explore and optimize the TCM formula by calculating ADME properties, which could be helpful to screen the potential active components of TCM, and further optimize the TCM formula, improve the research and development of new drugs from TCM. In this study, botanical drug components were evaluated by using the two representative ADME parameters, oral bioavailability (OB) and drug-like (DL), to screen the active components of TCM formula.

Our statistic results show that 26.81% (94) of the components in HJD meet OB ≥ 30% and DL ≥ 0.14 (**Table 2**). Specifically, 31.25% of the components in Huanglian satisfy OB ≥ 30% and DL ≥ 0.14. These components are regarded as the active components in Huanglian, which included berberine, coptisine, epiberberine, and palmitine, etc. Studies have shown that berberine could significantly reduce hyperglycemia and glycogen content in liver of diabetic mice, increase the expression of Akt and IRS, and inhibit the expression of GSK-3β (Xie et al., 2011). It has been reported that berberine can reduce the release of neuroamyloid through PI3K/Akt/GSK3 pathway, decrease the number of senile plaques in the brain of AD mice model, and play a therapeutic role in AD (Durairajan et al., 2012). Zhai et al. has reported that coptisine could improve oxidative renal injury in diabetic rats, and the potential mechanisms may be associated to activation of the Nrf2 signaling pathway (Zhai et al., 2019). Jung et al. found that epiberberine has a strong potential of inhibition and prevention of AD mainly through ChEs and beta-amyloids pathways, and additionally through antioxidant capacities (Jung et al., 2009). Previous pharmacological studies have shown that palmitine treatment can alleviate the hyperalgesia, allodynia and depressive behaviors of rats with comorbidity of diabetic neuropathic pain and depression (Shen et al., 2018). 27.27% of the components in Huangqin meet OB ≥ 30% and DL ≥ 0.14, including most common active components such as coptisine, epiberberine, wogonin, and oroxylin A, etc. Khan et al. (2016) found that wogonin administration could suppress hyperglycemia, improve cardiac function, and mitigate cardiac fibrosis in STZ-induced diabetic mice. 29.28% of the molecules in Huangbo meet OB ≥ 30% and DL ≥ 0.14, a total of 41 components meet the threshold selection criteria, such

as coptisine, berberine, and palmatine, etc. Only 20.41% of the molecules in Zhizi meet  $OB \geq 30\%$  and  $DL \geq 0.14$ , including oleic acid, kaempferol and mandenol, etc. The above results suggest that the number of active components retained by Huanglian are the highest compared with those before screening. This shows that more components in Huanglian have better OB and DL properties, and indicates that these components may play a major therapeutic role in the treatment disease. Huangqin and Huangbo have the second highest proportion of active components, and have more overlapping components with Huanglian, which intimates that Huangqin and Huangbo can assist and enhance therapeutic effect of Huanglian. In HJD, Zhizi is the Zuo botanical drug with the lowest content of active components, indicating that it may have auxiliary effect on Jun botanical drugs and/or Chen botanical drugs.

## Coverage Rate Based on Functional Pathway

Most complex diseases are not caused by a single pathological change, but a series of physiological reactions caused by abnormal pathways due to disorder of multiple proteins or genes in the cell. In order to further explore the “Jun-Chen-Zuo-Shi” compatibility principle of HJD at the potential molecular mechanism level, we evaluated it through the functional pathway enrichment analysis based on KEGG (Figure 3A). Previous reports confirm that HJD has significant therapeutic effects on Alzheimer’s disease (AD), Parkinson’s disease (PD) and diabetes mellitus (DM) etc. The top

15 enriched pathways were selected for further analysis. The targets of each botanical drug in HJD was mapped to the enriched genes involved in these 15 enriched pathways for enrichment analysis. It was found that 40.54, 33.14, 38.10, and 29.69% of the targets in the Jun (Huanglian), Chen (Huangqin and Huangbo) and Zuo (Zhizi) botanical drug were enriched in the top 15 enriched pathways, respectively (Figure 3B). The above analysis show that Huanglian has a higher target contribution rate among all the genes enriched in the top 15 functional pathways, which means that targets of Huanglian could play primary therapeutic roles in the treatment of disease, and the target contribution rate of Chen botanical drugs is slightly lower, which indicates that the relatively low target utilization rate may play a role in assisting Jun botanical drug in the treatment process. Zuo botanical drug have the lowest target contribution rate, indicating that the ability of therapeutic role in the treatment of diseases is slightly weak, and may play an auxiliary role in other aspects. The above results once again confirm the major functional role of the Jun botanical drug Huanglian, the auxiliary effects of the Chen botanical drugs Huangqin and Huangbo, and the supplementary effects of the Zuo botanical drug Zhizi in the functional level of HJD.

## C-T-P Network Construction and Analysis

In the process of treating complex diseases, TCM formula usually acts in the form of multi-component and multi-target. These components and targets form the most direct target-protein network, which can reflect some therapeutic effects but cannot reflect the propagation mode of this therapeutic effect. More and

more evidences show that the therapeutic effect of drugs on diseases can be propagated through PPI (Andras et al., 2013). Hormozdiari et al. proposed that identified potential multiple-drug targets in pathogenic PPI networks can help us to better discover the therapeutic effect of drugs (Hormozdiari et al., 2010). Chu et al. applied a nonlinear stochastic model and maximum likelihood parameter estimation to identify the cancer-perturbed PPI involved in apoptosis and to identify potential molecular targets for the development of anti-cancer drugs (Chu and Chen, 2008). How to characterize this propagation effect has not been systematically reported.

In this study, we first constructed the C-T network of HJD, then integrated multiple PPI data to construct a comprehensive PPI network. C-T network and PPI networks were integrated as the C-T-P network. By analyzing the C-T-P network, comprehensive information can be obtained and intricate relationships that manage cellular activities can be revealed. In a network, the number of nodes directly interacting with a node is called degree. Several reports have confirmed that the greater the degree, the more biological functions it participates in, and the stronger its biological importance. Under this concept, we made further analysis of C-T-P network. Our results show that the targets of Jun botanical drug Huanglian has the highest average degree 131.75 in C-T-P network. It indicates that these targets affect more proteins in the C-T-P network and have the possibility to play more important roles. By comparative analysis, we found that the degree of Huangqin and Huangbo in C-T-P network are 102.46 and 110.33, respectively. The degree of targets of Huangqin and Huangbo are relatively smaller, which indicate that the number of target protein is not as high as that of Jun botanical drug and may play a supplementary role. Zhizi has the lowest average degree 101.42, while indicates that the number of targeted proteins is smallest, and together with Chen botanical drugs to assist the Jun botanical drug.

## Functional Communities Structure Predication and Analysis

In complex life activities such as diseases, development, and drug intervention, etc, a plurality of genes, proteins, and other constituent components in cells are involved, and these genes, proteins, and components form a complex regulation network in cells. In the process of drug intervention, drugs play an intervention regulatory role on the complex network by targeting specific proteins. This intervened regulation and intracellular gene regulation network form a drug-target-pathway complex network at the molecular level. Further research found that the neighbors of drug responding genes in the network tend to be related to the same or similar intervention responses (Li and Zhan, 2006; Zhang et al., 2014).

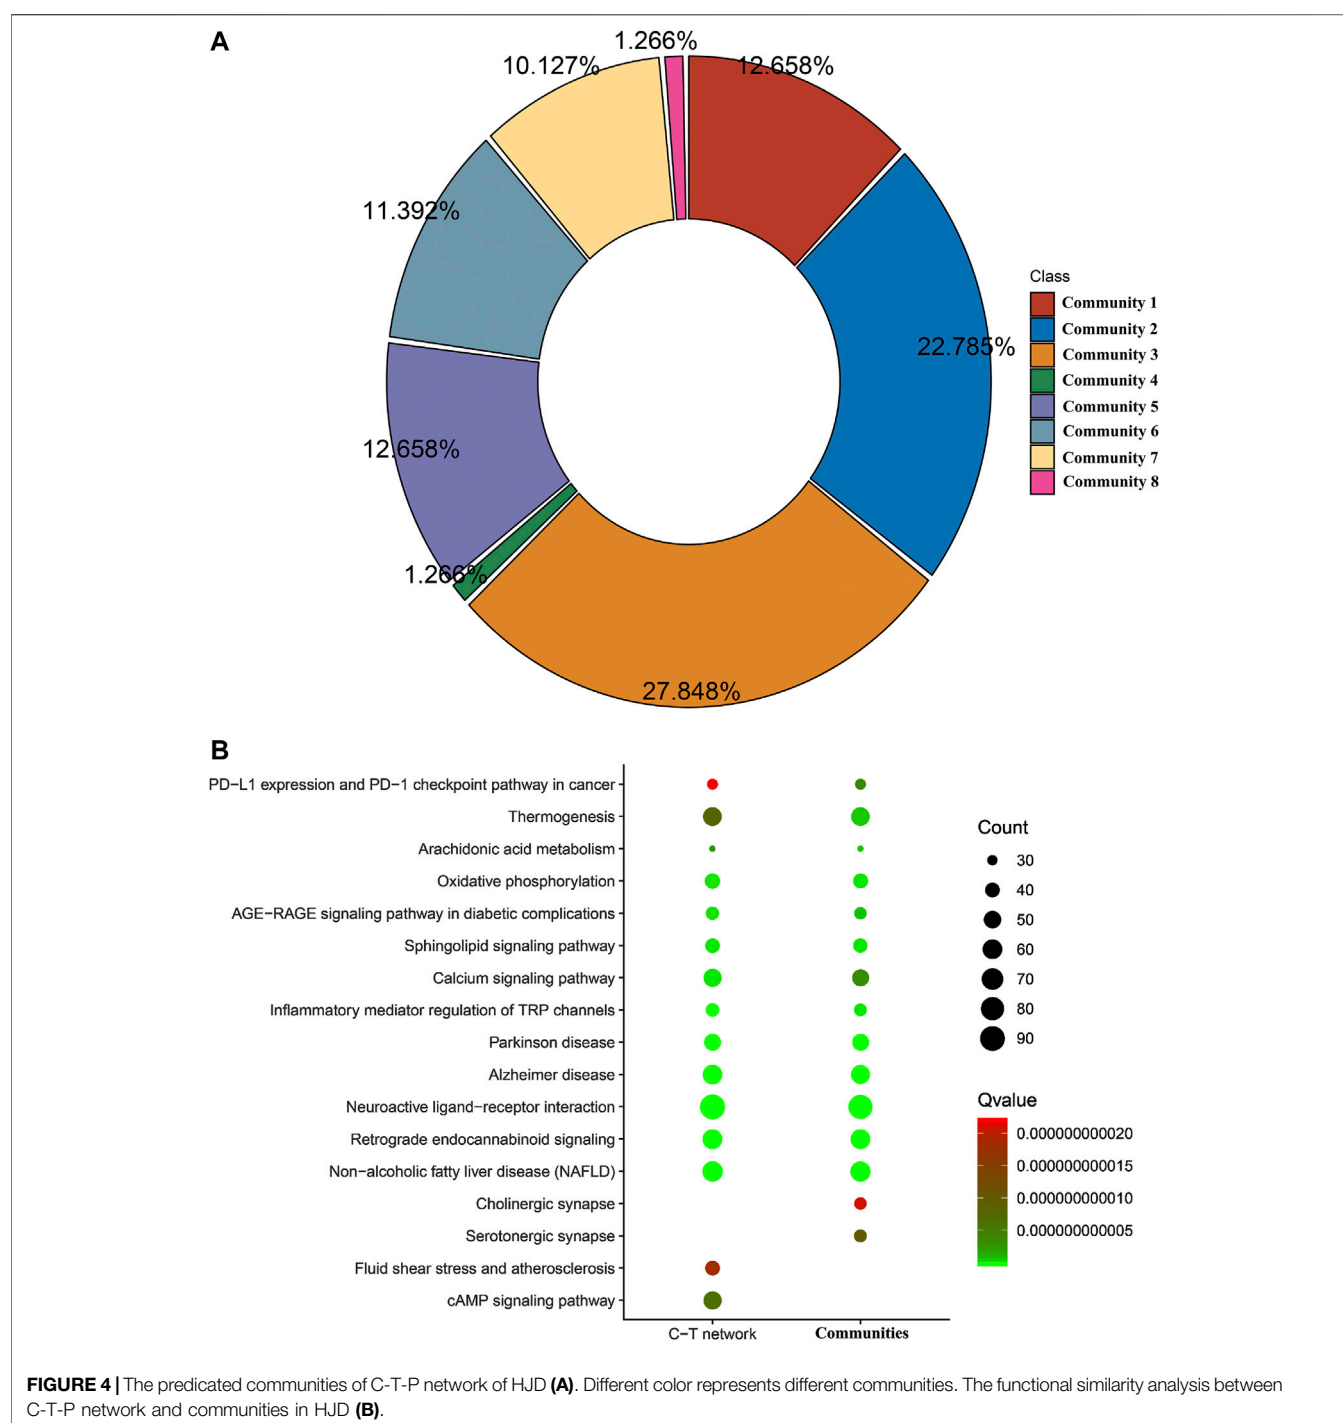

Genes with the same drug response are often functionally related and form biological network communities (Tari et al., 2005). At the molecular level, the community can be considered as a group of genes, proteins or metabolites that are functionally related, physically interact or jointly response to drug. The molecules in these communities usually jointed together to drive a biological process or respond to the treatment of drugs

(Tripathi et al., 2019). For drug intervention in complex diseases, single gene analysis cannot effectively consider the cooperative relationship among genes, and is difficult to explain its biological mechanism. However, community-based analysis can identify response gene sets with cooperative relationships. Revealing the functions of these simple network modules at the molecular level is the key step for understanding the drug response regulation mechanism of more complex networks and even for understanding the mechanism of drug treatment.

In this study, we construct the C-T-P network by integrating C-T network of HJD and PPI network. This extremely complex C-T-P network with 12,324 nodes and 84,138 interactions is difficult to clarify drug MOA, so discovery of functional communities in the C-T-P network is very important for understanding the organization and function units of the HJD under the concept of the compatibility principle “Jun-Chen-Zuo-Shi”. The extraction of these community structures can reduce the dimension of complex networks and could be considered as the key factor for further clarify the compatibility principle of HJD’s “Jun-Chen-Zuo-Shi”, we identify the functional communities in the C-T-P network based on the information graph algorithm combining random walk theory and Huffman encoding. The algorithm performs to optimize the discovery of communities in C-T network heuristically by using a reasonable global metric. The results show that 8 significant functional communities are found in the C-T-P network (Figure 4A). In order to determine whether communities found in HJD can represent their complete C-T network. We evaluate the importance of communities at the gene functional level based on enrichment pathway analysis. The analysis results showed that genes enriched pathways of HJD communities accounts for 93.4% of genes enriched pathways of the full C-T network in HJD (Figure 4B), which indicated that the enriched pathways of genes involved in communities of HJD are highly compatible with enriched pathways of genes in C-T network. Further analysis of the components identified by these functional communities shows that 93.33, 87.5, 84.62, and 75% of the components in the Jun botanical drug Huanglian is covered by functional communities, which once again indicates that Huanglian plays a leading role in the function of C-T-P network (Figure 5).

## Coverage Rate Based on Pathogenic Genes

In order to better explore how HJD exerts its therapeutic effect based on the compatibility principle of “Jun-Chen-Zuo-Shi”, DM and AD were selected for further evaluation. Both of two diseases have been reported with significant therapeutic effects of HJD. Pathogenic genes of both diseases were collected from GeneCards database (Safran et al., 2010). PPI data of both diseases were extracted from STRING database (Szklarczyk et al., 2019). The weighted gene regulatory network of disease was constructed by mapping pathogenic genes to PPI data, the weight was assigned by using relevance scores in GeneCards database (Figure 6A,B; Supplementary Table S1). The relevance score of genes in GeneCards takes into account three aspects: the frequency of the term in the disease related document would raises the score, while the frequency of the term in disease related documents across the site would lower the score, and the size of the subfield

containing the term, if the term appears in a smaller field, such as gene name, the score would be increased (Stelzer et al., 2016). This indicates that the higher the relevance score, the more important that the genes are involved in pathogenesis of the disease. For further analyzed the “Jun-Chen-Zuo-Shi” compatibility principle of HJD, we design a pipeline to capture the role of each botanical drug in HJD based on botanical drug targets and their associated pathogenic genes. Firstly, we get

common gene datasets by overlapping pathogenic genes of each diseases and component targets of each botanical drug, and then analyze the average relevance score of the common gene datasets, then we calculate the possession rate by compare the common gene datasets to targets genes of each botanical drug in HJD. For DM, 87.91% of the targets in the Jun botanical drug Huanglian overlap with the pathogenic genes with an average relevance score of 6.91, 80.67% and 81.41% of the targets in the

**FIGURE 5** | Venn diagram was used to visualize the overlap number between C-T-P network and communities in HJD, the pink represents the C-T-P network, and the green represents communities.

Chen botanical drugs Huangqin and Huangbo overlap with the pathogenic genes with average relevance scores of 5.44 and 6.13, and 82.93% of the targets in the Zuo botanical drug Zhizi overlap with the pathogenic genes with an average relevance score of 6.51. For AD, 73.08% of the targets in the Jun botanical drug Huanglian overlap with the disease genes with an average relevance score of 12.55, 65.83 and 67.80% of the targets in the Chen botanical drugs Huangqin and Huangbo overlap with the pathogenic genes with average relevance scores of 9.74 and 10.52, and 66.11% of the targets in the Zuo botanical drug Zhizi overlap with the pathogenic genes with an average relevance score of 11.02 (**Figure 6**). The above results show that the Jun botanical drug Huanglian has the highest possession rate and average relevance score, which indicate that Huanglian acts on as many important targets as possible in pathogenic genes.

## Calculation and Analysis of Propagation Coefficient

The interactions between genes or proteins in cells form complex biological networks. Molecular interactions in biological networks have dynamic and spatiotemporal specific features. At present, protein interaction network and drug regulatory network can only provide static interaction information. In the function analysis of drug targets and pathogenetic genes, the dynamic characteristics of molecular interactions are more significant than static characteristics for understanding the MOA and propagation features of drug intervention in the disease networks. In order to analyze and understand the propagation characteristics of drugs in the disease network more effectively, this study proposed an important monitor which named as propagation coefficient to characterize the drug response network-propagation characteristics by integrating the data of botanical drug targets, PPI, and pathogenic genes. The propagation coefficient contains propagation modes and effector proteins, which could be used to indicate the propagation power of drug. Based on the novel calculate method, the propagation coefficient of single botanical drug in HJD is analyzed, and the scientific basis of the compatibility rule of

“Jun-Chen-Zuo-Shi” is revealed from the perspective of propagation characteristics.

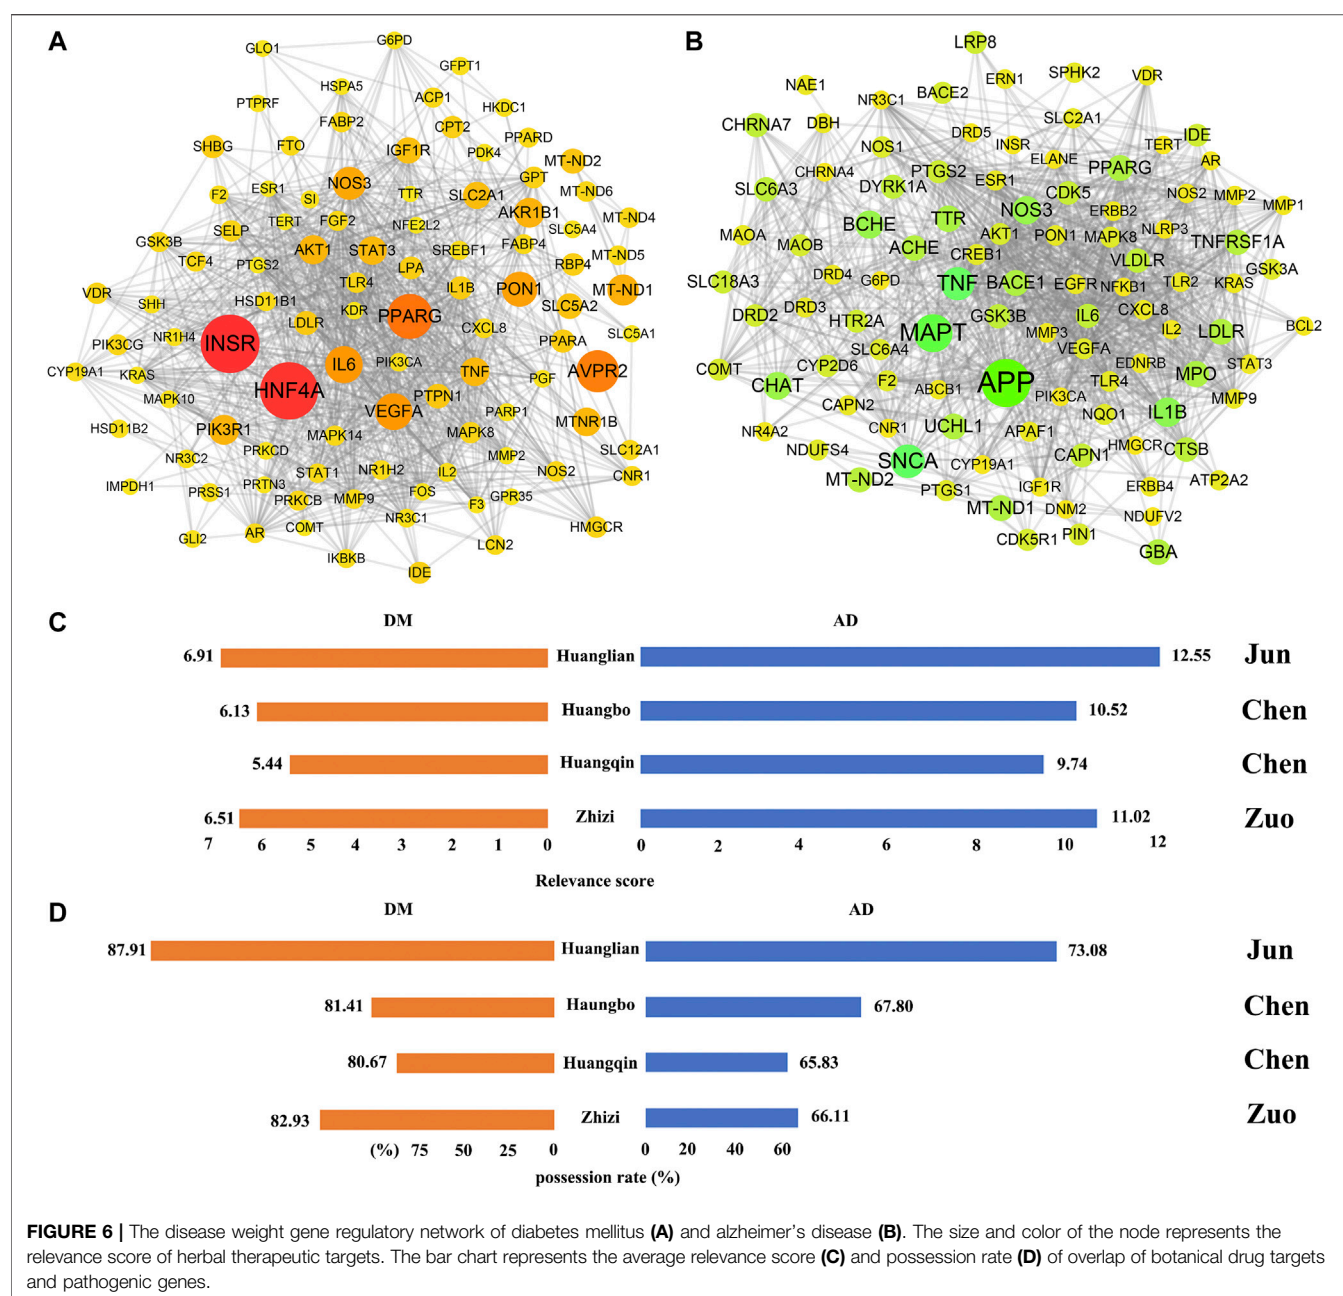

The propagation coefficient value of each botanical drug in HJD is calculated and showed in **Figure 7**. According to the calculation results, for DM and AD, the Huanglian with a propagation coefficient of 72.62 and 67.05, the Huangbo with a propagation coefficient of 63.69 and 59.30, the Huangqin with a propagation coefficient of 59.55 and 55.54, and the Zhizi with a propagation coefficient of 59.10 and 54.87, respectively. From the above analysis, Huanglian has highest propagation coefficient both in DM and AD, the propagation coefficient of Huangqin and Huangbo is lower than Huanglian and Zhizi has the lowest propagation coefficient, which indicate that Huanglian plays a major role in disease treatment by spreading the intervention effect at a more powerful level, and Chen botanical drugs and Zuo botanical drugs play a role in assisting Huanglian. This once again confirmed the compatibility rules of “Jun-Chen-Zuo-Shi” in HJD at quantitative level.

## Experimental Evaluation

In order to further explore the accuracy and reliability of the above strategies for analyzing the compatibility rules of HJD “Jun-Chen-Zuo-Shi,” components absorbed into blood were used to validate our strategy. In the study of complex components system of TCM, it is generally believed that the components which can be absorbed into blood are the active components with therapeutic effect. Analysis of the components in blood after oral administration of TCM is an effective and accurate way to study the substance basis of drug effect of TCM. The absorbed components in rat plasma after oral administration of HJD were collected from the previous reports (Zuo et al., 2014). A total of 22 prototype components were obtained, the detailed information was shown in **Supplementary Table S2**.

For the components obtained by functional communities structure prediction and active components screening in the above strategy, 26.67% of the predicted components in the Jun botanical drug of Huanglian overlap with the components were absorbed into blood; 10.26 and 7.5% of the predicted components in the Chen botanical drugs Huangqin and Huangbo overlap with

**FIGURE 6 |** The disease weight gene regulatory network of diabetes mellitus (A) and Alzheimer's disease (B). The size and color of the node represents the relevance score of herbal therapeutic targets. The bar chart represents the average relevance score (C) and possession rate (D) of overlap of botanical drug targets and pathogenic genes.

the components were absorbed into blood. There is no overlap between the predicted components and the components were absorbed into blood in the Zuo botanical drug Zhizi. The above results indicate that the proportion of components in Jun botanical drug were absorbed into blood is higher, followed by Chen botanical drugs, which confirm the accuracy and reliable of our analysis strategy. Meanwhile, the results once again confirm the important role of the Jun botanical drug Huanglian through a higher absorbed into blood rate, the auxiliary effects of the Chen botanical drugs Huangqin and Huangbo, and the supplementary effects of the Zuo botanical drug Zhizi.

## DISCUSSION

TCM usually exerts its efficacy in the form of formula, which is not only a simple combination of botanical drugs, but follows reasonable compatibility principles to treat complex diseases (Sucher, 2013). The main purpose of these compatibility principles is to enhance efficacy or reduce toxicity, so that different chemical components in botanical drugs can promote, coordinate, and restrict each other, thus ensuring the safety and effectiveness of clinical medication (Sucher, 2013). "Jun-Chen-Zuo-Shi" is one of the most common used rules in the

**FIGURE 7 |** The propagation coefficient of HJD botanical drugs in diabetes mellitus (DM) and Alzheimer's disease (AD).

compatibility principles of TCM (Yao et al., 2013; Wu et al., 2014). The botanical drugs in a formula can be divided into “Jun”, “Chen”, “Zuo” and “Shi” botanical drugs according to their functions. Based on the compatibility principles of “Jun-Chen-Zuo-Shi”, the function of each botanical drug and its relationship with other botanical drugs are revealed. For example, Yujinfang is based on the compatibility rules of “Jun-Chen-Zuo-Shi” in the treatment of cardiovascular and cerebrovascular diseases (Li et al., 2014). The “Jun” botanical drug *Curcuma wenyujin* Y.H.Chen and C. Ling accounts for the largest proportion of active ingredients and action targets, and treats diseases by acting on the main targets of cardiovascular and cerebrovascular diseases. “Chen” botanical drug *Gardenia jasminoides* J. Ellis can enhance the effect of *Curcuma wenyujin* Y.H.Chen and C. Ling. The “Zuo” and “Shi” botanical drugs can achieve their auxiliary effects by reducing the toxicity of *Curcuma wenyujin* Y.H.Chen and C. Ling and *Gardenia jasminoides* J. Ellis. Many botanical drugs in TCM have both unique effects and strong toxicity in clinical application. According to the needs of clinical treatment, the effectiveness of these botanical drugs should be utilized as much as possible and the toxic and side effects should be reduced at the greatest extent. Based on the compatibility rules of “Jun-Chen-Zuo-Shi”, botanical drugs with toxicity usually are compatible with other botanical drugs to inhibit their toxicity and side effects and to play unique curative effects. This is an important aspect of improving the efficacy of TCM. For example, *Pinellia cordata* N.E.Br. in Xiaobanxia decoction is a commonly used medicine for resolving phlegm and arresting vomiting, but it is toxic. Compatibility with *Zingiber officinale* Roscoe can not only relieve the toxicity of *Pinellia cordata* N.E.Br. but also enhance the anti-vomiting effect of *Pinellia cordata* N.E.Br. to achieve synergistic effect (Gong-Chang et al., 2015).

Recently, more and more attention has been paid to the practice of verifying and explaining the compatibility theory of TCM by using different modern technologies, such as component combination and computer modeling (Wu et al., 2014). However, most of these analysis of compatibility rules of “Jun-Chen-Zuo-Shi” in TCM only focuses on one or several aspects. There is a lack

of systematic and multi-dimensional analysis of the compatibility rules of “Jun-Chen-Zuo-Shi.” Network pharmacology mainly focus on problems from the perspective of mutual connection, which is exactly consistent with the core idea of TCM (Li and Zhang, 2013). Therefore, the application of network pharmacology in Chinese medicine research has unique advantages and great development potentiality. However, most of the current network pharmacology research focuses on the interpretation of the functional mechanism of formula in the treatment of specific diseases, and does not interpret the compatibility rules of “Jun-Chen-Zuo-Shi” at a systematic level.

In this study, the compatibility rules and possible mechanisms of TCM in treating complex diseases are analyzed through six detail properties, include the physical and chemical properties of each component in single botanical drug of HJD, ADME properties and functional enrichment analysis of component targets, the characterization of degree and key communities in C-T-P network, the characterization of intervention propagation properties in the treatment of different complex diseases. The pharmacological action of drugs depends on the physical and chemical properties of drugs, which can reflect ADMET characteristics of drugs in the body and is also a basic attribute to be considered in interpreting the compatibility rules of TCM. Complex networks are made up of a large number of nodes, of which the important nodes are a few special parts that can deeply influence on the structure and function of the whole network. Node degree in the topological structure can reflect the importance of nodes, and is a key topological parameter to characterize the most influential nodes in the network (Lv et al., 2014). For example, in order to evaluate the influence of components in ZZW on FD treatment, Wang et al. constructed a contribution index model based on the topological parameter degree in the network. By using this algorithm, they selected key component groups for FD treatment and clarified possible cooperative mechanisms (Wang et al., 2018).

Modularity is a very important characteristic of complex networks and a common phenomenon in biological systems (Yang and Leskovec, 2012). Studying the response network

modules of different chemical components in different botanical drugs is very important to analyze the drug mechanism. It is also an important way to systematically validate the rules of “Jun-Chen-Zuo-Shi.” The intervention effect of compounds in herbal medicine could propagate through PPI (Comola and Prina, 2013). The propagation of this intervention in the network has specific propagation modes and paths. The propagation coefficient defined based on the propagation method and path is also different in the principle of “Jun-Chen-Zuo-Shi.” Enrichment analysis of gene function is a routine method for gene group function analysis, which is of great significance for revealing the molecular mechanism of different Chinese medicines in formula, and is a further explanation for the correlation between compatibility rules and mechanisms of Chinese medicines based on “Jun-Chen-Zuo-Shi”. Based on the above-mentioned features, we designed a new system pharmacology strategy, which can systematically interpret the compatibility rule of “Jun-Chen-Zuo-Shi” from structure to function and then to propagation mode at a multi-level perspective.

Taking HJD as an example, we deeply decoded the compatibility rules of TCM. Jun botanical drugs play a leading role in formula, and exert the strongest effect in treating diseases through the best chemical properties, the highest occupancy rate of active components, the highest topological structure of drug action network, the highest occupancy rate of functional communities of drug response network and the highest drug intervention coefficient and potential molecular pathways of action. The Chen botanical drugs can enhance the pharmacological effects of Jun botanical drugs and reduce the dosage required by Jun botanical drugs through slightly lower functional targets. Zuo and Shi botanical drugs could be improved the bioavailability and active component of Jun and Chen botanical drugs. In addition, the C-T-P network proves the multidirectional pharmacological treatment mechanism of TCM, i.e. multiple components, multiple targets and multiple therapeutic effects. The prescription principle of different botanical drugs provides a unique opportunity to explore multiple therapeutic mechanisms according to the efficacy of botanical drugs. The combination of different botanical drugs can not only treat diseases by increasing bioavailability or promoting the synergistic effect of different botanical drugs, but also reduce the toxicity of some botanical drugs. The synergistic mechanism and toxicity-reduced effect embodied by these compatibility rules also indicate that the botanical drug combination is more effective than the use of single botanical drug.

Additionally, HJD was widely used in the treatment of AD and PD, thus, the study of brain tissue distribution of HJD is particularly important. Passing through the blood-brain barrier (BBB) is crucial for drugs to enter the central nervous system and play therapeutic roles. Through the analysis of components absorbed into blood in HJD, we found the components that can be absorbed into blood in the Jun botanical drug of Huanglian have strong permeability of BBB ( $>0.3$ ), including berberine, palmatine, coptisine, and epiberberine. However, specific components wogonin and oroxylin absorbed into blood in the Chen botanical drug of Huangqin only have moderate permeability of BBB. This proves once again that Jun

botanical drugs are the core of the formulas, and they play a major role in treating diseases.

In this study, the compatibility rule of “Jun-Chen-Zuo-Shi” of HJD was in-depth decoded from multi-scale perspective. At the components and targets level, the Jun botanical drug Huanglian plays a leading role at the functional level and has good performance in most physical and chemical properties, ADME properties and functional enrichment analysis of component targets. At the C-T-P interaction level, the leading role of the Jun botanical drug Huanglian is also confirmed by having the highest average degree in C-T-P network and targets coverage rate of functional communities. At the intervention propagation level, the Jun botanical drug Huanglian has highest propagation coefficient both in DM and AD, this once again confirmed the Jun botanical drug plays a leading role in a formula for treating diseases. Finally, the results of experimental validation showed that the proportion of components in Jun botanical drug were absorbed into blood is higher than Chen and Zuo botanical drugs, including berberine, palmatine, and coptisine etc. Our approach confirmed the compatibility rules of “Jun-Chen-Zuo-Shi” in HJD at multiple quantitative level. This research shows the scientific basis of “Jun-Chen-Zuo-Shi” from a multi-dimensional perspective, which providing a good methodological reference for the subsequent interpretation of key components and speculation mechanism of the formula.

However, there are still some limitations of this study. This research is a computational pharmacological work based on pharmacological experiment data and public data. Pharmacological calculation is the forerunner and basis of the experiment, which provides a feasible scheme to reduce the verification scale for the experiment. Evidence from pharmacological experiments should be added in future research.

## AUTHOR CONTRIBUTIONS

K-XW and YG contributed equally to this work. D-GG, A-PL, and X-MQ provided the concept and designed the study. K-W and YG conducted the analyses. K-XW and YG wrote the manuscript. K-XW, YG, W-XG, X-FY, CW, L-YF, and X-FG participated in data analysis. X-MQ, G-HD, LG, and A-PL provided oversight. D-GG and A-PL contributed to revising and proof-reading the manuscript.

## FUNDING

This study is financially supported by the Startup fund from Southern Medical University (grant No. G619280010), the Natural Science Foundation Council of China (grant No. 31501080), Hong Kong Baptist University Strategic Development Fund (grant No. SDF13-1209-P01, SDF15-0324-P02(b) and SDF19-0402-P02), the Key

Laboratory of Effective Substances Research and Utilization in TCM of Shanxi Province (No. 201705D111008-21), Hong Kong Baptist University Interdisciplinary Research Matching Scheme (grant No. RC/IRCS/17-18/04), the General Research Fund of Hong Kong Research Grants Council (grant No. 12101018, 12100719, 12102518).

Hydroxysafflower yellow A (HSYA), as a principal natural ingredient extracted from  
safflower (*Carthamus tinctorius* L.), has significant pharmacological activities, such as  
antioxidant, anti-inflammatory, anticoagulant, and anticancer effects. However, chemical  
instability and low bioavailability have been severely hampering the clinical applications of  
HSYA during the treatment of cardiovascular and cerebrovascular disease. Therefore, this  
present review systematically summarized the materials about HSYA, including acquisition  
methods, extraction and detection methods, pharmacokinetics, pharmacological effects  
and molecular mechanism, especially focus on the possible causes and resolutions about  
the chemical instability and low bioavailability of HSYA, in order to provide relatively  
comprehensive basic data for the related research of HSYA.

**Keywords: hydroxysafflor yellow A, bioavailability, biological activity, chemical stability, delivery systems, botanical  
resources**

## INTRODUCTION

Cardiovascular and cerebrovascular disease (CCD), as one of the leading causes of mortality  
worldwide, has been increased rapidly and presented younger trend, with high mortality all of the  
world (Collins et al., 2017; Donahue and Hendrikse, 2017). Although many types of therapeutic  
strategies were used to treat patients with CCD, such as angiotensin converting enzyme inhibitor  
(ACEI),  $\beta$ -receptor blocker, and statins, the outcome remains not satisfactory due to the  
inevitable side effects and high treatment expenditure. To address the problem, more and  
more studies are trying to seek treatment strategy from Traditional Chinese Medicine (TCM).  
Characterized by minor side effects, TCM has become an important source of natural product,  
such as Aspirin, Digoxin, Hydroxysafflor yellow A, which exhibit substantially protective effects  
against CCD (Eichhorn and Gheorghiadu, 2002; Dai and Ge, 2012; Desborough and Keeling 2017;  
Hu et al., 2020).

Hydroxysafflor yellow A (HSYA) is a primary active product derived from safflower (*Carthamus tinctorius* L.), a plant of the *Compositae* (*Asteraceae*) family, which was used to improve blood circulation, eliminate blood stasis, and relieve menstrual pain as early as recorded in *Kaibao Bencao*. HSYA, as an indicator component to characterize the medical value of safflower recorded in *The Pharmacopoeia of the People's Republic of China* from 2005 edition, possesses a broad spectrum of pharmacological activities, such as antioxidant, anti-inflammatory and anticoagulant effects, which play an important role acting on cardiovascular and cerebrovascular disease (Sun et al., 2010; Wu et al., 2012; Ma et al., 2019a; Zhou et al., 2019; Bacchetti et al., 2020). However, chemical instability and low bioavailability of HSYA severely hamper the clinical applications. It can be easily oxidized, hydrolyzed, polymerized by light, high temperature, and alkaline conditions due to its structural characteristics. The high polarity directly leads to difficulty of transmembrane transport, resulting in low bioavailability. To address these problems, new drug delivery systems were developed to improve the therapeutic efficacies of HSYA based on lipid-based carriers, such as microemulsions, self-emulsifying systems, nanoparticles, chitosan, and the combination of HSYA with other drugs, which may have a good application prospect.

The present review systematically summarized the literatures about HSYA, including botanical resources, extraction and detection methods, pharmacokinetics, pharmacological effects and molecular mechanism, especially focus on the possible causes and resolutions about the chemical instability and low bioavailability of HSYA, in order to provide relatively comprehensive basic data for the related research of HSYA.

## ACQUISITION OF HYDROXYSAFFLOWER YELLOW A

HSYA is mainly extracted from safflower, but the amount is not enough to support current clinical applications. Therefore, it is

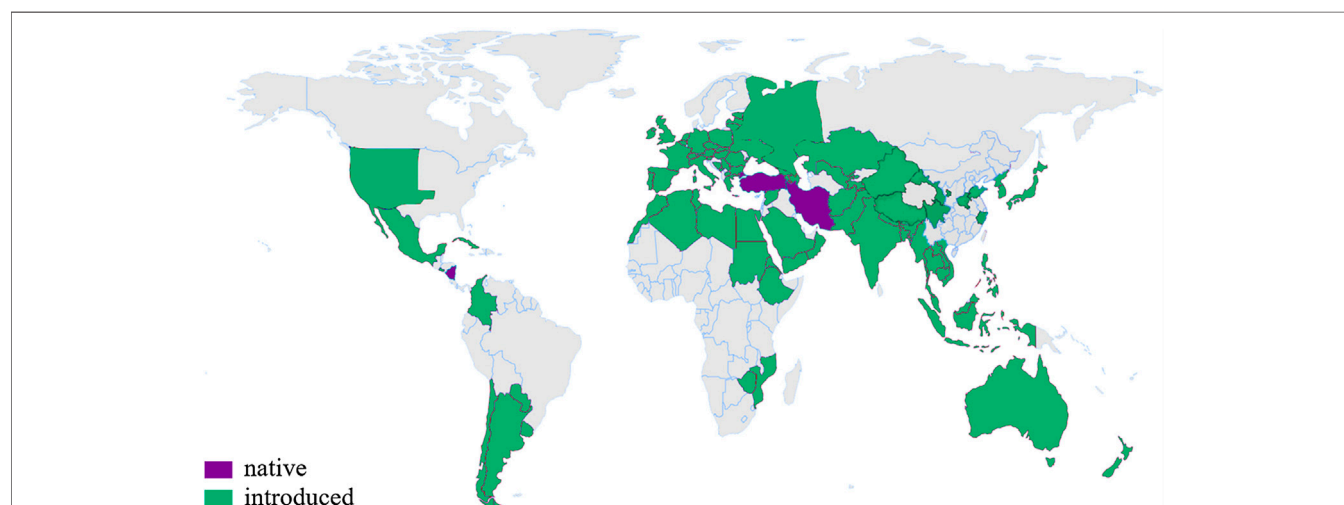

urgent find other ways to obtain HSYA. At present, chemical synthesis and biosynthesis are two promising ways to obtain HSYA. The information was detailed as follows.

### Acquisition From Safflower

Safflower, as the natural source of HSYA, is widely planted worldwide. It is said that safflower originated in West Asia (Iran, Nicaragua and Turkey), and were later introduced for cultivation on almost every continent except Antarctica, such as America, Australia, China, Ethiopia, India, Italy, Mexico, Spain, and so on (**Figure 1**). India has developed into the most productive country with the planting areas of over 760,000 hm<sup>2</sup>, and the yield of about 460,000 t, accounting for 50% of the total area and yield in the world (Liang et al., 2015).

Safflower is also widely cultivated in China with planting area of about 30,000–58,000 hm<sup>2</sup>, and dried flowers yield of about 1,500–2,000 t every year. Xinjiang province has become the major safflower production area, covering an area of 16,700–40,000 hm<sup>2</sup>, which accounts for more than 3/4 of the total planting areas and provides more than 80% dried flowers and seeds in China. Henan province (*Weihonghua*, 卫红花), Zhejiang province (*Duhonghua*, 杜红花) and Sichuan province (*Chuanhonghua*, 川红花) are described as the authentic product areas of safflower in the history of China.

The content of HSYA containing in safflower were affected by many factors, including geographical origins, color and harvest time. The content of HSYA ranged from 0.05 to 14.99 mg/g by comparing 80 safflower cultivars collected from Africa, America, Asia, and Europe. HSYA in Africa cultivars was higher than that in Asia and Europe, and China cultivars is higher than that in Turkey, India and Kenya. Moreover, color is another factor to influence the content of HSYA. The darker the color of safflower, the higher the content of HSYA (red > orange > yellow > white according to PANEONE) (Tong et al., 2011; Xu et al., 2018). For example, Hebei safflower (red) was richer in HSYA (26.943 mg/g) than that in Wei safflower (white flowers, 0.472 mg/g) in China (Zhao, 2015). The most appropriate time to pick safflower is the

**FIGURE 1** | The distribution of safflower in the world (The global planting area is about 1.1 million hm<sup>2</sup>). According to <http://www.plantsoftheworldonline.org/taxon/urn:lsid:ipni.org:names:324467-2>

morning of the third or fourth day after flowering (Tian et al., 2007).

## Oxidation Synthesis Pathway

Chemical synthesis is an efficient way to obtain the natural or unnatural products within a short time period. Oxidation synthesis for HSYA is a rapid and highly efficient chemical synthesis method, and the synthetic pathway was shown in **Figure 2A**.

According to a retrosynthetic analysis of HSYA, di-C-glucosyl chloroacetophenone (3) transformed into di-C-(per-O-acetylglucosyl) phloroacetophenone (4) with  $\text{BF}_3 \cdot 2\text{AcOH}$  at room temperature for 5 h. A further oxidation afforded the phenolic hydroxyl-free glycoside (5) with the quinol. Moreover, the two enantiomers of 4-(S)-2-acetyl-4,5-dihydroxy-4,6-di-C- $\beta$ -D-glucosyl-3-methoxycyclohexa-2,5-dienone (6) was obtained after diazomethane added to acetic acid solution of product 4 at 0°C. Finally, compound 6 transformed into HSYA (7). Compared the oxidant synthesis pathway mentioned above, di-C-glucosyl chloroacetophenoneoxidation (1) was converted into di-C-glycosylquinol(2) via an oxidation, and then was directly transformed into HSYA (7) with the yield at 18%, suggesting it is worthy promoting in the future (Suzuki et al., 2017).

## Biosynthetic Pathway

Biosynthesis is a multi-step enzymatic process, in which a simple product is converted into a more complex desired product in a living organism. Biosynthesis is characterized by continuous and effective production, low-carbon and friendly environment, which

provides a great support to the development of natural products (Pang et al., 2015). This production model will be the main source of HSYA in the future. However, the biosynthetic pathway of HSYA in plant remains unclear. According to the vital reaction of chalcone biosynthetic pathway, one molecular of 4-coumaroyl-CoA and three molecules of malonyl-CoA are converted into naringenin chalcone (4,2',4',6'-tetrahydroxychalcone) via the intervention of chalcone synthase, and it was transformed into HSYA after glycosylated (Heller and Hahlbrock, 1980; Knogge et al., 1986). The possible biosynthetic pathway of HSYA in phytosomal was shown in **Figure 2B**.

The content of HSYA is controlled by a nuclear gene with two alleles, HSya and hsyA gene. HSya gene dominates completely over hsyA gene to promote HSYA biosynthesis (Zhang et al., 2009; Yang et al., 2011). *sHSP* is a small heat shock protein and encoded by CTL-*hsyap*, which might be directly or indirectly disturb HSYA biosynthetic pathway (Tang et al., 2010). When safflower is under external pressure, CT-*wpr* (TDF-11) was activated, which might arouse *sHSP* and inhibit the expression of HSya to some extent, finally leading to the inhibition of biosynthetic pathway of HSYA (Li et al., 2010b).

## EXTRACTION AND DETECTION

### Extraction Methods

HSYA is highly soluble in water, while hardly dissolve in lipophilic solvents such as ethyl-acetate, ether, benzene, and

**FIGURE 2 | (A)** Oxidative synthesis pathway of HSYA; **(B)** The possible biosynthetic pathway of HSYA in phytosomal.

**TABLE 1** | Representative examples of the extraction and purification methods of HSYA.

No	Total sample	Method	Pre-treatment	Extraction	Purification	Yield	Additional notes	References
1	800 g	Water immersion	NA	Distilled water (10 L, 80°C, 20 min) for 2 cycles	The extracts were combined, evaporated and filtered	0.023%	NA	Li et al. (2013)
2	2000 g	Water immersion	The fresh flowers were shade dried and powdered	Distilled water (60°C, 30 min, 20 L) for three times	The solvent by evaporation under the reduced pressure, the residue was dissolved in 10% ethanol (1,000 ml), then evaporated to dryness under vacuum to afford a residue	0.066%	NA	Bai et al. (2012)
3	1 g	MAS-I microwave extraction system	NA	Distilled water at 70 °C for 20 min with solid and liquid ratio 100 for 3 cycles, and then the extracts were filtered	NA	6.96%	NA	Yang et al. (2008)
4	0.5 g	UAE extraction system	NA	Ultra-pure water (55°C, 39 min, liquid-to-solid ratio of 16) in ultrasonic (40 kHz, 250 W) for 3 times	The extracts were filtered, and transferred to 100 ml volumetric flask, filtered by a 0.22 µm filter	1.798%	Reflow by cold water during ultrasonic procedure	Sun et al. (2013)
5	20 g	Smashing tissue extraction system	NA	Distilled water with liquid-to-solid ratio of 40, at 2.5 min for 90 V, and filtered	NA	1.359%	NA	Wang et al. (2012)
6	500 g	Alcohol extraction method	NA	75% aqueous ethanol (3,000 ml, 12 h) for 10 cycles	The extracts were concentrated to dryness in <i>vacuo</i> at 55°C, re-solved with water, and extracted by petroleum ether and ethyl acetate for five times	0.584%	RP-MPLC was used to isolate and purify	Zong et al. (2013)
7	2.5 g	DMSO extraction method	Stirred 14 times the amount of DMSO at room temperature to avoid light for 30 min, impurity removal, filtered	The filter residue added DMSO to soaking, heating extraction in seal condition at 80°C for 50 min, filtered. Then residue again added 12 times the amount of DMSO, heating extraction in seal condition at 80°C for 50 min. Filtered and combined the filtrate	The filtrate added 3 times of the amount of butyl acetate, centrifuged. Washed the precipitate with ethanol, dried	14.564%	A comparison of hot, cold and ultrafiltration models	Li et al. (2016)

**TABLE 2 |** Summary of the detection methods of HSYA.

No	Methods	Sample source	Sample preparation	Chromatographic method details	Advantage	Reference
1	HPLC-DAD and UPLC-Q-TOF-MS	Plant extracts	Dried in the cabinet drier at 35°C for 24 h, crushed and passed through an 80-mesh sieve and stored in a desiccator at room temperature	Waters ACQUITY BEH C18 column (30.0°C), elution solvent: Methanol: Water (1: 3, v: v) And flow-rate of 0.8 ml/min	High-speed separation and structural identification of multiple constituents	Hong et al. (2015)
2	UFLC-Q-TOF/MS	Bile, urine, plasma and feces samples from SD rat	Mixed sample at same time point, loaded onto a SupelClean™ LC-18 SPE tube	Thermo hypersil gold C18 column (35.0°C), elution solvent: Phase gradient, methanol A and 0.5% acetic acid in water B, flow rate of 0.2 ml/min	NA	Jin Y.et al. (2016)
3	LC-MS/MS	Human plasma	Mixed with internal standard working solution and vortexed for 30 s	Shim-pack VP-ODS C <sub>18</sub> column (30.0°C), isocratic elution system: Methanol and 5 mM ammonium acetate (80:20, v/v), flow rate of 0.4 ml/min	High selectivity, wide linear range, short run time (5.5 min per sample), low LOQ and small injection volume	Wen et al. (2008)
4	LC-MS/MS	Human plasma	Added to an internal standard working solution, vortexed and centrifuged, the supernatant loaded to the activated SPE solid phase cartridge, and then washed with water	Agilent ZORBAX SB C18 column (4.6 mm × 150 mm, 5 μm, 35°C), elution solvent: 0.2 mol L <sup>-1</sup> ammonium acetate aqueous solution/ methanol (30/70), flow rate of 400 μL/min	NA	Li et al. (2014)
5	UPLC-MS-MS	Human urine	Freeze-dried, added 10% perchloric acid and 1 ml ethyl acetate, centrifuged, and dried under nitrogen gas blower	UPLC BEH C18 column (2.1 × 100 mm, 1.7 μm), elution solvent: Gradient elution, Acetonitrile-0.5% acetic acid (42:58), flow rate of 0.35 ml/min	NA	Zeng et al. (2013)
6	UPLC-DAD-MS	Xue fu zhu yu (XFZY)	Pills and granules of XFZY ground to fine powder, separated by 50% methanol–water solution extraction. Liquids of XFZY, 1 ml was diluted to 50 ml by 50% methanol–water solution	ZORBAX SB-C18 column (4.6 mm × 100 mm, 1.8 μm): (50.0°C), mobile phase: 0.1% formic acid–water A and acetonitrile B, gradient program, flow rate of 0.5 ml/min	High-speed detection, excellent peak shapes, and less solvent usage	Zhang et al. (2012)
7	RP-HP LC-UV	Xuebiqing injection	XBJ injection of 1.0 ml was diluted to 10 ml with millipore water and filtered through 0.45 mm membrane filters	Zorbox SB C18 column, elution solvent: Gradient elution, water with 0.2% phosphoric acid A and acetonitrile B, flow rate of 1.0 ml/min	Better biocompatibility, larger specific surface area, good conduction effect and catalytic activity	Wang et al. (2016)
8	Novel multilayered porous silicon-based immunosensor	NA	Synthesized the polyclonal anti-HSYA antibody and HSYA artificial antigen by the immediate coupling method	NA	High surface area, easily preparation, label-free procedures and compatibility with standard microelectronics processing	Lv et al. (2011)

chloroform. So, the most general and traditional extraction method to get HSYA is water immersion. However, water immersion has the characteristic of low yield and high consumption of raw materials (e.g., the yield of 0.023%, 800 g of safflower; the yield of 0.066%, 2000 g of safflower) (Bai et al., 2012; Li et al., 2013a). Simultaneously, high temperature, alkaline conditions, and illumination all accelerate the degradation of HSYA in the traditional procedure.

As shown in **Table 1**, many other extraction systems were developed. Smashing tissue extraction holds an absolute advantage in time consumption compared with other extraction systems, with a yield of 1.359% in two minutes (Wang et al., 2012). MAS-I microwave extraction system with a solid and liquid ratio of 100 maintained at 70°C for 3 cycles in 20 min could obtain HSYA with higher yield of 6.96% (Yang et al., 2008). Hong et al. (2015) compared the effectiveness of MSPD, ultrasound extraction, and Soxhlet extraction methods. MSPD system obtained the highest yield at 14.89% compared with ultrasonic (12.25%) and Soxhlet extraction (13.09%), and also achieved the lowest consumption of raw materials.

Solvents also affect the extraction efficiency. Li et al. (2016) developed the DMSO extraction method as follows: Soak 2.0 g safflower with 14 volumes DMSO and stir for 30 min to remove impurities at room temperature in dark environment. Then soak the filter residue with 14 volumes of DMSO at 80°C for 1 h before heating for 50 min in the same environment. Soak the filter residue with another 12 volumes DMSO and repeat the steps above. Then add 3 volumes butyl acetate to the filtrate and centrifuge to obtain crimson precipitates. Finally, wash the precipitates with an appropriate amount of ethanol before drying to obtain light yellow powder with yield at 14.56%. DMSO is a “universal solvent” in areas of pharmaceutical sciences and cell biology, so it is inevitable to dissolve a lot of impurities during the extraction process, and the toxicity of DMSO is difficult to remove. Therefore, this method is not recommended to be extensively promoted.

## Detection Methods

Several detectors coupled with a liquid chromatography (LC) system have already been used for HSYA detection, including diode (DAD) (Qi et al., 2007), electrochemical (ECD), mass spectrometer (MS), and ultraviolet (UV). In addition, the novel multilayer porous silicon-based immunosensor has also been applied for HSYA detection. Detailed information is provided in **Table 2**.

MS is the most effective detector for qualitative analysis of HSYA with a high detection sensitivity, selectivity and low-interference. HSYA and its metabolites can be accurately identified, based on mass-to-charge ratio ( $m/z$ ) and fragmentation patterns.

The content of HSYA in human plasma was determined after oral administration of safflower. LC-MS/MS method with isocratic elution system composing of methanol and 5 mM ammonium acetate (80:20, v/v) was proved with a linear range of 1–1,000 ng/ml, a correlation coefficient  $\geq 0.999$  (Wen et al., 2008). Li et al. (2014) optimized the sensitivity and selectivity of this method to be more simplified and effective. The researchers replaced the Thermo synchronis C8 with Agilent ZORBAXSB C18,

added ammonium acetate to the mobile phase and increased concentration dilution ratio. The modified method reduced the injection volume, improved the response intensity and peak shape, and shortened the retention time.

UPLC-DAD-MS method had the advantages of fast detection speed, good peak shape and less solvent consumption. Twenty-eight compounds were identified only in 30 min, including HSYA from Xue Fu Zhu Yu decoction, a classic prescription of TCM (Zhang et al., 2012).

UPLC-TOF-MS is the most powerful tool with accurate activity measurement and full spectral sensitivity to determine HSYA using gradient elution with acetonitrile and 0.1% (v/v) formic acid aqueous solution in ESI<sup>+</sup>. This method showed good linearity ( $r^2 \geq 0.9992$ ) and precision (RSD  $\leq 3.4\%$ ) with the limits of detection (LOD) at 35.2 ng/ml (Hong et al., 2015). Jin et al. (2016b) successfully developed a UFLC-Q-TOF-MS method to detect HSYA and its multiple metabolites in the plasma, bile, urine and feces of SD rats after oral administration with HSYA using the mobile phase consisting of methanol and 0.5% acetic acid in water.

The analysis speed of UV detector for HSYA is very fast, but its sensitivity and selectivity are slightly weaker than that of MS system (Chen et al., 2010). Novel multilayer porous silicon-based immunosensor is an easy way to alter the etching current periodically, which fabricated of *p*Si photonic crystal. The linear relationship was ranging from 1 to 3 g/ml and detection limit at 0.78 ng/ml for HSYA detection (Lv et al., 2011).

## PHYSICOCHEMICAL PROPERTIES

### Physical Properties

HSYA, a C-glucosyl quinochalcone, is a yellow amorphous powder with a molecular formula of  $C_{27}H_{32}O_{16}$  (Meselhy et al., 1993). It is usually used as a dye owing to its attractive color. It shows maximum absorption at 403 nm due to *p*-conjugated system coupled with several hydroxyl groups (Ma et al., 2014). The C-glycoside bond, located between the 1,3-diketone on the ring A, is unstable in HSYA. The hydroxyl group located at the C-2 position in the glycoside is easily condensed with the adjacent enol due to the strain effect. The pyranose ring is opened, and then forms an oxyfuran [3,2 days] benzofuran ring by a cyclization reaction (Suzuki et al., 2017). HSYA is easily degraded by light, high temperature, and alkaline conditions. HSYA emits weak fluorescence at 450 nm in aqueous solution owing to the lack of rigid planar configuration in the molecular structure, and borax can significantly increase the HSYA fluorescence intensity by 20 times (Cao et al., 2020). Due to the existence of phenolic hydroxyl groups, HSYA exists in protonated form in natural or alkaline aqueous solutions, which seriously affects its transmembrane ability and leads to low bioavailability.

### Chemical Stability

#### Effect of pH

HSYA is easy to degrade under alkaline conditions. Pu et al. (2017) had illustrated the pH profile (1–14) of HSYA stability in

aqueous solution follows an inverted V curve, and it was most unstable at pH 9. When HSYA was transferred from the aqueous solution to the buffer solution at pH 9.16, the UV absorbance was red-shifted from 404 nm to 426 nm, with the gradually increased absorbance of degradation products at 300 and 380 nm, which indicated that the electron cloud density of the conjugate system increased after rapid ionization under alkaline conditions.

As shown in **Figure 3**, there were two degradation products proposed in HSYA aqueous solution. The hydroxyl group at C-2' was ionized under the moderate solution (pH 7–9). Intramolecular nucleophilic attacks C $\beta$  and add O $_2$  to the  $\alpha$ ,  $\beta$ -unsaturated double bond. The two products are isomers, which obtained after hydrogen migration. There were chalcone, flavones, and carbanion intermediates detected in HSYA acidic neutral and aqueous solution. However, only flavones were found under strong alkaline conditions (pH 13).

### Effect of Temperature

When HSYA was incubated in boiling water under dark conditions for 0, 0.5, 1, 2, and 4 h, the degradation rate of HSYA was increased gradually detected by HPLC system. The possible mechanism of HSYA degradation was that the colorless glycoside of HSYA bonded with H $_2$ O to form conjugate system, which reacted with the adjacent enol to transform the chromophore structure under the high temperature (Yue et al., 2003; Li et al., 2009). HSYA can be directly hydrolyzed and transformed into *p*-coumaric acid. And the hydroxyl group at the 2-position of C-glycoside of HSYA can be also condensed with the adjacent enol on A ring, and oxidized by O $_2$  at pH 8 under the high-temperature condition, then obtained the degradations (**Figure 4**). Due to the instability of the degradations as enols, a mixture of the two degradations were obtained (Fan et al., 2011).

### Effect of Light

HSYA degrades when exposed to light, so it is generally stored in dark conditions. When distilled water solution of HSYA was exposed under sunlight, ultraviolet, incandescent light, and the dark environment respectively, the content of HSYA decreased in turn analyzed by HPLC (Li et al., 2011). The content of HSYA in aqueous solution decreased when stored under natural light at room temperature for 20 days (Wang, 2017).

### Effect of Fe $^{3+}$ /Fe $^{2+}$

When HSYA was incubated with Fe $^{3+}$  (0.1  $\mu$ g/ml) or Fe $^{2+}$  (0.05  $\mu$ g/ml) at 60°C for 10 h, the multiple nucleophilic hydroxyl groups and carbonyl groups of HSYA combined with Fe $^{3+}$  and Fe $^{2+}$  to form chelate compounds, leading to accelerate degradation of HSYA. Ethylenediaminetetraacetic acid (EDTA) competes with Fe $^{3+}$  or Fe $^{2+}$  to reduce HSYA degradation (Wang, 2017).

## DRUG DELIVERY SYSTEM

A drug delivery system is responsible to control the release rate, extend the duration of drug action, and eliminate side effects, which can be divided into 4 types, including lipid-based carriers, polymer nanoparticles, inclusion complexes, and capsules. At present, the studies on the HSYA drug delivery systems mainly focuses on lipid-based carriers, which can improve the bioavailability by reducing the high-water solubility of HSYA. Moreover, microemulsions, self-emulsifying systems, and nanoparticles can also enhance the transmembrane capacity of HSYA. In this review, we also summarized other drug deliveries, such as chitosan, and the combination of HSYA with other drugs. A detailed description is provided in Ahmed and Aljaeid, 2016, **Figure 5**.

**FIGURE 3** | The pathway of HSYA degradation (Pu et al., 2017).

**FIGURE 4 |** Proposed degradation pathways of HSYA in the buffer solution at pH 8.0 at 100°C.

**FIGURE 5 |** Scheme of the pharmacokinetics of HSYA.

## Microemulsions

Microemulsions are stable liquid solution consisted of water, oil, surfactant, and co-surfactant, with the characteristic of isotropic and thermodynamics. They are transparent or translucent with small droplet size, typically up to 150 nm (Lopes et al., 2014; Lv et al., 2018). Microemulsions are used to increase the permeability of hydrophilic peptides by enhancing the fluidity of cell membranes and opening tight connections between cells, which is a potential tool for hydrophilic drug molecules. Qi et al. (2011) investigated the bioavailability of HSYA microemulsion by intraduodenally administration. The microemulsion of HSYA was prepared by mixing Cremophor RH40 (surfactant), ethanol

(cosurfactant), and PG (oil phase) together. Compared with HSYA aqueous solution, the bioavailability of HSYA microemulsion was increased by almost 1937%. It is worth noting that bile has a significant effect on the absorptive capacity of microemulsions. The microemulsion showed lower enhanced bioavailability of only 181% in bile duct-ligated rats. Microemulsion digested by pancreatic lipase increased 5.56 times permeability than the diluted microemulsion. The lipids and surfactants in the HSYA microemulsion might increase the fluidity of cell membranes and open the tight junctions between cells, thereby improving the permeability of hydrophilic drug molecules.

Self-emulsifying drug delivery system (SDEDDS) is a kind of the microemulsions. It could rapidly and spontaneously form a microemulsion in the gastrointestinal tract, where the peristalsis of the gastrointestinal tract and small intestine provides the necessary agitation for emulsification. SDEDDS have multiple advantages, including 100% drug entrapment capacity, physically stable formulations, no dissolution required, and submicron droplet sizes (Ghasemiyeh and Mohammadi, 2018). SDEDDS of HSYA were synthesized by inner water phase of 0.5% gelatin solution, and the external oil phase of bean phospholipids, medium chain triglycerides, Tween 80, oleic acid, and labrasol (20/65/7.4/2.5/0.1, in wt%). The study demonstrated that SDEDDS significantly improved the permeability of HSYA through Caco-2 cells monolayers, and plasma concentration increased by 2.17 times. The apparent permeability coefficient (Papp) of HSYA and HSYA-SDEDDS were  $(3.52 \pm 1.41) \times 10^{-6}$  cm/s and  $(6.62 \pm 2.61) \times 10^{-6}$  cm/s at the same concentrate (0.4 mg/ml), which improved to 1.88-fold by SDEDDS (Lv et al., 2012).

Labrafac lipophilic WL1349 (WL1349) is a medium-chain triglyceride that can be digested, absorbed, and hydrolyzed by pancreatic lipase after being emulsified by an endogenous emulsifier (such as bile). Preparation of HSYA-phospholipid complex increased lipophilicity, and dissolved in WL1349 to form a stable oil solution (a lipid-based preparation). Compared with HSYA aqueous solution, the oral bioavailability of HSYA-phospholipid complex WL 1349 oil solution in rats increased by about 37 times (Cmax of

2.79  $\mu$ g/ml vs. 0.08  $\mu$ g/ml within 24 h) and reduced the excretion of the drugs ( $8.80 \pm 2.30\%$  vs.  $44.66 \pm 8.00\%$  in feces within 24 h) (Wang et al., 2008; Li et al., 2010a).

## Nanoparticles

Solid lipid nanoparticles (SLN) is the earliest lipid-based nanocarriers formulated from lipids with a submicron size less than 1,000 nm, which are solid at body temperature and stabilized by emulsifiers (Koga et al., 2010). They can protect drugs against harsh environmental and are easy to mass-produce. However, owing to the crystalline structure existed in SLN, the drug-loading efficiency is poor. Some of the main lipids that have been used so far are monostearic acid, stearyl alcohol, stearic acid, glyceryl monostearate, cetyl palmitate, poloxamer 188, Tween 80, and dimethyl octadecyl ammonium bromide (DDAB) (Lee et al., 2016; Tapeinos et al., 2017; Ghasemiyeh and Mohammadi, 2018). As reported by Zhao et al. (2017), 1% Tween 80 was used as an emulsifier. HSYA-SLN with w/o/w structure prepared by micro emulsification procedure significantly improved oral bioavailability. HSYA SLNs is spherical with an average diameter of  $174 \pm 20$  nm, zeta potential of  $-12.4 \pm 1.2$  mV, and the encapsulation efficiency is 55%. The SLNs of HSYA were stable within ten days at 4 or 30°C. SLNs of HSYA increased the oral bioavailability of HSYA in rats about 3.97-fold. It also significantly enhanced the  $C_{max}$  and AUC by 7.76 and 3.99 folds. The pharmacodynamic evaluation showed that HSYA-SLNs had a better therapeutic effect on the cerebral ischemia rats compared to HSYA aqueous solutions (Zhao et al., 2018).

**FIGURE 6 |** Proposed metabolic pathways of HSYA (Jin et al., 2016; Wu et al., 2018).

## Others Delivery System

The combination of *Ligusticum* chuanxiong volatile oil (CVO) and HSYA also improved the bioavailability in rats. When HSYA co-administered with CVO of 0.02 mg/ml, the bioavailability of HSYA in rats was increased by 6.48 folds. The emulsification of CVO increased Papp of HSYA and the paracellular transport by opening the integral tight junction of Caco-2 cells.

Chitosan, a kind of biological polysaccharide, is a molecule usually obtained by deacetylation of chitin with the carbohydrate backbone structure similar to cellulose, which is composed of two kinds of repeating units, N-acetyl-D-glucosamine and D-glucosamine, combined with (1–4)- $\beta$ -glucoside linkage. It is characterized by the presence of a lot of amino groups on the chain (Ahmed and Aljaeid, 2016; Hong et al., 2017). HSYA-Chitosan complex effectively improved the oral absorption of HSYA, and the bioavailability increased to 476% (Ma et al., 2015).

Drug delivery system has great potential to improve the bioavailability and chemical instability of HSYA. However, there are also some several challenges, such as high preparation cost and poor promotional effect, which need further improvement.

## PHARMACOKINETICS

HSYA is one of the representative chemical compounds of biopharmaceutics classification system (BCS) class III drugs.

Pharmacokinetic studies showed that HSYA had low bioavailability. The oral bioavailability of HSYA is only 1.2%, and 48% of the prototype drug is excreted in urine, 2.9% in feces, and only  $0.062\% \pm 0.011\%$  in bile (Zhang, 2006). Similarly, 88.6% was directly excreted through urine after intravenous administration (Sun et al., 2009) (Ahmed and Aljaeid 2016, **Figure 6**).

Caco-2 cell monolayer model was usually used to study the transmembrane characteristic of HSYA, and the result prompted that the absorption of HSYA is basically in line with the passive diffusion. P-gp inhibitors (verapamil) and energy metabolism inhibitors (sodium azide) failed to block the intake of HSYA, which demonstrated that the absorption of HSYA is irrelevant to the P-gp protein (Zhou et al., 2014). However, this conclusion needed more evidence to verify owing to the opposite result in another study (Wang et al., 2009). The peak concentration of HSYA generally appeared at 10 min after oral administration (Li et al., 2007). A study has shown that healthy volunteers received intravenous injections of 35, 70, and 140 mg of HSYA, the elimination half-life values ( $t_{1/2}$ ) of HSYA was 3.32 h, and the  $C_{max}$  was  $(2.02 \pm 0.18)$ ,  $(7.47 \pm 0.67)$ ,  $(14.48 \pm 4.70) \text{ mg L}^{-1}$ , respectively, (Qiao et al., 2009). HSYA has a low plasma protein binding rate (48%–54.6%, 72 h, *i. v.*), and it has no competitive binding to other drugs. So, HSYA is highly safe *in vivo* (Chu et al., 2006). Yang et al. (2009) suggested that the therapeutic effect of the single-dose HSYA indicated proportional to the dose ranging from 35 to 140 mg/kg, which conformed to first-order kinetics in

TABLE 3 | Pharmacological effects of HSYA.

Pharmacological effects	Species	Study model	Detail	Effective concentration/dose/pattern	Remark	References
Cardioprotective effects	<i>In vivo</i> : SD rats	LAD of the coronary artery ligation	Reduce the myocardial infarct size (MIS), decrease CK-MB, MDA, increase eNOS, SOD, NO	HSYA + NTG (10 mg/kg+0.3 mg/kg)	HSYA combined with NTG	Wang et al. (2017)
	<i>In vivo</i> : SD rats <i>In vitro</i> : H9c2 cells	<i>In vivo</i> : isoproterenol-induced myocardial injury <i>In vitro</i> : Oxygen-glucose deprivation (OGD) model	Reduce the levels of CK-MB, ROS, LDH, inhibit apoptosis, increase PGC-1 $\alpha$ and NF2	<i>In vivo</i> : HSYA + AKBA (50 mg/kg+50 mg/kg) via intragastric tubes. <i>In vitro</i> : HSYA + AKBA (5 $\mu$ M + 5 $\mu$ M)	HSYA and AKBA	Chen et al. (2016)
	<i>In vitro</i> : Cells from SD rats	Hypoxia/Reoxygenation (H/R)	Enter the cardiac myocyte and able to modulate H/R-induced damage by interacting with the MPTP	200 $\mu$ M	NA	Huber et al. (2018)
	<i>In vivo</i> : SD rats	Ischemia-reperfusion (I/R) Langendorff apparatus model	Inhibit MPTP opening, enhance nitric oxide production	0.05, 0.1 mmol/L	NA	Liu et al. (2008)
	<i>In vivo</i> : Wistar rats, TLR4-knockout C57 mice <i>In vitro</i> : NPMs cells	<i>In vivo</i> : Hyperlipidemia combined with M/R model. <i>In vitro</i> : LPS injured	Alleviate myocardial inflammatory injury, decrease MIS, CK-MB, LDH, LPS, TNF- $\alpha$ and IL-1 $\beta$ ability	Wistar rats: 8, 16, 32 mg/kg, TLR4-knockout mice: 16, 32, 64 mg/kg	NA	Han et al. (2016)
	<i>In vivo</i> : SD rats. <i>In vitro</i> : H9c2 cells	<i>In vivo</i> : LAD of the coronary artery ligation. <i>In vitro</i> : H/R model	Decrease apoptosis, improve antioxidant capacity, decrease the release of cTnI, IL-6, LDH, and JAK2/STAT1 activity, maintain MMP, decrease ROS generation	<i>In vivo</i> : 5 mg/kg ( <i>p.i.</i> ), <i>In vitro</i> : 20 $\mu$ M	NA	Zhou et al. (2019)
	<i>In vitro</i> : BV2 cells	OGD model	Decrease 1L-1 $\beta$ , TNF- $\alpha$ , iNOS, COX-2, MCP-1 ability, inhibit NF- $\kappa$ B ability, phosphorylation of p38	20, 40, 80, 160, 320, 640, and 1,280 $\mu$ M	NA	Li et al. (2013)
	<i>In vivo</i> : Male C57 mice. <i>In vitro</i> : HUVECs cells	<i>In vivo</i> : LAD of the coronary artery ligation	Improve ischemia-induced cardiac hemodynamics, enhance the survival rate, alleviate the myocardial injury, increase the level of CD31, VEGF-A and nucleolin	25 mg/kg ( <i>p.i.</i> ) twice a day for 2 weeks	NA	Zou et al. (2018)
	<i>In vivo</i> : SD rats. <i>In vitro</i> : H9c2 cells	<i>In vivo</i> : LAD of the coronary artery ligation. <i>In vitro</i> : H/R injury	Reduce CK-MB, cTnI, MDA and 8-OHdG, enhance SOD, NF2 and HO-1	1, 10, 35, 60, and 80 $\mu$ M DSS + HSYA	Daneshmandi (DSS) and HSYA	Hu et al. (2016)
	<i>In vitro</i> : H9c2 cells	<i>In vitro</i> : H/R injury	Improve cardiomyocyte viability, maintain mitochondrial membrane potential, reduce apoptotic cardiomyocytes, decrease caspase-3 activity, and inhibit NOD-like receptor 3 (NLRP3) inflammasome activation through the AMPK signaling pathway	12.5 $\mu$ M for 4 h	NA	Ye et al. (2020)
Neuroprotective effect	<i>In vivo</i> : SD rats	<i>In vivo</i> : LAD of the coronary artery ligation	Reduce MIS, inhibit CK-MB and MDA content, increase SOD, eNOS and NO	2, 4, or 8 mg/kg via the tail vein injection	NA	Tu et al. (2009)
	<i>In vivo</i> : Male C57BL/6 mice	<i>In vivo</i> : MCAO model. <i>In vitro</i> : OGD/R model	Reduce ROS, suppress cellular apoptosis, promote mitochondrial function and biogenesis	<i>In vivo</i> : 5, 20 mg/kg for 3 days. <i>In vitro</i> : 1, 10 $\mu$ M	NA	Chen et al. (2019)
	<i>In vivo</i> : Wistar rats. <i>In vitro</i> : PC12 cells	MCAO/R model	Attenuate pressure overloaded hypertrophy, inhibit platelet aggregation, NF- $\kappa$ B/p65 nuclear translocation, p65 binding activity, ICAM-1 and the infiltration of neutrophils	8, 4, 2 mg/kg ( <i>i.v.</i> )	NA	Sun et al. (2010)
	<i>In vivo</i> : SD rats	MCAO model	Protect cognitive function and synaptic plasticity, promote learning and memory ability	8, 16 mg/kg via common carotid artery (CCA) injection	NA	Yu et al. (2020)
	<i>In vivo</i> : Wistar rats	MCAO model	Decrease neurological deficit scores, reduce the percentage of infarction, attenuate MDA content, increase SOD and the T-AOC activity	2, 4, 8 mg/kg ( <i>i.v.</i> )	NA	Wei et al. (2005)
	<i>In vivo</i> : C57BL/6J mice	MCAO model	Inhibit TLR4, NF- $\kappa$ B, p-p65 expression, ERE/2, JNK and p38 phosphorylation, suppressed TNF- $\alpha$ , IL-1 $\beta$ , NO	2 mg/kg via the tail vein injection	NA	Ly et al. (2015)
	<i>In vivo</i> : SD rats	MCAO/R model	Increase GFAP, NGF and Bcl-2 expression, suppress the expression of bax, caspase-3 and ICAM-1, IL-1 $\beta$ , TNF- $\alpha$ and NF- $\kappa$ B	10 mg/kg HSYA+300 mg/kg acetylglutamine (NAG) once each day for 7 days	HSYA and NAG	Deng et al. (2018)
	<i>In vivo</i> : SD rats. <i>In vitro</i> : Cortical neurons cells	<i>In vivo</i> : MCAO model. <i>In vitro</i> : OGD model	Decrease LDH, TNF- $\alpha$ , IL-1 $\beta$ and IL-6, increase SOD, MDA, GSH-Px, suppress TLR4 and NF- $\kappa$ B expression, enhance NF2 and HO-1 expression	<i>In vivo</i> : 7.5 mg/kg+3 mg/kg (DSS + HSYA). <i>In vitro</i> : 40 $\mu$ M + 40 $\mu$ M (DSS + HSYA)	HSYA and DSS	Xu et al. (2018)
	<i>In vivo</i> : Male C57BL/6 mice	NA	Prevent the appearance of motor abnormalities, attenuate the reduction of dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) in striatum	2, 6 mg/kg for five days ( <i>i.v.</i> )	NA	Han and Zhao (2010)
	<i>In vivo</i> : C57BL/6 mice	Rotenone-induced PD model	Increase the expression BDNF, p-TKBT/KB, DRD3, p-Pi3K/Pi3K, p-AKT/AKT, improve motor dysfunction	20 mg/kg for 28 days	NA	Wang et al. (2017)
	<i>In vivo</i> : SD rats	Unilateral 6-OHDA lesion (PD model)	Increase the levels of dopamine and its metabolites, glial cell line-derived neurotrophic factor and brain-derived neurotrophic factor	2 or 8 mg/kg via caudal vent injection for 4 weeks	NA	Han et al. (2016)
	<i>In vivo</i> : SD rats	Hcy-induced AD model	Attenuate ab accumulation, improve synaptic function, and reversed hcy-induced cognitive impairment	6 mg/kg ( <i>i.v.</i> ) for 2 weeks	NA	Lu et al. (2013)

(Continued on following page)

TABLE 3 | (Continued) Pharmacological effects of HSYA.

Pharmacological effects	Species	Study model	Detail	Effective concentration/dose/pattern	Remark	References
Anticancer effect	<i>In vivo</i> : Wistar Kyoto (WKY) rats <i>In vivo</i> : SD rats	MCAO model MCAO model	Increase the ratio of 6-keto-PGF1 $\alpha$ and TXB2 inhibit protein oxidation and nitration, 12/15 lipoygenase (12/15-LOX), oxidative stress, attenuate BBB breakdown, infarct volume, BBB permeability, and brain edema	1.5, 3.0, 6.0 mg/kg via sublingual vein injection 1, 5 and 10 mg/kg via caudal vein injection	NA NA	Zhu et al. (2015) Sun et al. (2012)
	<i>In vivo</i> : Wistar rats	Cervical lymphatic blockade model	Alleviate the neurological deficits, attenuated cell apoptosis, prevent the decrease of eNOS mRNA and protein expression	5 mg/kg (i.p.)	NA	Pan et al. (2012)
	<i>In vivo</i> : SD rats	Isolate brain mitochondria of SD rat	Inhibit Ca <sup>2+</sup> - and H <sub>2</sub> O <sub>2</sub> -induced swelling of mitochondria, improve mitochondrial energy metabolism, enhance ATP levels and the respiratory control ratio	10–80 $\mu$ mol/L	NA	Tian et al. (2008)
	<i>In vivo</i> : SD rats	Vascular dementia (VaD) model	Reduce escape latency in the water maze, enhance the LTP at CA3-CA1 synapses, up-regulated both VEGF and NRI, promote angiogenesis and increase synaptic plasticity, improve spatial learning and memory	0.6 mg/100 g via tail-vein injection for two weeks	NA	Zhang et al. (2014)
	<i>In vivo</i> : SD rats	Traumatic brain injury	Increase superoxide dismutase activity, decrease MDA content, enhance the t-PA activity, decrease the PAI-1 activity, decrease the MMP-9 expression	4 mg/kg (i.v.)	NA	Bie et al. (2010)
	<i>In vivo</i> : SD rats and balb/c male mice cell line	PC12 <i>In vivo</i> : MCAO model. <i>In vivo</i> : H <sub>2</sub> O <sub>2</sub>	Reduce the volume of cerebral infarction, improve the histopathological morphology, recruit brain-derived neurotrophic factors, down-regulate NLRP3, ASC, Caspase-1, GSDMD, IL-1 $\beta$ , IL-18, LDH, NF- $\kappa$ B, and p-p55 expression	<i>In vivo</i> : 5, 10 and 20 mg/kg (i.v.) NA	HSYA with lexscan	Tan et al. (2020)
	<i>In vivo</i> : Pregnant C57BL/6 mice	LPS-induced neurotoxicity and neuroinflammation	Decrease the content of IL-1 $\beta$ , TNF- $\alpha$ and NO, attenuate the LPS-induced dopaminergic neurons damage, inhibit the expressions of NF- $\kappa$ B, p65 and iNOS, decrease the content of IL-1 $\beta$ , TNF- $\alpha$ and NO	0, 20, 40, 80, 160, 320, 640 $\mu$ M	NA	Wang et al. (2018)
	<i>In vivo</i> : C57BL/6 mice. <i>In vitro</i> : SH-SY5Y cells	<i>In vivo</i> : PD model ( <i>6</i> -hydroxydopamine)	Reduce iNOS, COX-2 and NF- $\kappa$ B, attenuate neuronal apoptosis, reduce the levels of p-p38 and p-JNK and increase that of p-ERK	<i>In vivo</i> : 2, 4, or 8 mg/kg (i.v.), <i>In vitro</i> : 1.5, or 10 $\times$ 10 <sup>-6</sup> mol/L	NA	Yang et al. (2020a)
	<i>In vivo</i> : Wistar rats. <i>In vitro</i> : Primary neuronal cells	<i>In vivo</i> : MCAO model. <i>In vitro</i> : OGD model	Reduce infarct volume, decrease neurological deficit scores, elevate GSK3 $\beta$ phosphorylation and inhibit the activation of iNOS, NF- $\kappa$ B, and caspase-3	<i>In vivo</i> : 2, 4, or 8 mg/kg (i.v.)	NA	Yang et al. (2020b)
	<i>In vitro</i> : Human brain microvascular endothelial cells (HBMEC)	Methylglyoxal (MGO)-induced injury	Inhibit MGO-induced cell apoptosis, attenuate AGEs accumulation	10–100 $\mu$ mol/L	NA	Li et al. (2013)
	<i>In vivo</i> : SD rats	MCAO/R model	Promote neurological and functional recovery, suppress JAK2/STAT3 activation, activate of SOCS3	4, 8 or 16 mg/kg injected via the unilateral common carotid artery of rat	NA	Yu et al., 2020
	<i>In vivo</i> : SD rats	A rat model of vascular dementia	Reduce escape latency in the water maze, promote angiogenesis and increase synaptic plasticity, improve spatial learning and memory, increase VEGF-A expression, protect neurons against hypoxia, increase NR1 expression, promote LTP and increase synaptic plasticity	0.6 mg/100 g for two weeks via tail-vein injection	NA	Zhang et al., 2014
	<i>In vivo</i> : BALB/c mice. <i>In vitro</i> : Hepa1-6 murine HCC cells	A mouse model of hepatocellular carcinoma	Inhibit the proliferation of liver cancer cells, reduce the extent of tissue damage induced by cisplatin, increase the thymus index of HCC model mice, reduce the expression of Foxp3 and rory mRNA, improve the tumor immune microenvironment of HCC model mice	2.25, 1.13 and 0.57 mg/kg twice per day (i.v.) for 11 days	NA	Ma et al., 2019a
	<i>In vitro</i> : Human umbilical vein endothelial cell (HUVEC) <i>In vitro</i> : Skov3 cells	High-glucose induced HUVEC injury	Attenuate cells apoptosis, decrease hyperpermeability, inhibit ROS levels	0–50 $\mu$ M	NA	Chen et al. (2019)
	<i>In vitro</i> : KYSE-30 cells	NA	Decrease ovarian cancer cell proliferation, decrease ovarian cancer cell viability and sensitizes cells to chemotherapeutic agents, downregulate WSB1 expression	0, 10, 20, 50, 100, and 150 mg/L for 72 h	NA	Ma et al., 2019b
(Continued on following page)	<i>In vitro</i> : KYSE-30 cells	NA	Suppress proliferation, invasion, and migration, simultaneously induce apoptosis, regulate NF- $\kappa$ B signaling pathway, ICAM1, MMP9, TNF- $\alpha$ , and VCAM1	0.1, 1, 10, 20, 50 $\mu$ M	NA	Chen et al. (2020)
	<i>In vivo</i> : Kunming mice. <i>In vitro</i> : HepG2 cells	H22 liver cancer cells injected into the abdominal cavity of Kunming mice	Suppress p38MAPK phosphorylation, decrease HepG2 cell viability, proliferation, and migration, inhibit apoptosis of HepG2 cells	<i>In vivo</i> : 1.125 mg/kg, 2.25 mg/kg for 14 days (i.v.), <i>In</i> <i>vitro</i> : 80 $\mu$ M	NA	Zhang et al., 2019

TABLE 3 | (Continued) Pharmacological effects of HSYA.

Pharmacological effects	Species	Study model	Detail	Effective concentration/dose/pattern	Remark	References
Immunoprotection	<i>In vivo</i> : C57BL/6	Bleomycin-induced mice lung injury model	Attenuate the loss in body weight, alleviate bleomycin-induced increase of mRNA level of TNF- $\alpha$ , IL-1 $\beta$ and TGF- $\beta$ 1 in lung homogenates, inhibited NF- $\kappa$ B and phosphorylation of p38 MAPK in lung tissue	28, 7, 40, 60 mg/kg/d ( <i>i.v</i> ) for 1 week	NA	Wu et al., 2012
	<i>In vivo</i> : C57BL/6 mice	LPS-induced acute respiratory distress syndrome	Alleviate expressions of TNF- $\alpha$ , IL-1 $\beta$ , IL-6, TGF- $\beta$ 1, Ccl-1, ccl11, $\alpha$ -SMA, MD-2, TLR and CD14, inhibit the elevated levels of NF- $\kappa$ B and $\alpha$ -SMA, alleviated the slight collagen deposition in pulmonary tissues, attenuated increased levels of p65	14, 28, 56 mg/kg/d for 10 days ( <i>i.v</i> )	NA	Zhang et al., 2017
	<i>In vivo</i> : Hep-G2 liver cancer cell line	NA	Increase LC3-II and beclin 1 expression, decrease the level of p62 and phosphorylated-ERK1/2	20 mg HSYA solved in 1.02 ml PBS	NA	Liu et al., (2020)
	<i>In vivo</i> : ICR mice	LPS-induced acute lung injury (ALI)	Attenuate lung vascular permeability and edema, down-regulate myeloperoxidase (MPO), inhibited p38, ERK, JNK, TRF4, MyD88 and TRIF and the phosphorylations of Interferon regulatory factor 3 (IRF3)	40, 80, and 120 mg/kg ( <i>i.p.</i> )	NA	Liu et al., 2014
	<i>In vivo</i> : Specific-pathogen-free mature male hartley Guinea pigs	Ovalbumin (OVA)-induced asthma in Guinea pigs	Reduce airway resistance, improve dynamic lung compliance, attenuate the pathologic changes, inhibit the phosphorylation of JNK, p38, ERK, and IkBa, and inhibited IgE, PAF, IL-1b, IL-6, IL-4, IL-5, and IL-13 and increase in TNF- $\alpha$ , IFN- $\gamma$ , IL-2, and IL-3	50, 75, 112.5 mg/kg once daily from days 2-22 ( <i>i.v</i> )	NA	Zheng et al., 2019
	<i>In vitro</i> : Human non-small cell lung cancer cell line (A549)	LPS-mediated inflammatory injury	Suppress the expression of TLR-4, Myd88, ICAM-1, TNF- $\alpha$ , IL-1 $\beta$ and IL-6, inhibit the adhesion of leukocytes, decrease NF- $\kappa$ B p65 nuclear translocation, inhibit the phosphorylation of p38 MAPK	1, 4 and 16 $\mu$ mol/L	NA	Han and Zhao (2010)
	<i>In vitro</i> : A549 and H1299	LPS-mediated inflame matory injury	Suppress proliferation, migration, invasion, and EMT, inhibit the PI3K/Akt/mTOR and ERK/MAPK signaling pathways	5, 10, and 20 $\mu$ M for two weeks	NA	Jiang et al. (2019)
	<i>In vitro</i> : Human bronchial smooth muscle cells (HBSMCs)	NA	Suppress MLC phosphorylation, inhibit the activation, block asthma-related signal transduction pathways, block the binding of PAF to the PAFR on the target cell membrane	9, 27, 81 $\mu$ mol/L	NA	Guo et al. (2019)
	<i>In vitro</i> : Early626 human endothelium cell	LPS-induced endothelium inflammatory injury	Attenuate ICAM-1 and E-selectin mRNA levels elevation, phosphorylation of p38 MAPK, Jun MAPK, inhibit leukocyte adhesion to EC	1, 10 and 100 $\mu$ mol/L	NA	Jin et al. (2016)
	<i>In vitro</i> : Human small airway epithelial cells (HSAECs)	PAF-induced activation of HSAECs	Inhibit PAF-induced inflammatory activation, inhibit the PKC and MAPK signaling pathways, suppress the activities of NF- $\kappa$ B and AP1	9, 27, and 81 $\mu$ mol/L	NA	Guo et al., 2018
	<i>In vivo</i> : Male NIH mice	Cecal ligation and puncture mouse model of sepsis	Improve sepsis induced immunosuppression via inhibiting CD4 $^{+}$ lymphocytes apoptosis under septic conditions, upregulate the expression of Bcl-2 protein, inhibit protein expression of clyc, bax, cleaved caspase-3, and cleaved caspase-9	120 mg/kg ( <i>i. v</i> )	NA	Wang et al., 2017
	<i>In vitro</i> : Mouse 3T3-L1 preadipocytes	NA	Inhibit the proliferation and adipogenesis of 3T3-L1 preadipocytes, increase hormone-sensitive lipase (HSL) mRNA expression and promoter activities, increase HSL promoter activity	1 mg/L	NA	Zhu et al., 2015
Vascular dementia	<i>In vivo</i> : Wistar rats	PE (phenylephrine)-induced vascular constriction	Possess vascular relaxation effects, activate the KV channel in pulmonary vascular smooth muscle cells	10 $^{-9}$ M, 10 $^{-8}$ M, 10 $^{-7}$ M, 10 $^{-6}$ M, 10 $^{-5}$ M	NA	Bai et al., 2012
	<i>In vivo</i> : C57BL/6J mice, <i>in vitro</i> : HUVEC cells	Mouse hindlimb ischemia model	Increase the capillary-like tube formation and migration of HUVEC, increase phosphorylation of Tie-2, akt, and extracellular signal-regulated kinase 1/2, promote reperfusion of ischemic hindlimb tissue	<i>In vivo</i> : 6 mg/kg for 11 days via the tail vein, <i>in vitro</i> : 0, 1, 10, 50, and 100 $\mu$ M for 24 h	NA	Chen et al. (2016)
	<i>In vivo</i> : Wistar-Kyoto (WKY) rats and spontaneously hypertensive rats (SHR), <i>in vitro</i> : HEK293cells	NA	Activate BKCa channels, inhibit Ca $^{2+}$ channels, reduce intracellular free Ca $^{2+}$ level	<i>In vivo</i> : 1, 10 mg/kg, <i>in vitro</i> : 50 $\mu$ M, 100 $\mu$ M, 150 $\mu$ M	NA	Wang et al. (2020)
	<i>In vivo</i> : Wistar rats, <i>in vitro</i> : Rat mesenteric endothelial cells (primary)	NA	Decrease TRPV4-dependent influx of Ca $^{2+}$ in endothelium cells, promote PKA-dependent eNOS phosphorylation and increase NO production mechanism	<i>In vitro</i> : 10 $^{-7}$ , 10 $^{-6}$ , 10 $^{-5}$ , 10 $^{-4}$ M	NA	Yang et al. (2020)
	<i>In vitro</i> : HUVEC cells	NA	Inhibit the expression of VEGF and KDR, reduce Ras, p-raf, p-ERK and p-p38MARK, inhibit the expression of c-myc, N-ras, and NF- $\kappa$ B	NA	NA	Wang et al. (2016)

(Continued on following page)

TABLE 3 | (Continued) Pharmacological effects of HSYA

Pharmacological effects	Species	Study model	Detail	Effective concentration/dose/pattern	Remark	References
Hepatoprotective effects	<i>In vivo</i> : C57BL/6 mice	D-galactose- D-gal.) induced aging	Increase SOD, CAT, GSH-Px and MDA, decreased the mRNA and protein level of cyclin-dependent kinase inhibitor p16, increase CDK4/6 protein expression and decrease the phosphorylation of retinoblastoma (pRb)	25 mg/kg HSYA daily (i.v.) for 8 weeks	NA	Min et al. (2020)
Pulmonary arterial hypertension	<i>In vivo</i> : male wistar rats	A model of monocrotaline (MCT)-induced pulmonary arterial hypertension (PAH)	Reduce hemodynamic changes, right ventricular hypertrophy and morphometric changes; suppressed inflammation and oxidative stress	10 mg/kg (i.p.)	NA	Han et al. (2016)
Obesity	<i>In vivo</i> : C57BL/6J mice; <i>In vitro</i> : HepG2 cells and 3T3-L1 adipocytes	<i>In vivo</i> : diet-induced obese (DIO) mice; <i>In vitro</i> : H <sub>2</sub> O <sub>2</sub> -induced oxidative stress	Increase the expression of Nrf2, GCLC and CAT; improve glucose metabolism and liver function; decrease body weight gain	<i>In vivo</i> : 200 mg/kg/d for 10 weeks (i.v. <i>In vitro</i> : 10, 50, and 100 mg/L	NA	Yan et al. (2020)
Skin photoprotective effect	<i>In vivo</i> : female KM mice	Photodamaged mouse model	Prevent UV-induced macroscopic skin lesions, promote the ability of the skin to regain its initial shape, elevated the activities of skin anti-oxidant enzymes, increased skin collagen content, maintained the structural integrity of the skin	50, 100, and 200 l g/mouse following each UV exposure	NA	Kong et al. (2013)
Anti-anaphylactoid activity	<i>In vivo</i> : C57BL/6 mice; <i>In vitro</i> : Laboratory of allergic disease 2 (LAD2) human mast cells and mouse peritoneal mast cells	a mouse model of hindpaw extravasation	Attenuate calcium flux, decrease degranulation, attenuated degranulation triggered by endogenous and exogenous substances, decrease the activation of the ploy-pkc-IP3 signaling pathway regulating calcium fluctuations	<i>In vivo</i> : 0, 2.5 mg/kg, 5 mg/kg, 10 mg/kg (i.v.). <i>In vitro</i> : 0, 50 μM, 100 μM, 200 μM, NA	NA	Liu et al. (2014)
Inhibition of hepatic fibrosis	<i>In vivo</i> : SD rats	CCl <sub>4</sub> -caused fibrogenesis	Decrease in fibrosis, protein expression of α-SMA and MEF-2C gene expression, decreased expression of Tβ-R1, Tβ-RII, MEK3, MEK5, and phosphorylation of ERK5	5 mg/kg/d for 12 weeks	NA	Zhang et al. (2012)
Type 1 diabetes	<i>In vivo</i> : SD rats; <i>In vitro</i> : Human epithelial and keratinocytes (HEKs)	<i>In vivo</i> : Type 1 diabetes mellitus (T1DM) model	Accelerate diabetic wound healing through promoting angiogenesis and reducing inflammatory response, enhance angiogenesis by upregulation of hypoxia inducible factor-1 alpha (HIF-1α) expression	2/0.4 mg/ml of HSYA/DFO hydrogel solution for five weeks	Deferoxamine (DFO) and HSYA	Gao et al. (2018)
Type 2 diabetes mellitus	<i>In vivo</i> : Wistar rats	<i>In vivo</i> : HFD feeding-induced T2DM model	Reduce fasting blood glucose and insulin resistance, up-regulate of PI3K and AKT, inhibit the apoptosis	120 mg/kg (i.v.)	NA	Lee et al. (2020)
Polycystic ovary syndrome (PCOS)	<i>In vivo</i> : ICR female mice	<i>In vivo</i> : Dihydroepiandrosterone-induced PCOS model	Elevate serum E2, P4, LH and AMH levels, reduce FSH, Level, reverse the expression of steroid hormone secretion-related genes Star, hsd3b1, cyp11a1 and cyp19a1, improve GSH content, enhance the activities of antioxidant enzymes SOD, GSH-Px and CAT	3.5 mg/kg (i. p.)	HSYA and ginsenoside Rb1	Luo et al. (2020)

healthy Chinese female volunteer. The  $t_{1/2}$  corresponded to the median of the range from 2.23 to 4.63 h (the average value of 3.17 h) at each dose. But this research had some potential limitations, such as a low-volume sample and only female volunteers, which lack of universality. Moreover, the combination therapy of HSYA and protocatechuic aldehyde greatly promoted the intake of HSYA (Ao et al., 2018).

HSYA is reduced and hydrolyzed, such as hydroxylation, hydroxylation and methylation, dehydration, hydrogenation and hydration, to obtain phase I metabolites under the action of hepatic microsomal drug-metabolizing enzyme in the liver. Phase II metabolism included acetylation and glucuronidation, dehydration, hydrogenation, hydration, hydroxylation with glucuronidation, deglycosylation, methylation and glucuronic acid conjugation reactions (Jin et al., 2016b; Wu et al., 2018). The possible metabolic pathways were summarized in Ahmed and Aljaeid, 2016, **Figure 7**. HSYA and its metabolites are distributed in the heart, liver, spleen, lung, kidney, brain and intestines. In addition, it is almost impossible to cross the healthy blood-brain-barrier (BBB), but easily to penetrate damaged BBB (Sheng et al., 2019).

The low bioavailability of HSYA directly blocks its therapeutic efficiency. It is difficult for HSYA to pass through phospholipid bilayer because of its strong polarity and poor membrane permeability, which is also an important reason for its low bioavailability. Therefore, the design of HSYA delivery systems mainly focused on improving its lipsolubility. Despite, HSYA exists as an undivided molecule in the strong acid environment of the stomach, it cannot be absorbed by the stomach due to its high molecular weight and strong hydrophilicity (Zhang, 2006). Besides, the small intestine actually is the main absorption site of HSYA. However, gastrointestinal metabolism in a weak

alkaline environment is not conducive to the absorption of HSYA, on the contrary, it promotes degradation (Wu et al., 2018).

## PHARMACOLOGICAL EFFECTS AND MOLECULAR MECHANISM

HSYA shows excellent therapeutic effects on various diseases, such as cardiovascular and cerebrovascular diseases, cancer, and so on. This part provided the biological activity of HSYA in detail (**Table 3**, **Figure 8**).

### Cardioprotective Effects

HSYA has been proved to be a superior agent on the cardioprotective system *in vivo* and *in vitro*. HSYA (5 mg/kg, 30 min before ischemia, *i. p.*) was found to improve ischemia/reperfusion (I/R) injury by reducing the releases of cTnI, IL-6, LDH and the myocardial infarction size (Zhou et al., 2019). Similarly, HSYA (4 or 8 mg/kg) could reduce the expression of MIS, CK-MB, and MDA in experimental acute myocardial ischemic model, which induced by left anterior descending coronary artery (LAD) ligation (Tu et al., 2009). Furthermore, HSYA combined with nitroglycerin showed a better therapeutic action on acute myocardial infarction than HSYA alone, which produced a marked increase in SOD, eNOS, and NO content.

The mechanisms of HSYA on cardioprotective effects are related to antioxidant, free radical scavenging abilities, and anti-inflammatory activity. The nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor responsible for the regulation of cellular redox balance and protective antioxidant and phase II detoxification responses in mammals. On basal condition, Nrf2 binding with the chaperon protein Kelch like-ECH-associated

protein 1 (Keap1) located in cytoplasm with inhibition abilities. When facing oxidant stress, Nrf2-Keap1 combination is separated. Nrf2 transports to the nucleus and activates the transcription of genes encoding. Heme oxygenase-1 (HO-1), as one of Nrf2-dependent gene, protects against oxidant stress (Loboda et al., 2016; Reuland et al., 2013). Hu et al. (2016) reported that the combination of HSYA and DSS exerted the markedly antioxidant capacity on increasing the expression of HO-1, the phosphorylation of Akt, and the translocation of Nrf2 (**Figure 8**). Similarly, HSYA attenuated the expression of IL-1 $\beta$ , TNF- $\alpha$ , iNOS, COX-2, MCP-1 on BV2 cells of oxygen and glucose deprivation models (OGD). HSYA also inhibited NF- $\kappa$ B signaling pathway, TLR4 signaling pathway and phosphorylation of p38 (Han et al., 2016; Li et al., 2013). In addition, HSYA decreased the formulation of mitochondrial permeability transition pore in hypoxic cardiac myocytes, thereby inhibiting cardiomyocytes from damage during cardiomyocyte reoxygenation (Huber et al., 2018). In summary, oxidative stress and inflammation related signaling pathways (e.g., Nrf2/OH-1, p38 MAPK, NF- $\kappa$ B signaling pathway and TLR4 signaling pathway all play an important role during the treatment of cardiovascular disease with HSYA.

## Neuroprotective Effect

HSYA showed excellent neuroprotective effect. HSYA injection (50 mg/d and 75 mg/d) in patients with acute ischemic stroke of blood stasis syndrome might be to undergo for a phase III clinical trial (Zhu et al., 2020). HSYA (2 mg/kg, tail vein injection) protected the C57BL/6J mice against middle cerebral artery occlusion (MCAO) by decreasing the expression of inflammatory genes factors, including TNF- $\alpha$ , IL-1 $\beta$ , and NO (Lv et al., 2015). HSYA (0.6 mg/100 g, tail vein injection) could also improve spatial learning and memory ability of vascular dementia model rat by promoting angiogenesis and increasing synaptic plasticity (Zhang et al., 2014). Moreover, HSYA (6 mg/kg per day, 2 weeks, *i. v.*) could reduce the accumulation of amyloid precursor protein, improve synaptic function and reverse homocysteine (Hcy) induced cognitive impairment in Alzheimer's disease mice (Lu et al., 2013).

The neuroprotective effect of HSYA might be related to the regulation of TLR4, NF- $\kappa$ B, p-p65, MAPK, PI3K/Akt and Nrf2/HO-1 signaling pathways (Wei et al., 2005; Lv et al., 2015; Deng et al., 2018). NF- $\kappa$ B is a family of dimeric transcription factors central to regulate immune development, immune responses, inflammation, cancer, and other diseases. HSYA inhibited NF- $\kappa$ B to exert neuroprotective effect (Yu et al., 2020). Similarly, HSYA (20 mg/kg for 28 days) could improve motor dysfunction in C57/BL6 mice model of Parkinson by promoting the expression of BDNF, p-TrkB/TrkB, DRD3, p-PI3K/PI3K and p-AKT/AKT (Wang et al., 2017).

## Anticancer Effect

Some studies have found that HSYA exerted anticancer activity in several cancer cells, such as human umbilical vein endothelial cells (HUVEC), HepG2 cells, Skov3 cells, as well as some *in vivo* studies. HSYA could eliminate reactive oxygen species (ROS), prevent apoptosis from membrane permeability, and inhibit proliferation and migration (Ma et al., 2019a; Chen et al.,

2019; Zhang et al., 2019). HSYA also increased the thymus index, and effectively down-regulate the mRNA levels of forkhead box P3-positive (Foxp3) and retinoic acid receptor-related orphan receptor-gamma-t (ROR $\gamma$ t), which contributed to improve the tumor immune microenvironment-the key points of tumor cell proliferation and invasion (Ma et al., 2019b). What is particularly noteworthy is the anticancer abilities of HSYA might related to the excellent antioxidant effect.

## Anticoagulant Effect

PAF, as the most effective platelet activator known so far, has a wide range of biological activities, and can be synthesized by a variety of cells such as platelets, leukocytes, endothelial cells. Anticoagulant effect of HSYA plays a significant mediating role in many pathological processes, such as tissue IR injury, coronary heart disease, atherosclerosis, cerebrovascular disease and many other cardiovascular diseases. HSYA dose-dependently inhibited the specific binding between [ $^3$ H] PAF and washed rabbit platelet, which is considered as a new generation PAF receptor antagonist in the future (Zang et al., 2002). PAF-activated human small airway epithelial cells model was pretreated with HSYA. Guo et al. (2018) proposed that HSYA could attenuate the PAF-induced inflammatory factors, destruct cell-barrier function, and inhibit the expression of protein kinase C, MAPK, activator protein-1, and NF- $\kappa$ B activation to show anticoagulant effect.

## Other Pharmacological Effects

In addition to the biological activities discussed above, HSYA also has other diverse pharmacological effects, such as immunodeficiency, anaphylactoid, hepatic fibrosis, pulmonary arterial hypertension, skin photosensitivity, Type 1 diabetes, vascular dementia, and so on.

HSYA is an immunomodulator that regulates the inflammatory response induced by lipopolysaccharide in various cells, including human non-small lung cancer cell line (A549 cells), H1299 and EaHy926 human endothelium cells. It could inhibit many kinase activities related to inflammatory factors, such as TNF $\alpha$ , IL-1 $\beta$ , and IL-6. HSYA could also inhibit the pro-inflammatory proteins expression, such as NF- $\kappa$ B p65, PI3K/Akt/mTOR, MAPK TLR-4, Myd88 and ICAM-1 (Han and Zhao, 2010; Jin et al., 2016; Jiang et al., 2019). HSYA was also proved to relieve certain respiratory conditions by decreasing mRNA levels of ICAM-1 and E-selectin elevation (Liu et al., 2014; Zhang et al., 2017). Moreover, another study implemented by Zheng et al. (2019) showed that HSYA could attenuate ovalbumin-induced allergic asthma in guinea pigs.

HSYA possesses a strong vascular relaxation effect on pulmonary arterial hypertension (PAH). It reduced the vascular tension by activating the Kv channel in pulmonary vascular smooth muscle cells (PVSMCs) (Bai et al., 2012). HSYA (6 mg/kg for 11 days) promoted angiogenesis in ischemic mice. The therapeutic mechanisms of HSYA might be associated to significantly increase the capillary-like tube formation and migration of HUVEC, enhance the expression of angiopoietin 1 and Tie-2, phosphorylations of Tie2, Akt and extracellular signal-regulated kinase 1/2 (Chen T. et al., 2016).

It is also reported that HSYA could exert protection on macroscopic skin lesions induced by ultraviolet rays (UV). It could promote the skin to regain its initial shape, elevate the activities of skin anti-oxidant enzymes, increase skin collagen content and maintain the structural integrity of the skin (Kong et al., 2013).

The combination of HSYA and deferoxamine (DFO) was discovered to improve type 1 diabetes by accelerating diabetic wound healing, promoting angiogenesis, reducing the inflammatory response, and up-regulating the expression of hypoxia-inducible factor-1  $\alpha$  (HIF-1  $\alpha$ ) (Gao et al., 2018).

## DISCUSSION AND CONCLUSION

In the present review, we systematically summarized the materials about HSYA, including acquisition methods, extraction and detection methods, pharmacokinetics, pharmacological effects and molecular mechanism. HSYA is proved to be an excellent antioxidant, anti-inflammatory and anticoagulant agent, so it plays an exceptional role in the treatment of cardiovascular and cerebrovascular diseases by down-regulating NF- $\kappa$ B signaling pathways, inhibiting MAPK signaling pathways, and attenuating the activation of Nrf-2/HO-1 signaling pathways. However, it is easily to degrade in the process of storage, extraction and separation procedure due to its chemical instability, which brings great challenges to the application of HSYA. Another major challenge is the low bioavailability caused by strong polarity. A large number of studies have been carried out to improve the chemical instability and bioavailability. Microemulsions, self-emulsifying systems, nanoparticles and other drug delivery systems have gradually improved the bioavailability, chemical stability, cellular uptake and biological activity of HSYA, which will be evaluated in clinical trials later.

Although great progress has been made in the research and application of HSYA in the past few decades, there are still many problems and challenges. First of all, chemical instability and low bioavailability of HSYA are still far from being resolved, which is still a key issue of the future research. It is important to continue the development of viable drug delivery systems for HSYA. The

crucial aspects will involve in the enhancement of the solubility and bioavailability, as well as methods for selectively targeting these delivery systems to disease sites. Secondly, HSYA has been used to treat cardiovascular and cerebrovascular diseases clinically in China, but the drug target has not been completely revealed at present, which needs in-depth study later. Finally, the approach of obtaining HSYA from plants is cumbersome and complicated, and the yield is unsatisfactory. Chemical synthesis might pollute the environment, so it does not recommend to popularize. Biosynthesis is characterized by high efficiency, energy saving, and environmental protection, and it will transform into the major source of HSYA in the near future.

In short, it is the first time to systematically summarize the basic information about HSYA, which might provide relatively comprehensive basic data for the related research of HSYA.

## AUTHOR CONTRIBUTIONS

HX, FZ and PW performed the frame design of the manuscript. FZ collected the data and drafted the manuscript. YJ, XZ and DC helped to organize the data. PW revised the manuscript. All authors read and approved the final manuscript.

## FUNDING

This work was supported by grants from National Key Research and Development Program of China (2017YFC1702104, 2017YFC1702303), the National Natural Science Foundation of China (81830111, 81774201), National Science and Technology Major Project of China (2019ZX09201005-001-003), the Youth Innovation Team of Shaanxi Universities and Shaanxi Provincial Science and Technology Department Project (2016SF-378), the Fundamental Research Funds for the Central public welfare research institutes (ZXKT17058). Natural Science Foundation of Shandong Province (ZR2019ZD24, ZR2019YQ30).

The funding agencies had no role in the study design, the collection, analysis, or interpretation of data, the writing of the report, or the decision to submit the article for publication.

Skeletal muscle dysfunction, a striking systemic comorbidity of chronic obstructive pulmonary disease (COPD), is associated with declines in activities of daily living, reductions in health status and prognosis, and increases in mortality. Bufei Jianpi formula (BJF), a traditional Chinese herbal formulation, has been shown to improve skeletal muscle tension and tolerance via inhibition of cellular apoptosis in COPD rat models. This study aimed to investigate the mechanisms by which BJF regulates the adenosine monophosphate-activated protein kinase (AMPK) pathway to improve mitochondrial function and to suppress mitophagy in skeletal muscle cells. Our study showed that BJF repaired lung function and ameliorated pathological impairment in rat lung and skeletal muscle tissues. BJF also improved mitochondrial function and reduced mitophagy via the AMPK signaling pathway in rat skeletal muscle tissue. *In vitro*, BJF significantly improved cigarette smoke extract-induced mitochondrial functional impairment in L6 skeletal muscle cells through effects on mitochondrial membrane potential, mitochondrial permeability transition pores, adenosine triphosphate production, and mitochondrial respiration. In addition, BJF led to upregulated expression of mitochondrial biogenesis markers, including AMPK- $\alpha$ , PGC-1 $\alpha$ , and TFAM and downregulation of mitophagy markers, including LC3B, ULK1, PINK1, and Parkin, with increased expression of downstream markers of the AMPK pathway, including mTOR, PPAR $\gamma$ , and SIRT1. In conclusion, BJF significantly improved skeletal muscle and mitochondrial function in COPD rats and L6 cells by promoting mitochondrial biogenesis and suppressing mitophagy via the AMPK pathway. This study suggests that BJF may

have therapeutic potential for prophylaxis and treatment of skeletal muscle dysfunction in patients with COPD.

**Keywords:** mitophagy, mitochondrial biogenesis, chronic obstructive pulmonary disease, Bufeijianpi formula, skeletal muscle dysfunction

## INTRODUCTION

Chronic obstructive pulmonary disease (COPD), a common and preventable disease, is characterized by persistent airflow limitations caused by chronic inflammatory responses to noxious particles and gases (Patel et al., 2019). In China, COPD has become the third leading cause of death and the third most prevalent chronic disease (Collaborators, 2015), with an estimated 99.9 million individuals aged 20 years or older with spirometry-defined COPD (Wang et al., 2018a). Skeletal muscle dysfunction (SMD), a serious systemic comorbidity of COPD (Ceco et al., 2017), has been recognized as an early disease feature and an important causative factor in the limited mobility and mortality of patients with this disease (Maltais et al., 2014; Barreiro, 2016). Studies have shown that muscle wasting is experienced in up to 30%–40% of COPD patients, with significant impairments in activities of daily living, health status, and prognosis (Mowery, 2017).

Development of SMD is likely multifactorial, with inflammation and mitochondrial dysfunction playing predominant roles. Other pathophysiological factors, including oxidative stress, imbalance of protein synthesis/degradation, hypoxia, and cellular apoptosis have also been postulated to contribute to the muscle wasting experienced by COPD patients (Barreiro and Gea, 2016). Recent studies have identified major mitochondrial abnormalities in COPD skeletal muscle cells, including decreases in mitochondrial density and biogenesis, reductions in oxidative capacity, impairments in activity and coupling of mitochondrial respiratory chain complexes, increases in production of mitochondrial reactive oxygen species (ROS), and enhancements in autophagy and apoptosis (Meyer et al., 2013; Taivassalo and Hussain, 2016).

Decreased mitochondrial biogenesis and enhanced mitophagy play particularly important roles in mitochondrial impairment. Peroxisome proliferator-activated receptor gamma coactivator (PGC)-1 $\alpha$  has been shown to be a master regulator of mitochondrial biogenesis (Tadaishi et al., 2011). PGC-1 $\alpha$  acts as a cotranscriptional regulatory factor that induces mitochondrial biogenesis by activating nuclear respiratory factors (NRF) 1 and 2, which then activate mitochondrial transcription factor A (TFAM), an essential factor for replication, maintenance, and transcription of mitochondrial DNA (Grabacka et al., 2016; Yu et al., 2017).

Mitophagy, on the other hand, is closely associated with the AMPK pathway. AMPK directly facilitates phosphorylation of UNC-51-like kinase (ULK1), which stimulates the mitophagic activity of ULK1 (Allavena et al., 2016). The PTEN-induced putative kinase 1 (PINK1)/Parkin pathway has also been implicated as an important molecular mechanism mediating mitophagy. While PINK1 is a protein kinase primarily located

in the mitochondrial outer membrane, Parkin is an E3 ubiquitin ligase generally located in the cytoplasm. When mitochondrial damage occurs, PINK1 phosphorylates the Parkin ubiquitin ligase at S65 and initiates its recruitment to the mitochondria. Once activated, Parkin ubiquitinates substrates on the outer mitochondria for two divergent processes, autophagosome recruitment and proteasomal degradation of ubiquitinated mitochondrial substrates. Mitochondrial fission-1 protein (Fis1), a receptor on the outer membrane, governs the developing light chain (LC) 3 isolation membrane to generate an autophagosome around the damaged mitochondria. The autophagosome is then delivered to the lysosome for degradation (Hardie, 2011; Wei et al., 2017).

Traditional Chinese medicine (TCM) has been successfully used to treat COPD for thousands of years. Lung-spleen qi deficiency syndrome is believed to be the main underlying pathologic mechanism for the SMD observed in patients with COPD (Medicine, 2012). Bufeijianpi formula (BJF), which is composed of 12 medicinal herbs, has been proven to have efficacy in patients with COPD by improving respiratory function, reducing the frequency of acute exacerbations, and enhancing exercise tolerance (Li et al., 2012a). In previous experimental studies, we also found that BJF significantly improved skeletal muscle tension and tolerance in COPD rats, reduced cellular apoptosis, and improved mitochondrial function (Dong et al., 2015; Mao et al., 2019). It remains unclear, however, if mitochondrial dysregulation underlies the SMD observed in COPD.

In this study, we aimed to explore the mechanism by which BJF affects mitochondrial regulation via the AMPK pathway in an *in vivo* COPD rat model and an *in vitro* cigarette smoke extract (CSE)-induced skeletal muscle cell line to identify potential underlying mechanisms and to provide a basis for further research.

## MATERIALS AND METHODS

### Reagents and Animals

*Klebsiella pneumoniae* (strain: 46114) was obtained from the National Center for Medical Culture Collections (Beijing, China). HongqiQu<sup>®</sup> filter cigarettes (tobacco-type of tar: 10 mg, nicotine content: 1.0 mg, carbon monoxide fumes: 12 mg) were purchased from Henan Tobacco Industry (Zhengzhou, China). Aminophylline (APL) tablets were obtained from Shandong Xinhua Pharmaceutical Co., LTD. (lot H37020630) (Shandong, China). 5-Aminoimidazole-4-carboxamide ribonucleotide (AICAR) was purchased from Selleck Chemicals (lot 2627-69-2) (Houston, TX, USA).

**TABLE 1** | Components of BJF.

Dorsomorphin dihydrochloride (BML-275 dihydrochloride) was purchased from MedChemExpress (lot 1219168-18-9) (Shanghai, China).

Thirty-six male and 36 female Sprague-Dawley (SD) rats with an average body weight of  $200 \pm 20$  g were purchased from the Experimental Animal Center of Henan Province (Zhengzhou, China). The rats were housed in specific pathogen-free cages under standard temperature ( $25 \pm 2^\circ\text{C}$ ) and light conditions, with a 12-h light/dark cycle, and free access to food and water. All animal studies were conducted in accordance with the Institute's Guide for the Care and Use of Laboratory Animals and were approved by the Experimental Animal Care and Ethics Committee of the First Affiliated Hospital of the Henan University of Chinese Medicine.

## Preparation of Herbal Medicines

BJF, consisting of 12 herbs (Table 1), was prepared by the Laboratory of Pharmacology in Henan University of Chinese Medicine. All herbs were prepared in a fluid extract in accordance with the standard operating procedures. The high performance liquid chromatography (HPLC) fingerprint was performed to identify the main chemical constituents in BYF. A high-resolution HPLC column (Venusil XBP C18,  $4.6 \times 250$  mm,  $5 \mu\text{m}$ ) (Thermo Scientific, United States) were used at a flow rate of 1.0 ml/min at  $30^\circ\text{C}$ . Mobile phase A was 0.1% formic acid in water and mobile phase B was acetonitrile. The gradient elution program was 5–30 min, 5–100% B. The UV spectrophotometer detector was set at 270 nm.

## Preparation of BJF-Containing Serum

Sixty Sprague-Dawley rats were randomized into control and Bufe Jianpi groups. Rats in the Bufe Jianpi group were administered BJF (4.5 lg/kg/d) intragastrically 10 times once per day for 7 days. Rats in control group were administrated distilled water (2 ml per animal). On day 7, all rats were narcotized with 4% chloral hydrate and blood samples were collected, centrifugated at 3,500 rpm for 15 min,

inactivated at  $56^\circ\text{C}$ , and stored in a  $-80^\circ\text{C}$  freezer for further study.

## Preparation of COPD Rat Model and Drug Administration

Seventy-two rats were randomly assigned to the following groups: control, model, Bufe Jianpi Formula (BJF), 5-Aminoimidazole-4-carboxamide ribonucleotide (AICAR), Bufe Jianpi Formula + 5-Aminoimidazole-4-carboxamide ribonucleotide (BJF + AICAR), and Aminophylline (APL), with 12 animals in each group. The detailed procedures for creation of the COPD rat model have been described in a previous report (Li et al., 2012b); however, in brief, rats were exposed to cigarette smoke (concentration:  $3,000 \pm 500$  ppm) for 30 min twice per day from week 1 through week 12. In addition, 0.1 ml of *Klebsiella pneumonia* suspension ( $6 \times 10^8$  CFU/mL, 100  $\mu\text{L}$ ) was slowly dropped into the nasal cavities of rats every 5 days for the first 8 weeks. The successful generation of a COPD rat model was evaluated based on symptoms, lung function, and pulmonary pathology (Li et al., 2012a).

Starting from week 9, rats in the control and model groups were intragastrically administered normal saline (2 mL/animal). BJF (4.51 g/kg/d) was administered to rats in the BJF and BJF + AICAR groups, while APL (2.7 mg/kg/d) was administered to rats in the APL group twice per day for 12 weeks. AICAR (25 mg/kg/d) was intraperitoneally administered to rats in the AICAR and BJF + AICAR groups once a day during week 20. The equivalent dosages of BJF and APL were calculated using the equation:

$$D_{\text{rat}} = D_{\text{human}} \times \left( \frac{I_{\text{rat}}}{I_{\text{human}}} \right) \times \left( \frac{W_{\text{rat}}}{W_{\text{human}}} \right)^{2/3}$$

in which  $D$  represents dose,  $I$  represents body shape index, and  $W$  represents body weight.

All rats underwent necropsy after intraperitoneal injection of 10% chloral hydrate at 100 mg/kg of body weight at the end of

week 20, and lung and quadriceps muscle tissues were collected for further analysis.

## Respiratory Function Analysis in Rat Model

Lung function was measured by a whole-body plethysmography system (Buxco Inc., Wilmington, NC, USA) at weeks 0, 4, 8, 12, 16, and 20. Tidal volume (TV), peak expiratory flow (PEF), and 50% tidal volume expiratory flow (EF50) were evaluated.

## Lung and Skeletal Muscle Histopathology in Rat Model

After being fixed in 10% formalin for 72 h, left lung and quadriceps muscle tissues were embedded with paraffin, cut into 4- $\mu$ m thick sections, and stained with hematoxylin and eosin (HE) for light microscopy.

## Skeletal Muscle Ultrastructure Morphology in Rat Model

After being cut into sections with 1-mm thicknesses, fresh quadriceps muscle tissue was fixed in 2.5% glutaraldehyde for 2 h followed by 1% osmium tetroxide. Sections were then stained with uranyl acetate, dehydrated in a methanol series and propylene oxide, and embedded with Epon-812. Ultrathin sections were obtained, and ultrastructural changes and mitophagy of skeletal muscle cells were examined using a JEM-1400 transmission electron microscope (OLYMPUS, Japan).

## Measurement of Mitochondrial Function in Skeletal Muscle

Mitochondrial characteristics, including mitochondrial membrane potentials (MMP), ATP production, and opening of mitochondrial permeability transition pores (MPTPs) were measured with a JC-1 kit (Beyotime Biotech Co., Ltd., Shanghai, China), an ATP assay kit (Beyotime Biotech Co., Ltd., Shanghai, China), and an MPTP assay (Genmed Scientifics Inc., DE, USA), respectively, according to the manufacturer's instruction and as previously described (Mao et al., 2019).

## Cell Culture and Transfection

Rat L6 myoblasts (obtained from the Cell Bank of Chinese Academy of Sciences, Shanghai) were cultured in Dulbecco's modified Eagle's medium (DMEM) (Solarbio Tech Co., Ltd., Beijing, China) supplemented with 10% fetal bovine serum (FBS) in a 5% CO<sub>2</sub>-humidified atmosphere at 37°C. When cells had grown by 70–90%, they were plated on dishes at a density of  $1 \times 10^5$  cells/mL and incubated in 5% CO<sub>2</sub>-95% air for 24 h. On the next day, cells were treated with 10% cigarette smoke extract (CSE), 10% CSE + AICAR (2.5 ng/mL), or 10% CSE + 10% BJF-containing serum in DMEM and harvested 24 h later.

## Preparation of Cigarette Smoke Extract

CSE was prepared using a modified version of Sheridan's method (Sheridan et al., 2015). Briefly, a filterless HongqiQu cigarette was

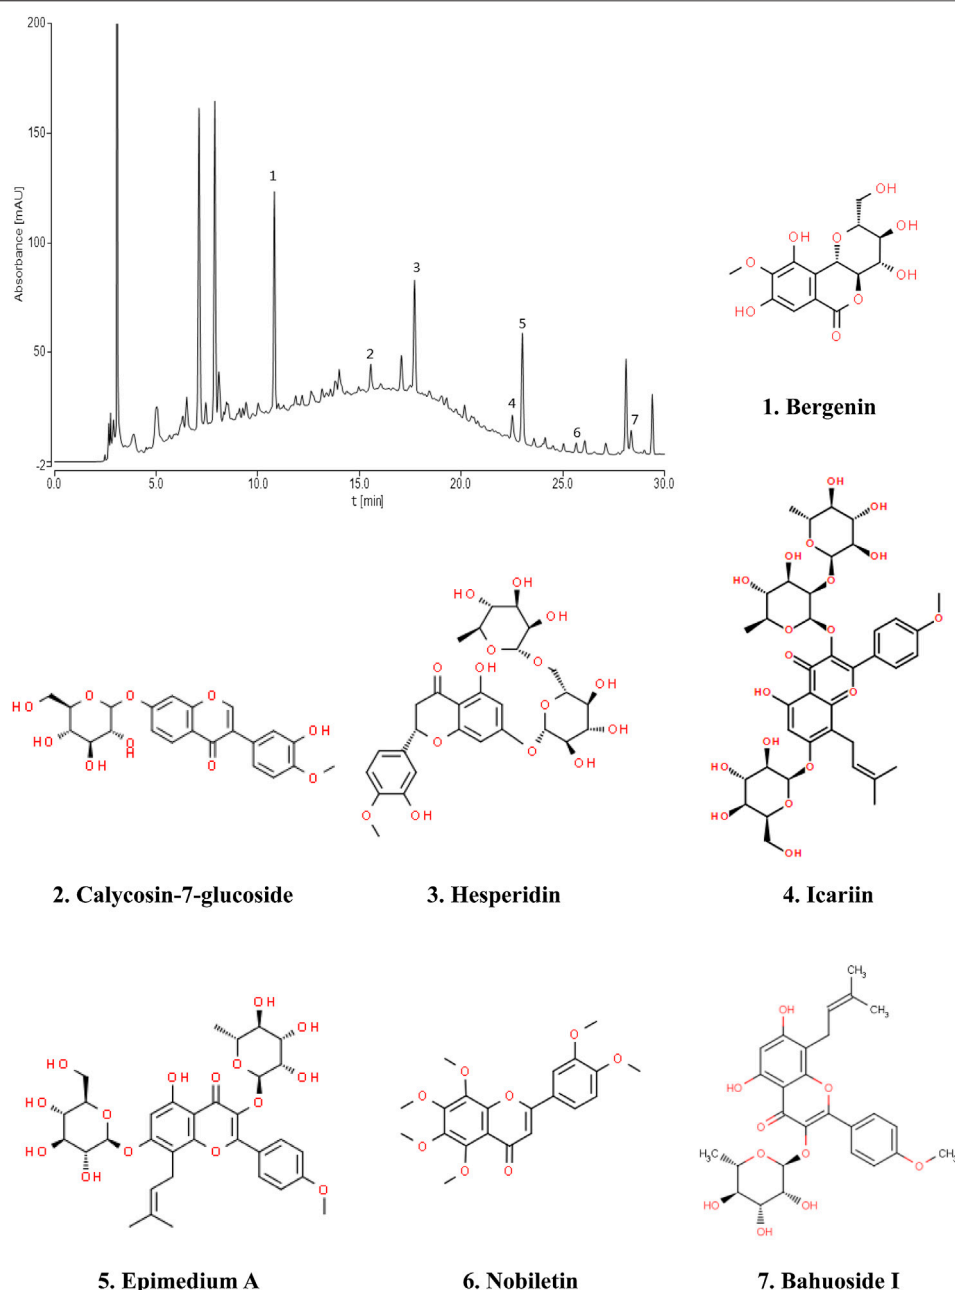

combusted through a modified 50-ml syringe apparatus, and the smoke was dissolved in 20 ml of DMEM. The pH was adjusted to 7.4 with 1 mol/L sodium hydroxide and 37.5%-concentrated hydrochloric acid, and then diluted with DMEM until the optical density was measured to be  $2.0 \pm 0.05$  using an ultraviolet spectrophotometer (Thermo Fisher Scientific, MA, USA). This solution represented "100%" strength. Smoked medium was then passed through a 0.22- $\mu$ m filter to sterilize the solution. Finally, smoked medium was diluted in DMEM to the required strength and used for the experiment within 30 min.

## Measurement of Mitochondrial Respiration in L6 Cells

Mitochondrial respiration was measured with a Seahorse XF Cell Mito Stress Test Kit (Agilent Technologies, CA, United States) on a Seahorse XF24 Extracellular Flux Analyzer (Seahorse Bioscience, MA, United States) according to the manufacturer's instruction. L6 cells were seeded (10,000 cells per well) onto Seahorse assay plates in DMEM media and treated with 10% CSE for 24 h. During the experiment, cells were switched to an XF assay medium (HCO<sub>3</sub>-free modified DMEM) supplemented with 10 mM of L-glutamine, 10 mM of glucose, and 10 mM of pyruvate, while a pH of 7.4 was maintained at 37°C. After baseline measurement of oxygen combustion rate (OCR), a mitochondrial respiration test was performed by sequential additions of 1.0  $\mu$ M oligomycin, 2.0  $\mu$ M carbonyl cyanide 4-(trifluoromethoxy) phenylhydrazone, and 0.5  $\mu$ M rotenone/antimycin A. Several mitochondrial parameters were determined, including basal respiration, maximal respiratory capacity, proton leak, and non-mitochondrial respiration. The results were expressed as OCRs (pmol/min/lg protein).

## Measurement of Mitochondrial Membrane Potentials in L6 Cells

For measurement of mitochondrial membrane potentials, L6 cells were seeded in 6-well plates with a density of  $1 \times 10^5$  cells per well and treated with 10% CSE, 10% CSE + AICAR, or 10% CSE + 10% BJF-containing serum for 24 h. Before the experiment, cells were treated with carbonyl cyanide *m*-chlorophenyl hydrazone (CCCP) (100  $\mu$ M, Sigma) for 1 h as a positive control. Changes in mitochondrial membrane potentials of L6 cells in different groups were then assessed using the JC-1 mitochondrial membrane potential detection kit according to the manufacturer's instruction. Red fluorescence represented JC-1 aggregates, whereas green fluorescence represented the monomeric form of JC-1. Fluorescence intensity was analyzed by a Varioskan® Flash Microplate Reader (Thermo Fisher Scientific, MA, USA). MMPs in each group were calculated as the ratio of red/green fluorescence. In addition, cells were visualized using confocal laser scanning microscopy at a 514-nm excitation and a 529-nm emission for green and a 585-nm excitation and a 590-nm emission for red.

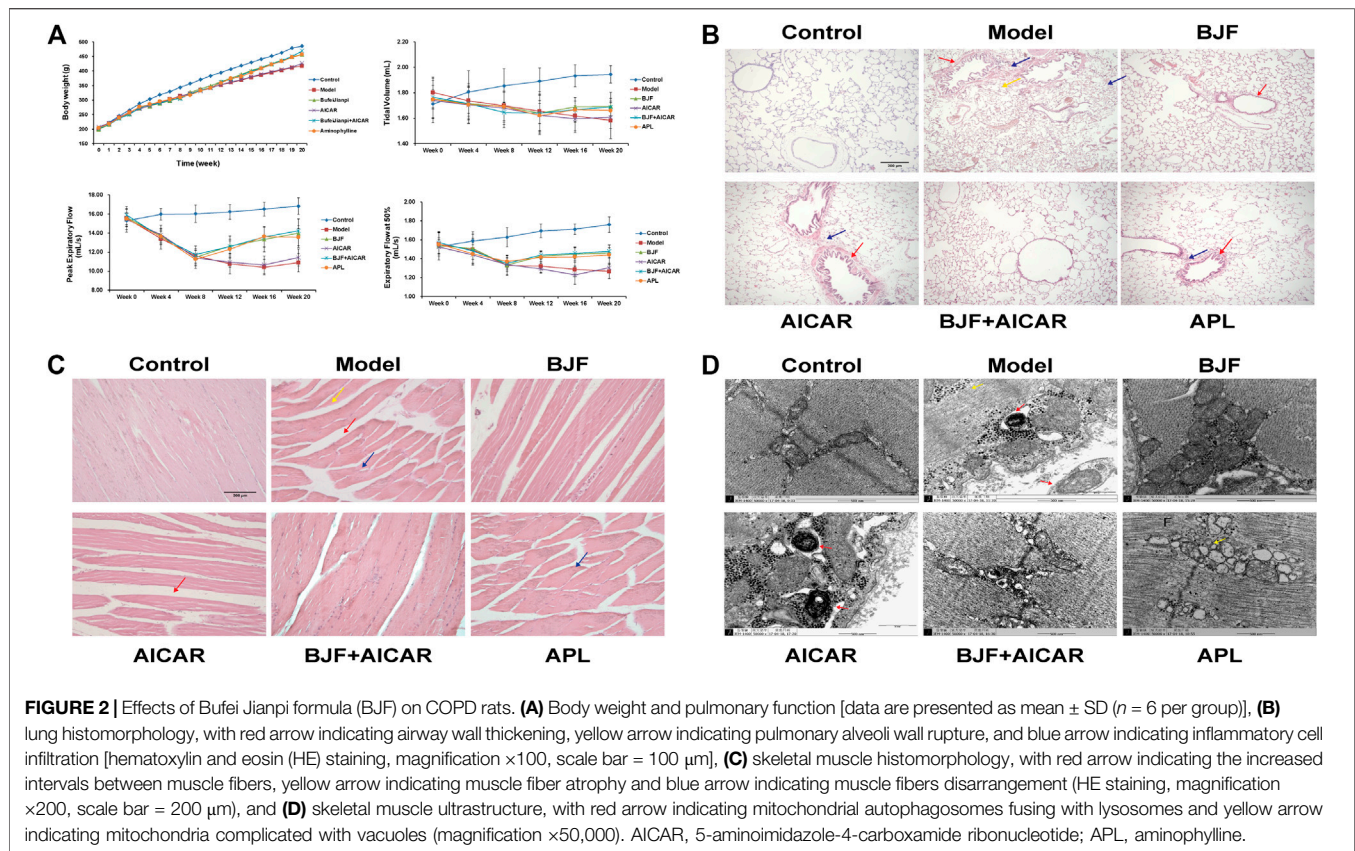

**FIGURE 1 |** Chromatogram fingerprint of Bufei Jianpi formula (BJF). The 7 compounds were identified in BJF: 1, Bergenin; 2, Calycosin-7-glucoside; 3, Hesperidin; 4, Icariin; 5, Epimedium A; 6, Nobiletin; 7, Bahuoside I.

## Measurement of ATP Levels in L6 Cells

For measurement of ATP levels, L6 cells were seeded in 6-well plates with a density of  $1 \times 10^5$  cells per well for 24 h. After treatment with study drugs, cells were lysed using a cell lysis reagent, and the ATP content in cell lysates was measured using an ATP assay kit (Beyotime Biotech Co., Ltd., Shanghai, China) following the manufacturer's protocol. The total and mitochondrial protein concentrations were determined using a bicinchoninic acid (BCA) protein assay kit (Beyotime Biotech Co., Ltd., Shanghai, China).

## RNA Isolation and Real-Time PCR Analysis

Expression levels of mRNA in quadriceps muscle tissue were analyzed by semiquantitative polymerase chain reactions (qPCR). Total RNA was extracted from the quadriceps muscle using a total RNA isolation kit (Solarbio Tech Co., Ltd., Beijing, China) according to the manufacturer's protocol. Real-time (RT)-qPCR was performed using a reverse transcriptase kit (Solarbio Tech Co., Ltd., Beijing, China) and a SYBR Green Master Mix (Vazyme Biotech Co., Ltd. Nanjing, China). To normalize the amount of total RNA in each reaction, a reference gene (*GAPDH*) was used as an internal standard.

## Western Blotting

Total proteins from cells or tissue samples were lysed in a lysis buffer and quantified using a BCA assay. Ten-cell lysates were loaded into each well in 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) gels and transferred to a polyvinylidene difluoride (PVDF) membrane. Membranes were blocked in 5% nonfat milk in tris-buffered saline and polysorbate 20 (TBST) for 2 h at room temperature and incubated with the indicated primary antibodies, including anti-AMPK- $\alpha$ , anti-p-AMPK- $\alpha$ , anti-PGC-1 $\alpha$ , anti-TFAM, anti-LC3B, anti-ULK1, anti-PINK1, anti-Parkin, anti-mammalian target of rapamycin (mTOR), anti-sirtuin 1 (SIRT1), anti-peroxisome proliferator-activated receptor (PPAR) $\gamma$  (Abcam, Cambridge, United Kingdom), or anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (Proteintech, Wuhan, China) at 4°C overnight. After incubation with the HRP-coupled secondary antibody (Proteintech, Wuhan, China) at room temperature for 2 h, signals were detected using a super-enhanced chemiluminescence plus reagent and scanned and quantified by a ChemiDoc MP imaging system (Bio-Rad, CA, USA).

## Statistical Analysis

Data are expressed as mean  $\pm$  SD. Statistical differences between the groups were identified by one-way analysis of variance (ANOVA). Differences were considered to be significant at  $P$ -values of  $< 0.05$ .

## RESULTS

**Fingerprint of BJF** The retention time values of the identified compounds were compared with that of the reference substances. A representative chromatogram of BJF was shown in **Figure 1**. 7 compounds including Bergenin (1.3456 mg/g), Calycosin-7-glucoside (0.5616 mg/g), Hesperidin (1.1755 mg/g), Epimedium A (0.6869 mg/g), Icariin (1.1195 mg/g), Nobiletin (0.0951 mg/g), Baohuosidl (0.0806 mg/g) were identified and their structures had also been shown.

## BJF Attenuated the Severity of Respiratory and Skeletal Muscle Dysfunction in COPD Rats

To assess potential effects on skeletal and lung tissues, BJF was orally administered to COPD rats for 12 weeks using APL as a positive control. We found that BJF attenuated declines in body weight and respiratory function in COPD rats. As shown in **Figure 2A**, the body weight of rats in the model group increased slowly and was significantly lower than the control group at week 8. This decrease in body weight was markedly inhibited by treatment with BJF, APL, and AICAR, with no significant differences between the effects of these substances.

As shown in **Tables 2–4**, respiratory function analysis revealed that the PEF was significantly decreased in the model group at week 4 and that the VT and EF50 declined in the model group at

Data are presented as mean ± SD (n = 6 per group). \*\*P < 0.01, \*P < 0.05 vs. control group; ##P < 0.01, #P < 0.05 vs. model group; <sup>ΔΔ</sup>P < 0.01, <sup>Δ</sup>P < 0.05 vs. BJF group; <sup>▲▲</sup>P < 0.01, <sup>▲</sup>P < 0.05 vs. 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) group; and <sup>□□</sup>P < 0.01, <sup>□</sup>P < 0.05 vs. BJF + AICAR group. APL, aminophylline.

week 8. Treatment with BJF, APL, and AICAR resulted in increased VT, PEF, and EF50.

We also found that BJF obviously reduced lung injury identified on histopathological examination. As shown in **Figure 2B**, the structure of the pulmonary alveoli and airways were fully intact in control rats, while marked airway wall thickening, alveolar wall rupture and inflammatory cell infiltration were observed in the lungs of COPD rats. These pulmonary histopathological impairments were significantly improved in rats treated with BJF, APL, and AICAR, with reductions in inflammatory cell infiltration, especially in the BJF and BJF + AICAR groups.

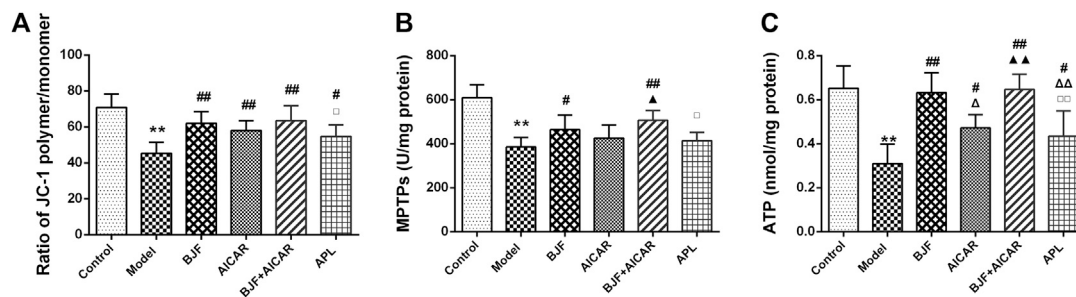

BJF also obviously improved morphological and ultrastructural changes in skeletal muscle of COPD rats. As shown in **Figures 2C,D**, marked morphological changes, including muscle fiber atrophy and disarrangement, increased intervals between muscle fibers, uneven myocyte cytoplasmic staining, and differently sized nuclei were observed in the skeletal muscle of model rats. These changes were improved after treatment with BJF, APL, and AICAR, particularly in the BJF

and BJF + AICAR groups. While the model, APL, and AICAR groups showed marked ultrastructural changes, including an abundance of swollen mitochondria with increased number of vacuoles, a fracturecrest of the mitochondria, and increased mitophagy, BJF ameliorated these abnormal mitochondrial findings.

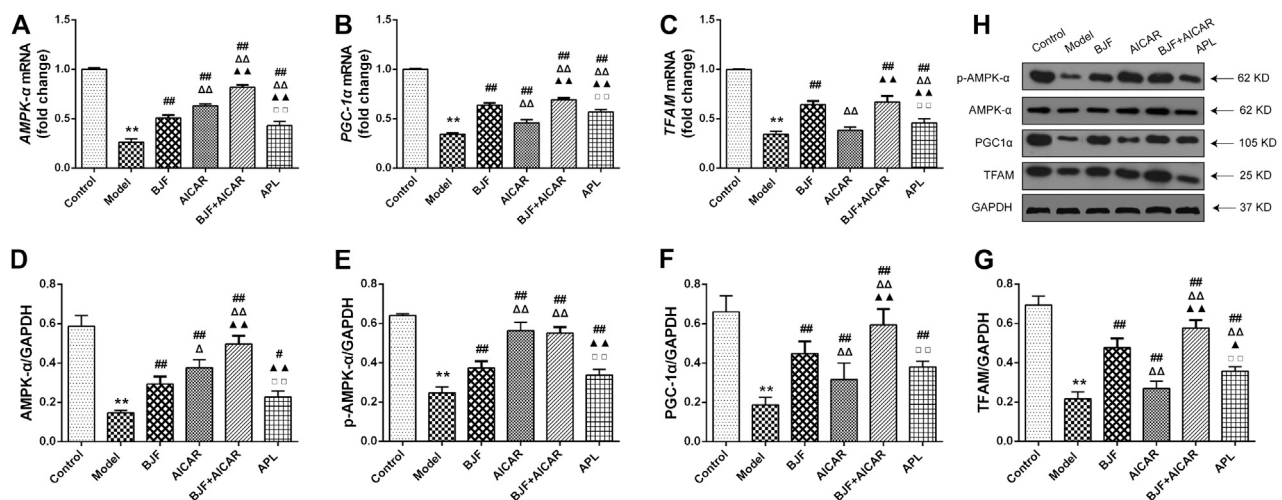

## BJF Ameliorated Mitochondrial Function in COPD Rats

To confirm the effect of BJF on mitochondrial function, we measured the levels of mitochondrial functional indicators. As shown in **Figures 3A–C**, MMPs, MPTP openings, and ATP levels in model rats were significantly lower than in control rats, with BJF administration significantly increasing MMPs, MPTP openings, and ATP levels. Meanwhile, AICAR and APL increased levels of MMPs and ATP but had no effect on MPTP openings.

BJF Promoted Expression of Mitochondrial Biogenesis Factors via Regulation of the AMPK Signaling Pathway in COPD Rats

**FIGURE 3 |** Effects of Bufeijianpi formula (BJF) on mitochondrial function of COPD rats. **(A)** Mitochondrial membrane potential **(B)** mitochondrial permeability transition pore openings (MPTPs); and **(C)** adenosine triphosphate (ATP) levels. Data are presented as mean ± SD ( $n = 6$  per group). \*\* $p < 0.01$ , \* $p < 0.05$  vs. control group; ## $p < 0.01$ , # $p < 0.05$  vs. model group;  $\Delta\Delta p < 0.01$ ,  $\Delta p < 0.05$  vs. BJF group;  $\blacktriangle\blacktriangle p < 0.01$ ,  $\blacktriangle p < 0.05$  vs. 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) group; and  $\square\square p < 0.01$ ,  $\square p < 0.05$  vs. BJF + AICAR group. APL, aminophylline.

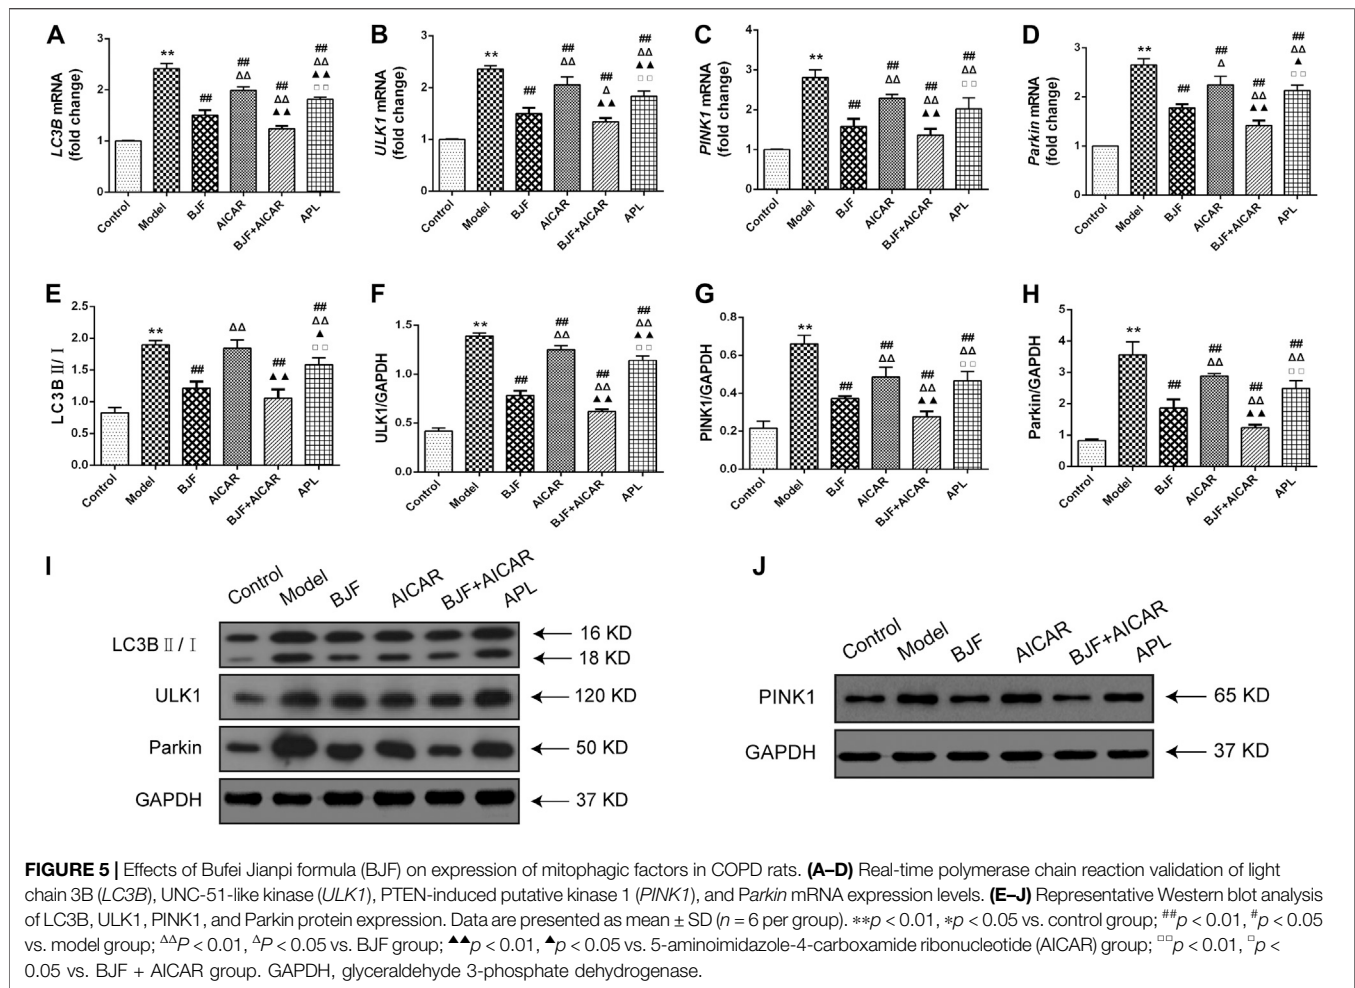

**FIGURE 4 |** Effects of Bufeijianpi formula (BJF) on expression of mitochondrial biogenesis factors in COPD rats. **(A–C)** Real-time polymerase chain reaction validation of adenosine monophosphate-activated protein kinase (AMPK- $\alpha$ ), peroxisome proliferator-activated receptor gamma coactivator (PGC- $\alpha$ ), and mitochondrial transcription factor A (TFAM) mRNA expression changes and **(D–H)** representative Western blot analysis of AMPK- $\alpha$ , p-AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM protein expression levels. Data are shown as mean ± SD ( $n = 6$  per group). \*\* $p < 0.01$ , \* $p < 0.05$  vs. control group; ## $p < 0.01$ , # $p < 0.05$  vs. model group;  $\Delta\Delta p < 0.01$ ,  $\Delta p < 0.05$  vs. BJF group;  $\blacktriangle\blacktriangle p < 0.01$ ,  $\blacktriangle p < 0.05$  vs. 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) group;  $\square\square p < 0.01$ ,  $\square p < 0.05$  vs. BJF + GAPDH, glyceraldehyde 3-phosphate dehydrogenase.

To explore the mitochondrial biogenesis-related mechanisms of BJF, we measured mRNA and protein levels of AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM in skeletal muscle tissues of COPD rats. As shown in **Figures 4A–C**, mRNA levels of AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM were markedly decreased in model rats. While treatment with BJF and APL significantly promoted expression of AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM mRNA, AICAR upregulated levels of AMPK- $\alpha$  and PGC- $\alpha$  but not TFAM. As shown in **Figures 4D–H**, protein expression of AMPK- $\alpha$ , p-AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM were lowered in model rats compared with control rats. BJF, AICAR, and APL treatment resulted in dramatic increases in AMPK- $\alpha$ , p-AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM protein expression.

#### BJF Downregulated Expression of Mitophagic Factors via Regulation of the AMPK Signaling Pathway in COPD Rats

To identify the mitophagy-related mechanisms of BJF, we measured mRNA and protein levels of LC3B, ULK1, PINK1, and Parkin in skeletal muscle tissues of COPD rats. As shown in **Figures 5A–D**, we found that LC3B, ULK1, PINK1, and Parkin mRNA levels were significantly upregulated in COPD rats in comparison to control rats. While treatment with BJF, AICAR, and APL downregulated expression of LC3B, ULK1, PINK1, and Parkin mRNA, AICAR upregulated levels of all the above-mentioned indicators. Additionally, protein expression of LC3B, ULK1, PINK1, and Parkin were markedly decreased in COPD rats compared with control rats. While BJF and APL treatment

upregulated protein expression of LC3B, ULK1, PINK1, and *Parkin*, AICAR showed no effect on the level of LC3B (Figures 5E–J).

## BJF Improved CSE-Induced Mitochondrial Injury in L6 Cells

To explore the effects of BJF treatment on mitochondrial membrane potentials, a JC-1 fluorescent probe was measured in rat L6 cells under CSE conditions. The ratio of JC-1 red to green fluorescence was significantly decreased in CSE-exposed L6 cells; however, treatment with BJF and AICAR significantly increased MMPs in L6 cells (Figures 6A,B). As shown in Figures 6C,D, BJF also markedly improved opening of MPTPs and ATP levels in CSE-exposed L6 cells.

## BJF Restored Mitochondrial Respiration in CSE-Exposed L6 Cells

To determine the effects of BJF on mitochondrial respiration, L6 cells were treated with a 10% CSE, 10% CSE + 10% BJF-

containing serum, or a 10% CSE + AICAR for 24 h, and OCRs were measured. As demonstrated in Figures 7B–F, significant reductions in basal respiration, ATP production, proton leak, and maximal respiratory capacity were observed in L6 cells after exposure to CSE. BJF treatment markedly reversed these CSE-induced changes.

## BJF Regulated Expression of Mitochondrial Biogenesis Factor in CSE-Exposed L6 Cells

To explore the effects of BJF on mitochondrial biogenesis, mRNA and protein levels of AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM were measured in L6 cells exposed to CSE. As shown in Figures 8A–C, mRNA expression levels of AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM were markedly lower in L6 cells exposed to CSE than in control cells, and BJF administration markedly reversed these changes. Meanwhile, AICAR upregulated levels of AMPK- $\alpha$  and PGC- $\alpha$  but had no effect on levels of TFAM. As shown in Figures 8D–H, protein expression of AMPK- $\alpha$ , p-AMPK- $\alpha$ , PGC- $\alpha$ , and TFAM were lowered in L6 cells exposed to CSE compared with control cells. BJF treatment resulted in dramatic increases in these changes, while AICAR upregulated levels of AMPK- $\alpha$ , p-AMPK- $\alpha$  and TFAM.

**FIGURE 6 |** Bufeji Jianpi formula (BJF) improved cigarette smoke extract (CSE)-induced mitochondrial injury in L6 cells. **(A)** Effect of BJF on mitochondrial membrane potential. Red fluorescence represents the mitochondrial aggregate form of JC-1, indicating an intact mitochondrial membrane potential. Green fluorescence represents the monomeric form of JC-1, indicating dissipation of  $\Delta\Psi_m$  (confocal laser scanning microscope, magnification  $\times 200$ , scale bar = 50  $\mu\text{m}$ ), **(B)** mitochondrial membrane potential, **(C)** ATP, and **(D)** mitochondrial permeability transition pore (MPTP) openings. Data are presented as mean  $\pm$  SD. \*\* $p < 0.01$ , \* $p < 0.05$  vs. control group; ## $p < 0.01$ , # $p < 0.05$  vs. model group;  $\Delta\Delta p < 0.01$ ,  $\Delta p < 0.05$  vs. BJF group. AICAR, aminoimidazole-4-carboxamide ribonucleotide; CCCP, carbonyl cyanide *m*-chlorophenyl hydrazone.

## BJF Downregulated Expression of Mitophagic Factor in CSE-Exposed L6 Cells

We measured mRNA and protein levels of ULK1, PINK1, and Parkin in L6 cells under CSE conditions. As shown in **Figures 9A–G**, *ULK1*, *PINK1*, and *Parkin* mRNA levels were significantly upregulated in CSE-induced L6 cells in comparison to control cells. Meanwhile, BJF treatment downregulated *ULK1*, *PINK1*, and *Parkin* mRNA and protein expression levels. Similarly, AICAR increased *Parkin* protein expression.

## BJF Regulated the AMPK Signaling Pathway in CSE-Exposed L6 Cells

To further explore the effects of BJF treatment on the AMPK signaling pathway, mRNA and protein levels of factors downstream of AMPK, including mTOR, PPAR $\gamma$ , and SIRT1 were analyzed. As shown in **Figures 10A–G**, mRNA levels of *mTOR*, *PPAR $\gamma$* , and *SIRT1* were significantly decreased after administration of CSE for 24 h, and treatment with BJF and AICAR inhibited these changes. Similarly, BJF increased protein expression of mTOR, PPAR $\gamma$ , and SIRT1, while AICAR upregulated levels of PPAR $\gamma$  and SIRT1 but had no effect on mTOR levels. BML increased mRNA expression of *PPAR $\gamma$* , *SIRT1* and protein expression of PPAR $\gamma$ .

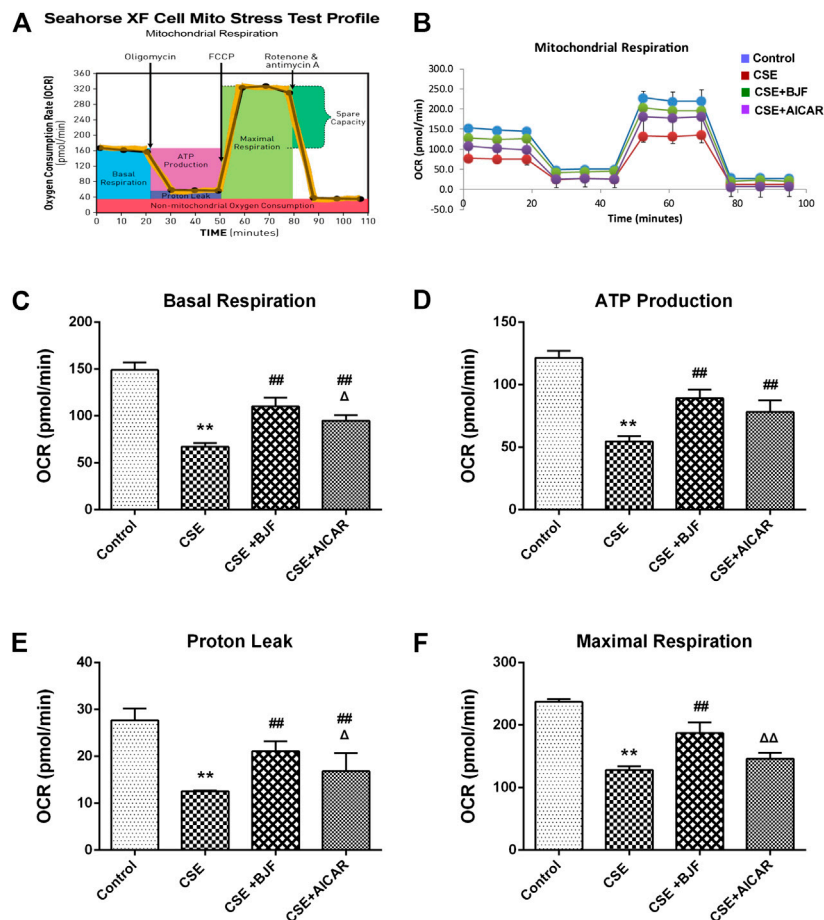

## DISCUSSION

TCM has been widely used for treatment of COPD for thousands of years. BJF, a traditional Chinese herbal formula for lung-spleen

qi deficiency syndrome, has been shown to have reproducible efficacy for treatment of COPD in previous clinical and experimental studies (Li et al., 2012a; Dong et al., 2015; Mao et al., 2019). In this study, we showed that BJF significantly improved SMD in rats with COPD via regulation of the AMPK pathway which is shown in **Figure 11**. It also improved mitochondrial function and decreased mitophagy in model rats and a myocyte cell line exposed to cigarette smoke extract.

Mitochondria, an important and essential organelle in the skeletal muscle, is involved in metabolic regulation and ATP production, which are two key elements of muscle contractility and plasticity (Abrigo, 2019). Many evidence has accumulated to support the notion that mitochondrial dysfunction contribute to the poor endurance capacity and atrophy that characterize locomotor muscle dysfunction in patients with COPD (Allaire, 2004). There are several potential therapeutic agents targeted at reducing mitochondrial impairment in skeletal muscle of patients with COPD, including polyunsaturated fatty acids (PUFA), exercise rehabilitation, and mitochondria-targeting antioxidant therapies (Taivassalo and Hussain, 2016). TCM has also been shown to have clinically beneficial effects on mitochondrial impairment. For example, Astragalus polysaccharide has been shown to improve mitochondrial dysfunction via inhibiting the opening of a mitochondrial permeability transition pore, improving synergistic interactions between mitophagy and mitochondrial fusion. (Huang et al., 2016; Sun et al., 2014.). Our previous study also showed that BJF reversed the reductions in mitochondrial density observed in COPD rats and improved skeletal muscle tension and tolerance (Dong et al., 2015). In the present study, we demonstrated that BJF treatment elevated

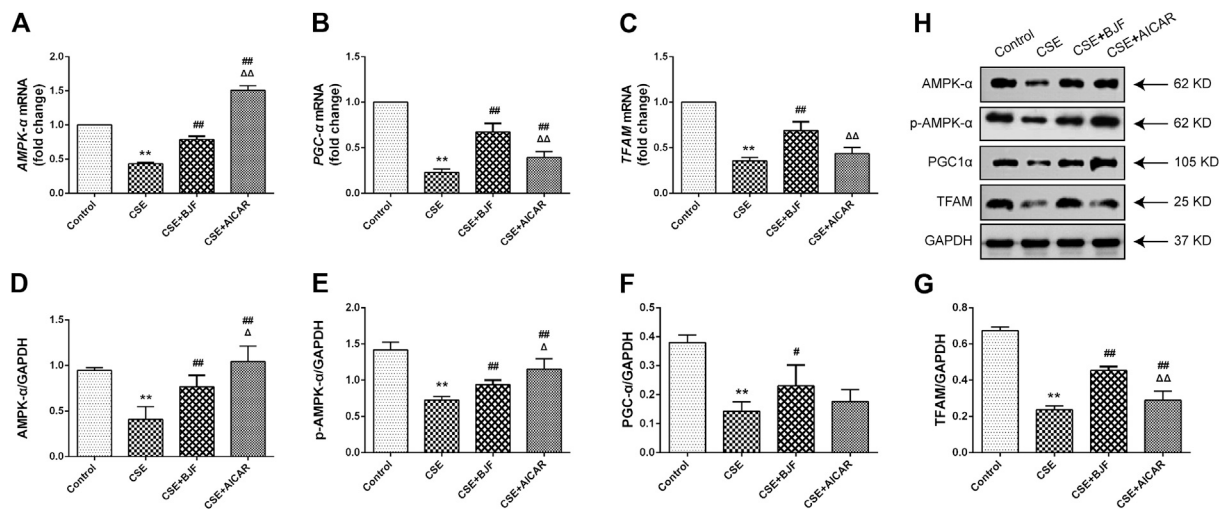

**FIGURE 7 |** Bufeijianpi formula (BJF) restored mitochondrial respiration in cigarette smoke extract (CSE)-exposed L6 cells. **(A)** Schematic representation of the mitochondrial functional assay, and **(B)** mitochondrial respiration under CSE conditions. L6 cells were treated with 10% CSE, 10% CSE + 10% BJF-containing serum, or 10% CSE + 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) for 24 h. The cells were then switched to unbuffered Dulbecco's modified Eagle's medium supplemented with pyruvate, followed by real-time analysis of oxygen consumption rate (OCR). Analysis of **(C)** basal respiration, **(D)** adenosine triphosphate (ATP) production, **(E)** proton leak, and **(F)** maximal respiration. Data are presented as mean  $\pm$  SD. \*\* $p < 0.01$ , \* $p < 0.05$  vs. control group; ## $p < 0.01$ , # $p < 0.05$  vs. model group;  $\Delta p < 0.01$ ,  $\Delta p < 0.05$  vs. BJF group.

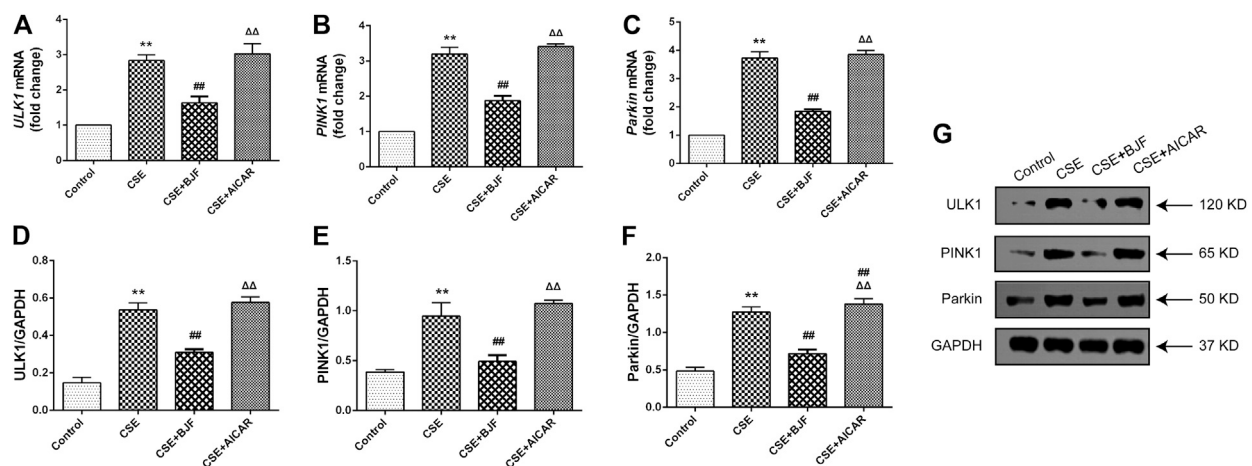

indicators of effective mitochondrial functioning, including ATP, MMP, and MPTP openings in COPD rats, as well as restored levels of mitochondrial respiration in CSE-exposed L6 cells.

Mitochondria use oxidative phosphorylation to synthesize ATP, which provides 90% of the energy required for all cellular activities (Zhang L. et al., 2017). Thus, damage to the mitochondria reduces ATP synthesis; this not only directly leads to mitochondrial swelling, disruption of cristae, and uncoupling of oxidative phosphorylation but also exacerbates ion metabolism disorders (Formentini et al., 2017). Repeated vicious cycles ultimately lead to myocyte damage and cause impairment. Several studies have found that the skeletal muscle cells of patients with COPD hold features of mitochondrial dysfunction, such as increased synthesis of ROS and decreased ATP production (Puente-Maestu et al., 2009). A normal mitochondrial membrane potential is a prerequisite for maintaining oxidative phosphorylation and ATP synthesis, to ensure normal mitochondrial activity. The MPTP is located

between the outer and inner mitochondrial membranes and is a nonselective complex pore composed of several proteins. The MPTP cyclical opening maintains the calcium ion flow, pH, and charge equilibrium in the mitochondrial matrix, ensuring a stable membrane potential while maintaining mitochondrial homeostasis. Pathological or other factors can stimulate the MPTP and induce its excessive opening, which results in the influx of a large number of protons from the inner membrane to the matrix and, hence, in the loss of mitochondrial membrane potential, uncoupling of oxidative phosphorylation, and ATP synthesis failure. In addition, aberrant opening of the MPTP may allow solute molecules to freely pass through the mitochondrial matrix and trigger significant mitochondrial swelling. Ultimately, mitochondrial swelling can lead to the disruption of the mitochondrial outer membrane and the release of cytochrome C and other pro-apoptotic factors, thereby activating apoptosis or necrosis pathways (Bernardi et al., 2015; Ong et al., 2015; Teixeira et al., 2018). One study

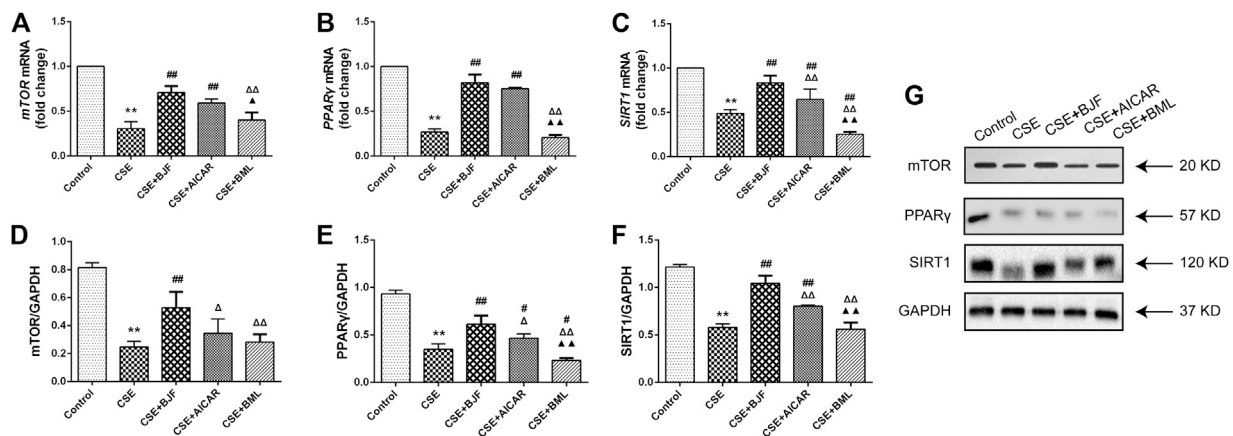

**FIGURE 9 |** Bujfai Jianpi formula (BJF) downregulated expression of mitochondrial autophagic factors in cigarette smoke extract (CSE)-exposed L6 cells. **(A–C)** Real-time polymerase chain reaction validation of UNC-51-like kinase (ULK1), PTEN-induced putative kinase 1 (PINK1), and Parkin mRNA expression levels and **(D–G)** Representative Western blot analysis of ULK1, PINK1, and Parkin protein expression levels. Data are presented as mean  $\pm$  SD. \*\* $p < 0.01$ , \* $p < 0.05$  vs. control group; ## $p < 0.01$ , # $p < 0.05$  vs. model group; ΔΔ $p < 0.01$ , Δ $p < 0.05$  vs. BJF group. GAPDH, glyceraldehyde 3-phosphate dehydrogenase.

found that MPTP opening is aberrant in the skeletal muscles of COPD patients (Puentes-Maestu et al., 2009). In contrast, another study reported that COPD patients were less prone to aberrant MPTP opening in the skeletal muscles compared with healthy individuals (Picard et al., 2008). To date, relatively few studies have explored the MMP and MPTP opening in the skeletal muscles of COPD patients; therefore, further research on these factors is warranted. This study showed that ATP synthesis, MMP levels, and MPTP opening were significantly increased in BJF and BJF+AICAR group.

These results suggest that “the spleen is the source of qi and blood” and is closely associated with mitochondrial function. In addition, BJF can significantly improve mitochondrial function, thereby ameliorating skeletal muscle atrophy.

The mitochondria are essential for cellular aerobic respiration, partaking in stages 2 and 3 (i.e., Krebs cycle and oxidative phosphorylation). Our study measured the respiratory characteristics of mitochondria under cellular baseline and stress conditions. There is evidence indicated that mitochondrial aerobic

**FIGURE 10 |** Bufeijianpi formula (BJF) regulated the adenosine monophosphate-activated protein kinase (AMPK) signaling pathway in cigarette smoke extract (CSE)-exposed L6 cells. **FIGURE 11 |** The Proposed Pathway of BJF for the Treatment of Skeletal Muscle Dysfunction in COPD. BJF improves skeletal muscle and mitochondrial function in COPD rats and L6 cells by promoting mitochondrial biogenesis and suppressing mitophagy via the AMPK pathway.

respiration was inhibited in L6 skeletal muscle cells exposed to high-dose fructose, with significantly reduced oxygen consumption rate, basal and maximal respiration, and ATP synthesis (Jaiswal

et al., 2015). Nevertheless, another study found that resveratrol could partially overcome dexamethasone-induced impaired mitochondrial respiration in C2C12 myoblasts, thereby preventing

mitochondrial dysfunction. The results of this study showed that treatment with CSE could decrease basal mitochondrial oxygen consumption rate, ATP synthesis, and proton leakage in L6 cells (Liu et al., 2016). Taken together, these results suggest that CSE-induced mitochondrial dysfunction and BJF can significantly increase aerobic respiration in mitochondria.

Different factors related to mitochondrial dysfunction, including abnormalities in mitochondrial biogenesis and mitophagy, may contribute to the loss of skeletal muscle strength that leads to functional declines in patients with COPD (Wiegman et al., 2015). AMPK, a vital regulator of bioenergetic metabolism, is critical for mitochondrial biogenesis and mitophagy in muscle cells (Zhang et al., 2018). AMPK activates TFAM via regulation of PGC-1 $\alpha$  and NRF, which contributes to mitochondrial biogenesis when activated by hypoxia and oxidative stress. PGC-1 $\alpha$  has been shown to play a central role in enhancing mitochondrial biogenesis (Islam et al., 2018). TFAM is another key molecule in the regulation of mtDNA copy numbers and mitochondrial function (Kang et al., 2018). Emerging evidence indicates that levels of PGC-1 $\alpha$  and TFAM are decreased in COPD rats (Remels et al., 2007; Lu et al., 2017; Zhang M. et al., 2017). Meanwhile, other studies have demonstrated that protein expression of PGC-1 $\alpha$  is significantly lower in patients with COPD due to decreased numbers of type I fibers (van den Borst et al., 2013; Puente-Maestu et al., 2013). These studies suggest that these factors may serve important regulatory functions in COPD-related mitochondrial dysfunction. In the present study, BJF was shown to effectively upregulate mitochondria biogenesis by increasing expression levels of AMPK- $\alpha$ , PGC-1 $\alpha$ , and TFAM.

The PINK1/Parkin pathway is one of the main molecular mechanisms mediating the mitophagic process. A previous study showed that the number of autophagosomes was clearly increased in skeletal muscles of patients with COPD, which was associated with functional impairments in lungs and muscular atrophy. Increased expressions of LC3BII/I and *p*-ULK have also been observed in COPD patients (Kneppers et al., 2017), indicating abnormalities in autophagy. In the present study, we found that the levels of ULK1, PINK1, Parkin, and LC3B were significantly increased in the skeletal muscle of COPD rats, while treatment with BJF or APL could inhibit mitophagy to different degrees. MTOR is a 289-kDa serine/threonine protein involved in multiple cellular processes, including autophagy (Maiese, 2016). AMPK plays an important role in the signaling cascade of mTOR by inhibiting mTORC1 activity, which results in induction of autophagy (Duan et al., 2016). SIRT1 is a downstream target of AMPK and is therefore downregulated when *p*-AMPK is downregulated (Qi et al., 2014). In the present study, we found that BJF upregulated expression of mTOR, PPAR $\gamma$ , and SIRT1 via regulation of the AMPK signaling pathway in CSE-exposed L6 cells. Therefore, these results suggest that BJF can improve mitochondrial dysfunction by

suppressing mitophagy and enhancing mitochondrial biogenesis via regulation of the AMPK signaling pathway.

Nevertheless, further study is needed to figure out which chemical components in BJF are responsible for suppressing mitophagy and enhancing mitochondrial biogenesis, maybe other mechanism involve in this process.

## CONCLUSION

In conclusion, this study demonstrated that BJF can improve the SMD observed in COPD both *in vitro* and *in vivo* by promotion of mitochondrial biogenesis and by suppression of mitophagy via regulation of the AMPK pathway. The results of this study indicate potential mechanisms for future therapeutic agents and provide a basis for further study of SMD in COPD patients.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Experimental Animal Care and Ethics Committee of the First Affiliated Hospital of Henan University of Traditional Chinese Medicine.

## AUTHOR CONTRIBUTIONS

JM performed the research, analyzed the data, and wrote the manuscript. YL, YT, and SL designed and conceptualized the research and revised the manuscript. QB, JL, YH, LZ, and HJ contributed to animal experiments and cell culture. SF and XL contributed to the preparation of BJF. All authors read and approved the final manuscript.

## GLOSSARY

**AICAR** 5-aminoimidazole-4-carboxamide ribonucleotide

**AMPK** adenosine monophosphate-activated protein kinase

**APL** aminophylline

**ATP** adenosine triphosphate

**BCA** bicinchoninic acid

**BFJ** Bufei Jianpi formula

**CCCP** carbonyl cyanide *m*-chlorophenyl hydrazone

**COPD** chronic obstructive pulmonary disease

**CSE** cigarette smoke extract

**DMEM** Dulbecco's modified Eagle's medium

**EF-50** mid-tidal expiratory flow

**FBS** fetal bovine serum

**FCCP** carbonyl cyanide 4-(trifluoromethoxy) phenylhydrazone

**Fis-1** mitochondrial fission-1 protein

**GAPDH** glyceraldehyde 3-phosphate dehydrogenase

**HE** hematoxylin and eosin

**LC3B** light chain 3B

**MMP** mitochondrial membrane potential

**MPTP** mitochondrial permeability transition pores;

**mTOR** mammalian target of rapamycin

**NRF** nuclear respiratory factor

**OCR** oxygen combustion rate

**PEF** peak expiratory flow

**PGC-1 $\alpha$**  peroxisome proliferator-activated receptor gamma coactivator

**PINK-1** PTEN-induced putative kinase 1

**PPAR** peroxisome proliferator-activated receptor

**PVDF** polyvinylidene difluoride

**ROS** reactive oxygen species

**SD** Sprague–Dawley

**SDS-PAGE** sodium dodecyl sulfate polyacrylamide gel electrophoresis

**SIRT1** (sirtuin 1)

**SMD** skeletal muscle dysfunction

**TCM** traditional Chinese medicine

**TFAM** mitochondrial transcription factor A

**TV** tidal volume

**ULK-1** UNC-51-like kinase

Due to the complex nature of traditional medicines, quality control methods need to cover two aspects: compliance of raw materials with quality standards and process control. Astragali radix (AR), the roots of *Astragalus mongholicus* Bunge, was selected in this study as an example of a widely used traditional medicine in various formulations. Astragaloside IV (AG IV) and calycosin 7-O- $\beta$ -D-glucoside (CG) are used as the markers for the quality control of AR and its products in the Chinese Pharmacopoeia. However, in the raw materials, malic acid esters of the CG and acetate esters of the astragaloside are easily decomposed into CG and AG IV during storage and processing of AR to make extracts for various preparations. The thermal stability of the isoflavonoids and astragalosides in decoction was studied. The level of CG and astragalosides (AG I/AG II/AG IV) was strongly affected by prolonged heat during processing, while calycosin was stable in the conditions. Also the major astragalosides in AR could fully converted into AG IV which eventually reaches a stable level under certain conditions. With calycosin and AG IV as marker components, practical, reproducible, and precise methods were established and applied to the quality analysis of AR from its raw materials to its intermediates and products. This study demonstrates that a full chemical profiles analysis of the whole manufacturing process (from “raw materials—intermediates/extracts—final product”) is important to identify quality markers (Q-markers) and even to establish proper analysis methods for traditional Chinese medicine products.

**Keywords:** astragali radix, quality control, process analysis, quality markers, fingerprint analysis

## INTRODUCTION

Astragali radix (AR) (Huang Qi in Chinese) is derived from the dried roots of *Astragalus mongholicus* or *A. membranaceus* (Fisch.) Bge (National Commission of Chinese Pharmacopoeia, 2015). For more than 2,000 years it is one of the most widely used Chinese herbal medicines and also functional food for reinforcing “Qi” (vital energy). It’s traditionally used for revitalizing, tonifying, skin reinforcement diuretic, abscess-draining, and tissue-generative purpose (National Commission of Chinese Pharmacopoeia, 2015). Modern pharmacological studies have demonstrated that AR possesses a variety of biological activities, such as immunomodulating (Jin et al., 1994), anti-oxidative (Lee et al., 2005), and cardiovascular protective function in diabetic nephropathy (Fu et al., 2014). AR is widely used in different complex formulations, and there are almost 150 traditional

**FIGURE 1 |** Flow chart of integrated strategy for screening process independent markers and establishing quality control methods for raw materials and its products with Astragali Radix.

Chinese patent medicines (TCPMs) containing AR described in the Chinese Pharmacopoeia (2015 version) (National Commission of Chinese Pharmacopoeia, 2015).

The TCPMs that contain AR include granules, capsules, tablets, syrups, plasters/concentrated decoctions, and so on. The manufacturing processes of these products must at least include the extraction of AR pieces with hot water, followed by concentration of the decoction (National Commission of Chinese Pharmacopoeia, 2015). During the processing, from raw materials to concentrated extract, conversions of constituents may occur due to e.g., high temperature, and prolonged contact with air, pH and water (Lin et al., 2000; Chu et al., 2014). For a proper quality control ensuring reproducible end products, Q-markers are required that have a stable level during the whole production process. The Q-markers should be chemically stable and its levels can be followed during the whole manufacturing process. So whole process (i.e., from “raw materials—intermediates/extracts—final product”) analysis is very necessary to identify Q-markers.

Isoflavonoids and triterpene saponins are important active compounds in AR. Astragaloside IV (AG IV) and calycosin 7-O- $\beta$ -D-glucoside (CG) are used as the marker substances for the quality control of AR and its products in the Chinese Pharmacopoeia (National Commission of Chinese Pharmacopoeia, 2015). However, it has been reported that calycosin 7-O- $\beta$ -D-(6"-malonyl) glucoside (CGM) is unstable

during sample preparation and may degrade into CG (Lin et al., 2000). Astragaloside I (AG I), isoastragaloside I (iAG I), astragaloside II (AG II), and acetylastragaloside I (acetyl AG I) were also shown to be unstable and to be converted into AG IV under basic conditions (Chu et al., 2014). These observations imply that the CG and AG IV contents detected in AR are the results of chemical transformations during manufacturing process and sample preparation, and thus their levels are affected by the degree of transformation. Therefore, the present quality analysis methods based on AG IV and CG as Q-markers of AR and its products should be reconsidered. Previous studies on AR, have identified the major small molecules and different quantification methods have been developed for AR and its products (Qi et al., 2006; Song et al., 2007; Qi et al., 2008; Song et al., 2008; Zhao et al., 2018). However, the stability of the levels of Q-markers during the whole manufacturing process and sample preparations were neglected. Specific studies on the stability of the levels of these constituents and their possible chemical conversions during manufacturing processes and sample preparation are essential to guarantee the accuracy of the quality control methods.

This study aims to analyze the stability of the major components of AR during the manufacturing process to identify proper Q-markers for AR, and then develop a practical analytical method for the quality control of AR and its preparations based on these markers. The analysis of the stability of the levels of major components of AR was done by following the changes of chemical profiles throughout the manufacturing process (i.e., from “pieces—freeze-dried powders of extracts—granules”) (Figure 1). To achieve a proper quality control protocol, fingerprint analysis of isoflavonoids including quantitation of calycosin content was established, as well as an optimized method for the determination of AG IV content in AR and its products. This study demonstrates how to develop quality control methods for TCPMs that are independent of processing in the whole production chain from raw materials to its final products. The Q-markers can be accurately detected in raw materials to terminal products, which provides methods for the whole chain analysis of traditional Chinese medicine (TCM) and facilitates the traceability analysis of the quality of TCM.

## MATERIALS AND METHODS

### Chemicals, Materials and Reagents

Pieces, freeze-dried powders of extracts, and formula particles (the final formulated product in the form of granules, batch NO. 406209L, 1406002, 1506027, 1601057, 6101141, 5090891) of AR were obtained from Tianjiang Yifang Company, China. A voucher specimen (RA-YP-1~RA-YP-12; RA-DGF-1~RA-DGF-12; RA-PFKL-1~RA-PFKL-6) were deposited in the herbarium of the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences. The dosage forms and batch numbers used are listed in Table 1. Reference compounds, including astragaloside IV (AG IV, S1, CHB170727), calycosin 7-O- $\beta$ -D-glucoside (CG, F1, CHB161105), and calycosin (C, F7,

**TABLE 1 |** The batch numbers, correlation coefficients to the mean chromatogram of pieces of Astragali Radix, and mean content of quality marker (calycosin and astragaloside IV) for pieces (YP-1–YP-12), freeze-dried powders (DGF-1–DGF-12), and formula granules (PFKL-1–PFKL-6) of Astragali Radix in this study. The mean content was calculated with the weight of target compounds divided by the weight of the samples.

CHB161104) were obtained from the National Institute for the Control of Pharmaceutical and Biological Products. Their purity, as determined by HPLC, was above 98%. The structures of these compounds are shown in **Supplementary Figure S1**. The quality of the AR pieces used met the requirement of the Chinese Pharmacopoeia (2015 version) (National Commission of Chinese Pharmacopoeia, 2015).

HPLC-grade acetonitrile (Fisher Scientific, United States), Optima liquid chromatography–mass spectrometry (LC-MS)-grade formic acid (Fisher Scientific, Czech Republic), and pure water (Wahaha, China) were used as mobile phases. UniElut C<sub>18</sub>EC column (500 mg/6 ml) were bought from Acchrom Instrument (Beijing) Technologies Co., Ltd. Other reagents and chemicals were of analytical grade. All solvents and samples were filtered through 0.45-μm membrane filters (Jinteng, Tianjin, China) before being injected into the HPLC system.

## Preparation of Solutions

### Preparation of Standards Solution

Reference compounds, including AG IV, CG, and C, were accurately weighed and dissolved in methanol to form 1 mg/ml stock solutions, and stored at 4°C for further use.

### Sample Preparation for Isoflavonoid Analysis

Dried pieces of AR were milled to a homogeneous powder and then sieved through a No. 65 mesh listed in Chinese pharmacopoeia. Samples of the powder were accurately weighed to a mass of 1 g, placed in a 50 ml centrifuge tube, and ultrasonicated (40 kHz, 500 W) with 15 ml of methanol for 30 min. After being centrifuged (at 3,000 × g) for 5 min, the methanol solution was collected and filtered. The residue was washed twice with 7.5 ml of methanol, ultrasonicated (40 kHz, 500 W) for 5 min, centrifuged (at 3,000 × g) for 5 min, and filtered again. The filtrates were combined, passed through a membrane filter (0.45 μm), and then a sample was injected into the HPLC system.

Freeze-dried powder and granule sample were accurately weighed to a mass of 0.3 and 0.8 g, respectively, and then placed in a 50 ml centrifuge tube and ultrasonicated (40 kHz, 500 W) with 20 ml of an aqueous solution containing 5% methanol for 10 min. After being allowed to cool, the methanol solution was filtered through a membrane filter (0.45 μm) and injected into the HPLC system for analysis.

## Sample Preparation for Astragaloside IV Content Determination

Extraction and preparation of AR pieces was carried out as described in our previous study (Zhao et al., 2018).

Each sample of freeze-dried powder and formula granules was accurately weighed, 0.3 and 0.5 g, respectively, placed in a 50 ml centrifuge tube. After addition of 20 ml of aqueous solution containing 60% methanol, the sample was ultrasonicated (40 kHz, 500 W) 30 min. After adding 10 ml of ammonia, the aqueous methanol solution was centrifuged (at  $3,000 \times g$ ) for 30 min and filtered. The residue was washed with a mixture of 2 ml of a 60% methanol solution and 1 ml of ammonia, and then centrifuged (at  $3,000 \times g$ ) for 30 min. The filtrates were combined and loaded onto a solid-phase extraction column (SPE column, UniElut C18EC column, 500 mg/6 ml), which had been activated with 5.0 ml methanol. The SPE column was washed with 5.0 ml of water, and then eluted with 5.0 ml methanol. The methanol eluent was collected and filtered through a membrane filter (0.45  $\mu\text{m}$ ), and finally injected into the HPLC system for analysis.

## HPLC and MS Analysis Conditions

### HPLC-DAD Conditions for Isoflavonoid Analysis

HPLC-DAD analyses were performed using a 1200 Series HPLC (Agilent)-DAD system. A YMC-Triart C18 column (250  $\times$  4.6 mm, 5  $\mu\text{m}$ ) was used for the chromatographic separations. The mobile phase consisted of 0.1% formic acid in acetonitrile (A) and water with 0.1% formic acid (B), using a gradient elution of 5–20% A at 0–8 min, 20–25% A at 8–15 min, 25% A at 15–20 min, 25–40% A at 20–30 min, and 40–60% A at 30–40 min. The wavelength was set at 260 nm. The injection volume was 20  $\mu\text{l}$ , and the flow rate was 1 ml/min.

### HPLC-ELSD Conditions for Astragaloside Content Determination

HPLC with evaporative light scattering detector (HPLC-ELSD) analyses were performed using a 1200 Series HPLC (Agilent)-ELSD system (Alltech 2000 ES). A YMC-Triart C18 column (250  $\times$  4.6 mm, 5  $\mu\text{m}$ ) was used for chromatographic separations. The mobile phase consisted of 0.1% formic acid in acetonitrile (A) and water with 0.1% formic acid (B), using a gradient elution of 5–10% A at 0–5 min, 10–32% A at 5–10 min, 32–45% A at 10–30 min, 45–95% A at 30–35 min, and 95–5% A at 35–40 min. The injection volume was 20  $\mu\text{l}$ , and the flow rate was 1 ml/min. ELSD was performed with nitrogen as the carrier gas at a flow rate of 2.5 L/min, and the nebuliser temperature was set to 100°C.

### HPLC-Linear Trap Quadrupole-MS Analysis

To identify the major peaks in the HPLC-UV/ELSD chromatograms, the high-performance liquid chromatography system coupled with a high-resolution linear trap quadrupole Orbitrap mass spectrometry (Thermo Scientific, United States) was used. A full-scan model was employed, and the  $m/z$  range was set to 150–1,000. Electrospray ionization was done with the following conditions: a source heater temperature of 400°C, capillary temperature of 350°C, ion spray voltage of 3.5 kV, capillary voltage of 35 eV, gas flow rate of 35 arb, and

auxiliary gas flow rate of 10 L/h. A data-dependent scan was used for tandem mass spectrometry (MS/MS).

## Method Validation

### Calibration Curves and Linearity Range

A series of analyses were conducted to validate the performance of the methods, including determinations of their linearity, precision, repeatability, stability, and accuracy. The relative standard deviation (RSD) was used to evaluate the precision of the developed method. Methanol stock solutions of AG IV and C were prepared and diluted to appropriate concentration ranges for the construction of calibration curves. The calibration curve of C was constructed using its peak areas and its calculated concentrations. The calibration curve of AG IV was constructed by plotting the logarithm of the peak areas vs. the logarithm of its concentrations.

### Precision, Repeatability, Stability, and Accuracy

Analyses of intra-day variations among six successive injections were chosen to determine the precision of the developed method. To confirm its repeatability, six different working solutions from the same sample were prepared and analyzed. The sample stability was determined by examining one sample at different times during one day, at 0, 1, 2, 4, 12, and 24 h. Over this period, the solution was stored at room temperature.

The recovery of the marker components was determined by spiking the same amount of reference standards into samples with known contents, and these were then extracted and analyzed as described in *Preparation of Solutions* and *HPLC and MS Analysis Conditions* sections. The recoveries were calculated with the following formulas: recovery (%) = (detected amount – original amount)/added amount  $\times$  100%; and RSD (%) = (SD/ Mean)  $\times$  100.

## Stability Test of AR Decoction During Processing

### Preparation of AR Decoction

Pieces of AR (100 g) were placed in 800 ml of water for 30 min at room temperature, and then refluxed for 1 h (at 100°C). Each decoction was filtered, and the residue was refluxed for another 30 min in 600 ml of water (at 100°C). The filtrates were combined and evaporated to a final volume of <500 ml under reduced pressure at a temperature not exceeding 50°C, and then the volume of the concentrated solution was adjusted to 500.0 ml in a volumetric flask using water. The solution was centrifuged at 12,000 rpm for 20 min prior to analysis of the supernatant.

### Stability Test of AR Decoction in the Heating Process

The final AR decoction was separated into nine Eppendorf (EP) tubes, which were then closed and sealed with sealing film. Three of them were heated for 0, 0.5, and 2 h at 100°C, respectively, and the processed solutions were then cooled to room temperature, centrifuged at 12,000 rpm for 20 min, and analyzed by HPLC with DAD/ELSD.

## Stability Tests of Aqueous Solution of Standards

Stability tests were conducted using pure compounds (AG II and AG IV) as representative of astragalosides and an aqueous solution of a mixture of main astragalosides (AG II, iAG II, AG I, and iAG I) in AR. Known amounts (10–50  $\mu$ l) of the solutions of the target compounds were added to water prior to vortex mixing and centrifugation. The supernatant was divided into six tubes, which were closed and heated at 100°C for 2 h. The samples were then cooled to room temperature, filtered, and analyzed using HPLC-ELSD. These analyses were conducted as described in *HPLC and MS Analysis Conditions* section, and the peaks were identified using pure standard compounds and a high-resolution linear trap quadrupole Orbitrap, as described in *HPLC-Linear Trap Quadrupole-MS Analysis* section.

## Data Analysis

The software “Similarity Evaluation System for Chromatographic Fingerprint of TCM” published by GPC (Version 2004A) was employed. This software was used to generate the mean chromatogram as a representative standard fingerprint chromatogram for a group of chromatograms, calculate the correlation coefficients among these, and carry out a similarity analysis to compare the samples with the mean chromatogram based on the peak areas. The relative retention time (RRT) and relative peak area (RPA) of each common peak in the mean chromatogram were calculated, using calycosin (C) as reference within each preparation, respectively, to semi-quantitatively express the different chemical properties in the chromatographic profiles of the samples.

# RESULTS AND DISCUSSION

## Method Optimization for the Analysis of Isoflavonoids

### Optimization of Sample Preparation Methods for AR Pieces

The Chinese Pharmacopoeia (National Commission of Chinese Pharmacopoeia, 2015) uses reflux heating for 4 h in methanol for the sample preparation method for the determination of CG and AG IV contents in AR roots. However, such a method is not convenient for analysis of a large number of samples. To shorten the time of sample preparation, we developed an ultrasonic extraction method. Different parameters were investigated, including the amount of MeOH, ultrasonication times, and extraction time, to reach a complete extraction of C. The reason why C instead of the CG was selected as the Q-marker of AR was demonstrated in *The Stability of Isoflavonoids in AR During Manufacturing Process* section. The amount of sample was kept the same as used in the Chinese Pharmacopoeia (version 2015) (National Commission of Chinese Pharmacopoeia, 2015). The results indicated that the most efficient dissolution was sonication with methanol for three times (**Supplementary Table S1**), as described in *Sample Preparation for Isoflavonoid Analysis* section.

## Optimization of the Sample Preparation Methods for Freeze-Dried Powder and Formula Granules of AR

Different sample preparation methods for freeze-dried powder and formula granules of AR were investigated. The amount of sample was calculated in accordance with the extraction rate (~33.0%) and the proportion of its excipients in granules to ensure that the amount in the sample was consistent with that in the AR pieces. The extraction ability of different solvents (water, 5% methanol, and 50% methanol) and extraction times (10, 30, and 60 min) to extract C were tested. The results indicated that the most efficient solvent was the one using 5% methanol as solvent with sonication for 10 min (**Supplementary Table S1**), as described in *Preparation of Solutions* section.

## Optimization of HPLC Separation

An HPLC-DAD fingerprint analysis of the isoflavonoids in AR was established based on the literature (Qi et al., 2008). The chromatographic conditions were further optimized based on the following principles: 1) to be suitable for the analysis of both the alcohol and the aqueous extract of AR; and 2) to be able to detect the main isoflavonoids in the extracts of AR with baseline separation. After optimizing different chromatographic parameters, including the elution gradient, column temperature, and injection volume, were set as described in *HPLC and MS Analysis Conditions* section.

## The Stability of Isoflavonoids in AR During Manufacturing Process

### Fingerprint Analysis of Isoflavonoids

The fingerprints of 12 batches of AR pieces, 12 batches of freeze-dried AR powders, and six batches of AR formula granules, from the same manufacturer, were analyzed using the established conditions of fingerprint analysis. The mean chromatograms of AR pieces, freeze-dried powders, and formula granules were generated as described in *Data Analysis* section (**Figure 2**), and 10 common peaks were observed for AR among raw materials, intermediates, and final preparations. The common peaks were identified with high-resolution MS by comparisons with our in-house database, and confirmed with analyses of standard compounds. These common constituents included isoflavones [calycosin 7-O- $\beta$ -D-glucoside (CG, F1), calycosin (C, F7), calycosin 7-O- $\beta$ -D-(6''-malonyl)-glucoside (CGM, F2), formononetin-7-O-glucoside (FG, F3), formononetin (F, F8), and 6''-O-malonylononin (FGM, F6)], pterocarpan [(6aR, 11aR)-3-hydroxy-9,10-dimethoxypterocarpan-3-O- $\beta$ -D-glucoside (F4) and (6aR, 11aR)-3-hydroxy-9,10-dimethoxypterocarpan (F9)], and isoflavans [(3R)-7,2'-dihydroxy-3',4'-dimethoxyisoflavan-7-O- $\beta$ -D-glucoside (F5) and (3R)-7,2'-dihydroxy-3',4'-dimethoxyisoflavan (F10)] (Qi et al., 2008; Qi et al., 2009) (**Table 2**). The RRT and RPA of these 10 common peaks were calculated using C (F7) as the reference peak in the mean chromatogram of each respective preparation (**Table 3**).

**FIGURE 2 |** The mean chromatograms of isoflavonoids used as representative fingerprint chromatograms in analyses of the extracts of *Astragali radix* pieces (S1), freeze-dried powders (S2), and formula granules (S3) by HPLC-DAD at 260 nm [F1: calycosin 7-O-β-D-glucoside; F2: calycosin 7-O-β-D-glucoside-6''-O-malonate; F3: formononetin-7-O-glucoside; F4: (6αR, 11αR)-3-hydroxy-9,10-dimethoxypterocarpan-3-O-β-D-glucoside; F5: (3R)-7,2'-dihydroxy-3',4'-dimethoxyisoflavan-7-O-β-D-glucoside; F6: 6''-O-malonylononin; F7: calycosin; F8: formononetin; F9: (6αR, 11αR)-3-hydroxy-9,10-dimethoxypterocarpan; F10: (3R)-7,2'-dihydroxy-3',4'-dimethoxyisoflavan].

### Difference Between the Fingerprint of Isoflavonoids in Pieces, Freeze-Dried Powder, and Formula Granules of AR

The correlation coefficients between the mean chromatograms of the pieces, freeze-dried powder, and formula granules of AR showed that there were differences in the chemical compositions of the raw materials, intermediates, and final preparations of AR (**Supplementary Table S2**). Compared with AR pieces, the RPA of CG in freeze-dried powder and formula granules was significantly higher, while that of CGM was much lower. In

formula granules, the content of CG was four times higher than that in other forms of AR, while the peak of CGM (F2) was almost absent. The same phenomenon was observed for FG and FGM. The chromatographic profiles of the aglycones (F8–F10) in the different preparations were similar.

### The Thermal Stability of Isoflavonoids in the Water Decoction of AR

The remarkable increase in the RPA of CG and FG and the significant decrease in the RPA of CGM and FGM from raw

**TABLE 3 |** Relative retention time and relative peak area of common peaks in the mean chromatograms of pieces, freeze-dried powders, and formula granules of Astragali Radix with peak F7 in each chromatogram as reference.

No. <sup>a</sup>	Relative retention time	Relative peak area		
		Pieces	Freeze-dried powders	Formula granules
F1	0.53	1.14	1.61	4.74
F2	0.68	1.74	1.09	0.22
F3	0.84	0.44	0.54	1.74
F4	0.90	0.12	0.16	0.52
F5	0.94	0.06	0.13	0.28
F6	0.97	0.59	0.36	0.11
F7(s)	1.00	1.00	1.00	1.00
F8	1.23	0.59	0.36	0.38

<sup>a</sup>Refer to the same numbers in **Figure 2**.

materials to granules may be related to the instability of CGM and FGM. For further study, a decoction of AR was prepared and its thermal stability was investigated at 100°C. The results showed that the RPA of CGM and FGM decreased significantly after heating for 30 min, and after 4 h heating these peaks were not detectable anymore. Meanwhile, the RPA of CG and FG increased significantly with heating (**Supplementary Figure S2**). The duration of heating seems to be a major reason for the degradation of CGM and FGM into CG and FG in the aqueous decoction of AR. The levels of CG and FG in the final preparations of AR are thus dependent on the exposure time to heat in the manufacturing process. A previous study on FGM and CGM showed that these esters were almost completely converted into their related glycosides when the decoction was refluxed for 16 h in an 80% ethanol extract or stored in an 80% methanol extract at room temperature for 4 weeks (Lin et al., 2000). Apparently the levels of FGM and CGM seems to be good indicators for the processing of the aqueous and alcoholic preparations of AR roots, low levels of these compounds means that the material has been exposed to heat for prolonged time or has been stored for long periods.

At present, CG is used as the index for isoflavonoids in the quality evaluation of AR in the Chinese Pharmacopoeia (version 2015) (National Commission of Chinese Pharmacopoeia, 2015). However, due to the thermal instability of CGM, the content of CG will increase during sample preparation and storage. Therefore, although CG itself is stable during sample preparation, it is not suitable as a Q-marker of AR and its preparations. Our data show that C remains stable during the manufacturing process. A similar observation was reported for F in *Hedysari radix* (Liu et al., 2006). Calycosin has a variety of pharmacological properties, such as vascular endothelial cell protection, anti-osteoporosis, antioxidant, anti-tumor, and immunomodulating properties (Zhang et al., 2015). In addition, it is a typical phytoestrogen, with estrogen-like effects. Our previous studies found that the estrogen receptor activity of C is greater than that of CG. Therefore, C can be considered as a marker compound for AR because of its chemical properties as well as its activity. The sample preparation and determination methods of C were optimized as described in *Method Optimization for the Analysis of Isoflavonoids* section

and the final established methods were described in *Preparation of Solutions* and *HPLC and MS Analysis Conditions* sections.

## The Stability of Saponins in AR During Manufacturing Process

### The Chemical Profile of Saponins in AR and Its Preparations

We first analyzed the saponins' profile in AR by HPLC-ELSD (**Figure 3A**). A total of more than seven peaks were found to be in common for the different materials analyzed. By high-resolution MS they were identified as Astragaloside IV (AG IV), astragaloside III (AG III), astragaloside II (AG II), isoastragaloside II (iAG II), astragaloside I (AG I), isoastragaloside I (iAG I), and acetylAG I. A method for the simultaneous determination of the content of different saponins (AG IV, AG II, iAG II, AG I, iAG I, and acetyl AG I) was established using UPLC time-of-flight MS (UPLC-TOF-MS) (Qi et al., 2008). Analyzing the content of astragalosides in different preparations, the following observations were made: 1) in AR pieces, the content of AG I was significantly higher than that of other astragalosides; 2) in formula granules of AR, the content of AG II was significantly higher than that of other astragalosides; and 3) in the oral liquids of AR, AG IV was the main components. The astragalosides (AG I, iAG I, AG II, iAG II, and acetyl AG I) are acetylated derivatives of astragaloside IV, which differ only in the number and positions of the acetyl groups in their  $\beta$ -D-xylose attached at position C-3 (**Supplementary Figure S1**). The differences in the astragalosides' profiles in the different preparations seem to be related to the loss of the acetyl groups of the xylose group during the manufacturing process. Loss of all acetyl groups results in AG IV as final product.

## The Stability of Astragalosides in Aqueous Solution at High Temperature

A decoction of AR was prepared and its thermal stability was investigated at 100°C. The results showed that the RPA of AG I, iAG I and iAG II decreased significantly with heating, while the RPA of AG IV increased significantly (data not shown). This result indicates that AG I, iAG I and iAG II in the decoction of AR were unstable and they may be transformed into AG IV during

heating. Then, the stability of an aqueous solution of a mixture of astragalosides (AG II, iAG II, AG I, and iAG I) was tested. The HPLC chromatograms of the samples heated for 2 h at 100°C showed that the levels of AG II, iAG II, AG I, and iAG I decreased while the content of AG IV increased (data not shown). Further investigations of the stability of two single standard compounds (AG II and AG IV) showed that in an aqueous solution, at room temperature, AG II was partly transformed into AG IV, and heating at 100°C further promoted the conversion of AG II into AG IV, while AG IV was stable in this condition (**Supplementary Figure S3**). Thus, heating is a major factor promoting the deacetylation reaction, leading to the transformation of astragalosides. The proposed chemical degradations of astragalosides were summarized in **Supplementary Figure S4**. This explains the different saponin profiles of AR preparations. Heat and long term storage lead to preparations with only AG IV, as found in oral liquid samples of AR (Qi et al., 2008). This implies that the saponins' fingerprint for AR gives information about the manufacturing process and storage.

## Method Optimization for the Analysis of Astragaloside IV

The sample preparation for the AG IV determination in the Chinese Pharmacopoeia (National Commission of Chinese

Pharmacopoeia, 2015) (version 2015) involves reflux extraction, liquid-liquid separation with *n*-butanol, and liquid-liquid separation with ammonia, which may take more than 2 days to complete per sample. Therefore, we optimized and established practical method for the determination of AG IV content in raw materials and pieces of AR (Zhao et al., 2018). This method replaces all of the time-consuming preparation steps with sonication extraction and ammonia hydrolysis, shortening the preparation time from around 2 days to less than 2 h. Sample preparation methods and analysis methods were optimized in this study for freeze-dried powder and formula granules of AR as described below.

## Optimization of Extraction Methods for Freeze-Dried Powder and Formula Granules of AR

The sample preparation methods for freeze-dried powder and formula granules of AR were investigated. The extract ability of different solvents [5% methanol (v/v), 60% methanol (v/v), and methanol] and extraction times (10, 30, and 60 min) to extract AG IV were tested. The results indicated that extraction with 60% (v/v) methanol and sonication for 30 min showed the best performance in sample preparation (**Supplementary Table S1**), as described in *Sample Preparation for Isoflavonoid Analysis* section.

## Optimization of the Amount of Ammonia

One critical step for the sample preparation of AR in Chinese Pharmacopoeia was reverse extraction with ammonia (National Commission of Chinese Pharmacopoeia, 2015). The purpose of this step was to transform other saponins into AG IV (Zhao et al., 2018). As an important parameter, the amount of ammonia solution needed for the transformation of astragalosides into AG IV was investigated. The fingerprint profiles of the astragalosides of AR extracts before and after adding 10 ml of ammonia solution ammonia were analyzed by HPLC–ELSD and compared (**Figure 3**). The results show that, under the specific conditions, the content of AG IV increased, while the peaks of all other astragalosides disappeared. The peak area of AG IV increased with the increased amount of ammonia solution, reaching its highest amount with 10 ml or more of ammonia solution. This implies that AG II, iAG II, AG I, iAG I, and acetyl AG I can be completely converted into AG IV which was stable under this alkaline conditions. Therefore, 10 ml of ammonia solution was used in this study.

## Optimization of the Enrichment Methods of Astragaloside IV

The most practical method for the determination of AG IV content is the HPLC–ELSD. ELSD is a universal detector that gives very strong signals of primary compounds in the water extracts of herbal materials. Therefore it is necessary to remove the major primary metabolites from the aqueous AR extracts and the AR preparations, before the analysis of the saponins. Especially in case of formulated granules, the various excipients may interfere with the analysis. An SPE column separation method was applied to enrich AG IV in samples and remove the primary compounds. The following

parameters were investigated in a step-by-step approach: the amount of ammonia added (1, 5, 10, 12, and 15 ml), the size of the SPE column (1,000 mg/6 ml and 500 mg/3 ml), the volume used in the water elution (3, 5, and 6 ml), and the volume used in the methanol elution (3, 5, and 6 ml). Finally, the content of AG IV was compared among procedures and the optimized methods were described in *HPLC-ELSD Conditions for Astragaloside Content Determination* section.

### Optimization of ELSD Conditions for the Determination of Astragaloside IV

The effects of the elution gradient, carrier gas velocity (2.3, 2.4, 2.5, 2.7, and 2.8 L/min), and temperature of the drift tube (100, 105, and 110°C) of ELSD were investigated simultaneously. The largest peak area of AG IV was obtained at the flow rate of 2.4 L/min and the drift tube temperature of 110°C. The analytical method to determine AG IV content was described in *HPLC-ELSD Conditions for Astragaloside Content Determination* section.

## Method Validation and Sample Analysis

### Method Validation

The calibration curve of C was successfully constructed as follows:  $Y = 90,909X - 19.877$ , where Y is the peak area and X is the concentration of C (mg/ml). The calibration curve of AG IV was also constructed, as:  $\ln(Y) = 1.6723\ln(X) - 1.8336$ , where  $\ln(Y)$  is the natural logarithm of the peak area and  $\ln(X)$  is the logarithm of the concentration of AG IV (mg/L). The LOD, LOQ, precision, stability, repeatability, and accuracy of the established methods for the determination of C and AG IV content are summarized in **Supplementary Table S3**. All results for the precision, stability, repeatability, and accuracy of these methods confirmed their validity and acceptability.

### Sample Analysis

Samples of 12 batches of AR pieces, 12 batches of AR freeze-dried powders, and six batches of AR formula granules from the same manufacturer were analyzed by applying the specific extraction procedure for each type of material and the chromatographic methods for isoflavonoids and saponins. All analyses were repeated three times, and the data were recorded and expressed as the mean contents of C and AG IV (**Table 1**). The results demonstrated that this developed method was suitable for the determination of C and AG IV content in AR, from its raw materials to its final preparations.

## CONCLUSION

This study demonstrates that investigating the manufacturing process of traditional medicines from their raw materials to final preparations/products by chemical profile analysis is useful and effective for both the selection of suitable marker components and establishment of proper analytical methods

for the quality control of traditional medicines. The quality control of the whole manufacturing process needs the process independent markers from the original raw plant material. For AR roots that is calycosin in case of the isoflavonoids and astragaloside IV in case of saponins. The established fingerprint methods for isoflavonoids and quantification methods for calycosin and AG IV were further validated by the analysis of a large number of samples, ranging from raw materials to final products. The developed methods were found to be simple, robust and reproducible, and thus suited as reliable quality control procedures for AR and its derived products. This work provides a demonstration study on the whole-process quality control of TCM and provides reference for improving the quality control methods of AR in Chinese Pharmacopoeia. The results suggest that it is necessary to reanalyze the quality control methods of other Chinese herbal medicines and their products derived from their water decoctions.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## AUTHOR CONTRIBUTIONS

YD, XQ, and SC designed the study. DW, MZ, LY, and PL did the experiments. YD, DW, and RV wrote the manuscript. All authors gave approval to the final version.

## FUNDING

This work was supported by the Natural Science Foundation (grant numbers: 81473340, 81803734) and Project of China Academy of Chinese Medical Sciences (grant numbers: ZXKT17009, GH201701).

## ACKNOWLEDGMENTS

We would like to thank Tianjiang Yifang Company, China, to provide pieces, freeze-dried powders, and formula particles of AR for this study.

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2020.554777/full#supplementary-material>.

Several clinical therapies such as tissue repair by replacing injured tissues with functional ones have been reported; however, there is great potential for exploring traditional herbal-induced regeneration with good safety. Tongqiao Huoxue Decoction (TQHDX), a well-known classical traditional Chinese medicinal formula, has been widely used for clinical treatment of stroke. However, biological activity and mechanisms of action of its constituents toward conferring protection against cerebral ischemia-reperfusion (I/R) injury remain unclear. In this present study, we evaluated TQHDX quality using HPLC; then, it was screened for its potential active ingredients using a series of indices, such as their drug-likeness and oral bioavailability. Subsequently, we analyzed the potential mechanisms of TQHDX anti-I/R using gene ontology functional enrichment analyses. The network pharmacological approach enabled us to screen 265 common targets associated with I/R, indicating that TQHDX had remarkable protective effects on infarction volume, neurological function scores, and blood-brain barrier (BBB) injury. In addition, TQHDX significantly promoted the recovery of regional cerebral blood flow (rCBF) 7 days after reperfusion compared to rats in the vehicle group. Immunofluorescence results revealed a significantly higher CD34 expression in TQHDX-treated rats 7 days after reperfusion. TQHDX is not merely effective but eventually develops a secretory profile composed of VEGF and cerebral blood flow, a typical signature termed the angiogenesis-associated phenotype. Mechanistically, our data revealed that TQHDX (6 g/kg) treatment resulted in a marked increase in expression of p-focal adhesion kinase (FAK) and p-Paxillin proteins. However, Ki8751-mediated inhibition of VEGFR2 activity repealed its angiogenesis and protective effects and decreased both p-FAK and p-Paxillin protein levels. Taken together, these findings affirmed the potential of TQHDX as a drug for the management of stroke, which might be exerted by increasing the angiogenesis via the VEGF pathway. Therefore, these results provide proof-of-concept evidence that

angiogenesis is a major contributor to TQHXD-treated I/R and that TQHXD is a promising traditional ethnic medicine for the management of this condition.

## INTRODUCTION

Stroke is the second leading cause of death in the world owing to its high morbidity, mortality, and disability rates (Benjamin et al., 2018). Approximately four-fifths of all patients with stroke suffer from ischemia stroke, and most of them live with disabilities for a long time (Mozaffarian et al., 2015). One of the principles of clinical treatment of ischemic stroke is to restore blood flow in time. Although this approach is an effective protection measure, long-term accumulation of reperfusion can lead to cerebral ischemia-reperfusion (I/R) injury. Treatment of I/R injury-induced ischemic stroke is challenging. To date, recombinant plasminogen activator is still the only drug approved by the Food and Drug Administration (FDA) for treating stroke. Therefore, the development of novel drugs is necessary to aid in the management of patients with stroke.

Angiogenesis, a basic biological process that aids in the development of new blood vessels from existing capillaries, has been implicated in multiple pathological and physiological processes (Beck and Plate, 2009). Although the connection between the brain and blood is a new focus in scientific researches, theories have linked this connection to traditional Chinese medicine. For example, many studies have shown that angiogenesis plays a pivotal role in many pathological conditions, such as cerebrovascular and cardiovascular diseases and cancer (Ferrara and Kerbel, 2005). These diseases involve actions of multiple growth factors, receptors, and molecules, resulting in diverse signaling pathways that affect the pathogenicity of angiogenesis across different diseases (Carmeliet, 2000). In addition, angiogenesis mediates the production of new blood vessels, thereby contributing to patient recovery after ischemic injury (Liu et al., 2017). Although angiogenesis is elevated during ischemia and hypoxia, this process is too slow to meet the needs of body recovery (Krupinski et al., 1994). Therefore, accelerating angiogenesis during the establishment of collateral circulation has been proposed as an attractive approach for treating cerebral ischemia injury (Liu et al., 2014).

Traditional Chinese medicine (TCM), which has been used for more than 2000 years with the characteristics of multiple pathways and multiple targets, is likely to represent novel therapeutic targets for developing effective treatment against I/R (Wu et al., 2019; Peng et al., 2019). In fact, numerous TCM-based remedies for stroke have been introduced into the market, owing to their unique advantages (Wu et al., 2019; Chen et al., 2009; She et al., 2019). For example, Tongqiao Huoxue Decoction (TQHXD), a classic traditional Chinese herbal formula, has been used to treat stroke. It had subsequently been embodied in Corrections on the Errors of Medical Works prescribed by Qingren Wang, comprising eight Chinese herbs (Table 1). Currently, TQHXD is widely used to treat

patients with ischemic stroke (Yang and Fan, 2009; Liu et al., 2003). The key active components for this drug include paeoniflorin, ferulic acid, and muscone (Xu et al., 2008; Wu et al., 2018). Collectively, TQHXD controls stroke via various mechanisms. For instance, the drug can module permeability of the blood-brain barrier (BBB) and activity of plasminogen activator inhibitor-1 (Li et al., 2017; Wang et al., 2012; Kim et al., 2016; Wu et al., 2019). However, the mechanisms involved in TQHXD have only partially been unraveled. There is still a thought-provoking question of whether TQHXD can protect against the I/R injury by targeting angiogenesis.

The present study sought to provide new insights into TQHXD's anti-I/R effects in rats. Summarily, we employed network pharmacology, an approach by using high-throughput data from public databases to identify interactions among "compound-target-disease," and gave a holistic cognition of the relationship between formula and diseases (Hopkins, 2008). This approach's systemic and holistic traits are in line with the concept of TCM (Pan et al., 2020; Mou et al., 2020). In this work, the network pharmacology approach was used to provide a new understanding of TQHXD that exert anti-I/R effects, and TQHXD was intragastrically administered to rats with MCAO for 7 days to explore the mechanism.

## METHODS AND MATERIALS

### Animals

Male healthy Sprague Dawley rats weighing 240–260 g were purchased from the Laboratory Animal Center of Anhui Medical University (Hefei, certificate of quality: No. SXCK 2011-002, China). All rats had free access to standard diet and water. All experimental rats were approved by the Institutional Animal Care and Use Committee at Anhui University of Chinese Medicine. In addition, rats had undergone treatments according to "3 Rs" rules (Reduction, Refinement, and Replacement) in all experiments.

**TABLE 1 |** The composition of TQHXD.

	Chinese medicine	Family	Weight (g)
1	Taoren (Semen Persicae)	Rosaceae	9
2	Chishao (Radix Paeoniae Rubra)	Ranunculaceae	3
3	Chuanxiong (Rhizoma Ligustici Chuanxiong)	Apiaceae	3
4	Honghua ( <i>Flos carthami</i> )	Asteraceae	9
5	Dazao (Fructus Jujubae)	Rhamnaceae	5
6	Cong (Scallion)	Liliaceae	3
7	Shexiang ( <i>Moschus</i> )	Cervidae	0.15
8	Shengjiang ( <i>Zingiber officinale</i> Roscoe)	Zingiberaceae	9

## Herbs and Reagents

Herbs of TQHXD were purchased from Xin He Traditional Chinese Medicines Group Corporation (Hefei, China). Furthermore, each herb was authenticated by the herbal medicinal botanist, Professor Shoujin Liu, at the Anhui University of Chinese Medicine. Nimodipine Tablets (NMDP) were purchased from Bayer (Batch Number: H20003010), and 2% triphenyltetrazolium chloride (TTC) dye solution was purchased from Sigma Chemical. Ki8751 (VEGFR2 special inhibitor) was selected from Selleck Chemicals Co., Ltd. Rabbit primary antibodies for VEGF-A, p-FAK (Tyr576), p-Paxillin (Tyr118), and  $\beta$ -actin were bought from CST (Boston, United States). The mouse antibodies against FAK and Paxillin were bought from Abcam (Cambridge, MA, United States). The secondary horseradish peroxidase- (HRP-) labeled antibodies were acquired from Santa Cruz Biotechnology (Santa Cruz, CA, United States). All of the reagents or herbs were standard and commercially available.

## Network Pharmacology

In this section, the intersect target enrichment analysis and protein-protein interaction (PPI) network were utilized to reveal the multitarget, multifunction, and multipathway therapeutic advantages of TQHXD in protecting I/R.

### Collection of Potential Active Ingredients and Disease Targets in TQHXD

Three TCM databases were used to collect the active ingredients of TQHXD, including the traditional Chinese medicine systems pharmacology database (TCMSP) (Ru et al., 2014), (TCMSP™, <http://lsp.nwsuaf.edu.cn/tcmsp.php>), the Traditional Chinese Medicine Integrated Database (Xue et al., 2013) (TCMID, <http://www.megabionet.org/tcmid/>), and the TCM Database @Taiwan (Chen et al., 2014) (<http://tcm.cmu.edu.tw/>). Importantly, the interrelated scientific literature databases (PubMed, MEDLINE, and China National Knowledge Infrastructure) were also employed in this work. Subsequently, we set an OB (oral bioavailability) value of  $\geq 30\%$  and DL (drug-like quality) value of  $\geq 0.18$  as standard to screen out the potential ingredients of TQHXD. Secondly, the 2D structure of components was transformed into SDF structure format through the PubChem database (<https://pubchem.ncbi.nlm.nih.gov/>). Subsequently, the targets were obtained using SwissTargetPrediction (<http://new.swisstargetprediction.ch/index.php>) and TCMSP, an online tool for predicting targets. In addition, related targets belonging to *Homo sapiens* were renamed retrieved from the UniProt database (<https://www.uniprot.org/uniprot/>). Finally, the NIMNT database (<http://www.idrug.net.cn/NIMNT/>) was used to enrich the possible indications of TQHXD.

## Disease Target

The keyword “cerebral ischemia reperfusion injury” was used in GeneCards (<https://www.genecards.org/>), OMIM (Online Mendelian Inheritance in Man, <https://omim.org/>) and DrugBank databases (<https://www.drugbank.ca/>) to search for I/R-related targets. These databases (Wishart et al., 2018) are free

bioinformatics resources that combine disease data with comprehensive targets. Finally, these targets were intersected with related targets of TQHXD by the online tool (<http://bioinfo.gp.cnb.csic.es/tools/venny/index.html>).

## Gene Ontology Functional Enrichment Analysis

The Database for Annotation, Visualization, and Integrated Discovery (DAVID; <http://david.abcc.ncifcrf.gov/home.jsp>, version 6.8), together with pathway data obtained from the KEGG database, was used to find the identification of characteristic biological attributes of the potential target for I/R in TQHXD. Finally, FunRich tool (<http://www.funrich.org/>) was used to analyze more biological characteristics of a common target.

## Protein-Protein Interaction Network

Generally speaking, it is difficult for a single protein to complete a series of complex biological processes. Hence, it is important to find the PPI network. The overlapped components-targets belonging to *Homo sapiens* were imported to the STRING database (<https://string-db.org/>, version 11.0), and an organism entry was set with the minimum required interaction score = 0.900. Finally, the PPI network was visualized in Cytoscape (<https://cytoscape.org/>, version 3.7.2). A higher degree value node represented putative crucial targets of herbs in the PPI network.

## Experimental Verification of the Protective Effect of Tongqiao Huoxue Decoction Against Ischemia-Reperfusion

### Establishment of Ischemia-Reperfusion Model

The cerebral I/R injury model *in vivo* was performed according to Longa's method (E. Z. Longa et al., 1989). Firstly, rats were anesthetized with 4% isoflurane (4% for anesthesia induction; 2% for anesthesia maintenance, 3 ml/kg). Then, the internal carotid artery (ICA), external carotid artery (ECA), and left common carotid artery (CCA) were carefully separated by tweezers. Subsequently, the left CCA and ECA were blocked by microvascular aneurysm clips, followed by occluding the middle cerebral artery (MCA) through inserting a filament (Doccol, United States) coated through the ECA ( $18 \pm 2$  mm). Two hours later, the filament was removed to achieve reperfusion. Sham group received the same procedures, but no filament was inserted into the MCA. The temperature of the operation chamber was maintained at  $37 \pm 0.5^\circ\text{C}$  throughout the whole surgery. After waking up, the rats were put back into the cages and had free access to water and food.

## Preparation of Tongqiao Huoxue Decoction Sample

The ethanol extract of TQHXD was prepared as previously described in (Chao-Liang et al., 2015). *Prunus persica* (L.) Batsch 90 g (Xin He Traditional Chinese Medicines Co., Ltd.,

Hefei, China, product batch number: 1702181), *Paeonia anomala* subsp. *veitchii* (Lynch) D.Y.Hong and K.Y.Pan [Paeoniaceae] 30 g (Xin He Traditional Chinese Medicines Co., Ltd., Hefei, China, product batch number: 1709201), *Conioselinum anthriscoides* “Chuanxiong” [Apiaceae] 30 g (Xin He Traditional Chinese Medicines Co., Ltd., Hefei, China, product batch number: 1701033), *Carthamus tinctorius* L. 90 g (Xin He Traditional Chinese Medicines Co., Ltd., Hefei, China product batch number: 1707213) 90 g, *Ziziphus jujuba* Mill. 50 g (Huidu Traditional Chinese Medicines Co., Ltd., Bozhou, China, product batch number: 1707223), *Zingiber officinale* Roscoe 90 g (Zhejiang Chinese Medical University prepared pieces Co., Ltd., Hangzhou, Zhejiang, China, product batch number: 190601), and fresh *Allium fistulosum* L [Amaryllidaceae] 30 g (WalMart Inc. Hefei, China) were extracted in 3200 ml 75% ethanol for 2 h and filtered. After the confluent solutions pump vacuum, 1,600 ml 75% ethanol was added to it and then pump-vacuumed again until there is no alcoholic taste. Finally, 1.5 g *Moschus* (Lasa Chinese Medicines Co., Ltd., Lasa, China, product batch number: 62523635662) was added to the solutions to form the extract solutions with a concentration of 2 g/ml (equivalent to the dry weight of raw materials). The medicinal plant scientific names have been unified using the Kew Science database ([https://mpns.science.kew.org/mpns-portal/?\\_ga=1.111763972.1427522246.1459077346%20or%20http://www.plantsoftheworldonline.org/%20or%20www.theplantlist.org](https://mpns.science.kew.org/mpns-portal/?_ga=1.111763972.1427522246.1459077346%20or%20http://www.plantsoftheworldonline.org/%20or%20www.theplantlist.org)).

### High-Performance Liquid Chromatography (HPLC)

The quality control reproducible experiments of TQHXD were conducted using HPLC. The quality control of TQHXD was completed by paeoniflorin (a characteristic pharmaceutically active component of TQHXD) in our work. Firstly, TQHXD solutions were put into the HPLC facilities (Agilent 1100 HPLC system, United States). The separations were carried out on a Phenomenex C18 column (4.6 mm × 250 mm, 5 μm) with the following conditions: temperature, 30 °C; flow rate, 1.0 ml min<sup>-1</sup>. The mobile phase consisted of methanol (A)-H<sub>2</sub>O (0.05% V/V phosphoric acid), and gradient elution was set as follows: 0–15 min, 10% A–28% A; 15–30 min, 28% A–40% A; 30–55 min, 40% A–48% A; 55–70 min, 48% A–54% A. Finally, the detection wavelength and the injection volume were 254 nm and 20 μL, respectively.

### Experimental Groups and Drug Administration

Firstly, to investigate whether the protective effects of TQHXD were involved in angiogenesis (experiment 1), rats were randomly divided into six groups: the sham group, vehicle group, TQHXD group (3 g/kg, 6 g/kg, and 12 g/kg), and positive group (NMDP, 0.02 g/kg). Dosages of TQHXD (3, 6, and 12 g/kg) and NMDP (0.02 g/kg) groups were equivalent to the dose of clinical adult patients. Rats in the TQHXD and NMDP groups were treated with respective doses by intragastric administration once a day for 7 days after reperfusion. Rats in sham or vehicle groups were given normal saline.

Secondly, to explore the mechanisms of TQHXD-associated angiogenesis (experiment 2), rats were randomly divided into five groups: the sham group, vehicle group, TQHXD group (6 g/kg),

Ki8751 (0.5 mg/kg) group, and combine group (TQHXD + Ki8751). As mentioned in experiment 1, TQHXD and TQHXD + Ki8751 combine groups were treated with TQHXD by intragastric administration for 7 days. Rats in sham, vehicle, and Ki8751 groups were given the same volume of normal saline for 7 days. Tail vein injection Ki8751 (final dose: 0.5 mg/kg (Hou et al., 2015)) was administered to rats 30 min prior to operation (Figure 1).

### Neurological Score

Neurological recovery was examined at day 1 and day 7 after 24 h reperfusion using Longa's method (Longa et al., 1989): 0, no neurologic deficit; 1, failure to extend forepaw fully; 2, circling to the left; 3, falling to the left or no spontaneous motor activity; 4, not walking spontaneously and experiencing a lowered stage of consciousness. Rats with scores of 0 and 4 were excluded from the experiment.

### Monitoring Local Blood Flow Changes by Laser Doppler Flow

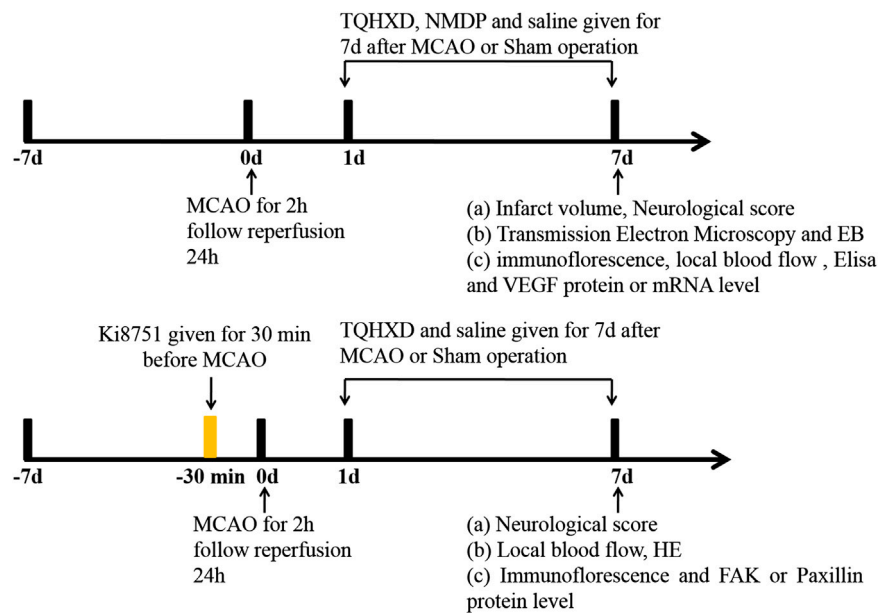

The rCBF of the left brain was measured by laser Doppler flow (LDF). Rats were anesthetized with 4% isoflurane; the skin and subcutaneous tissue were cut slowly. The fascia on the skull of rats was separated by nipper to fully expose the area of the skull. The position of assessment was recorded in the following coordinates relative to Bregma: ML: +2.0 mm, AP: +1.0 mm (Schmid-Elsaesser et al., 1998). Routine zero-calibration with front probe and monitoring the blood flow during the operation were performed. Finally, the blood flow was detected through LDF at days 1 and 7.

### Triphenyltetrazolium Chloride Staining

Rats were sacrificed at 30 min after the last drug administration; then frozen brains were sliced into coronal sections of 2 mm thickness. The slices were stained with 2% TTC (pH = 7.4, Sigma Chemical Co., United States) at room temperature. The change of cerebral infarct volume in all groups was analyzed by ImageJ. The infarct volume was calculated by infarct size \* average slice thickness (2 mm).

### Immunofluorescence

Rats were sacrificed after the last drug treatment; brain tissues were isolated after being perfused with 0.9% normal saline followed by 4% cold paraformaldehyde. The brains were quickly frozen after gradient elution with sucrose and cut into 5 μm coronal thick slices. The sections were transparent with 0.5% Triton X-100 for 5 min and then blocked with 10% BSA for 1 h. Slices were incubated with primary anti-CD34 antibody (1:100, Abcam, United States) at 4 °C overnight. Then, the slices were washed with PBST 3 times. Slices were incubated with anti-rabbit secondary antibody (1:1,000, Cell Signal, United States) for 50 min at 37 °C. After counterstaining with 4, 6-diamidino-2-phenylindole (DAPI) and covering slices with anti-fluorescent quenching, the slices were observed and photographed under fluorescent microscopy (Leica, Germany) and then analyzed by Image-Pro 6.0 software.

**FIGURE 1 |** Experimental design and schedules. MCAO: middle cerebral artery occlusion; TQHXD: Tongqiao Huoxue Decoction; EB: Evans blue; ELISA: enzyme-linked immunosorbent assay; HE: hematoxylin-eosin staining; VEGF: vascular endothelial growth factor; FAK: focal adhesion kinase.

### Blood-Brain Barrier Permeability

The BBB permeability was determined by measuring the amount of Evans blue (EB). EB dye (2%, 4 ml/kg body weight) was slowly injected by tail vein injection intravenously 30 min after last drug treatment and allowed to circulate for 2 h. Rats were anesthetized with 4% isoflurane and then transcardially perfused with 0.9% normal saline to wash away any remaining dye in the blood vessels. The brain was incubated in 3 ml formamide at 45 °C for 72 h. The solutions were centrifuged for 40 min at 25,000 g. Finally, the absorption of each well was measured at 632 nm with a microplate reader (Thermo Scientific, United States). The content of EB in all groups was expressed as  $\mu\text{g/g}$  of the brain according to the standardized curve (Ren et al., 2015).

### Hematoxylin and Eosin Staining

At 24 h after reperfusion, rats were anesthetized with 4% isoflurane and perfused transcardially with 0.9% saline and then reperused with pre-ice cold 4% paraformaldehyde. The brain was embedded in paraffin after being dehydrated in graded ethanol and cleared in xylene. Finally, the slices of 4  $\mu\text{m}$  sections were stained with hematoxylin and eosin (HE) staining following histochemical procedures.

### Ultrastructural of Tight Junction Detection Through Transmission Electron Microscopy

In brief, rats were anesthetized with 4% isoflurane and then perfused with 0.9% normal saline, followed by precold 4% paraformaldehyde. The frontoparietal cortex of the ischemia brain was separated into pieces of 1  $\text{mm}^3$  and then blended with 2.5% glutaraldehyde at 4 °C. Then, these pieces were dunked in 2%  $\text{OsO}_4$  for 2 h. The pieces were embedded in

Epon 812 after being incubated with  $\text{OsO}_4$ . Finally, ultrathin pieces of cortex were stained with citramalic acid and acetic acid uranium and then scanned by transmission electron microscopy (TEM).

### Detection of Vascular Endothelial Growth Factor in Serum by Enzyme-Linked Immunosorbent Assay

At 30 min after the last drug treatment, rats were anesthetized with 4% isoflurane. Blood was collected from the abdominal aorta by a one-time negative pressure tube without anticoagulant. Blood was stood at room temperature for 3 h and then centrifuged at 2000 rpm for 20 min to collect serum. The expression of vascular endothelial growth factors (VEGF) in rats was detected using a VEGF ELSIA kit (RRV00, R&D Systems, Minneapolis, MN, USA). The absorbance of each well was measured at 450 nm through a microplate reader (Thermo Scientific, United States). The content of VEGF-A in the samples was calculated according to the standardized curve.

### Western Blot

The protein levels of VEGF-A, FAK, Paxillin, and  $\beta$ -actin were detected using Western blot. Cortex tissues were lyzed with precold RIPA lysis buffer and immediately mixed with phenylmethanesulfonyl fluoride (PMSF, Beyotime, Nanjing, China) centrifuged at 12,000 rpm at 4 °C for 15 min. The concentration of protein was quantified by bicinchoninic acid (BCA) (Beyotime, Nanjing, China). All proteins were run on 12% (w/v) or 10% SDS-PAGE gel and then transferred to polyvinylidene difluoride (PVDF) membrane with Bio-Rad electrophoretic transfer system. The membrane was blocked with 5% (w/v) nonfat milk for 2 h at 37 °C and incubated with

the primary antibody to VEGF-A (1: 800), p-FAK (1: 1,000), Paxillin (1: 1,000), and  $\beta$ -actin (1: 1,000) at 4°C overnight, respectively. After washing with Tris-HCl Buffered Saline containing 0.1% Tween-20 (TBS-T) 3 times, the membrane was incubated with coherent secondary (1:5,000) antibody for 2 h at 37°C.  $\beta$ -Actin was used as an internal reference. The protein bands were developed using enhanced chemiluminescence (ECL) reagents (Thermo, United States). Finally, images were scanned by an Amersham Imager 600 (GE, United States).

### Quantitative Real-Time PCR

In brief, RNA was isolated using a tissue RNA kit (Omega Bio-Tek, GA) and then was reverse-transcribed using a TAKARA reverse transcription kit. Real-time quantitative PCR (qRT-PCR) was performed on the Mx3000P qPCR System (Agilent Technologies, Santa Clara, CA, United States) using SYBR Premix Ex Taq™ (TAKARA). Primer sequences used to amplify fragments were synthesized by Sangon Biotech, Shanghai. The relative mRNA expression was normalized to GAPDH using the relative quantification method  $2^{-\Delta\Delta C_t}$ . The sequences of primers in this experiment were as follows: GAPDH Forward, 5-GGGTGTGAACCATGAGAAGTATG-3, GAPDH Reverse, 5-GATGGCATGGACTGTGGTCAT-3; VEGF Forward, 5-CTGCCATCCAATCGAGACCC-3, VEGF Reverse, 5-TGCATT CACATTTGTTGTGCTG-3.

### Statistical Analysis

The Shapiro–Wilk normality test was used to analyze whether the data were normally distributed. Then, the *t*-test was utilized to analyze the significance of differences. Statistical significance between groups was evaluated by one-way analysis of variance (ANOVA). All data were presented as mean  $\pm$  standard deviation (SD). Statistical analysis was performed using SPSS (SPSS, Inc., version 20.0). A significant difference was accepted at *p* values lower than 0.05.

## RESULTS

### Genes Associated with Ischemia-Reperfusion

A total of 929 significant genes were obtained from the GeneCards, OMIM, and DrugBank databases after screening out some targets with low credibility (Supplementary Table S1).

### Drug Targeting

According to the ADME thresholds of OB  $\geq$  30% and DL  $\geq$  0.18, 94 compounds of TQHXD were obtained from the three following databases: TCMSP, TCM Database@Taiwan, and TCMID after eliminating the common compounds, as listed in Supplementary Table S2. In addition, we also achieved quality control, that is, the HPLC system of herbs in TQHXD, such as precision, stability, repeatability, and wavelength, as shown in Supplementary Table S3. More importantly, some compounds with low OB or HL values but with significant protective effects on I/R injury, such as ligustrazine, muscone, and hydroxysafflor

yellow A, were also explored in our work (Wu et al., 2018; Li et al., 2017).

### Functional Enrichment Analysis of Intersection Targets of Tongqiao Huoxue Decoction

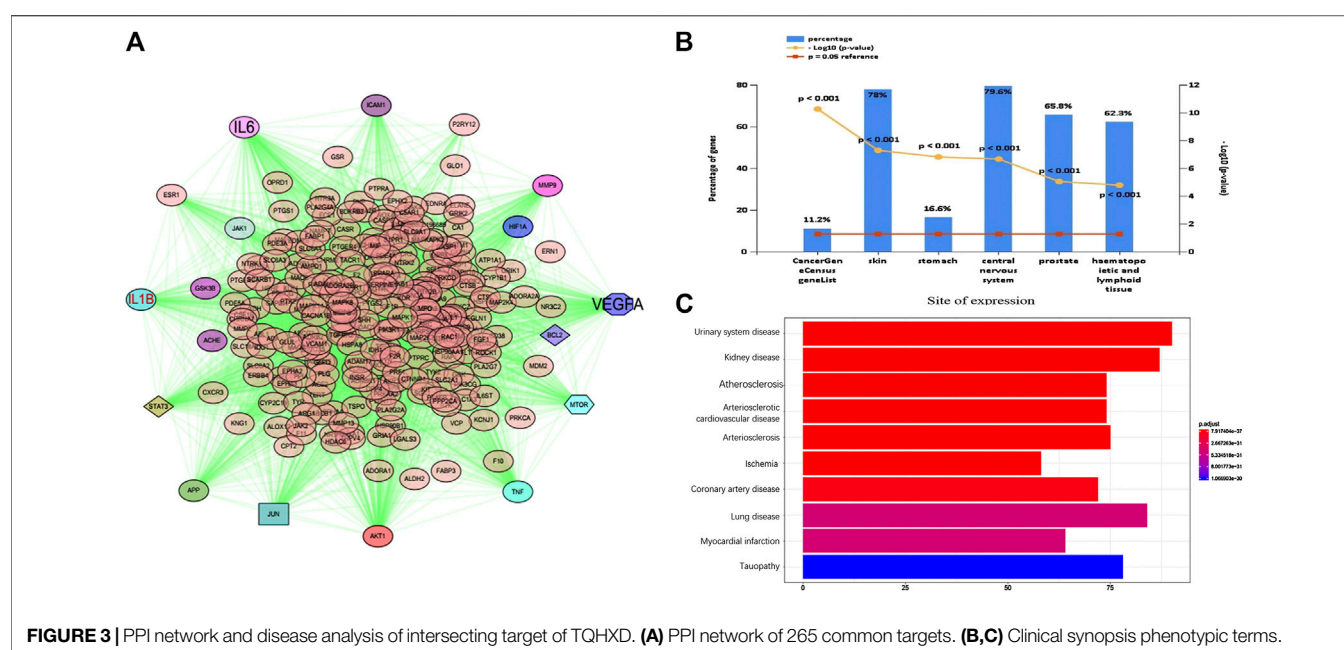

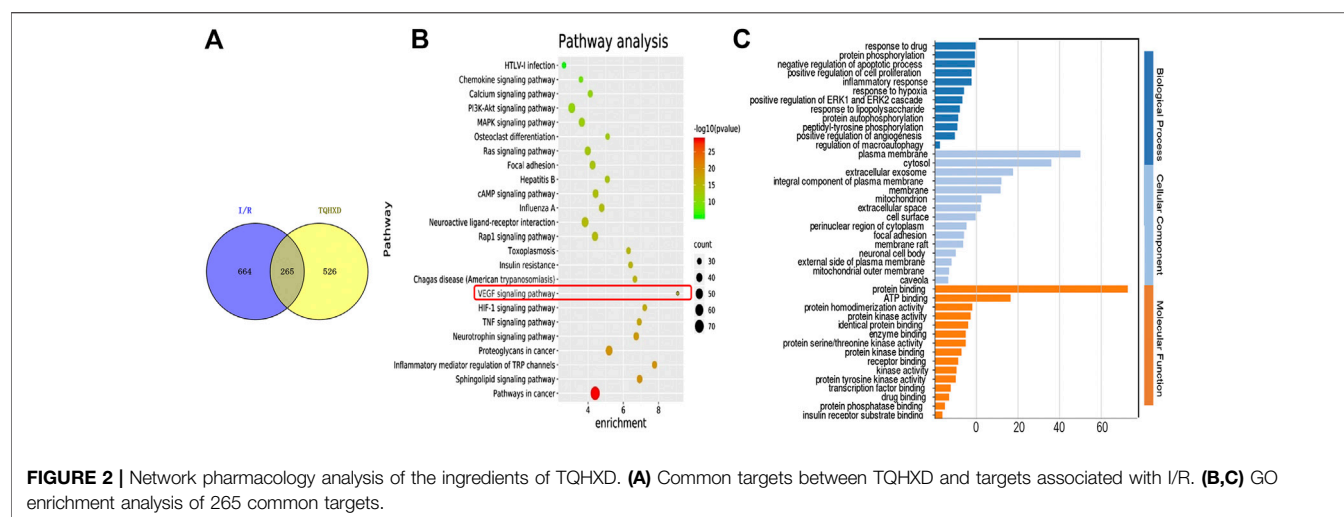

A total of 265 matching targets as the related targets of I/R and TQHXD are shown in Figure 2A. The multiple biological senses of TQHXD on I/R from a systematic level were assessed using the GO enrichment analysis (Figure 2C). For biological processes, potential targets of TQHXD were remarkably enriched in “response to hypoxia” (GO: 0001666), protein phosphorylation (GO: 0006468), and inflammatory response (GO: 0006954). For cellular components, mainly, plasma membrane (GO: 0005886), cytosol (GO: 0005829), and extracellular exosome (GO: 0070062) were enriched. Subsequently, the crucial pathways among the 265 potential targets in TQHXD treatment were also elucidated in this work. The threshold of FDR < 0.01 was used as an enrichment screening criterion, and the top 24 pathways were screened out (Figure 2B), including the VEGF signaling pathway (hsa04370) and TNF signaling pathway (hsa04668).

### PPI Network and Disease Analysis of Intersection Targets of Tongqiao Huoxue Decoction

Furthermore, the PPI network of those common targets was found in Figure 3 (Figure 3A). Ultimately, TNF, AKT1, IL-6, VEGF-A, JUN, EGFR, IL1B, IGF1, MMP9, and TGFB1 were identified as major nodes. Similarly, we analyzed the diseases of these targets. For the site of expression, the targets were enriched in the central nervous system and skin, etc. Finally, we used the disease analysis function of the NIMNT database and entered 265 intersection targets of TQHXD to enrich the possible indications of TQHXD. After setting *p.adjust* < 0.001, the top 10 diseases were observed, as shown in Figure 3, which mainly include ischemia, urinary system disease, and arteriosclerotic cardiovascular disease (Figure 3C).

### The Quality Control of Tongqiao Huoxue Decoction by HPLC

As shown in Figure 4A, the retention time of paeoniflorin of TQHXD was about 24.2 min. Subsequently, the HPLC method was validated by reproducibility, stability, and precision. It is worth noticing that there was an identical chromatographic pattern in six batches of TQHXD solutions. This suggested a good reproducibility for the HPLC system or TQHXD solutions. Finally, the relative standard deviation (RSD) of the instrument was less than 3%, indicating that the precision of the instrument was good. Similarly, the RSDs of relative retention time and relative peak area of each characteristic peak were less than 5%, indicating that it has good repeatability. The RSDs of relative retention time and relative peak area of characteristic peaks were less than 5% after 0, 2, 4, 8, 12, and 24 h injection, respectively,

indicating that the solution of the test sample was stable within 24 h (Figure 4B–D, Supplementary Table S3).

## Tongqiao Huoxue Decoction Ameliorated Ischemia-Reperfusion Injury and Attenuated Blood-Brain Barrier Damage

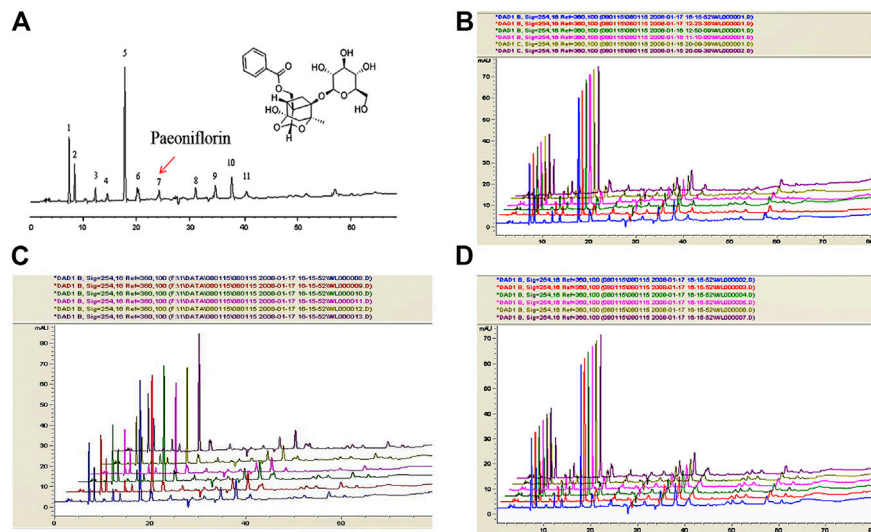

Neurological scores remarkably increased in the vehicle group compared with the sham group at 7 days. After reperfusion, treatment with TQHXD or NMDP showed significant neurological recovery, characterized by a decrease in neurological scores, compared with that in the vehicle group; however, TQHXD (6 g/kg) reduced the score compared to

NMDP. These data showed that TQHXD might exert an effect on improving the neural function of MCAO rats (Figure 5A).

Infarct volume was not observed in brain slices of the sham group, whereas a large area of infarct volume (41.10%) was seen in the vehicle group. The infarct volumes in the TQHXD groups were 29.3, 14.83, and 22.20%, respectively. Furthermore, infarct volume in the NMDP group (11.79%) was close to that observed in the TQHXD group at the dose of 6 g/kg, compared with the vehicle group (Figure 5B).

The protective effect of TQHXD on the permeability of BBB was quantified by EB dye (Figure 5C). On the dye solution, we found that there was a remarkable ( $p < 0.01$ ) increase in BBB permeability in rats from the vehicle group compared to that in

**FIGURE 4 |** The fingerprints of TQHXD for quality control by HPLC. Conditions: column, C18 column (250 × 4.6 mm, 5  $\mu$ m); mobile phase, methanol. The X-axis represents acquisition time (Min) and the Y-axis indicates intensity (mAU).

sham rats. TQHXD (3, 6, and 12 g/kg) or NMDP (0.02 g/kg) reduced the content of EB under I/R. The treatment of TQHXD (6 g/kg) and NMDP made a significant difference to the BBB permeability when compared with the vehicle group ( $p < 0.01$ ). Subsequently, we also detected the situation of tight junctions (TJ) by TEM. The TJ were normal in the sham group, whereas they were in an open state in the vehicle group (Figure 5D). However, different degrees of TJ reduction were observed in the TQHXD or NMDP group, indicating that TQHXD might repair the poststroke TJ completeness.

### Tongqiao Huoxue Decoction Strengthened Angiogenesis in MCAO/R Rats

The data of Western blot and ELISA demonstrated that an increased expression of VEGF exposed to I/R as compared to the sham group. Then, the TQHXD or NMDP treatment further upregulated the expressions of VEGF-A in both serum and cortex tissue, as compared with the vehicle group, which showed that TQHXD could be involved in angiogenesis. Finally, qPCR analysis of VEGF mRNA expression provided further proof of the effects of TQHXD on angiogenesis (Figure 6).

The cerebral blood flow was reduced rapidly to 30% during ischemia after 2 h and then was restored to 80% of the baseline after reperfusion. The rCBF showed that blood flow had no significant difference in the sham group between the time points of 1 and 7 days. The rCBF of the vehicle group or drug groups was lower than that of the sham group at day 1 ( $p < 0.01$ ). Similarly, the rCBF of the vehicle group rats had no significant difference at 7 days, as compared to the sham group.

Instead, compared with the vehicle group, TQHXD (6 g/kg) and NMDP groups significantly increased the rCBF at 7 days (Figure 6D).

Subsequently, we used CD34 immunofluorescence to mark the MVD at 7 days after TQHXD treatment. In the vehicle group, MVD increased at 7 days after I/R when compared with the sham group. More importantly, the expression of CD34 in the TQHXD group was significantly higher than that in the sham and vehicle groups (Figure 6E).

### Exogenous VEGFR2 Inhibition Reversed Angiogenesis in Tongqiao Huoxue Decoction

To further explore the molecular mechanisms associated with the phenotype observed upon TQHXD administration, we profiled angiogenesis from rats after being injected with Ki8751 (a specific VEGFR2 inhibitor). Firstly, we investigated whether Ki8751 could reverse the effect of TQHXD on neurological function score and cerebral blood flow. Notably, the neurological and neuronal death and rCBF were substantially protected by the TQHXD treatment in MCAO rats (Figures 7A,B,D). Subsequently, as shown in Figure 7C, the expression of p-FAK and p-Paxillin proteins in the cortex of brain induced by I/R was greater than that in the sham group ( $p < 0.05$ ). However, TQHXD (6 g/kg) remarkably promoted the expression of p-FAK and p-Paxillin proteins ( $p < 0.01$  vs. vehicle group) (Figure 7C). Conversely, the treatment of rats with VEGFR2 inhibitors, such as Ki8751, substantially reduced the TQHXD-induced angiogenesis. For example, the

**FIGURE 5 |** TQHXD ameliorated I/R injury and attenuated blood-brain barrier damage. **(A)** The neurological scores were evaluated by Longa's methods. **(B)** Representative TTC staining **(top)** and quantitative analysis **(bottom)** of brain infarct volumes,  $n = 6$ . **(C)** Quantitative analysis of the content of EB,  $n = 6$ . **(D)** Representative TEM images of ultrastructural changes in I/R-induced tight junction ( $n = 3$ ). Arrows imply electronically dense bands; the electronically dense bands represent TJ; the open state of electronically dense bands represents the injury degrees of TJ; scale bar = 200  $\mu\text{m}$  ( $\times 20,000$  magnification). Data are presented as means  $\pm$  SD. ## $p < 0.01$  vs. sham group; \* $p < 0.05$ , \*\* $p < 0.01$  vs. vehicle group.

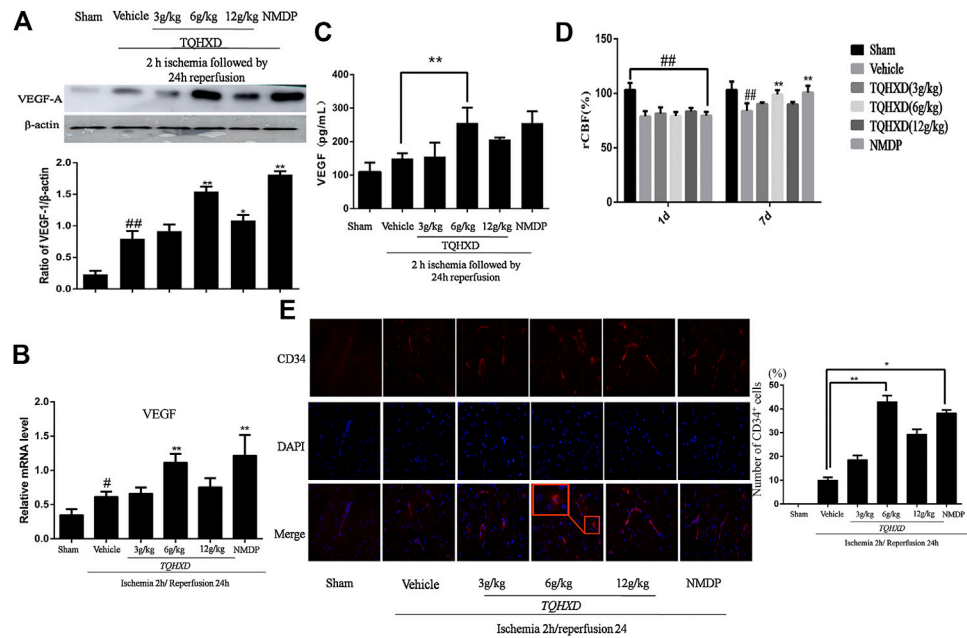

upregulating effect of TQHXD on p-FAK or p-Paxillin was impeded by the cotreatment with Ki8751 ( $p < 0.05$ ). Similarly, the expression of CD34 induced by TQHXD was also inhibited by Ki8751. These results demonstrated that TQHXD enhanced angiogenesis in a VEGFR2-FAK-Paxillin-dependent manner.

## DISCUSSION

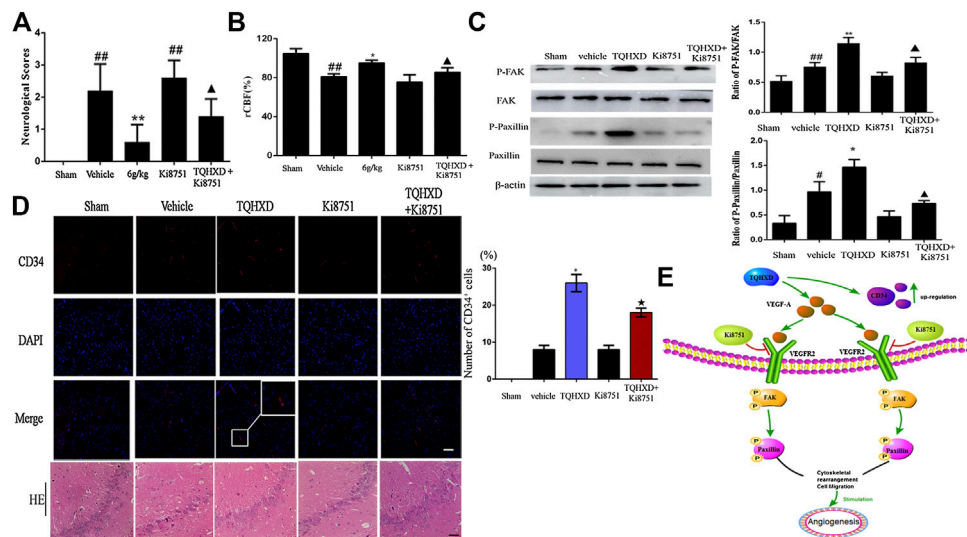

In the present study, a total of 94 potential compounds were screened according to OB and DL. The results revealed that TQHXD regulated the intersection of 265 targets with I/R, including VEGF-A, IL6, JUN, mTOR, TNF, and AKT1. These 265 targets were mainly enriched in cancer, VEGF, and neurotrophin signaling pathways. To ascertain TQHXD's role, our results of the network indicated that TQHXD regulated I/R through the pattern multiple components-multiple targets-multiple pathways. However, given the importance of angiogenesis in I/R, we linked the role of TQHXD with

angiogenesis by the results of network pharmacology and enrichment analysis of the KEGG pathway.

A huge percentage of elderly people reportedly suffer from ischemic stroke worldwide. Neurovascular unit (NVU), a conceptual model of stroke depending on the structure of blood vessels and brain, has been proposed by the National Institutes of Neurological Disorders and Stroke (Zhao et al., 2017). Previous studies have shown that angiogenesis is a key process in NVU recovery following ischemia stroke. This process leads to restoration of rCBF after cerebral ischemia and redounds to the neurological recovery of patients with stroke (Liu et al., 2017). In fact, recent research shows that patients with angiogenesis exhibit lower morbidity and mortality rates relative to those without the condition (Ducruet et al., 2010). In the present study, we show that TQHXD is a key mediator of angiogenesis. Specifically, our results show that the amount of blood flow in ischemic brain tissue is the most intuitive indicator for evaluating the maturity of neovascularization. We found no significant increase in rCBF in the MCA and cortical regions in rats from the sham group. In contrast, rats treated with TQHXD

or NMDP exhibited significantly higher CD34 or rCBF levels 7 days after reperfusion, compared to those in the vehicle group.

Ischemic injury causes endothelial progenitor cells to participate in the repair of new blood vessels. In fact, numerous cytokines reportedly play a critical role in this process, with a combination of these factors found to promote angiogenesis. Previous studies had shown that under specific environmental conditions, brain neurovascular cells produced and oozed VEGF, a central angiogenesis mediator following stroke (Yin et al., 2015). VEGF was upregulated both *in vivo* and *in vitro* during the I/R or oxygen-glucose deprivation induced by ischemia injury and continued 3–14 days poststroke (Zheng et al., 2018; Liu et al., 2018). This expression pattern indicates that ischemic injury induces angiogenesis, which was enhanced by TQHXD, to repair damaged blood vessels after stroke. In the present study, a significantly higher VEGF expression was observed in the TQHXD, compared to the vehicle group ( $p < 0.05$ ), with a concentration of 6 g/kg generating the highest levels. These results strongly indicated that TQHXD protects against I/R injury by upregulating angiogenesis either directly or indirectly.

Compared with NMDP, our results showed the therapeutic effects of TQHXD on the MCAO model. Notably, upon TQHXD administration, remarkably better levels of the neurological score and MVD were observed in the TQHXD group than those in the NMDP groups. These results illustrated that the nerve recovery activity of TQHXD was better than that of NMDP. As we all know, nerve recovery is a complex process involved in multiple-target and multiple-pathway. Compared with a single target drug (NMDP), the multitarget advantage of TQHXD could effectively regulate multiple processes to accelerate nerve recovery, which was also in agreement with our network pharmacology results. More importantly, despite the encouraging progress to apply NMDP in clinical trials, various adverse side-effects associated with NMDP may limit its clinical application. The relevant example is a reduction in blood pressure and a reversible increase in the serum concentrations of liver enzymes during intravenous therapy. On the contrary, compared with chemical medicines, TCMs are considered to be safe, with fewer side-effects. As such, the established safety and drug tolerability are the advantages of TCM over several Western medicines, which is exactly also the biggest benefit of TCM. Interestingly, our results showed that TQHXD's protective effect on I/R was not in a dose-dependent manner. Generally speaking, the effect of drugs may show a dose-dependent manner; previous studies had shown that the protective effect of some classical TCM does not always follow this trend (Yang et al., 2013; Xin-Xin et al., 2015). For example, some chemical and physical reactions may occur during the preparation of the formula, resulting in changes in some active components, which may not reflect dose-dependency (Xu et al., 2008). Herein, in-depth studies are required to elucidate the mechanisms of TQHXD action to provide valuable insights into its effects on I/R.

Previous studies have shown that VEGF combines with its receptors to promote angiogenesis against I/R (Beck and Plate, 2009; Greenberg and Jin, 2005). Specifically, the VEGF signaling pathway plays a fundamental role in angiogenesis response by regulating the release of growth factors. VEGFR2 regulates the

expression of vascular endothelial cell receptor proteins, thereby playing a critical role in the development of many diseases mediated by vascular endothelial cells. Notably, FAK is considered the key signaling molecule in cells and has been reported to regulate cell proliferation, migration, spreading, adhesion, and key processes in angiogenesis (You et al., 2014). In addition, Paxillin, a key downstream FAK protein that acts on adhesion plaque, has been found to mediate the formation of adhesion plaque, activate downstream proteins, and promote angiogenesis. Some studies have shown its phosphorylation directly affects the formation of adhesion plaques and ultimately affects the motility of endothelial cells (Blackstone et al., 2015). In addition, blocking FAK phosphorylation can significantly reduce the degree of angiogenesis (Masakazu et al., 2010). To determine whether TQHXD provokes angiogenesis through the VEGF machinery, we evaluated the effect of TQHXD with Ki8751, a potent VEGFR2 inhibitor known to block angiogenesis (Lu et al., 2017). Our results indicated that I/R-induced angiogenesis increased CD34 expression and decreased neuronal death in rats. However, TQHXD treatment promoted this effect. In addition, Ki8751 decreased the levels of FAK and Paxillin expression, with its Ki8751 treatment clearly attenuating TQHXD-induced angiogenesis. Overall, these results indicate that TQHXD confers protection against I/R in rats via angiogenesis by activating the VEGF-A/VEGFR2-FAK-Paxillin signaling pathway.

Although network pharmacology has revealed the effects of TQHXD, there are still some limitations to be addressed. First, the biggest challenge is the results from the database on Chinese herbs. The public database information on herbal medicine remains incomplete to some extent. Subsequently, in order to further substantiate the idea that TQHXD provokes angiogenesis through promoting the VEGF machinery, we could test whether the angiogenesis effect of TQHXD could be blocked by shVEGF or hVEGF-IN-1 (VEGF inhibitor), a potent VEGF interference known to block VEGF. Finally, although our study shows that TQHXD has an impact on angiogenesis, our results are not capable of distinguishing which angiogenesis cell types are responsible. Angiogenesis cells can be labeled in a specific manner, and this issue will be addressed in future research.

## CONCLUSION

In conclusion, the present study revealed that TQHXD administration was able to ameliorate the ischemic stroke of MCAO rats through promoting angiogenesis to active the VEGF-A/VEGFR2-FAK-Paxillin pathway.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved and animal experiments were approved by the Animal Care and Use Committee of Anhui University of Chinese Medicine, China, and implemented in accordance with the Guidelines of the National Institutes of Health on the Care and Use of Animals.

## AUTHOR CONTRIBUTIONS

SW and NW conceived the project and designed research. SW and LZ performed the experiments and wrote the manuscript. NW and SW revised the manuscript.

Effective-Component Discovery of  
Astragali Radix in the Treatment of  
Lung Cancer.  
Front. Pharmacol. 11:580978.  
doi: 10.3389/fphar.2020.580978

Lung cancer is one of the most devastating diseases worldwide, with high incidence and mortality worldwide, and the anticancer potential of traditional Chinese medicine (TCM) has been gradually recognized by the scientific community. Astragali Radix (AR) is commonly used in traditional Chinese medicine in the treatment of lung cancer and has a certain clinical effect, but effective components and targets are still unclear. In the study, we established an integrated strategy for effective-component discovery of AR in the treatment of lung cancer based on a variety of techniques. First, the effective components and potential targets of AR were deciphered by the “component-target-disease” network using network pharmacology, and potential signal pathways on lung cancer were predicted by Gene Ontology (GO) biological function enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses. Then, the therapeutic effects of AR in the treatment of lung cancer were evaluated *in vivo* using A/J mice, and the potential targets related to autophagy and potential signal pathway were verified by Western blot analysis, immunofluorescence staining, and real-time PCR technology at protein and gene expression level. Finally, metabolism *in vitro* by rat intestinal flora and cell membrane immobilized chromatography technology were used to screen the effective components of AR in the treatment of lung cancer, and remaining components from the cell immobilized chromatography were collected and analyzed by ultra-performance liquid chromatography–electrospray quadrupole time-of-flight mass spectrometry (UPLC-Q-TOF-MS). The screening results of the integrated strategy showed that calycosin-7-O-β-D-glucoside, ononin, calycosin, astragaloside IV, astragaloside II, cycloastragenol, and formononetin may be effective components of AR in the treatment of lung cancer, and they may play a role in the treatment of lung cancer through autophagy and p53/AMPK/mTOR signaling pathway. The integrated

**Abbreviations:** AR, astragali radix; TCM, traditional Chinese medicine; DDP, cisplatin; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; p53, protein 53; p-Bcl-2, phosphorylated B-cell lymphoma-2; mTOR, mammalian target of rapamycin; AMPK, AMP-activated protein kinase; PPI, protein–protein interactions; GO, gene Ontology; KEGG, kyoto encyclopedia of genes and genomes; CSE, cigarettes extract; HE, hematoxylin-eosin; IHC, immunohistochemistry; NHBE, primary normal human bronchial epithelial; UPLC-ESI-TO-MS, ultra-performance liquid chromatography–electrospray quadrupole time-of-flight mass spectrometry.

strategy for effective-component discovery provided a valuable reference mode for finding the pharmacodynamic material basis of complex TCM systems. In addition, the prediction for targets and signal pathways laid a foundation for further study on the mechanism of AR in the treatment of lung cancer.

**Keywords:** key word: effective components, traditional Chinese medicine, astragali radix, lung cancer, autophagy, potential targets, network pharmacology, cell membrane immobilized chromatography

## INTRODUCTION

As a global health burden, lung cancer is the highest incidence cancer at present (Torre et al., 2015; Wang et al., 2019). According to relevant statistics, lung cancer accounts for 19.4% of cancer-related deaths with 1.59 million deaths each year, which seriously endangers human health (Ke et al., 2019). As estimated by the International Agency for Research on Cancer, the number of deaths caused by lung cancer will raise to 10 million deaths per year by 2030 (Lou et al., 2016). However, the existing therapies, including radiotherapy, chemotherapy, and the emerging target therapy, are still unsatisfactory to improve the survival of lung cancer patients during the last 30 years (Cheng et al., 2018). So, it is an urgently required issue to achieve a breakthrough in medical treatment of lung cancer.

In recent years, the anticancer potential of traditional Chinese medicine (TCM) has been gradually recognized by the scientific community (Jiang et al., 2017; Zhu et al., 2019). In China, TCM is widely used in the treatment of cancer by preventing tumorigenesis, attenuating the toxicity, enhancing the therapeutic effect of radiotherapy and chemotherapy, reducing tumor recurrence, etc. (Wang et al., 2018; Zhang et al., 2018). Astragali Radix (AR), a well-known TCM, is the dried root of *Astragalus membranaceus* (Fisch.) Bge. var. *mongholicus* (Bge.) Hsiao or *Astragalus membranaceus* (Fisch.) Bge. has been used as a common clinical medicine in China for thousands of years. The accumulated data showed that AR was beneficial for the treatment of lung cancer in clinical practice (He et al., 2013; Xiao et al., 2019). However, the effective components and potential targets of AR in the treatment of lung cancer have not been reported.

Network pharmacology is a discipline for investigating pathogenesis of disease through constructing and analyzing biological networks (Chen et al., 2019), and provides a powerful tool for screening effective components and potential targets of TCM by establishing a “component-target-disease” network. Modern pharmacological research has proved that the combination of drugs with the lipid bilayer, receptors, and enzymes on the cell membrane is a main mechanism of drug action. Therefore, the effective components can be screened according to the affinity between the components and the cell membrane. Cell membrane immobilized chromatography, as a kind of cell membrane chromatography, uses active cells as the separation vector, TCM extracts as the object, and the separation was carried out according to whether the ingredients in the extract have specific affinity with the cells. In the study, we established an integrated strategy for effective-component discovery of AR in the treatment of lung cancer based on a

variety of techniques, and investigated the relationship between autophagy and the anticancer effect of AR *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Materials and Reagents

AR was obtained from Anhui Jingquan Group Herbal Pieces Co., Ltd (Anqing city, Anhui Province, China) and was identified by De-kang Wu (professor of Nanjing University of traditional Chinese medicine) as the dried root of *Astragalus membranaceus* (Fisch.) Bge. var. *mongholicus* (Bge.). Benzopyrene was purchased from Aladdin Reagent Co., Ltd. (Shanghai, China). Cisplatin (DDP, 1 mg/ml, 20 ml) was gained from Nanjing pharmaceutical factory Co., Ltd. (Nanjing, China). 4% paraformaldehyde fixative was purchased from Nanjing Nanao Technology Co., Ltd. (Nanjing, China). Hematoxylin dyeing solution (D005) was purchased from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). Eosin dye solution (KGA231), 0.25% trypsin, 1% Triton X-100, goat serum, 4',6-diamidino-2-phenylindole, and DMEM high glucose medium were purchased from Nanjing KeyGen Biotech logical Co., Ltd. (Nanjing, China). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH, 0802) antibody was purchased from Shanghai Kangcheng Biological Engineering Co., Ltd. (Shanghai, China). The antibodies against protein 53 (p53, ab131442), phosphorylated B-cell lymphoma-2 (p-Bcl-2, ab138406), mammalian target of rapamycin (mTOR, ab2732), AMP-activated protein kinase (AMPK, ab32047) and Beclin1 (ab133357) were obtained from Abcam (Cambridge, United Kingdom). NP-40 lysis buffer (1210600) was purchased from Nanjing Shengxing Biotechnology Co., Ltd. (Nanjing, China). Polyvinylidene fluoride (k8JN62911) was purchased from Millipore Corporation (Bedford, MA, USA). Pre-stained protein marker was purchased from Fermentas (Burlington, Canada).

Astragaloside I (MUST-16012906) and astragaloside II (MUST-16031010) were purchased from manster biotechnology Co., Ltd. (Chengdu, China). Cycloastragenol (HHQC20170921) was purchased from Nanjing Spring and Autumn Biological Engineering Co., Ltd. (Nanjing, China). Astragaloside IV (1107781-201616), calycosin (111920-201304), calycosin-7-O- $\beta$ -D-glucoside (111920-201505), formononetin (111703-200603), and ononin (111703-200501) were purchased from the National institute for Food and Drug Control of China (Beijing, China). LC-MS grade methanol and acetonitrile were purchased from Merk Company (Darmstadt, Germany). HPLC grade formic acid with a purity of 99% was

purchased from Anaqua chemical supply (ACS, Houston, USA). Purified water was prepared from a Milli-Q water purification system (Millipore Corporation, Bedford, MA, USA). Other chemicals (reagent grade) used were purchased from Nanjing Chemical Reagent Co, Ltd. (Nanjing, China).

## Database Construction

All components of AR were obtained and cross-validated from TCMSP (<http://lsp.nwu.edu.cn/tcmsp.php>) database (Ru et al., 2014), ETCM (<http://www.nrc.ac.cn:9090/ETCM/>) (Xu et al., 2019), TCMID (<http://www.megabionet.org/tcmid/>) (Xue et al., 2012), CNKI (<https://www.cnki.net/>), PubMed (<https://www.ncbi.nlm.nih.gov/pubmed>), and SciFinder (<https://scifinder.cas.org>), and saved in SDF and Canonical SMILES structure format. All targets related to components of AR were collected from several databases, including PharmMapper (<http://www.lilab-ecust.cn/pharmmapper/>) (Wang et al., 2017), similarity ensemble approach (SEA, <http://sea.bkslab.org/>) (Gu and Lai, 2020), and Swiss Institute of Bioinformatics (SIB, <http://www.swisstargetprediction.ch/>) (Gfeller et al., 2014), and were limited to homo sapiens. All obtained targets were retrieved from GeneCards (<http://www.genecards.org/>) (Fishilevich et al., 2016) and Therapeutic Target Database (TTD, <http://bidd.nus.edu.sg/group/cjttd>) (Li et al., 2018) to explore their function to confirm if related to lung cancer, as only targets related to lung cancer can be used in subsequent studies, and named as potential targets. All components related to lung cancer were obtained by matching targets related to lung cancer with components of AR, and named as potential effective components.

## Network Construction

The potential target-effective component network was constructed using Cytoscape software (version 3.6.1). In order to further explain the mechanism of AR in the treatment of lung cancer, the protein–protein interaction (PPI) network of lung cancer–related targets was explored by STRING (version 10.5, <https://string-db.org/>), and was visualized with Cytoscape software (version 3.6.1). Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses of potential targets were performed using the plugin ClueGo (version 2.5.4) from Cytoscape software (version 3.6.1). The signal pathways closely related to lung cancer were statistically analyzed, and those with  $p < 0.01$  after Benjamin's correction were considered to be significantly changed and selected for further research, named as potential signal pathways. Then, the potential signal pathways were evaluated by occurrence frequency of potential targets.

## Preparation of Astragali Radix Sample and Component Characterization

AR sample was gained by reflux extraction twice with ten times (w/v) 70% ethanol (v/v) in thermostatic water bath for 1.5 h. The two parts of extracts were combined, and the solvent was removed by rotary evaporation to obtain dried powder of AR. The dried powder of AR was stored in 4 °C refrigerator before use. The AR sample was analyzed by ultra-performance liquid

chromatography–electrospray quadrupole time-of-flight mass spectrometry (UPLC-Q-TOF-MS) to characterize chemical component, and main signals in chromatograph were identified, and compared with the reference substances. Eight components, including calycosin-7-O- $\beta$ -D-glucoside, ononin, calycosin, formononetin, astragaloside IV, astragaloside II, astragaloside I, and cycloastragenol, were accurately identified. The component information and typical total ion chromatogram (AR and reference substances) were shown in **Supplementary Material S1**.

## Cigarettes Extract Preparation

A vacuum pump was used to simulate the human lung; a cigarette with the filter (containing 11 mg tar and 1.1 mg nicotine) was ignited and the end of the cigarette attached to a rubber hose. Smoke emitted from the burnt cigarette was dissolved in the serum-free culture medium through a glass pipette tip by a vacuum pump (**Supplementary Figure S1**). The smoke-solubilized serum-free culture medium was filtered by 0.22  $\mu$ m sterile microporous membrane to obtain CSE.

## Animals and Experiment Design

Forty male A/J mice, weighing 18–20 g, were purchased from Shanghai Experimental Animal Research Center (License number SCKK (HU) 2013-0056, Shanghai, China) and housed under pathogen-free environment with a 12h/12 h light–dark cycle and fed with food and water *ad libitum*. All animal experiments were conducted in accordance with the guidelines of the laboratory animals and approved by the Animal Ethics Committee of Nanjing University of Chinese Medicine.

All the mice were randomly assigned to five groups: control group, model group, DDP group, 5.2 g/kg AR group, and 2.6 g/kg AR group. Except for the control group, the lung cancer model of several groups were created by intraperitoneally injecting with benzopyrene (100 mg/kg body weight dissolved in corn oil) twice a week for 4 weeks; the DDP group were intraperitoneally injected with DDP; mice in the 5.2 g/kg AR group and 2.6 g/kg AR group were orally administrated with AR at the dose of 5.2 g/kg/d and 2.6 g/kg/d (dose conversion according to the Chinese pharmacopoeia 2020 edition part one), respectively, while the control group was given normal saline solution by gavage. After that, all the groups continued to receive different treatments for 28 weeks and once a day. After 28 weeks, all mice were sacrificed, and the lungs were collected. Immediately, a portion of lung tissue was snap-froze in liquid nitrogen and stored at  $-70^{\circ}\text{C}$  for further analysis, and another portion was fixed in 4% paraformaldehyde for histopathological study.

## Histopathological Study

The lung tissues were fixed in 4% paraformaldehyde for 24 h, dehydrated and paraffin-embedded. The paraffin-embedded lung tissues were sectioned and stained with hematoxylin-eosin (HE) and immunohistochemistry (IHC). For IHC analysis, the paraffin-embedded lung tissue sections were deparaffinized in xylene and rehydrated through graded alcohol. Then, 3%  $\text{H}_2\text{O}_2$  was added to block endogenous peroxidase activity. Finally, sections were blocked with normal goat serum for 30 min at

room temperature and then incubated with anti-p-Bcl-2 and anti-p53 antibodies at 4 °C overnight. Sections were counterstained with hematoxylin and observed under light microscopy (Olympus, Tokyo, Japan) using  $\times 400$  magnification.

## NHBE Cell Culture and Treatments

Primary normal human bronchial epithelial (NHBE) cells were purchased from Beina Chuanglian Biotechnology Co., Ltd. (Beijing, China). NHBE cells were seeded into a plastic culture flask containing DMEM, and then placed in a humidified incubator containing 5% CO<sub>2</sub> at 37 °C. Culture medium was changed every two days, until NHBE cells reached 90% confluence. NHBE cells were digested by 0.25% trypsin and 0.02% EDTA solution, and prepared for the experiment with a density of  $1 \times 10^6$  cells/mL. An MTT assay was used to assess the viability of NHBE cells exposed to different concentrations of CSE and AR (**Supplementary Figure S2**). According to the screening results, 10% CSE was chosen as the modeling concentration, and 1000  $\mu$ g/ml and 500  $\mu$ g/ml were chosen as the AR administration concentration. NHBE cells were divided into five groups (six wells per group): control groups (no treatment), model group (10% CSE), DDP groups (10% CSE+10  $\mu$ g/ml DDP), 1000  $\mu$ g/ml AR group (10% CSE + 1000  $\mu$ g/ml AR), and 500  $\mu$ g/ml AR group (10% CSE + 500  $\mu$ g/ml AR). All cells were cultured in an incubator at 37 °C with 5% CO<sub>2</sub> for 24 h.

## Transmission Electron Microscope Observation

NHBE cells were digested with 0.25% trypsin to prepare single-cell suspension, centrifuged at 1000 rpm for 10 min, washed twice with prechilled PBS, and then fixed with prechilled 2.5% glutaric acid for 90 min at 4 °C. After washing in PBS, the cells were fixed with 1% osmium tetroxide at 4 °C for 30 min. After fixing, the cells were dehydrated with gradient ethanol and acetone, and then embedded in Epon812 resin (Sigma). The embedded blocks were cut into ultrathin sections using an ultramicrotome, and stained with uranyl acetate and lead citrate for ultrastructural examination under transmission electron microscopy (JEOL, Tokyo, Japan).

## Western Blot Analysis

The NHBE cells were collected and used for Western blot analysis. The protein was extracted on ice using NP-40 lysis buffer (1% NP-40, 150 mM NaCl, 50 mM Tris-HCl, pH 8.0). Lysates were centrifuged at 13,000 rpm for 10 min at 4 °C, and the supernatants were collected. Protein concentration was measured by using the DC protein assay (Bio-Rad). The separated protein samples were separated by SDS-polyacrylamide gel electrophoresis and then transferred onto polyvinylidene fluoride membrane (Millipore Corporation, Billerica, MA, USA). Membranes was blocked with 5% nonfat dry milk in Tris-buffered saline with 0.05% Tween-20 (TBST) buffer, and then incubated with primary antibodies against p53 (1:500), p-Bcl-2 (diluted: 1:1000), Beclin 1 (diluted: 1:1000), AMPK (diluted: 1:1000), mTOR (diluted: 1:1000), and GAPDH (1:

10,000) overnight at 4 °C. Subsequently, the membranes were incubated for 2 h at room temperature with secondary antibodies (1:10,000). Finally, the antigen-antibody complexes were visualized using enhanced chemiluminescence (Amersham) according to the manufacturer's instructions, and visualized using Azure c600 imaging system (Azure Biosystems, Dublin, CA, USA). The protein levels were expressed as relative integrated intensity and were normalized to that of GAPDH.

## Immunofluorescence Staining

The NHBE cells were washed three times with cold PBS and fixed by 4% paraformaldehyde for 15 min at room temperature, followed by permeabilization process with 1% Triton X-100 (Fisher). NHBE cells were subsequently immuno-stained with primary antibody for 2 h at room temperature and followed by fluorescein isothiocyanate-labeled secondary antibodies for 30 min at room temperature. The samples were washed twice, adhered onto coverslips, and mounted with 4',6-diamidino-2-phenylindole-containing mounting medium. Acquisition of images was performed using a fluorescence microscope (Leica Microsystems, Wetzlar, Germany).

## Real-Time PCR

Total RNA was extracted using the Trizol reagent (Invitrogen) according to the manufacturer's instructions. The RNA concentrations were determined using a spectrophotometer (ThermoFisher, Waltham, MA, USA). cDNA was synthesized from RNA (2  $\mu$ g) using First-strand cDNA Synthesis Kit (Thermo Fisher Scientific, Waltham, MA, USA). Real-time PCR analyses were conducted to quantitate p-53, p-Bcl-2, Beclin1, AMPK, and mTOR relative expression using SYBR Green real-time PCR kit (TaKaRa, Dalian, China) with GAPDH as an internal control. The cycle threshold values from all quantitative real-time PCR experiments were analyzed using  $2^{-\Delta\Delta CT}$  method, and were automatically determined by the ABI 7500 Real-Time PCR System (Applied Biosystems, USA). The primers used for real-time PCR analysis were as follow: p-53, forward primer 5'-CAGACAGGCTTTGCAGAATG-3', reverse primer 5'-GACCCCTGGCACCCTACAATGA-3'; p-Bcl-2, forward primer 5'-AAGCTGTACAGAGGGGCTA-3', reverse primer: 5'-CAGGCTGGAAGGAGAAGATG-3'; Beclin1, forward primer 5'-GTCCACGCTCGACCTTCTTAC-3', reverse primer 5'-CACTTGCCAGTCTTAACCTCTG-3'; AMPK, forward primer 5'-TGCCTGTACGAAGGAAGAATCC-3', reverse primer 5'-TGTGACTTCCAGGTCTTGGAGTT-3'; mTOR, forward primer 5'-CAGTTCGCCAGTGGACTGAAG-3', reverse primer 5'-GCTGGTCATAGAAGCGAGAC-3'; and GAPDH, forward primer 5'-AGGTCGGTGTGAACGGATTG-3', reverse primer 5'-TGTAAGCATGTAGTTGAGGTCA-3'.

## Metabolism *in vitro* of Rat Intestinal Flora Preparation of Anerobic Culture Medium

CaCl<sub>2</sub> (0.2 g) and MgSO<sub>4</sub>·7H<sub>2</sub>O (0.2 g) were dissolved on 800 ml of distilled water. After that, K<sub>2</sub>HPO<sub>4</sub>·3H<sub>2</sub>O (1.0 g), KH<sub>2</sub>PO<sub>4</sub> (1.0 g), NaHCO<sub>3</sub> (10.0 g), NaCl (2.0 g), and resazurin solution (10 ml, 2.0 g resazurin dissolved in 10 ml double-distilled water) were added and stirred until dissolving, and then boiled distilled

water was added to 1000 ml, mixed well, and cooled to room temperature. Then, tryptone (10.0 g), yeast extract (10.0 g), L-cysteine (1.0 g), and heme chloride solution (10 ml, 0.05 g heme chloride dissolved in 100 ml of 0.01 N NaOH solution) were supplemented. The pH was adjusted to 7.3 with NaOH test solution. All solution was autoclaved at 121 °C for 20 min and stored at 4 °C after cooling.

### Preparation of Intestinal Flora Culture Solution

Six male Sprague–Dawley (SD) rats were provided by Shanghai Laboratory Animal Center (License No. SYXK (HU) 2013-0056, Shanghai China). Fresh intestinal contents (5.0 g) taken from SD rats were placed in a sterilized penicillin vial and mixed with normal saline at a ratio of 1 g:4 ml to make a suspension, and then the filtrate and anaerobic culture solution were mixed in a ratio of 1:9 to obtain enteric bacteria culture solution.

### Sample Preparation

AR (1 mg/ml, 200 µL) was added to intestinal flora culture medium (1 ml), which was then filled with nitrogen without oxygen. The reactions were terminated by adding 1 ml n-butanol and 1 ml ethyl acetate after incubation for 0, 4, 8, 12, 24, 48, and 72 h, respectively. Next, the mixtures were vortexed for 5 min after adding 10 µL internal standard solution (nitrendipine, 2 µg/ml) and centrifuged at 14,000 rpm for 5 min. Subsequently, the organic phases were collected and evaporated under nitrogen gas, and 200 µL of methanol was added, vortexed, and centrifuged again at 14,000 rpm for 5 min, respectively. The supernatant was passed through the 0.22 µm millipore filter before injecting into the UPLC-Q-TOF-MS.

### Cell Membrane Immobilized Chromatography

A549 cells were purchased from Nanjing Kaiji biology Co., Ltd (Nanjing, China). A549 cells were seeded in a plastic culture flask containing DMEM, and then placed in a humidified incubator containing 5% CO<sub>2</sub> at 37 °C. The medium was replaced every day until A549 cells grew to 80–90% confluence. A549 cells were starved in serum-free medium for 3 h after washing with PBS. AR sample was incubated on intestinal bacteria ( $2 \times 10^{-4}$  g/ml) for 0, 4, 8, 12, 24, 48, and 72 h, and then the incubated solution was separately added into the A549 cells for 90 min, and was washed repeatedly with PBS until without detected component. The dissociation solution (10.95 g/L Na<sub>2</sub>HPO<sub>4</sub> and 12.91 g/L citric acid aqueous solution) was immediately added into the treated A549 cells, which were incubated at 37 °C and 5% CO<sub>2</sub> for 30 min to inactivate the cell effect target. Finally, the dissociation solution was collected.

A549 cells were digested with pancreatin and suspended into DMEM/high glucose medium. The cell suspension was centrifuged at 3,000 rpm for 2 min at 4 °C; the cell density ( $1 \times 10^7$  cells/mL) was adjusted by PBS and then dissociated at room temperature for 1 h with dissociation solution. The cells were quickly placed at –80 °C for 20 min, and thawed in a thermostatic water bath at 37 °C for 10 min. The

freezing–thawing process was repeated for 4 times and centrifuged at 2000 rpm for 20 min. Then, the dissociation solution and intracellular dissociation solution were collected and evaporated under nitrogen gas, and 200 µL of methanol was added, vortexed for 2 min, and centrifuged at 11,000 rpm for 10 min. Finally, the supernatant was passed through the 0.22 µm millipore filter before injecting into the UPLC-Q-TOF-MS.

### UPLC-Q-TOF-MS Analysis

Chromatographic analysis was performed on a LC-20AD UPLC system (Shimadzu Corporation, Kyoto, Japan) equipped with hybrid quadrupole time-of-flight tandem mass spectrometry (Triple TOF™ 5,600, AB SCIEX, Foster City, CA, USA) coupled with electrospray ionization (ESI) source. Chromatographic separation was performed on a ACQUITY UPLC HSS T3 column (50 mm × 2.1 mm, 1.8 µm). The flow rate was 0.3 ml/min, and the mobile phase consisted of solvent A (0.1% formic acid in water, v/v) and solvent B (acetonitrile) with the optimized gradient elution: 0–2 min, 2%–8% B; 2–8 min, 8%–20% B; 8–12 min, 20%–35% B; 12–18 min, 35%–60% B; 18–24 min, 60%–70% B; 24–28 min, 70%–80% B; 28–28 min, 80%–2% B; and 28–30 min, 2%–2% B. The column temperature was set at 30 °C. In order to get better analysis results, the mass spectrometer was conducted in electrospray and multiple reaction monitoring scanning mode, in negative ion modes. The optimized parameters for mass spectrometer were as follows: capillary voltage, 0.5 kV; ion source temperature, 100 °C; cone gas flow rate, 50 L/h; desolvation temperature, 400 °C; and desolvation gas flow, 800 L/h. The information-dependent acquisition techniques and dynamic background subtraction were used to reduce the impact of matrix interference.

### Statistical Analysis

All data are presented as the mean ± standard deviation. Data from mice and NHBE cells were statistically evaluated using *t*-test for pair-wise comparison. *p* < 0.05 was considered to be a significant difference, *p* < 0.01 was considered to be extremely significant difference, and *p* > 0.05 was considered to be no significant difference. All statistical analyses were performed using SPSS software (version 22.0, IBM, Chicago, IL, USA).

## RESULTS

### Network Pharmacology Analysis of AR in the Treatment of Lung Cancer Potential Targets and Components Prediction

In this study, the computer virtual screening technology was used to provide a fast and efficient approach to obtain potential targets. At length, 160 potential targets of AR in the treatment of lung cancer were obtained, and the information of potential targets (degree ≥ 5) are listed in **Table 1**. As shown in **Figure 1A**, the PPI network consisted of 160 nodes and 3,720 edges (average node degree of 46.5 and average local clustering coefficient of 0.634), and the node represents the potential target; the “degree” value

**TABLE 1 |** Information of potential targets of AR in the treatment of lung cancer (degree  $\geq 5$ ).

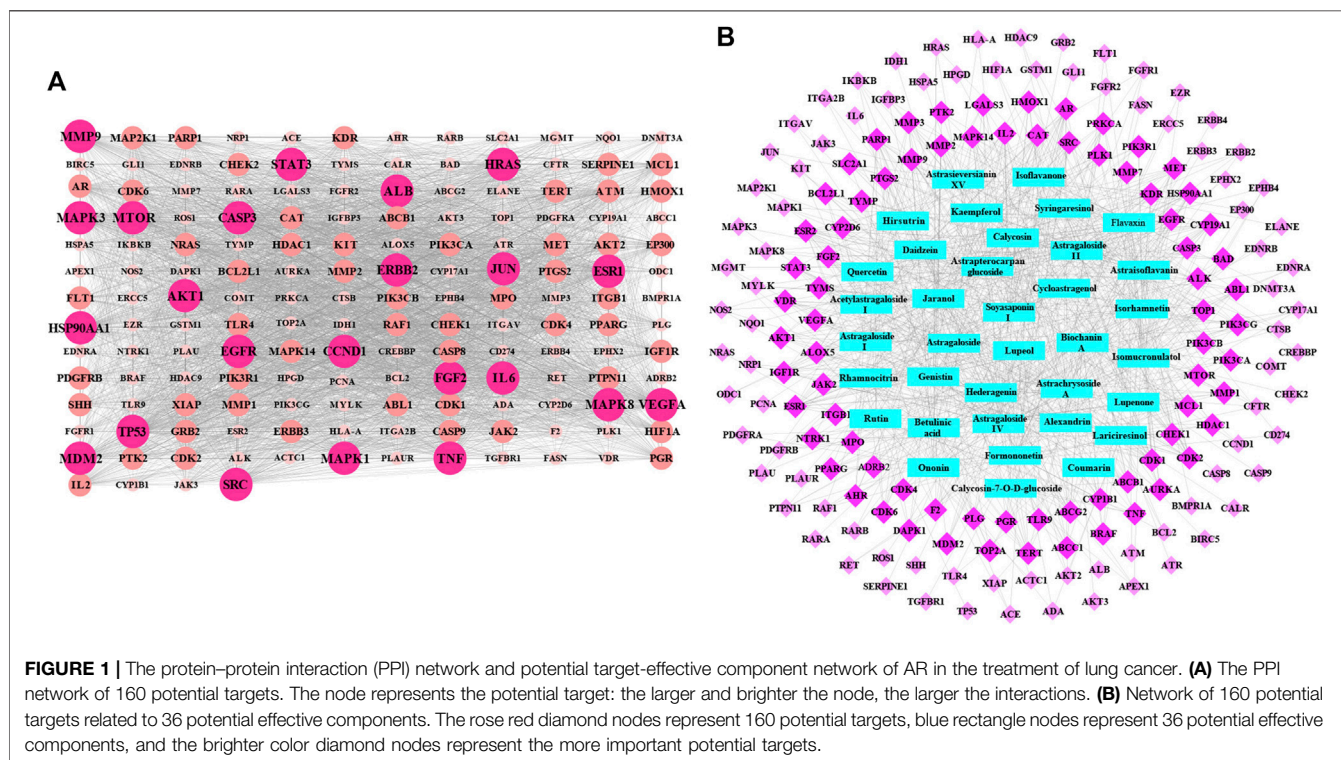

No.	Gene Name	Protein Name	Uniprot ID	Degree
1	ESR2	Estrogen receptor beta	Q92731	20
2	CDK1	Cyclin-dependent kinase 1	P06493	19
3	CDK2	Cyclin-dependent kinase 2	P24941	18
4	CYP19A1	Aromatase	P11511	18
5	CAT	Catalase	P04040	18
6	ESR1	Estrogen receptor	P03372	18
7	EGFR	Epidermal growth factor receptor	P00533	17
8	AR	Androgen receptor	P10275	16
9	IL2	Interleukin 2	P60568	16
10	ABCB1	ATP-dependent translocase ABCB1	P08183	15
11	HSP90AA1	Heat shock protein HSP 90- $\alpha$	P07900	15
12	PARP1	Poly(ADP-Ribose) polymerase 1	P09874	15
13	TOP1	DNA topoisomerase I	P11387	14
14	KDR	Vascular endothelial growth factor receptor 2	P25968	14
15	SRC	Proto-oncogene tyrosine-protein kinase Src	P12931	14
16	ABCG2	ATP-binding cassette sub-family G member 2	Q9UNQ0	14
17	MAPK14	Mitogen-activated protein kinase 14	Q16539	13
18	MMP2	72 kDa type IV collagenase	P08253	13
19	MET	Hepatocyte growth factor receptor	P08581	12
20	ALOX5	Arachidonate 5-lipoxygenase	P09917	12
21	MMP3	Stromelysin-1	P08254	11
22	MMP9	Matrix metalloproteinase 9	P14780	11
23	TYMS	Thymidylate synthase	P04818	11
24	IGF1R	Insulin-like growth factor I receptor	P08069	11
25	TERT	Telomerase reverse transcriptase	O14746	11
26	CYP1B1	Cytochrome P450 1B1	Q16678	11
27	CHEK1	Serine/threonine-protein kinase Chk1	O14757	10
28	MCL1	Induced myeloid leukemia cell differentiation protein Mcl-1	Q07820	10
29	PIK3CG	Phosphatidylinositol 4,5-bisphosphate 3-kinase catalytic subunit gamma isoform	P48736	10
30	PRKCA	Protein kinase C $\alpha$ type	P17252	10
31	PTGS2	Prostaglandin G/H synthase 2	P35354	10
32	F2	Prothrombin	P00734	10
33	MMP1	Interstitial collagenase	P03956	9
34	ABL1	Tyrosine-protein kinase ABL1	P00519	9
35	ALK	ALK tyrosine kinase receptor	Q9UM73	9
36	FGF2	Fibroblast growth factor 2	P09038	9
37	STAT3	Signal transducer and activator of transcription 3	P40763	9
38	VDR	Vitamin D3 receptor	P11473	9
39	VEGFA	Vascular endothelial growth factor A	P15692	9
40	AKT1	RAC- $\alpha$ serine/threonine-protein kinase	P31749	9
41	MTOR	Serine/threonine-protein kinase mTOR	P42345	8
42	PIK3CA	Phosphatidylinositol 4,5-bisphosphate 3-kinase catalytic subunit alpha isoform	P42336	8
43	PLK1	Serine/threonine-protein kinase PLK1	P53350	8
44	HMOX1	Heme oxygenase 1	P09601	8
45	CYP2D6	Cytochrome P450 2D6	P10635	8
46	PPARG	Peroxisome proliferator activated receptor gamma	P37231	8
47	CDK6	Cyclin-dependent kinase 6	Q00534	8
48	ABCC1	Multidrug resistance-associated protein 1	P33527	8
49	AURKA	Aurora kinase A	O14965	7
50	LGALS3	Galectin-3	P17931	7
51	PLG	Plasminogen	P00747	7
52	MPO	Myeloperoxidase	P05164	7
53	PIK3CB	Phosphatidylinositol 4,5-bisphosphate 3-kinase catalytic subunit beta isoform	P42338	6
54	CASP3	Caspase-3	P42574	6
55	PIK3R1	Phosphatidylinositol 3-kinase regulatory subunit alpha	P27986	6
56	SLC2A1	Solute carrier family 2, facilitated glucose transporter member 1	P11166	6
57	BCL2L1	Bcl-2-like protein 1	Q07817	6
58	NTRK1	High affinity nerve growth factor receptor	P04629	6
59	ADRB2	Beta-2 adrenergic receptor	P07550	6
60	TLR9	Toll-like receptor 9	Q9NR96	6
61	TNF	Tumor necrosis factor	P01375	6
62	HDAC1	Histone deacetylase 1	Q13547	5

**FIGURE 1 |** The protein-protein interaction (PPI) network and potential target-effective component network of AR in the treatment of lung cancer. **(A)** The PPI network of 160 potential targets. The node represents the potential target: the larger and brighter the node, the larger the interactions. **(B)** Network of 160 potential targets related to 36 potential effective components. The rose red diamond nodes represent 160 potential targets, blue rectangle nodes represent 36 potential effective components, and the brighter color diamond nodes represent the more important potential targets.

that indicated the strength of the potential target showed the larger the node, the brighter the color, and the larger the value. The results showed that the nodes of TP53, AKT1, VEGFA, EGFR, MAPK3, CCND1, HRAS, CASP3, SRC, ALB, JUN, STAT3, HSP90AA1, IL6, MAPK1, ESR1, ERBB2, TNF, MAPK8, MTOR, FGF2, and MMP9 are larger and brighter, indicating that they play a major role in the treatment of lung cancer. Further analysis found that these potential targets are mainly related to autophagy, apoptosis, and immune-mediated, cell cycle arrest and antioxidation. It is speculated that AR may play a role in the treatment of lung cancer through autophagy, apoptosis, and immune-mediated, cell cycle arrest and antioxidation.

Based on the acquisition of potential targets, 36 potential effective components were obtained by matching potential

targets, and their information is listed in **Table 2**. Potential target-effective component network was constructed by Cytoscape 3.6.1 software. As shown in **Figure 1B**, these 160 potential targets were associated with 36 potential effective components, and the blue nodes and rose red nodes represent 160 potential targets and 36 potential effective components, respectively. Potential target-effective component network indicated that the same component could act on multiple targets, and each target is usually associated with multiple components. These results suggested that different components in AR could regulate these same or similar targets to exert effect. So, in the study of TCM, as a complex system with multiple components and multiple targets, synergistic or antagonistic interactions among the different components of TCM should be considered.

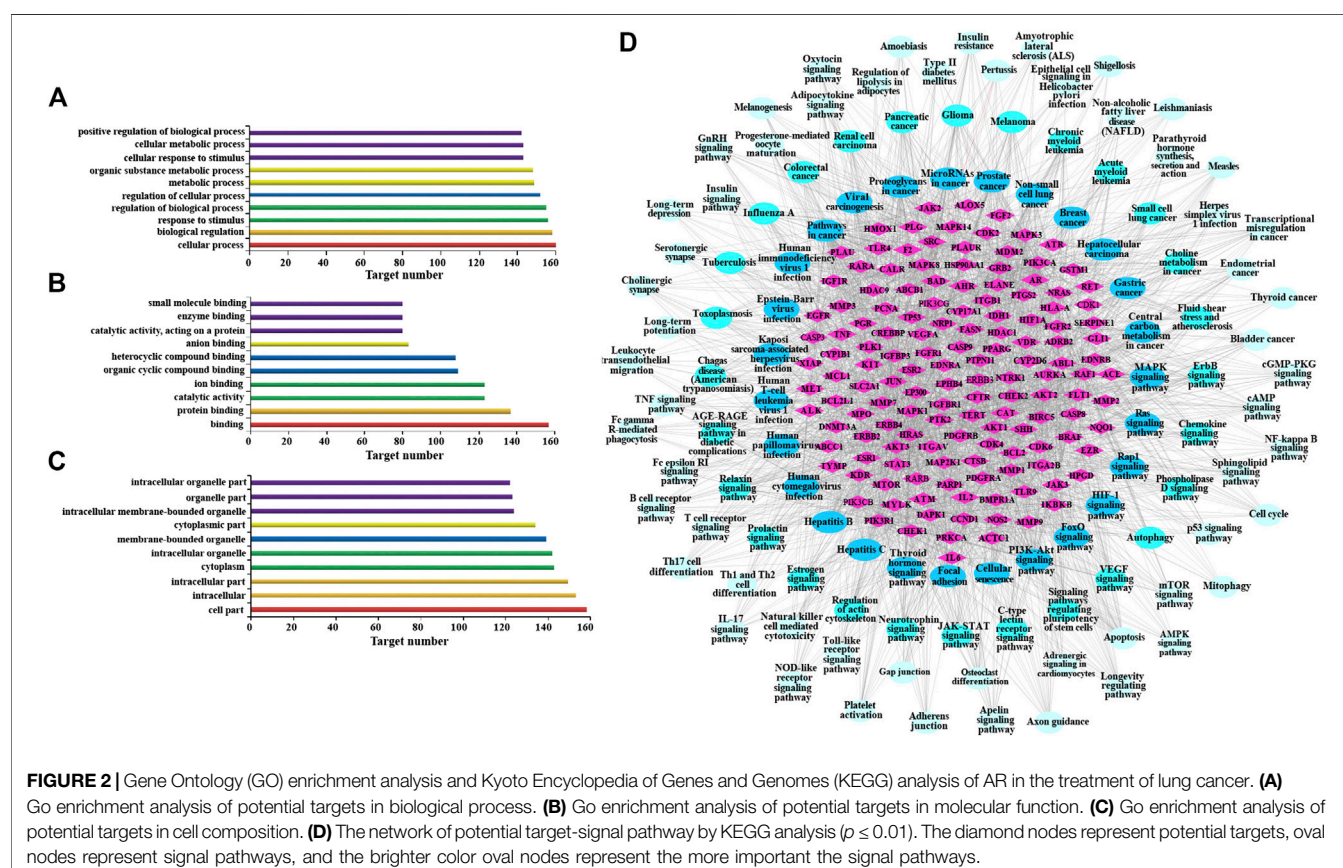

**TABLE 2 |** The summary of potential effective components of AR in the treatment of lung cancer.

Name	Molecular formula	CAS	Degree	Protein targets from effective components
Jaranol	C <sub>17</sub> H <sub>14</sub> O <sub>6</sub>	3301-49-3	42	ABCB1, ABCC1, ABCG2, ACTC1, AHR, AKT1, ALK, ALOX5, APEX1, AR, CAT, CDK1, CDK2, CDK6, CYP19A1, P1B1, DAPK1, EGFR, ESR1, ESR2, F2, IGF1R, KDR, KIT, MCL1, MET, MMP2, MMP3, MMP9, MYLK, NOS2, ODC1, ARP1, PIK3CG, PIK3R1, PLG, PLK1, PTGS2, PTK2, SRC, TERT, TOP2A

### Enrichment Analysis and Mechanism Prediction

Go enrichment analysis was performed on 160 potential targets, and limiting annotation was selected to homo sapiens. The top 10 terms of biological process (Figure 2A), molecular function (Figure 2B), and cell composition (Figure 2C) were selected. The results indicated that AR-regulated lung cancer mainly related to cellular process, biological regulation, response to stimulus, regulation of biological process, regulation of cellular process, and

metabolic process, and mainly involved binding, protein binding, and catalytic activity in molecular function, and cell part, intracellular, intracellular part, cytoplasm, and intracellular organelle in cell composition.

KEGG analysis was performed using the ClueGO database in Cytoscape 3.6.1, and 115 KEGG pathways with  $p$ -value less than or equal to 0.01 were obtained (Table 3). In order to more intuitively show the relationship among potential targets and signal pathways, the potential target-signal pathway network was

**FIGURE 4 |** AR on cell autophagy by transmission electron microscope and p53, p-Bcl-2, mTOR expression in NHBE by Western blot analysis. **(A)** AR on cell autophagy by transmission electron microscope. a, control group; b, model group (autophagosomes or autolysosomes were indicated by the red arrows); c, 1000 μg/ml AR group. **(B)** The protein bands of p53, p-Bcl-2, mTOR and GAPDH. **(C)** p53 expression in NHBE by western blot analysis. **(D)** p-Bcl-2 expression in NHBE by western blot analysis. **(E)** mTOR expression in NHBE by western blot analysis. constructed (Figure 2D). According to the KEGG analysis, AR in the treatment of lung cancer was related to PI3K-Akt signaling pathway, MAPK signaling pathway, Ras signaling pathway, etc.

## Experimental Validation of AR in the Treatment of Lung Cancer *In Vivo*

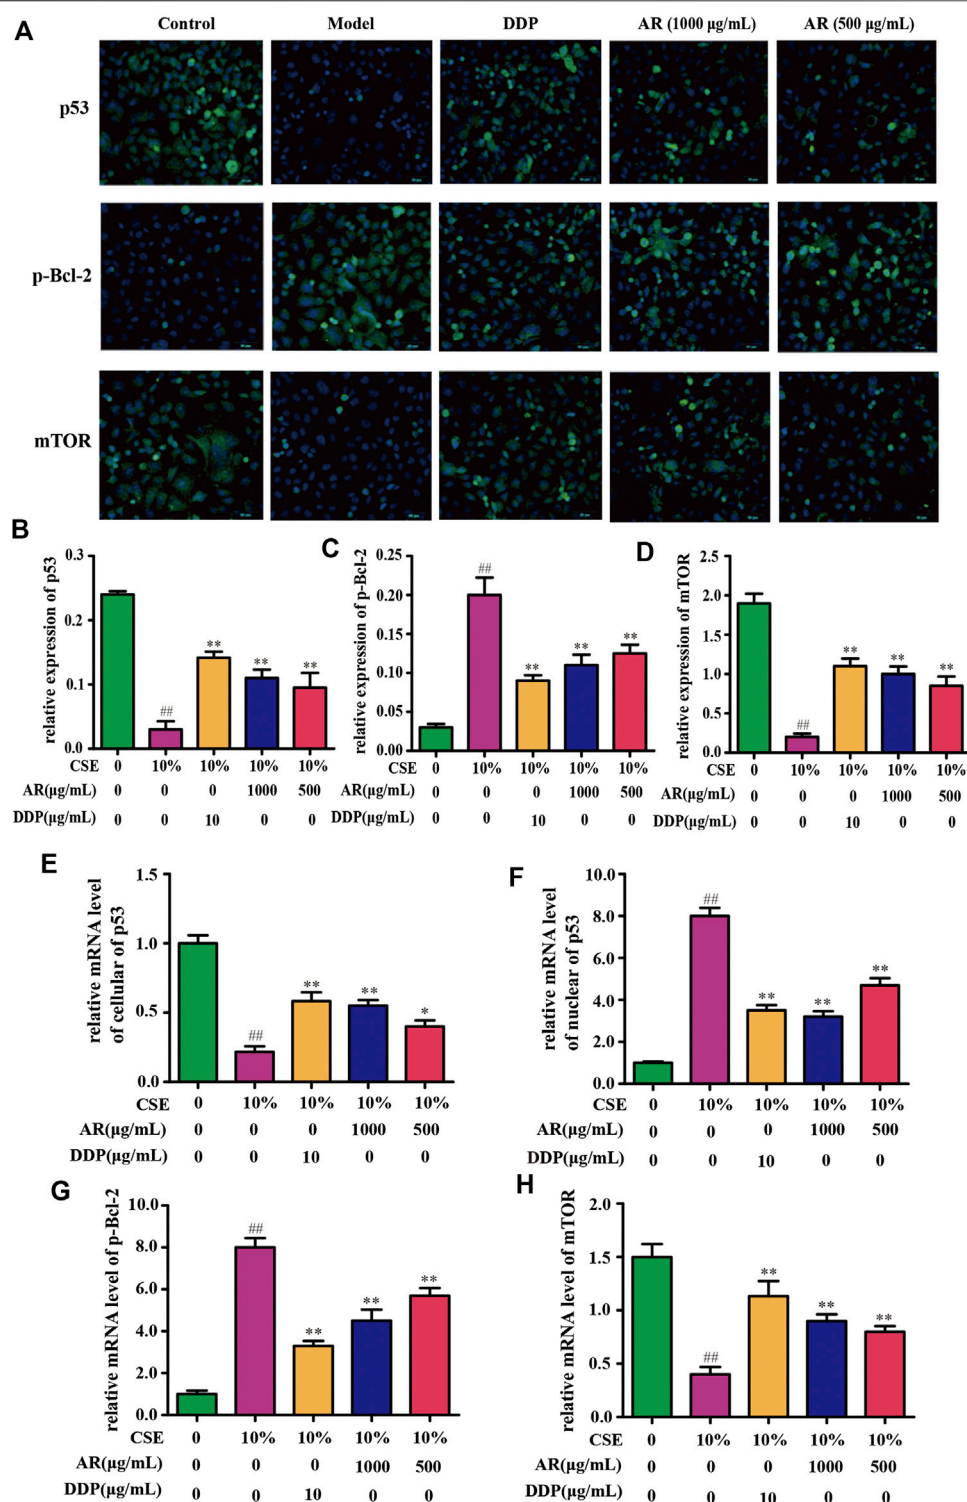

### Body Weight Change and Overall Appearance

The body weight changes of the animals in different groups were shown in Figure 3A. Compared with the control group, the body weight of mice in other four groups were decreased, and mice in model group had the smallest body weight among these four groups ( $p < 0.01$ ). Besides, compared with the model group, the body weight of 5.2 g/kg AR group and 2.6 g/kg AR group were significantly increased ( $p < 0.01$ ,  $p < 0.05$ ), and the most significant effect was observed in 5.2 g/kg AR group. The appearance of all mice were observations throughout the experimental period, and the results showed that the mice in

model group suffered from nose bleeding and sparse neck hair, and no obvious symptoms in other four groups were observed.

## Histopathological Study

After 28 weeks, lungs were removed from the mice for analysis. Except for the control group, what were observed in the other groups showed obvious lung lesions, tumor-like proliferation, and tumor nodules. Compared with the model group, the mice by DDP, 5.2 g/kg AR, and 2.6 g/kg AR treatment were able to significantly reduce ( $p < 0.01$ ) the number of lung tumor nodules (Figure 3B). The HE staining and IHC staining were used to determine the success of the lung cancer model and the therapeutic effect of AR against lung cancer. As shown in Figure 3C, the HE staining results showed that lung tissues of mice in the control group had the intact structure, clear alveolar outline, thin alveolar septum, and no sign of inflammation, while the lung tissues disappear in the model group had serious damage to the alveolar structure, cancerous proliferation, and fibrosis,

**FIGURE 5** | AR on p53, p-Bcl-2, and mTOR expression in NHBE cells by immunofluorescence staining and real-time PCR technology. **(A)** Representative pictures of p53, p-Bcl-2, and mTOR immunofluorescence in different groups. **(B)** **(C)** and **(D)** Relative p53, p-Bcl-2, and mTOR expression in NHBE by immunofluorescence staining. **(E)** and **(F)** Relative mRNA level of cellular and nuclear p53, respectively. **(G)** and **(H)** Relative mRNA level of p-Bcl-2 and mTOR, respectively. Compared with the model group, \* $p < 0.05$ , \*\* $p < 0.01$ ; compared with the control group, # $p < 0.05$ , ## $p < 0.01$ .

which indicates that the lung cancer model of A/J mice was successfully constructed. In addition, the administration of DDP and AR prevented the structural changes in the lung tissue and the infiltration of inflammatory cell, and improved lung tissue integrity. In addition, the above findings also suggest the effectiveness of AR in the treatment of lung cancer. The results of IHC staining were consistent with the HE staining results. In addition, the IHC staining results indicated that compared with the control group, the p53 expression (Figures 3D,E) was significantly decreased ( $p < 0.01$ ), and the p-Bcl-2 expression (Figure 3F,G) was significantly increased ( $p < 0.01$ ) in the lung tissue of model group. The administration of AR could upregulate the p53 expression and downregulate the p-Bcl-2 expression in the lung tissue, which indicated that AR can reverse the expression of p53 and p-Bcl-2 in lung cancer mice.

## Potential Targets and Mechanism Validation *In Vitro*

### Astragali Radix Treatment Inhibited Cell Autophagy Induced by CSE

CSE was used to induce autophagy in NHBE cells. The result showed that a large number of autophagy vacuoles appeared in the cytoplasm. Besides, autophagosome fuse with lysosome to form autolysosome, which decompose and destroy the organelles and damage the normal function of cells. After treatment with AR, the number of autophagosomes and autolysosomes in the cells was significantly reduced, and the structural integrity of the cells was increased, as shown in Figure 4A.

### Astragali Radix on p53, p-Bcl-2 and Mammalian Target of Rapamycin Expression in NHBE Cells

The potential targets, p53, p-Bcl-2, and mTOR, predicted by network pharmacology technology, were verified at the protein and gene levels. As shown in Figures 4B,C, compared with the model group, the p53 expression in NHBE cells was significantly increased in the 1000 µg/ml AR group and 500 µg/ml AR group ( $p < 0.01$ ). As shown in Figures 5A,B, immunofluorescence staining analyses showed that 1000 µg/ml AR and 500 µg/ml AR could increase the expression of p53 ( $p < 0.01$ ). RT-PCR results (Figures 5E,F) showed that the relative mRNA level of cellular p53 has been increased ( $p < 0.01$ ) and the relative mRNA level of nuclear p53 has been decreased ( $p < 0.01$ ) by the treatment of 1000 µg/ml AR, respectively. The above results indicated that AR could promote p53 expression, thereby inhibiting autophagy and protecting cells from autophagy.

Western blot analysis (Figures 4B,D) and immunofluorescence (Figures 5A,C) showed that p-Bcl-2 expression was significantly reduced in NHBE cells after treatment with AR ( $p < 0.01$ ). In addition, compared with model group, the relative mRNA level of p-Bcl-2 was significantly reduced ( $p < 0.01$ ) in 1000 µg/ml AR group and 500 µg/ml AR group (Figure 5G). The above results indicated that AR could reduce the phosphorylation level of Bcl-2, inhibit autophagy, and protect cells.

As shown in Figures 4B,E, compared with the model group, mTOR expression in NHBE cells was significantly increased in

the 1000 µg/ml AR group and 500 µg/ml AR group ( $p < 0.01$ ). RT-PCR results (Figure 5H) showed that the relative mRNA level of mTOR has also been increased by the treatment of 1000 µg/ml AR and 500 µg/ml AR ( $p < 0.01$ ). Immunofluorescence staining showed increased expression of mTOR expression in AR-treated cells at the concentration of 1000 µg/ml AR and 500 µg/ml AR (Figures 5A,D,  $p < 0.01$ ). mTOR is a major negative regulator of autophagy and a key protein for controlling autophagy. The above results showed that AR could increase mTOR expression and regulate cell autophagy to protect cells.

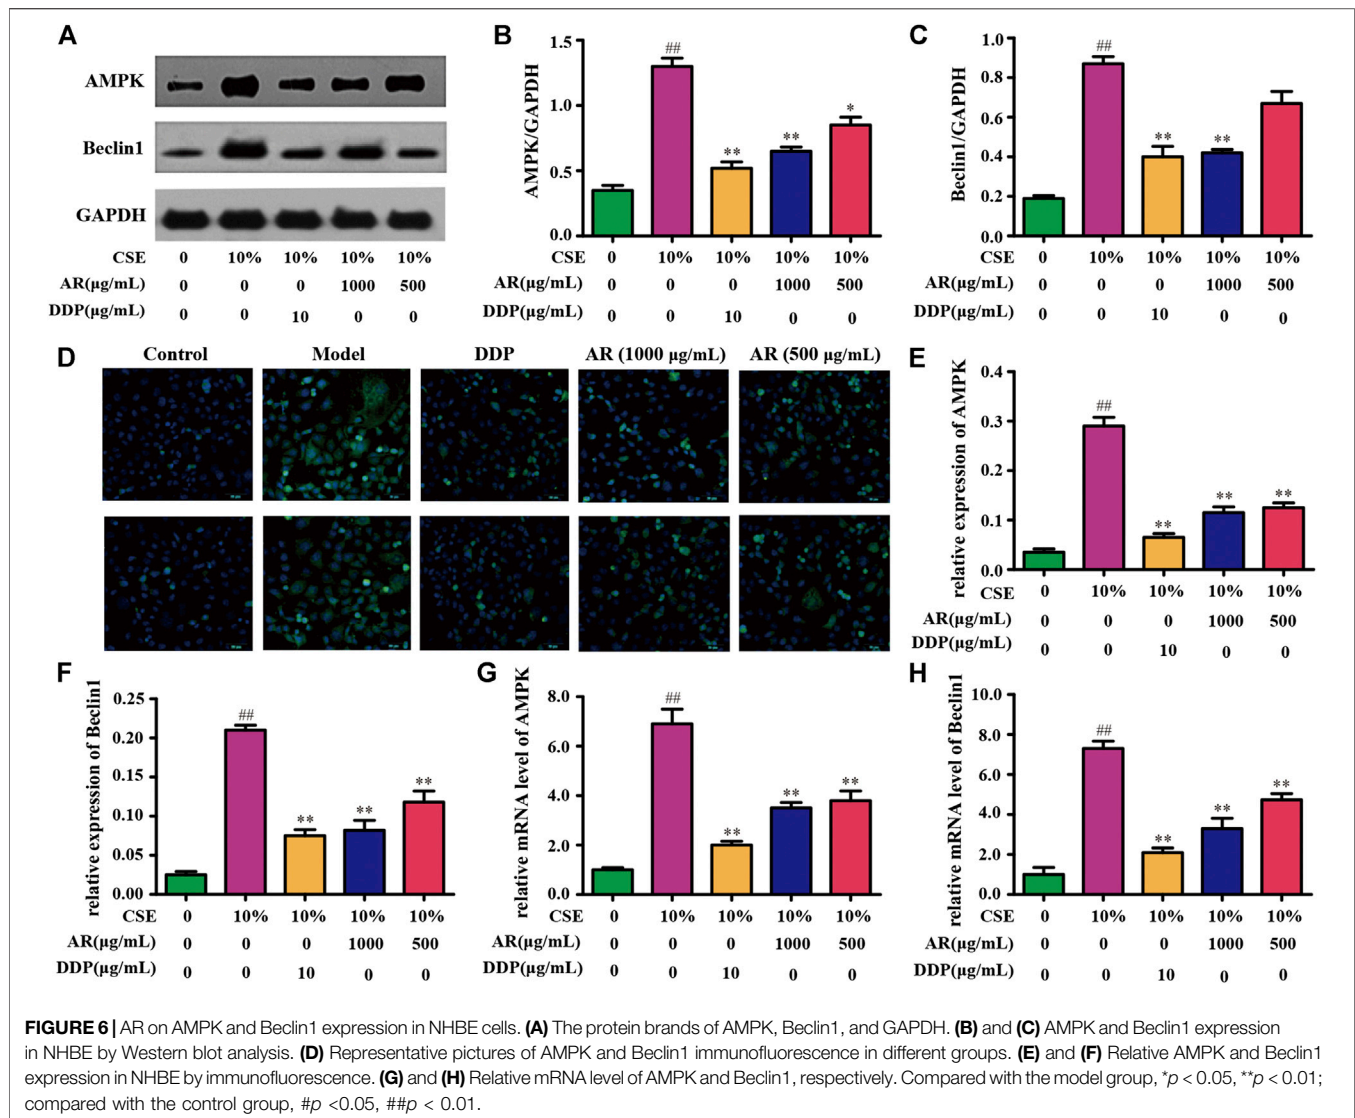

### Effect of Astragali Radix on p53/AMPK/Mammalian Target of Rapamycin Signaling Pathway

According to the KEGG analysis, AR in the treatment of lung cancer was mainly related to PI3K-Akt signaling pathway. So, the expression of molecules downstream of the PI3K-Akt signaling pathway was mainly explored. Except for p53, p-Bcl-2, and mTOR (Figures 4,5), the expression of AMPK and Beclin1 at the protein and gene levels was also determined. As shown in Figure 6, compared with model group, Western blot analysis and immunofluorescence staining showed a significant reduction ( $p < 0.01$ ) on AMPK and Beclin1 expression in NHBE cells after being treated with 1000 µg/ml AR. Besides, the relative mRNA level of AMPK and Beclin1 was significantly reduced ( $p < 0.01$ ) in 1000 µg/ml AR group and 500 µg/ml AR group. It has been documented that p53 mediates autophagy through an AMPK/mTOR-dependent pathway (Tasdemir et al., 2008). AMPK activation leads to autophagy through negative regulation of mTOR and that many other factors involved in the autophagic process govern autophagy through AMPK/mTOR signaling (Jing et al., 2011). Based on the above research results, we speculate that AR in the treatment of lung cancer may through p53/AMPK/mTOR signaling pathway (Figure 7), but further validation is still required.

### Screening of Effective Components by Metabolism *in vitro* of Rat Intestinal Flora and Cell Membrane-Immobilized Chromatography

The UPLC-Q-TOF-MS analysis results indicated that these components in AR have undergone different degrees of metabolic transformation under the action of intestinal flora, and the typical total ion chromatogram of blank bacterial solution and the intestinal flora incubation solution of AR (2 h) as shown in Supplementary Figure S3. Detailed metabolite information was listed in Table 4, and the metabolic pathway mainly involves oxidation, reduction, hydrolytic deglycosylation, etc. The results of cell membrane-immobilized chromatography are shown in Figure 8. The six effective components, such as calycosin-7-O-β-D-glucoside, ononin, calycosin, astragaloside IV, metabolite of astragaloside II (M5), and cycloastragenol, can bind to cell membranes (Figure 8A). The three components, that is, reduction product of calycosin (M9), calycosin, and formononetin, can enter into the cell through the cell membrane by passive diffusion (Figure 8B).

Ultimately, these effective components, that is, calycosin-7-O- $\beta$ -D-glucoside, ononin, calycosin, astragaloside IV, astragaloside II, cycloastragenol, and formononetin, together form the material basis of AR for prevention and treatment of lung cancer, and they come from the two-type components, flavone and saponin.

## DISCUSSION

In this study, an integrated strategy for effective-component discovery of AR in the treatment of lung cancer was established. The results indicated that the integrated strategy can be applied to the efficiently screen effective components in complex systems. In our research on the bioactivity of AR, we found that the administered doses were high compared with single component drug. Therefore, the screening and confirmation of effective components in this article will help to reduce the dose by removing the ineffective components.

Modern pharmacological studies have shown that the activity of drugs is closely related to their cell membrane affinity and permeability. An important step in the role of TCM is the binding of effective components to cell membranes, specific enzymes, or receptors in cells. In this study, A549 cells were used as the separation carrier, AR was taken as the research object, and the specific affinity between each component in AR and cells was determined by cell membrane-immobilized chromatography. It is worth noting that the screening results show that calycosin-7-O- $\beta$ -D-glucoside, ononin, calycosin, astragaloside IV, astragaloside II, cycloastragenol, and formononetin may be effective components of AR in the treatment of lung cancer, and which is consistent with the previous research results of AR in the prevention and treatment of cancer (He et al., 2013; Cheng et al., 2016; Xu et al., 2018). Through the ages, TCM have shown good efficacy in treating many and complex diseases (Sreenivasmurthy et al., 2017). The above research on the effective components of AR once again proved that the components of TCM are very complex and diverse, and

multicomponent and multi-target may be the characteristic of TCM in treating diseases.

Autophagy has been implicated in a wide range of human diseases, including lung disorders such as lung cancer, chronic obstructive pulmonary disease, and lung infection diseases (Ryter and Choi, 2010; Ryter et al., 2012; Liu, et al., 2017; He et al., 2019). The article mainly investigated the mechanism of AR in the treatment of lung cancer from the perspective of autophagy according to the predictions of network pharmacology. The results suggested that AR may inhibit the development of lung

cancer by reducing the p53 expression in the nucleus and promoting p53 expression in the cytoplasm, downregulating the level of p-Bcl-2 and promoting the autophagy inhibitory factor mTOR expression. In order to further explore the mechanism of AR in the treatment of lung cancer, except for the p53, p-Bcl-2 and mTOR, the expression of other molecules downstream of the PI3K-Akt signaling pathway was explored, including AMPK and Beclin1. Under stress, AMPK can promote the dissociation and phosphorylation of autophagy-related gene Bcl-2 (Zhou et al., 2011; He et al., 2012; Meng et al., 2015) and

**FIGURE 8 |** The typical total ion chromatogram of components bound to membrane proteins and intracellular protein. **(A)** Components bound to membrane proteins. 1, calycosin -7-O- $\beta$ -D-glucoside; 2, ononin; 3, calycosin; 4, astragaloside IV; 5, metabolites of astragaloside II (M5); 6, cycloastragenol. **(B)** Components bound to intracellular protein. 1, calycosin; 2, formononetin; reduction product of calycosin (M9).

inhibit mTOR expression (Chen et al., 2015; Prietodomínguez et al., 2016; Yu et al., 2017), and ultimately promote the occurrence and development of autophagy. Beclin1 is an interacting protein of Bcl-2 (He et al., 2013); binding of Bcl-2 to Beclin1 inhibits Beclin1-mediated autophagy *via* sequestration of Beclin1 away from class III PI3K; and the interaction between Bcl-2 and Beclin1 is related to mTOR kinase-dependent phosphorylation of Bcl-2 (Levine et al., 2008; Pattingre et al., 2008; Chiang et al., 2018; Xu and Qin, 2019). The preliminary research results indicated that the regulation of autophagy may be a useful strategy in the treatment of lung cancer.

In this study, an integrated strategy for effective-component discovery of AR in the treatment of lung cancer was established,

which provides a valuable reference mode for finding the effective components of TCM. In addition, preliminary research results indicated that AR in the treatment of lung cancer may through p53/AMPK/mTOR signaling pathway, which laid a foundation for further in-depth study of the mechanism of AR in lung cancer. Despite some promising results were obtained in the study, there are still several potential limitations to improve. First, we have to admit that network pharmacology virtual screening has some limitations, and the predicted effective components and potential targets may need to be further comprehensively verified through a variety of different technologies. Even though the study adopts an integrated research strategy combining network analysis and

*in vitro/vivo* studies, it still could not avoid some false positives. Moreover, we found that the dosage of AR was very high compared with single-component drug. Therefore, it is necessary to further knock out invalid components of AR to reduce dosage. Finally, the preliminary research results indicated that AR in the treatment of lung cancer may be through p53/AMPK/mTOR signaling pathway; certainly, further experimental validation should be needed to confirm this hypothesis.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, and further inquiries can be directed to the corresponding authors.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Animal Ethics Committee of Nanjing University of Chinese Medicine.

*Tripterygium wilfordii* Hook F (TwHF) is one of the most commonly used and effective traditional Chinese herbal medicines against rheumatoid arthritis (RA). Both *Tripterygium Glycoside* Tablets (TGT) and *Tripterygium wilfordii* Tablets (TWT) are the representative TwHF-based agents enrolled into the 2019 edition of Medicine Catalog for National Basic Medical Insurance, Injury Insurance, and Maternity Insurance. However, individual differences in TGT/TWT response across patients usually exist in the process of treating RA, implying that the clinical application of the two agents may not be standardized leading to the ineffective treatment and the risk of side effects. Growing evidence show that the bioactive constituents of TwHF may often have toxicity, the package insert of TGT and TWT may not be described in detail, and the therapeutic windows of the two agents are narrow. Thus, it is an urgent task to develop a standardized clinical practice guideline for TGT and TWT in the treatment of RA. In the current study, a group of clinical experts of traditional Chinese medicine and Western medicine in the research field of rheumatism diseases, pharmacists, and methodologists of evidence-based medicine were invited to select the clinical questions, to determine the levels of the evidence and the strength of the recommendations, and to develop the recommendations and good practice points. The guideline is formed based on the combination of clinical research evidence and expert experience (evidence-based, consensus, supplemented by

experience). The clinical problems which are supported by clinical evidence may form recommendations, and the clinical problems without clinical evidence may form experts' suggestions. Both recommendations and experts' suggestions in this guideline summarized the clinical indications, usage, dosage, combined medication, and safety of TGT and TWT against RA systematically and comprehensively, which may offer a professional guidance in the context of the clinical application of the two TwHF-based agents.

**Keywords:** *Tripterygium glycoside* tablet, *Tripterygium wilfordii* tablets, rheumatoid arthritis, clinical practice guideline, rational drug use

## INTRODUCTION

Rheumatoid arthritis (RA) is a common chronic autoimmune disorder characterized by synovitis, cartilage damage, and bone erosion (Chimenti et al., 2015). The morbidity of RA is 0.19–0.41% in China. During the progression of the disease, the damage of multiple joints may lead to deformity and disability, which severely influences the patients' quality of life and eventually leads to heavy social and economic burden (Wang et al., 2015). Although various conventional disease-modifying antirheumatic drugs (DMARDs) have been extensively used for the treatment of RA worldwide, the incidence of adverse reactions due to the application of DMARDs has been over 40% (Pavy et al., 2006; Li et al., 2016; Smolen et al., 2017).

*Tripterygium wilfordii* Hook F (TwHF) is one of the most commonly used medicines and has been widely used as an effective traditional Chinese herbal medicine against RA in China for centuries (Zhang et al., 2010). Both *Tripterygium Glycoside* Tablets (TGT) and *Tripterygium wilfordii* Tablets (TWT) are the representative TwHF-based agents enrolled into the 2019 edition of Medicine Catalog for National Basic Medical Insurance, Injury Insurance, and Maternity Insurance. Chemically, TGT mainly contains wilforlide A, triptolide, triptonide, wilforine, triptophenolide, tripterine, etc. (Wang Y.D. et al., 2019). Similarly, the constituents in TWT include triptolide, tripterine, wilforlide A, wtlfordine, triptophenolide, etc. (Gu et al., 2015). Among them, wilforlide A, triptolide, and tripterine have been demonstrated to exert good anti-inflammatory and immune inhibitory effects (Zhu et al., 2009; Xue et al., 2010; Venkatesha et al., 2012), which make both TGT and TWT be commonly used against RA. However, individual differences in TGT/TWT response across patients usually exist in the process of treating RA, implying that the clinical application of the two agents may not be standardized leading to the ineffective treatment and the risk of side effects. Growing evidence shows that the bioactive constituents of TwHF may often have toxicity, the package insert of TGT and TWT may not be described in detail, and the therapeutic windows of the two agents are narrow. Thus, it is an urgent task to develop a standardized clinical practice guideline for TGT and TWT in the treatment of RA.

With the approval and support of the Standardization Office of the Chinese Association of Chinese Medicine, in the current study, we invited a group of clinical experts of traditional Chinese medicine and Western medicine in the research field of

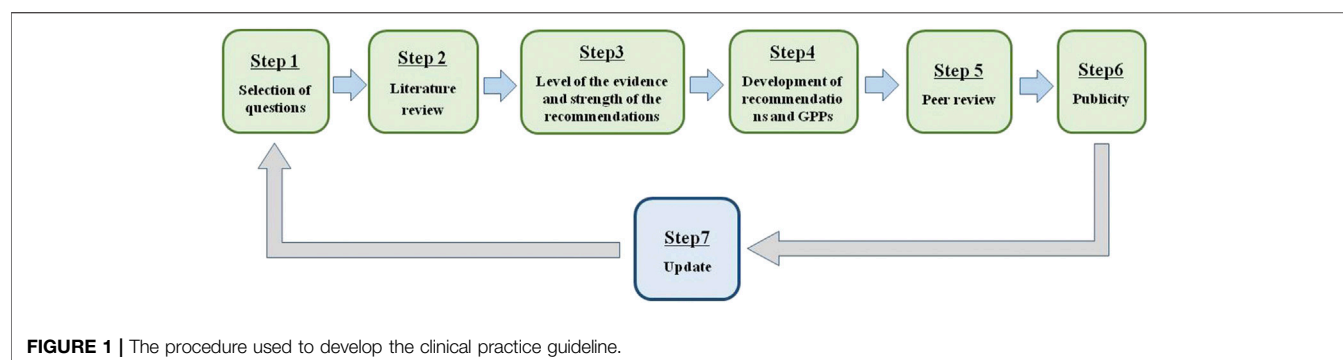

rheumatism diseases, pharmacists, and methodologists of evidence-based medicine to select the clinical questions, to determine the levels of the evidence and the strength of the recommendations, and to develop the recommendations and good practice points (GPPs). The guideline is formed based on the combination of clinical evidence and experts' experience (evidence-based, consensus, supplemented by experience). The clinical problems which are supported by clinical evidence may form recommendations, and the clinical problems without clinical evidence may form experts' suggestions. Both recommendations and experts' suggestions in this guideline summarized the clinical indications, usage, dosage, combined medication, and safety of TGT and TWT against RA systematically and comprehensively, which may offer a professional guidance in the context of the clinical application of the two TwHF-based agents (Lin et al., 2020a; Lin et al., 2020b).

## METHODS

The “Clinical practice guideline for *Tripterygium Glycosides/Tripterygium wilfordii* Tablets in the treatment of rheumatoid arthritis” was approved on June 2020 by the Standardization Office of the Chinese Association of Chinese Medicine. To develop an evidence-based and expert-approved Chinese patent medicine treatment guideline for RA, a multidisciplinary guideline development group was established. This guideline was developed according to the Manual for the clinical experts consensus of Chinese patent medicine (Fang et al., 2018). GPP (Liao and Xie, 2008) and the grading of recommendation assessment, development, and evaluation (GRADE) system (Atkins et al., 2004) were used to rate the quality of evidence and the strength of recommendations. Our clinical practice guideline was developed following a six-step plan (Figure 1).

## Selection of Questions

According to a Delphi prioritization procedure, the following three questions were selected: 1) Whether RA patients without fertility desire may achieve beneficial effects from the treatment of TGT/TWT alone at the active disease stage; 2) whether RA patients without fertility desire may achieve beneficial effects from the treatment of TGT/TWT in combination with Chinese patent medicine at the active disease stage; 3) whether RA

**TABLE 1 |** Significance of the four levels of evidence.

Quality level	Definition
High/I	We are very confident that the true effect lies close to that of the estimate of the effect
Moderate/II	We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different
Low/III	Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect
Very low/IV	We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

**TABLE 2 |** Significance of the four strengths of recommendations.

Strength of the recommendation	Meaning for clinicians or patients
Strong/A	The panel is highly confident of the balance between desirable and undesirable consequences; they make a strong recommendation for (desirable outweighs undesirable) or against (undesirable outweighs desirable) an intervention
Weak/B	The panel is less confident of the balance between desirable and undesirable consequences; they offer a weak recommendation

patients without fertility desire may achieve beneficial effects from the treatment of TGT/TWT in combination with Western medicine at the active disease stage.

## Literature Review

Our literatures were collected from the following databases: 1) Chinese articles: China National Knowledge Infrastructure (CNKI), WanFang Data Resource, Chongqing VIP Information Database, and China BioMedical Literature Service System (SinoMed); 2) English articles: MEDLINE, Embase, and Cochrane Library. Articles published in Chinese or in English before January 2019 were selected. Literature retrieval was run using the keywords related to RA/TGT/TWT. The enrolled articles included the existing guidelines, systematic reviews, meta-analyses, RCTs, nonrandomized controlled trials, and observational studies.

## Level of the Evidence and Strength of the Recommendations

The level of the evidence was evaluated according to the guideline of GRADE Working Group (Balsheem et al., 2011) (Table 1). The

evidence-based recommendations were formed based on the strength of recommendations (Andrews et al., 2013) suggested by GRADE Working Group (Table 2). The expert-approved GPPs were formed through two rounds of Delphi survey and the consensus development conference (Liao and Xie, 2008).

## Development of Recommendations and GPPs

Eight recommendations and seven GPPs on the clinical application of TGT and TWT against RA were developed by taking real-name vote among the experts of the scientific committee and working group based on the following procedures. At first, the articles were carefully reviewed and the level of evidence offered by each article was given. Then, adverse effects, economic considerations, applicability of the recommendation to the target population of each recommendations, and GPPs were also shown in GRADE Evidence to Decision (EtD) framework. After that, GRADE EtD framework of the evidence-based recommendation was using the five-category scale (strongly disagree, disagree, uncertain, weak recommendation, and strong

recommendation). The vote of any strongly disagree, disagree, weak recommendation, strong recommendation over 50% should be deemed to reach a consensus. The vote of any side of "uncertain" over 70% should be deemed to reach a consensus, and the strength of the recommendation should be recognized as weak. GRADE EtD framework of expert-approved GPP was using the three-category scale (consensus, uncertain, and against). The vote of any side of "uncertain" over 50% should be recognized as GPP.

## Peer Review

The guideline was assessed twice after the draft was completed by the guideline compiling team. For the first round of assessment, a total of 17 experts were invited to review the first draft of guideline. Following the revision, another 39 experts outside the working group were invited to review draft for the second time. After two rounds of experts' assessment and amendment, the guideline was approved by the Standardization Office of the Chinese Association of Chinese Medicine.

## Publicity

The introduction and announcement of this guideline have been published on the official account of the Chinese Association of Chinese Medicine website. The guideline will be publicized in various academic conferences in the future.

## Update

The working group will update guideline within three years based on new evidence of TGT and TWT administrations against RA.

## DIAGNOSTIC CRITERIA

### Diagnosis in Western Medicine

- (1) The 1987 American College of Rheumatology (ACR) classification criteria for RA (Arnett et al., 1988).

Seven diagnostic criteria proposed by ACR are as follows: 1) morning stiffness in and around joints lasting at least 1 h before maximal improvement; 2) soft tissue swelling (arthritis) of three or more joint areas observed by a physician; 3) swelling (arthritis) of the proximal interphalangeal, metacarpophalangeal, or wrist joints; 4) symmetric swelling (arthritis); 5) rheumatoid nodules; 6) the presence of rheumatoid factor (RF); 7) radiographic erosions and/or periarticular osteopenia in hand and/or wrist joints. Criteria one through four must have been present for at least 6 weeks. RA is defined by the presence of four or more criteria, and no further qualifications (classic, definite, or probable) or list of exclusions is required.

- (2) The 2010 ACR/European League Against Rheumatism (EULAR) classification criteria for RA (Aletaha et al., 2010).

The revised diagnostic criteria issued by ACR and EULAR in 2010 are as follows: 1) Target population (who should be tested?): patients 1) who have at least one joint with definite clinical synovitis (swelling); 2) with the synovitis not better explained by

another disease. 2) Classification criteria for RA (score-based algorithm: add score of categories A-D; a score of 6/10 is needed for classification of a patient as having definite RA): A. Joint involvement: 1) large joint calculated as 0; 2) 2–10 large joints calculated as 1; 3) one to three small joints (with or without involvement of large joints) calculated as 2; 4) 4–10 small joints (with or without involvement of large joints) calculated as 3; 5) 10 joints (at least one small joint) calculated as five; B. Serology (at least one test result is needed for classification): 1) negative RF and negative Anti-Citrullinated Protein Antibody (ACPA) calculated as 0; 2) low-positive RF or low-positive ACPA calculated as 2; 3) high-positive RF or high-positive ACPA calculated as three; C. Acute-phase reactants (at least one test result is needed for classification): 1) normal C-reactive protein (CRP) and normal erythrocyte sedimentation rate (ESR) calculated as 0; 2) abnormal CRP or abnormal ESR calculated as one; D. Duration of symptoms: 1) <6 weeks calculated as 0; 2) ≥6 weeks calculated as 1.

### Disease Activity Classification

According to Disease Activity Score with 28-joint counts (DAS28) (Anderson et al., 2012), the disease activity of RA could be classified into four stages: clinical remission is defined by  $\text{DAS28} < 2.6$ ; low/minimal stage of RA is defined by  $2.6 \leq \text{DAS28} < 3.2$ ; moderate stage of RA is defined by  $3.2 \leq \text{DAS28} \leq 5.1$ ; high/severe stage of RA is defined by  $\text{DAS28} > 5.1$ ; active stage of RA is defined by  $\text{DAS28} \geq 2.6$ ; reaching the target to RA treatment is defined by  $\text{DAS28} < 2.6$ .

### Diagnosis in Chinese Medicine (CM)

Those with pain and swelling of the small joints and morning stiffness as the chief complaint can be diagnosed with Wang Bi (National Administration of Traditional Chinese Medicine): 1) symmetric pain of the small joints, morning stiffness, and limited mobility are the initial performance of RA; 2) major characteristics of RA are as follows: slow onset, persistent, recurrent, and gradually angular wait; 3) with the progression of the disease, swollen joint, tenderness, and pain that worsens with activity appear gradually and eventually lead to stiffness or deformity of joints, muscular dystrophy, and rheumatoid nodules; 4) obvious changes into the presence of RF, ESR, radiographic erosions, periarticular osteopenia, subluxation and luxation of joint, joint ankylosis, and joint fusion at the active stage of RA appear.

## ACTIONABLE RECOMMENDATION

The aim of the administration of both TGT and TWT is to alleviate the disease severity of RA and inflammatory reactions, as well as to slow the progression of erosive osteoclasia.

### Suitable Crowd (GPP)

Both TGT and TWT are suitable for RA patients without fertility desire.

### Indication (GPP)

Both TGT and TWT are suitable for RA patients at the active stage ( $\text{DAS28} \geq 2.6$ ).

## Directions (GPP)

TGT: For oral administration, the regular dose is 1 mg for every kilogram of the body weight, and the highest dose is restricted to 1.5 mg for every kilogram of the body weight, three times per day after meals.

TWT: For oral administration, the regular dose is 1–2 pills each time, three times per day after meals.

## Course of the Treatment (GPP)

Routine course of the administration of both TGT and TWT is three months. After that, DAS28 should be evaluated to confirm the therapeutic effects of the drugs. If DAS28 < 2.6, the dosage of both TGT and TWT should be reduced gradually.

## Combination Therapy (GPP)

If DAS28 is still more than 2.6 at the third month following the administrations of TGT or TWT, the combination therapeutics of TGT/TWT and methotrexate (MTX)/leflunomide (LEF)/total glucosides of white paeony capsules/Zhengqing Fengtongning tablet should be used for the treatment of RA.

## Both TGT and TWT are suitable for RA patients with all kinds of TCM syndromes (GPP)

Both “Chinese guideline for the diagnosis and treatment of rheumatoid arthritis (2018 version)” (Chinese Rheumatology Association) and “Guidelines for diagnosis and treatment of rheumatoid arthritis based on the combination of disease and syndrome” (Jiang et al., 2018) recommend TGT and TWT as effective Chinese patent medicine against RA. According to “Guidelines for diagnosis and treatment of rheumatoid arthritis based on the combination of disease and syndrome”, both TGT and TWT are suitable for RA patients with all kinds of TCM syndromes.

## The single administration of TGT against RA may alleviate the inflammatory reactions (GRADE A, Level III)

A meta-analysis showed that there were four randomized controlled trials (RCTs) that demonstrated ESR and CRP to be the prognostic markers for TGT administration against RA. TGT can significantly decrease CRP and ESR in RA patients, which is similar to MTX, MD<sub>ESR</sub> = -2.66, 95%CI [-8.17, 2.86],  $p = 0.35$ ; MD<sub>CRP</sub> = -2.38, 95%CI [-9.01, 4.24],  $p = 0.48$  (Li et al., 2019).

## The combined administration of TGT and MTX against RA may alleviate the inflammatory reactions (GRADE A, Level II)

A meta-analysis showed that there were 24 RCTs that demonstrated ESR, CRP, and RF to be the prognostic markers for the combined administration of TGT and MTX against RA. The combination of TGT with MTX can be more effective in reducing the levels of CRP, ESR, and RF than MTX alone, MD<sub>ESR</sub> = 8.74, 95%CI [6.72, 10.76],  $p < 0.00001$ ; MD<sub>CRP</sub> = 5.37,

95%CI [3.71, 7.03],  $p < 0.00001$ ; SMD<sub>RF</sub> = 1.05, 95%CI [0.51, 1.60],  $p = 0.00001$  (Li et al., 2019).

## The single administration of TGT against RA may alleviate the symptoms (GRADE A, Level III)

A meta-analysis showed that there were three RCTs that demonstrated swollen joint count (SJC) and tender joint count (TJC) to be the primary outcome of the administration of TGT against RA. The therapeutic effects of TGT on alleviating joint swelling and tenderness in RA patients were similar to MTX, MD<sub>SJC</sub> = 0.18, 95%CI [-1.06, 1.42],  $p = 0.78$ ; MD<sub>TJC</sub> = -0.06, 95%CI [-1.69, 1.56],  $p = 0.94$  (Wang, X. Y et al., 2019).

## The combined administration of TGT and MTX against RA may alleviate the symptoms (GRADE A, SJC and TJC: Level II; MS: Level III)

A meta-analysis showed that there were 18 RCTs that demonstrated SJC, TJC, and morning stiffness time (MST) to be the prognostic markers of the combined administration of TGT and MTX against RA. The combination of TGT with MTX can more effective in reducing the levels of SJC, TJC, and MST than MTX alone, MDSJC = 3.01, 95%CI [2.09, 3.39],  $p < 0.00001$ ; MDTJC = 2.65, 95%CI [1.85, 3.44],  $p < 0.00001$ ; MDMST = 18.24, 95%CI [12.64, 23.84],  $p < 0.00001$  (Wang, X. Y et al., 2019).

## The single administration of TGT against RA may achieve good clinical efficacy (GRADE B, Level III)

A meta-analysis showed that there were three RCTs that demonstrated ACR criteria to be the prognostic criteria of the administration of TGT against RA. The clinical efficacy of TGT administration against RA patients was superior to MTX, RRACR = 1.31, 95%CI [1.15, 1.49],  $p < 0.00001$  (Chen et al., 2020).

## The combined administration of TGT and MTX against RA may achieve good clinical efficacy (GRADE A, Level III)

A meta-analysis showed that there were 10 RCTs that demonstrated ACR criteria to be the prognostic criteria of the combined administration of TGT and MTX against RA. The clinical efficacy of the combination of TGT with MTX was superior to MTX, RRACR = 1.28, 95%CI [1.20, 1.38],  $p < 0.00001$  (Chen et al., 2020).

## The combined administration of TGT and LEF against RA may alleviate the inflammatory reaction (GRADE A, Level II)

There were five RCTs that demonstrated CRP to be the prognostic markers of the combined administration of TGT and LEF against RA. Meta-analysis results showed that the

combined administration of TGT and LEF was more effective in decreasing CRP than LEF alone, SMDCRP = 1.05, 95%CI [0.59, 1.52],  $p < 0.0001$  (Zhang et al., 2011; Min et al., 2013; Long and Li, 2014; Cui and Yang, 2016; Sun et al., 2016).

### The single administration of TGT against RA may slow the progression of erosive osteoclasia (GRADE B, Level III)

A meta-analysis showed that there were three RCTs that demonstrated the modified Sharp score (including joint erosions, JE; and joint space narrowing, JSN) to be the prognostic marker of the administration of TGT against RA. The therapeutic effects of TGT on slowing the progression of erosive osteoclasia in RA patients were superior to MTX and salazopyridine, RRJE = -1.37, 95% CI [-3.25, 0.51],  $p < 0.15$ ; RRJSN = -1.25, 95%CI [-2.68, 0.18],  $p < 0.15$  (Zhu et al., 2019).

### Toxic side effects should be monitored during the administration of both TGT and TWT (GPP)

Both the administrations of TGT and TWT may achieve good therapeutic effects in RA patients at the active stage. Because the bioactive constituents of TwHF may often have toxicity, the adverse drug reactions (ADRs) occur occasionally. A meta-analysis (Li et al., 2020) showed that there were 79 studies that reported ADRs of the TGT administration against RA. Of 1,997 cases with ADRs in the experimental group, 792 (39.66%) were reported when TGT was used as the intervention. Of 1,361 cases with ADRs in the control group, 507 (37.25%) were reported when TGT was used as the intervention. The overall incidence of ADRs was 38.68% (1,299/3,358). Meta-analysis results of 49 studies with TGT as intervention in the experimental group showed that the overall incidence of ADRs was 0.23, 95%CI [0.22, 0.24],  $p = 0$ . ADRs mainly result in the

damage of the reproductive, gastrointestinal, skin and accessories, blood, and hepatobiliary systems.

## CONCLUSION

Collectively, the development of clinical practice guideline for TGT/TWT in the treatment of RA may offer a clinical decision support for healthcare professionals according to the available evidence and expert opinions, which enables optimal patient care. Furthermore, this will also identify limitations in existing research and knowledge in TwHF-based therapy that will form a research agenda for future investigations.

## AUTHOR CONTRIBUTIONS

All authors listed have made a substantial, direct, and intellectual contribution to the work and approved it for publication.

## FUNDING

This study was supported by National Natural Science Foundation of China (81974526, 81974529, 81974537, and 81873068), Beijing Municipal Natural Science Foundation (7192139), and Fundamental Research Funds for the central public welfare research institutes (Z2017082 and ZXKT19013).

Chronic heart failure (CHF) is a common cardiovascular disease with high mortality and a poor prognosis, which places heavy burdens upon society and families. Traditional Chinese medicine (TCM) has been used extensively as complementary treatment for CHF. *Guanxinshutong* (GXST) capsules are used commonly for the treatment of coronary heart disease (CHD). Experimental research and small-sample clinical trials have shown that GXST can attenuate CHF. However, the effects of GXST as complementary medicine in CHF treatment lack high-quality clinical evidence. We have designed a multicenter, randomized, double-blind, placebo-controlled clinical trial that explores the efficacy and safety of using GXST compared with placebo for patients with CHF with reduced left ventricular ejection fraction (LVEF). A total of 480 participants will be assigned randomly to the GXST group or placebo group at a 2:1 ratio. GXST and placebo will be added to standard treatment for 12 weeks, and then followed up for another 40 weeks. The primary outcome is the improvement value of 6-min walk distance, and the secondary outcomes include plasma levels of N-terminal pro-B-type natriuretic peptide, New York Heart Association classification, Minnesota Living with Heart Failure Questionnaire scores, echocardiographic parameters, and clinical endpoint events. Adverse events will be monitored throughout the trial. Data will be analyzed following a predefined statistical analysis plan. This study will show the effects of the specific use of GXST in CHF patients

**Abbreviations:** ARNI: angiotensin receptor neprilysin inhibitor; CHF: chronic heart failure; TCM: traditional Chinese medicine; CHD: coronary heart disease; GXST: *Guanxinshutong*; LVEF: left ventricular ejection fraction; ACEI: angiotensin-converting enzyme inhibitor; CFDA: China Food and Drug Administration; NT-proBNP: N-terminal pro-B-type natriuretic peptide; CONSORT: Consolidated Standards of Reporting Trials; FAS, full analysis set; PPS, per protocol analysis set; NYHA: New York Heart Association; eCRF: electronic case report forms; AEs: adverse events; SAE: serious adverse events; 6MWD: 6 min walk distance; SD: standard deviation; SAP: statistical analysis plan; ITT: intention to treat.

with reduced LVEF. The Research Ethics Committee of the Second Affiliated Hospital of Zhejiang Chinese Medical University has approved this study (2019-Y-003-02). Written informed consent of patients will be required. This trial is registered in the Chinese Clinical Trial Registry (ChiCTR1900023877). Our results will be disseminated to the public through peer-reviewed journals, academic conferences, and the Internet.

**Keywords:** Guanxinshutong (GXST), traditional Chinese medicine (TCM), heart failure, complementary medicine, clinical trial

## INTRODUCTION

Chronic heart failure (CHF) is a complex clinical syndrome characterized by reduced cardiac output, insufficient organ perfusion, and venous congestion due to cardiac dysfunction (Coronel et al., 2001; Tan et al., 2010). CHF affects about 26 million people worldwide, with more than one million people hospitalized in the USA and Europe each year (Ambrosy et al., 2014). In China, it is estimated that 4.5 million aged 35–74 years suffer from CHF, and, with an increasingly aging population, the incidence of common cardiovascular diseases, such as hypertension, coronary heart disease (CHD), and CHF, continues to rise (Guo et al., 2003; Huo et al., 2019). CHF brings a heavy economic burden to society, families, and individuals, so new therapies and prevention strategies are needed.

According to guidelines for the diagnosis and treatment of heart failure set by the Chinese government in 2018, angiotensin-converting enzyme inhibitors (ACEIs),  $\beta$ -receptor blockers, and aldosterone receptor antagonists are recommended as “the golden triangle treatment” for patients suffering from CHF with reduced ejection fraction (Heart Failure Group of Chinese Society of Cardiology and Editorial Board of Chinese Journal of Cardiology, 2018). Although the use of the golden triangle treatment has improved the curative effect, this treatment plan is associated with hyperkalemia, deterioration of renal function (Heart Failure Group of Chinese Society of Cardiology and Editorial Board of Chinese Journal of Cardiology, 2018), limited improvement of symptoms, and unsatisfactory improvement in long-term survival (Pitt et al., 2014; Maisel et al., 2018). In recent years, the use of angiotensin receptor neprilysin inhibitors (ARNIs) has been considered as a therapeutic strategy in heart failure (McMurray et al., 2014). The PARADIGM-HF trial provided evidence that combined inhibition of the angiotensin receptor and neprilysin is superior to inhibition of the renin-angiotensin system alone in patients with CHF (McMurray et al., 2014). However, the ARNIs (tablets of sacubitril valsartan sodium) are not widely used in China currently.

Traditional Chinese medicine (TCM) is a popular type of supplementary and complementary medicine. TCM formulations have been employed widely and successfully for CHF treatment in China for more than 2000 years. Currently, the integration of Chinese and Western medicine has shown promising benefits in controlling symptoms, reducing

mortality, improving cardiac function, and promoting quality of life in patients with CHF (Xu and Xu, 2011). In TCM, all the related symptoms, signs, tongue appearances, and pulse feelings at a certain stage of disease are summarized as a syndrome (“Zheng” in TCM) (Jiang et al., 2012). The syndrome is not only the core of TCM theory but also the base of the definitive diagnosis and efficacious therapies (Xu and Chen, 2008). According to Cui and colleagues, the basic syndrome type of CHF is “blood stasis syndrome” (Cui et al., 2009). The symptoms of CHF with blood stasis syndrome are palpitation, pain in the chest and hypochondrium, prominent blue veins in the neck, dark and purple complexion, cyanotic lips and nails, and edema of the lower extremities combined with a purple tongue, knotted/intermittent/uneven pulses.

*Guanxinshutong* (GXST) capsules have been developed by Shaanxi Buchang Pharmaceutical Co., Ltd. (Shaanxi, China) and gained approval by the China Food and Drug Administration (CFDA) for CHD treatment (approval number: Z20020055) in 2002. GXST consists of five herbal medicines (Table 1), and promotes blood circulation, removes blood stasis, and relieves pain (Zhang et al., 2016). Experimental studies have shown that GXST can inhibit ventricular remodeling through increasing mitochondrial productivity (Zhang et al., 2015; Zhang et al., 2016), repressing the expression of matrix metalloprotein-9, angiotensin receptors-1 and extracellular regulated protein kinases-2 (Zhang et al., 2012; Zhang et al., 2013), and the transforming growth factor- $\beta$ /Smad signaling pathway (Fang et al., 2019) in myocardial tissue to improve CHF. A clinical trial with 61 patients reported that, compared with conventional treatment, combination with GXST could significantly increase left ventricular ejection fraction (LVEF) and cardiac output, and reduce the end-systolic, diastolic volume in patients with acute myocardial infarction with CHF (Li, 2019). Meanwhile, in our previous clinical study, GXST exerted a therapeutic effect on CHF (unpublished data), which implied that it might be a potential Chinese-patent medicine for CHF treatment. However, the current clinical data of GXST as a complementary therapy in CHF are lack of high quality, and limited in terms of methodology and sample size. Therefore, we designed a large-scale, multicenter, double-blinded clinical trial to investigate the efficacy and safety of GXST in CHF patients with reduced LVEF. The primary hypothesis of this study is as follows: combined with routine standard treatment, GXST is superior to placebo in patients with reduced LVEF caused by CHD.

**TABLE 1** | Components of GXST (intervention drug).

## METHODS AND ANALYSES

### Design and Settings

This study is a multicenter, prospective, randomized, double-blind, placebo-controlled, superiority trial. The trial will be conducted by 11 centers throughout China (Table 2), and a total of 480 participants will be recruited. After the participants have been enrolled and provided written informed consent, they will be assigned randomly to the GXST group or placebo group in a 2:1 ratio. This trial consists of a 1-week baseline period, a 12-week intervention period, and a 40-week follow-up period. A flow diagram of the study procedures is illustrated in Figure 1. Participants will be monitored and assessed by the investigators at each study visit. The design follows the rules for Standard Protocol Items Recommendations for Interventional Trials (Chan et al., 2013) and Consolidated Standards of Reporting Trials (CONSORT) (Schulz et al., 2010).

### Recruitment

Recruitment strategies will include publishing recruitment advertisements on social media (e.g., QQ™, and We Chat™ in China, which are similar to Facebook™), online publications, and community centers. Patients who consent to participate will be examined and diagnosed by associate chief physicians to confirm their inclusion and will be registered on an online allocation system after written informed consent has been obtained.

### Study Population

The inclusion criteria and exclusion criteria are shown in Tables 3 and 4, respectively.

### Criteria for Withdrawal, Removal, Dropout, and Termination

The withdrawal criteria will be 1) exacerbation or deterioration that is clearly related to intake of the study drug; 2) an allergic reaction that is clearly associated with the study drug; 3) comorbidities, complications, adverse events (AEs), or serious adverse events (SAEs) during the trial, such as the necessity of long-term intravenous medication, repeated hospitalization for heart failure, or New York Heart Association (NYHA) class-IV symptoms; 4) the use of forbidden drugs or receipt of prohibited treatment affect the measures of efficacy and safety; 5) poor compliance by participants, or the amount of drug used does not meet the regulations (<80% or >120%); 6) participants request to withdraw from the study; 7) the blinding is uncovered or emergency unblinding is required.

Participants who fail to complete the observational period proposed in the trial, regardless of time and reasons, will be considered to be “dropout” cases. Reasons for dropout will be recorded in electronic case report forms (eCRFs), and the last data recorded will be included in data analyses. During the trial, a participant may be removed if he/she 1) is included mistakenly due to a misdiagnosis, 2) has not taken medication after study inclusion, 3) is participating in other clinical trials, and 4) has incomplete data and no evaluable records after inclusion. Another reason for removal is if the combined use of drugs has a great influence on the efficacy and safety of the study drug. Removal cases will not be included in analyses of the intention-to-treat (ITT) population.

The entire research study will be terminated if 1) there is a poor clinical effect of the test drug, and there is no need to continue the trial; 2) there are major defects in the trial; and 3) administrative authorities terminate the trial.

### Randomization, Allocation Concealment Mechanism, and Blinding

Participants will be randomized to the GXST group or placebo group in a 2:1 ratio using the Central Randomization System to achieve computerized randomization in blocks of six, stratified by center. The random sequence will be retained in an envelope and sealed subsequently. According to the randomization number, a statistician will send the envelope directly to Shaanxi Buchang Pharmaceutical Co., Ltd. for labeling of the intervention drug and placebo drug. All researchers, participants, physicians, drug administrators, and dispensing nurses will be blinded to the type of treatment until the study is completed. Unblinding will be available if participants experience an SAE or need to be rescued in an emergency situation. Once unblinded, the participant will withdraw from the study. Researchers should

report the reasons to the inspector within 24 h. The precise cause of unblinding, date of the AE, the treatment situation, and the results must be recorded in eCRFs.

## Interventions

Eligible participants will be allocated randomly to the GXST group or placebo group. If GXST have been used before randomized, a 2-week drug washout period should be implemented to avoid any potential complication from GXST. All participants will receive standard treatment.

The GXST group will receive GXST (batch number: 190214, 0.3 g per capsule, op, 3 capsules per time, thrice daily). The placebo group will receive capsule stimulants (batch number: 190215, 0.3 g per capsule, op, 3 capsules per time, thrice daily).

Concerning standard treatment, during the intervention period, according to the guidelines for CHF treatment (Ponikowski et al., 2016; Chinese Society of Cardiology and Chinese Medical Doctor Association, 2018), ACEIs, and/or angiotensin receptor blockers,  $\beta$ -blockers, aldosterone receptor blockers, or diuretics should be used. TCM formulations with a similar composition and efficacy to those of GXST will not be allowed to be used. Concomitant treatments for comorbidities (e.g., hypertension, diabetes mellitus, hyperlipidemia, and other

chronic conditions) are permitted during the intervention. Researchers should record the concomitant medication truthfully and maintain dose stability during the trial.

Concerning emergency treatment, in the event of an SAE or acute exacerbation of the disease during treatment (e.g., acute heart failure and acute coronary syndrome), participants should be treated first, and the treatment status should be recorded as an AE record form and combined medication record form. If the participant's condition deteriorates during treatment and it is not advisable to continue the trial (e.g., long-term intravenous medication, repeated heart failure that necessitates hospital admission, or NYHA class-IV symptoms), one should consider terminating the trial and switching to surgery or another type of clinical treatment. Patients will be classified in the analysis as "treatment ineffective."

GXST and capsule stimulants will be provided by Shaanxi Buchang Pharmaceutical Co. Ltd. The quality control of GXST is important. The method of determination of GXST components is based on the general principles of the 2018 edition of the *Chinese Pharmacopoeia*. Using gas chromatography (General Principle 0521), each GXST capsule should contain eugenol  $\geq 2.0$  mg and borneol  $\geq 14.0$  mg, and the total amount of borneol and isoborneol should be 25.5–34.5 mg. Using liquid chromatography (General Principle 0512), each GXST capsule

**TABLE 3 |** Inclusion criteria.

Meet all the diagnosis of CHD (Chinese Society of Cardiology and Chinese Medical Doctor Association, 2018), CHF (Ponikowski et al., 2016; Heart Failure Group of Chinese Society of Cardiology and Editorial Board of Chinese Journal of Cardiology, 2018), and TCM diagnosis of blood stasis syndrome according to the <i>Guidelines for Clinical Research of New TCM Drugs</i> (Zheng, 2002)
Aged 40–80 years, of both sexes
New York Heart Association class II–III (Hunt et al., 2005)
Left ventricular ejection fraction <50% (using two-dimensional echocardiographic Simpson's method)
Clinical findings of CHF for ≥3 months before screening
Clinically stable in the last 1 month or receiving standardized treatment for ≥1 month, and no modification of dosage or intravenous administration has been given.
Standardized treatment includes ACEIs and/or angiotensin receptor blockers, β-blockers, aldosterone receptor blockers, or diuretics
Plasma level of NT-pro-B-type natriuretic peptide ≥125 ng/L
Volunteer, understand, and provide written informed consent

**TABLE 4 |** Exclusion criteria.

Acute coronary syndrome within the past 1 month
Plan to have cardiac surgery during the trial
Patients with cardiogenic shock, acute myocarditis, uncontrollable malignant arrhythmia, hypertrophic obstructive cardiomyopathy, pulmonary embolism, or severe valvular disease necessitating surgery
Uncontrolled hypertension, systolic blood pressure (SBP) ≥180 mmHg, and/or diastolic blood pressure (DBP) >110 mmHg; or SBP <90 mmHg and/or DBP <50 mmHg
Combined with severe liver or kidney dysfunction or active liver disease, and/or aspartate transaminase, alanine aminotransferase ≥3 times the upper limit of normal
Patients with diseases affecting walking ability, such as vascular disease of lower extremities
Combined with psychiatric manifestations
Patients with alcohol addiction or history of substance abuse
Females who are pregnant or lactating, preparing for pregnancy during the trial, or have a positive pregnancy test at the time of hospital admission
Have severe allergies, or allergic to research drugs and its ingredients
Patients with a history of previous or present malignancy, or precancerous lesions confirmed by pathology
Participation in other clinical studies within 3 months
Researchers estimate that the patient unable to complete the study

should contain tanshinone II-A ≥0.15 mg and salvianolic acid B ≥2.9 mg. The primary content of capsule simulants is corn starch, silica, caramel (liquid), and sunset yellow. We have added 2% GXST powder to the capsule simulants to achieve smell, color, taste, and texture comparable with that of GXST. After treatment, the package will be returned to the researchers.

## OUTCOMES

### Primary and Secondary Outcomes

The details of items to be measured and the time window of data collection are shown in **Table 5**. The primary outcome is the improvement in 6-min walk distance (6MWD) (Holland et al., 2014). 6MWD will be measured within 24 h after enrollment and

12 weeks after treatment to evaluate the change in exercise tolerance. Improvement will be calculated using the following formula:

Improvement in exercise tolerance = 6MWD value after treatment – 6MWD value before treatment

The secondary outcomes are 1) changes in plasma levels of N-terminal pro-B-type natriuretic peptide (NT-proBNP) (Booth et al., 2014; Roberts et al., 2015). NT-proBNP will be detected centrally by Zhejiang Chinese Medical University using a standard kit and fixed operating procedures; 2) improvement in NYHA functional class (The Criteria Committee of the New York Heart Association, 1994); 3) improvement in the Minnesota Living with Heart Failure Questionnaire score (Rector and Cohn, 1992); 4) improvement in echocardiographic measurements of left ventricular end-diastolic diameter and LVEF; 5) the incidence rate of clinical endpoint events (rehospitalization for acute aggravation of CHF, cardiogenic death, and all-cause death).

### Safety Outcomes

Safety outcomes comprise vital signs (body temperature, heart rate, breathing, and blood pressure), imaging (radiographs or computed tomography), laboratory examinations (routine blood test, routine urinalysis, serum biochemistry, myocardial zymogram, and troponin test), and AEs (which will be recorded throughout the trial).

### Metabolomics and Proteomics Analyses

Fifty participants per group will be selected randomly for metabolomics and proteomics analyses to explore the biomarkers of GXST for treating CHF.

Metabolomics analyses will be on blood and urine samples. Gas chromatography–mass spectrometry and liquid chromatography–mass spectrometry will be used to detect chemical and biological “fingerprints,” describe the possible metabolic pathways, and identify biomarkers of GXST for CHF treatment.

Proteomics analyses will be of blood samples. Two-dimensional difference gel electrophoresis will be used to establish the proteome of each group before and after the intervention. Matrix-assisted laser desorption/ionization time-of-flight/time-of-flight mass spectrometry will be applied to identify differentially expressed proteins. Bioinformatic analyses are used to assess the biological functions of differentially expressed proteins. The Search Tool for the Retrieval of Interacting Genes/Proteins database and Ingenuity Pathway Analysis (IPA) are employed to establish a protein network affected by GXST.

Concerning the collection of blood samples, participants will fast for 10 h before each collection. Then, 5 ml of blood will be drawn and centrifuged, and serum stored in Eppendorf™ tubes at –70°C. Concerning the collection of urine samples, participants will fast for 10 h before taking the medication (and be allowed to drink water). They will fast, and water consumption will be prohibited 1 h before urine collection to 2 h after taking the medication. Water will be rationed to 200 ml/h for 2–8 h after taking the medication, and a low-fat meal can be consumed 4 h after taking the medication. Urine samples will be collected at

## Collection and Management of Data

According to the requirements of Good Clinical Practice and our research plan, the investigator shall input data to eCRFs accurately, completely, normatively, and in a timely fashion based on the original observations of participants. To ensure the accuracy of the data, two personnel specializing in data entry should undertake double-entry and proofreading independently. The auditor shall monitor whether the research is conducted following the research plan, ascertain whether all eCRFs have been completed correctly and are consistent with the original data, and issue questions at any time in case of any problem. If errors and omissions are made, the researcher shall be corrected promptly.

After inspection by the auditor, eCRFs must be transmitted to the department of data management in time. In this study, data management will be carried out with an electronic data-capture system by the Department of Medical Statistics within the First Hospital of Peking University (Beijing, China). The data

administrator shall adopt system-automatic and manual-logic verification to check the consistency of eCRF data and source data. For questions in the eCRFs, the data administrator will generate a question-answer form and send an inquiry to the investigator through the clinical monitor. The investigator should answer the question as soon as possible, and the data administrator will modify the data according to the investigator's answer. If necessary, a question-answer form can be issued again. After being reviewed and confirmed by the primary researcher, sponsor, statistical analyst, and data administrator, the data will be locked and submitted to the statistician for analyses.

Personal information about potential and enrolled participants will be protected confidentially throughout the trial, and researchers should maintain data secrecy for five years after termination of the trial.

## Sample Size

The formula for calculating the sample size is based on the superior clinical trial sample size estimation (Wan et al., 2017). The sample size is driven by the expected improvement

in 6MWD. Referring to clinical studies (Fan and Zhang, 2012; Guo and Li, 2013; Du, 2014; Wu et al., 2015), we assumed that the improvement in 6MWD is 30 m, and the combined standard deviation (SD) is 100 m in the present study. Given a rate of type-I error of  $\alpha = 0.025$ , a power of 80% (rate of type-II error of  $\beta = 0.2$ ), and, considering a possible dropout rate of 20%, 470 patients will need to be allocated. For the convenience of randomization, the final sample size was 320 cases in the intervention group and 160 cases in the placebo group, a total of 480 cases.

$$n_1 = \left[ \frac{(\mu_\alpha + \mu_\beta)\sigma}{\delta} \right]^2 \frac{(1+k)}{k}, \quad n_2 = k n_1.$$

In this formula,  $k$  is the ratio between two sample cases,  $\delta$  is the expected improvement in 6MWD, and  $\sigma$  is the combined SD.

## Trial Completion

The trial will end once 480 patients have been randomized and all patients have completed 52 weeks of treatment and follow-up.

## Statistical Analyses

The statistical analysis plan will be specified before data analyses. The statistical analyses will be undertaken *via* Statistical Analysis System v9.4 (or higher version) by the Department of Medical Statistics, Peking University First Hospital. Professional statisticians who are independent of all other processes of our study will carry out analyses. Consistent with the CONSORT statement and ITT principle, and the last observation, carried forward method will be used for missing values. Cases in the per protocol set (PPS) will be those who adhere to the protocol closely without the absence of baseline characteristics. Analyses of primary outcome and curative effect will be carried out using a full-analysis-set approach and PPS approach. The safety analysis set will include all randomized patients who have accomplished at least one study visit. Participating centers will be required to sum-up participant numbers in each center and list participants who have been removed from PPS.

For continuous variables, we will calculate the mean, SD, median, minimum, maximum, and interquartile range. For categorical variables, we will describe various frequencies or percentages. The chi-square test or Fisher's exact test will be used for categorical variables. The Student's *t*-test will be used for continuous variables with a normal distribution. For data that do not have a normal distribution, intragroup or intergroup differences before and after treatment will be analyzed by the Wilcoxon rank-sum test. The proportion of patients with AEs in two groups will be compared using the chi-square test or Fisher's exact test. Because patients who had use of ARNIs before the recruitment may constitute a specific population, we will run sensitivity analyses of the outcomes with patients used ARNIs as basic treatment, and adjusted for the effect of ARNIs. Significance will be assumed at a two-sided *p*-value less than 5%. The relative risk with corresponding 95% confidence interval to compare dichotomous variables will be calculated. **Table 6** shows the method of analysis for specific outcomes.

## Adverse Events

AEs that occur during the observation period will be monitored, reported to a research assistant, causality with the intervention will be evaluated, and the severity of AEs will be analyzed. SAEs will be reported to the ethics committee within 24 h. The classification and coding of AEs are formulated concerning Common Terminology Criteria for AEs version 4.03.

## Quality Control of the Intervention

To further ensure the quality of this trial, a multicenter trial coordination committee and general director will be set up for the implementation and solution of the problems related to this trial. The leaders of each center and the sponsor are the members of the coordination committee. Before each center recruits subjects, the sponsor will conduct unified preclinical trial training for all staff. Through such training, all staff (operators, investigators, physicians, data collectors, and analyzers) will fully understand the purpose and content of the trial, and standardize the process of data collection and CRF completion. This trial will be inspected by the CFDA, sponsor, and clinical research organization throughout the trial.

## Trial Status

This is an ongoing trial. The first participant was recruited on September 16, 2019. This study is recruiting participants currently.

## DISCUSSION

CHF continues to be a major cause of mortality, initial and recurrent hospitalizations, and suboptimal quality of life (Yao et al., 2020). Despite advances in management and treatment of CHF, many CHF patients continue to suffer from exercise intolerance and dyspnea (Simpson et al., 2015). An increasing volume of evidence demonstrates that the combination of TCM with Western medicine could be an optimal approach for achieving greater treatment efficacy in patients with CHF (Gao et al., 2017; Jia et al., 2020).

GXST is a widely used TCM formulation for the treatment of cardiovascular disease in China. Pharmacology results have shown the effects of GXST in multiple mechanism pathways to treat CHF, such as improving hemorheology (Liang et al., 2012); enhancing mitochondrial capacity, and improving myocardial energy metabolism (Zhang et al., 2015; Zhang et al., 2016); and reversing ventricular remodeling (Zhang et al., 2012; Zhang et al., 2013). However, whether GXST is efficacious in patients with CHF requires confirmation by large-sample, multicenter, randomized controlled clinical trials. Therefore, we designed a multicenter, double-blinded, placebo-controlled clinical trial with the hope of verifying the efficacy and safety of GXST for the treatment of CHF with reduced LVEF. The results could provide a strategy for combining TCM and Western medicine in CHF patients.

**TABLE 6 |** Outcomes and methods of analyses.

Outcome/variable	Hypothesis	Measures	Methods of analyses
Baseline balance test		Quantitative outcomes (age, temperature, heart rate, respiratory rate, and blood pressure)	<i>t</i> -test/Wilcoxon rank-sum test
		Qualitative outcomes (sex, marriage, and previous treatment)	Chi-squared test/Fisher's exact test/rank-sum test
Adherence at post-intervention		Percent and cases of adherence <80% and ≥80%	Chi-squared test/Fisher's exact test
Concomitant treatments		Percent and cases of concomitant treatments	Chi-squared test/Fisher's exact test
Primary outcome			
6MWD	Improvement occurred		<i>t</i> -test/Wilcoxon rank-sum test Covariance analysis
Secondary outcomes			
NT-proBNP	Improvement occurred		<i>t</i> -test/Wilcoxon rank-sum test
NYHA classification	Improvement occurred		Wilcoxon rank-sum test
MLHFQ	Improvement occurred	Questionnaire	<i>t</i> -test/Wilcoxon rank-sum test
Echocardiographic parameters	Improvement occurred	Left ventricular end-diastolic diameter and LVEF	<i>t</i> -test/Wilcoxon rank-sum test
Clinical endpoint events	Improvement occurred	Clinical-endpoint event rate	Log-rank test
Safety outcomes			
AEs, SAE		Percent and cases of AEs and SAEs	Chi-squared test/Fisher's exact test
Vital signs		Change value relative to baseline	<i>t</i> -test/Wilcoxon rank-sum test

6MWD, 6-min walk distance; NT-proBNP: N-terminal pro-B-type natriuretic peptide; NYHA, New York Heart Association; MLHFQ, Minnesota Living with Heart Failure Questionnaire; LVEF: left ventricular ejection fraction; AE, adverse event; SAE: serious adverse events.

We chose the 6MWD test to assess the functional capacity and exercise tolerance in patients with CHF. The 6MWD test is a simple and convenient test that requires no special equipment or advanced training for physicians and is well tolerated by patients. Although the plasma level of NT-proBNP is used widely in the differential diagnosis, risk stratification, and prognostic evaluation of CHF, use of ARNIs can affect the NT-proBNP level significantly (Yancy et al., 2017). Therefore, we chose the plasma level of NT-proBNP as a secondary outcome, and use sensitivity analyses to adjust the effect of ARNI on the outcomes. Furthermore, we have applied metabolomics and proteomics analyses to explore the therapeutic biomarkers of GXST in treating CHF, and to improve CHF therapy by providing an objective basis for precise treatment.

Our trial has three main limitations. First, this trial will be conducted in five provinces of China, and whether similar effects are obtainable in other regions and ethnic groups are unknown. Second, the treatment period will be 12 weeks with 40 weeks of follow-up, which is relatively short. Due to the limited time frame, the potential roles of GXST in reducing overall mortality and major vascular events over the long-term are uncertain, and further data on long-term clinical effect and safety will be needed. Third, GXST used in this trial is designed for the treatment of CHF with blood stasis syndrome, so the findings may not apply to other CHF syndromes.

## Ethics and Dissemination

The Research Ethics Committee of the Second Affiliated Hospital of Zhejiang Chinese Medical University (Hangzhou, China) has

approved the study protocol (2019-Y-003-02). All participating centers have received study approval from their local ethics committee. All participants will provide voluntary written informed consent after a full discussion about the potential benefits and risks before participation. This study will be published in scientific journals to target a wide range of groups, and presented at national conferences in the field of CHF. Study results will also be sent to study participants and disseminated to researchers, as well as the general public through courses, presentations, and the Internet, regardless of the magnitude or direction of influence.

## ETHICS STATEMENT

The Research Ethics Committee of the Second Affiliated Hospital of Zhejiang Chinese Medical University has approved this study (No. 2019-Y-003-02). The patients/participants provided their written informed consent to participate in this study.

## AUTHOR CONTRIBUTIONS

HW, SH, and FW designed the study. YW and JX contributed equally to the study, and conceptualized the study design and wrote the manuscript. LZ and JY modified the manuscript. YP, YH, and CL are responsible for the quality control of the test drug. LD, YX, JC, HZ, and LY participated in the modification of the study protocol. PZ and JY designed the method for statistical analyses. All authors read and approved the final version of the manuscript.

## FUNDING

This project is supported by the National Key R&D Program of China (2017YFC1700400, 2017YFC1700403) and the National Natural Science Foundation of China (81630105).

## ACKNOWLEDGMENTS

We acknowledge the help and contributions of the research assistants, cardiologists, experts, and investigators in each

participating center. We thank the patients with CHF for participating in this trial. This manuscript has been released as a preprint at Research Square ([www.researchsquare.com](http://www.researchsquare.com)) (Wang et al., 2020).

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2020.571106/full#supplementary-material>.

As a well-established multidrug combinations schema, traditional Chinese medicine (herbal prescription) has been used for thousands of years in real-world clinical settings. This paper uses a complex network approach to investigate the regularities underlying multidrug combinations in herbal prescriptions. Using five collected large-scale real-world clinical herbal prescription datasets, we construct five weighted herbal combination networks with herb as nodes and herbal combinational use in herbal prescription as links. We found that the weight distribution of herbal combinations displays a clear power law, which means that most herb pairs were used in low frequency and some herb pairs were used in very high frequency. Furthermore, we found that it displays a clear linear negative correlation between the clustering coefficients and the degree of nodes in the herbal combination network (HCNet). This indicates that hierarchical properties exist in the HCNet. Finally, we investigate the molecular network interaction patterns between herb related target modules (i.e., subnetworks) in herbal prescriptions using a network-based approach and further explore the correlation between the distribution of herb combinations and prescriptions. We found that the more the hierarchical prescription, the better the corresponding effect. The results also reflected a well-recognized principle called “Jun-Chen-Zuo-Shi” in TCM formula theories. This also gives references for multidrug combination development in the field of network pharmacology and provides the guideline for the clinical use of combination therapy for chronic diseases.

**Keywords:** network pharmacology, complex network, herb combination network, clinical prescription, network pattern

## INTRODUCTION

Human disease phenomenon is complicated due to its roots from the disturbance of diverse pathogens on the hierarchical organization of the human life system interacting with the complex natural and social environment. Therefore, finding effective clinical treatments for chronic complex diseases such as diabetes, heart disease, stroke, and cancer is extremely difficult. Furthermore, due to the individualized phenotypes and genotypes incorporated in distinct persons, adverse drug reactions (ADRs) or drug side effects have increasingly become a major health issue when using targeted drugs for patients in real-world clinical settings (Duke et al., 2011; Smyth et al., 2012; Aagaard and Hansen, 2013). For example, there are 106,000 deaths and 2.2 million serious events caused by ADRs in the United States each year (Lazarou et al., 1998), which were once considered as a leading cause of death in the United States (Lazarou et al., 1998). For elderly patients, the ADR is even serious due to the need for multiple prescribed drugs for chronic disease comorbidities (Routledge et al., 2004). However, this problem cannot be well addressed since, for modern drug discovery, the safety of new agents only can be known with certainty if a drug has been on the market for many years. Drugs were only used for selected populations and in limited periods (Lasser et al., 2002) before knowing their safety with great certainty.

To improve the effectiveness of treatment for patients with chronic diseases and comorbidities and the prevention of the emergence of resistance to individual drugs, combination therapy is a new trend in real-world clinical research (Luzuriaga et al., 1997; Mottonen et al., 1999; Wald et al., 2009; Ascierto and Marincola, 2011; Yardley, 2013), which has been effective in the treatment of HIV as well as certain forms of leukemia. Simultaneous combination therapy like two-drug therapy and triple therapy holds huge promise for cancer treatment from the point of cancer cell evolutionary dynamics (Bozic et al., 2013). However, the mechanism and principle underlying effective combination therapy is still a mystery waiting to be investigated (Pritchard et al., 2013).

As a kind of classical combination therapy, traditional Chinese medicine (TCM), which includes multiple herbal ingredients, has been used by Chinese practitioners for thousands of years in real-world clinical settings. Pioneer research (Wang et al., 2008) has already shown that TCM clinical herbal prescription, called formula, consists of both principal and adjuvant components to yield synergy for disease treatment. This demonstrates the molecular mechanism of a well-recognized principle called “*Jun-Chen-Zuo-Shi*” (JCZS) (He et al., 2015; Duan et al., 2018) in TCM formula theories, which illustrates that a well-organized formula should consist of multiple herbal ingredients with differentiated roles like principal role and adjuvant role. Some adjuvant components should be considered to facilitate the delivery of the principal element to the disease site in the body. In real-world clinical herbal prescriptions, some of these have a good therapeutic effect, while others have a poor therapeutic effect. However, the reason why some prescriptions are more effective than others remains to be studied, and there is still a lack of appropriate method to evaluate whether many herbs grouped in certain formulae

are suitable for the treatment of specific disease conditions. Therefore, investigation of herbal combination regularities in herbal prescription will benefit the pharmacological understanding of TCM treatment and discovery of novel combination drugs (Li et al., 2010b). In this study, we proposed a network-based approach to investigate the clinical principle of herbal prescribing and quantify the molecular network interactions between herb target modules of a given clinical prescription in the context of the human protein-protein interaction (PPI) network. In addition, we further investigate the correlation between the organization degree of herbal combinations in clinical prescription and their underlying molecular network interaction closeness, which might partially elucidate the organization principle of JCZS in TCM formula theories.

## MATERIALS AND METHODS

### Herbal Prescription Dataset

To investigate the regularities of herbal combinations in TCM clinical herbal prescriptions, we collected five different datasets from real-world TCM clinical encounters. These five datasets are described in brief in **Table 1**.

Outpatient formula data was extracted from the outpatient encounters with one and a half years in one well-recognized general TC hospitals in Beijing, China. The data includes 531,284 different clinical formulae that were used by hundreds of TCM physicians for the management of various diseases (e.g., diabetes, CHD (coronary heart disease), stroke, cancer, chronic gastritis, insomnia, and menopause syndrome) in outpatient encounters. The other four datasets are from inpatient clinical cases, which particularly were prescribed for the patients with type 2 diabetes, CHD, qi deficiency, and blood stasis, respectively. The above-mentioned two diseases (i.e., type 2 diabetes and CHD) are major chronic diseases (He et al., 2019) treated by TCM in real-world clinical settings. The other two syndromes, namely, qi deficiency and blood stasis, are two popular TCM diagnoses for various diseases (Wang et al., 2017). These four inpatient datasets are from a TCM clinical data warehouse (Zhou et al., 2010), which collected structured electronic medical record data from real-world clinical settings in about ten top-level TCM hospitals or wards mostly located in Beijing, China. We calculated the distribution of the number of herbs in one formula for each of the five datasets that represent five clinical prescriptions. The average number in each of the five clinical prescription datasets is 13.43 (outpatient), 9.66 (qi deficiency), 11.6 (diabetes), 12.03 (CHD), and 10.13 (blood stasis). We see that most clinical herbal prescriptions have 5–20 different herbs (over 95% of the five clinical formula datasets have 5–20 herbs) and have more than ten herbs averagely, which showed that clinical herbal prescription is a kind of particular multi-ingredients or drug therapy.

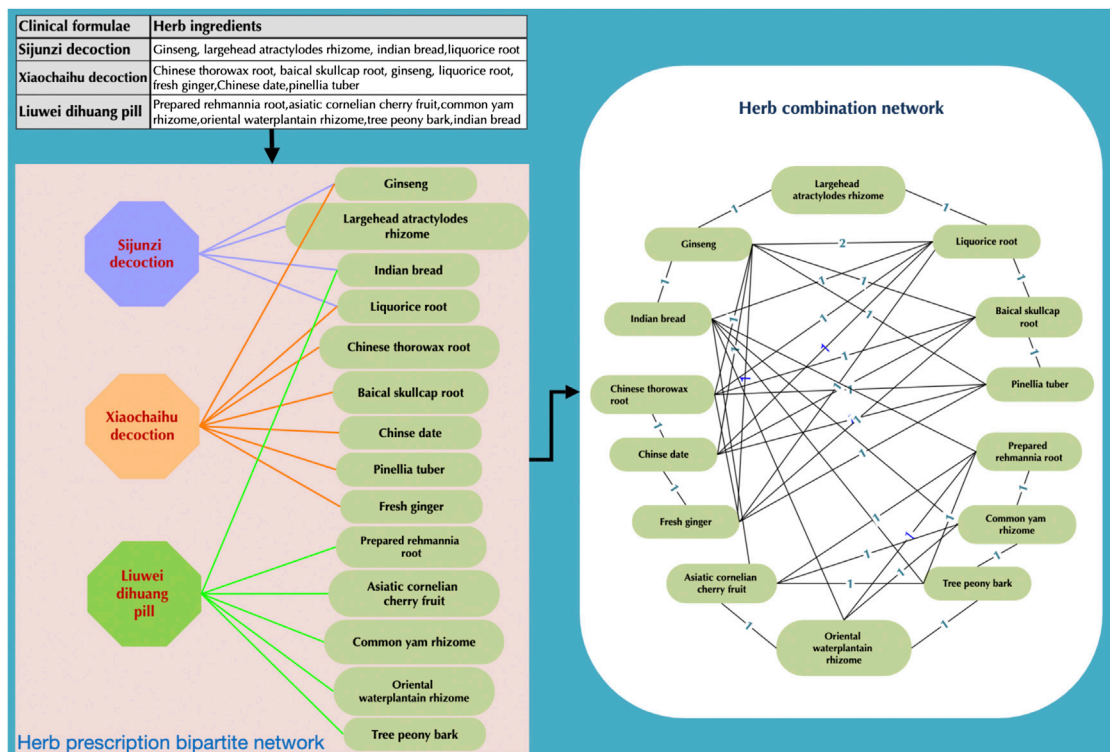

### Construction of Herbal Combination Network

Considering a clinical formula with multiple herbal ingredients, we can construct a bipartite graph (**Figure 1**) which has clinical formulae and herbs as two types of nodes. The herbal

**TABLE 1 |** The outline information of five different data sets (in columns) used for analysis.

	Outpatient	Diabetes	CHD	Blood stasis	Qi deficiency
Total number of formulae	531,284	21,626	9,054	2,802	2,393
Distinct number of herbs	576	492	436	439	422
Average frequency of herbs	14,230.02	551.57	270.51	70.65	59.98
Average number of herbs in one formula	15.43	12.55	13.03	11.07	10.58

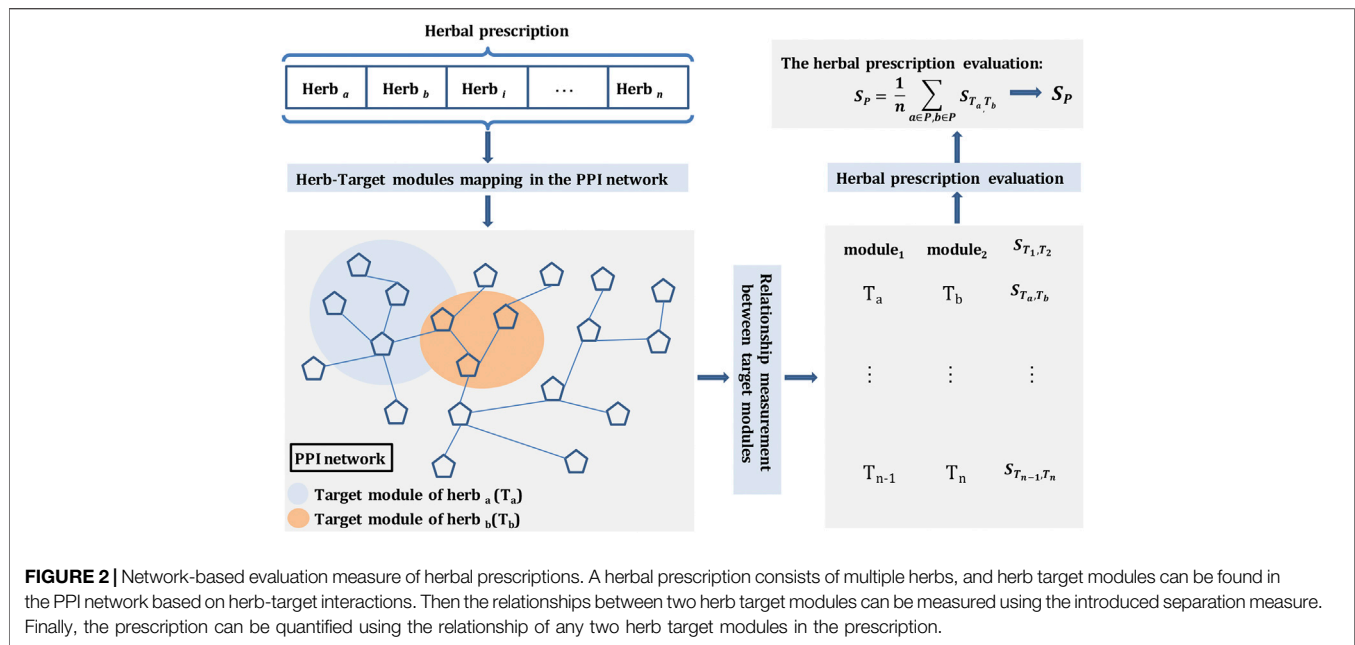

**FIGURE 1 |** Construction of the bipartite network of TCM clinical formulae. (Table in the left) Three records of clinical formulae, for instance, which include their corresponding herbs. (Left graph) The corresponding bipartite graph of these three clinical formulae, where octagons and oval rectangles correspond to clinical formulae and herbs, respectively. (Right) The herbal combination network where two herbs are connected if they are involved in the same clinical formula. Moreover, the link weight of two herbs corresponds to the number of clinical formulae cooccurring in both herbs.

combination network was constructed by considering herb pairs used in one specific clinical formula if they have been prescribed in more than one clinical formula. Then we would generate links (edges) between these herb pairs. This also means that we would generate a complete graph with each herb in one clinical formula. While a large number of clinical formulae are considered, we can generate a herbal combination network (HCNet, see **Figure 1**) with nodes representing herbs (herbal ingredients) and edges with a weight representing prescribing cooccurrence in clinical formulae. If two herb pairs are used more frequently than other herb pairs, they would be having a higher weight than other pairs. Furthermore, to compare the patterns of real-world data to those of randomly generated data, we generated the corresponding simulation data with random permutation by using Fisher

shuffling (Fisher and Yates, 1948) to get random herb ingredients from herb dictionary to a clinical formula.

## Network Topological Measurements

To investigate the topological properties of HCNet, we use node degree, clustering coefficient, and link weight distribution measurements, which have been widely used in complex network-related studies. The degree of a node is the number of edges incident to the node, which also means the number of herbs combined with an herb in the HCNet. Clustering coefficient evaluates the link density of the neighborhood of a node, which would be near one if most of the nodes were linked in the neighborhood of a node. We used local clustering coefficient of the undirected network to

calculate for each node in HCNet, which is calculated as follows:

$$C_i = \frac{2|e_{jk} : v_j, v_k \in N_i, e_{jk} \in E|}{k_i(k_i - 1)} \quad (1)$$

in which  $N_i$  is the node set of the neighborhood of a node  $v_i$  in a graph  $G(V, E)$  and  $k_i$  is the degree of the node  $v_i$ . As a weighted network, HCNet has weight  $w_{ij}$  between nodes  $v_i$  and  $v_j$ , which represents the combination occurrence of herb pairs. We use link weight distribution  $P(w)$ , which denotes the possibility of a link to have a weight  $w$ , to investigate the herbal combination behaviors in HCNet and a given single clinical formula.

## Network-Based Measures of Molecular Interactions Among Herbs in Prescriptions

As a kind of classical combination therapy, the herbal prescription consists of multiple herbs to treat clinical diseases. Therefore, we adopted a molecular network-based measurement (Menche et al., 2015; Cheng et al., 2019) to quantify the degree of molecular interactions of herbal combinations in each prescription through calculating the average shortest path length between herb target modules (molecular subnetwork of targets) in the context of human PPI network (Figure 2).

Firstly, we measured the network relationship of herb target modules  $T_a$  and  $T_b$  in the prescription using the recently introduced separation measure (Menche et al., 2015) to reflect their target localization (Eq. 2):

$$S_{T_a, T_b} = \langle d_{T_a, T_b} \rangle - \frac{\langle d_{T_a, T_a} \rangle + \langle d_{T_b, T_b} \rangle}{2} \quad (2)$$

in which  $T_a$  and  $T_b$  represent the target modules of herb  $a$  and herb  $b$ , respectively.  $S_{T_a, T_b}$  compares the mean shortest distances

between proteins within each herb,  $d_{T_a, T_a}$  and  $d_{T_b, T_b}$ , to the shortest distances  $d_{T_a, T_b}$  between herb  $a$  and herb  $b$  target pairs. If proteins are associated with both  $a$  and  $b$ ,  $d_{T_a, T_b} = 0$ . For  $S_{T_a, T_b} < 0$ , the targets of the herb  $a$  and herb  $b$  are located in the same network neighborhood, while for  $S_{T_a, T_b} \geq 0$ , the two herb targets are topologically separated.

Then, we quantified the herbal prescription using the average of  $S$  value between any two herb target modules in the prescription (Eq. 3):

$$S_P = \frac{1}{n} \sum_{a \in P, b \in P} S_{T_a, T_b} \quad (3)$$

in which  $S_P$  represents the herbal prescription score and  $n$  is the number of herbs in the prescription.

## Hierarchical Organization Measure of Clinical Prescriptions

To further explore the associations between the hierarchical property of prescriptions and the molecular network correlations of the herb ingredients in prescriptions. We use entropy to measure the hierarchical organizing degree of a given prescription in terms of the distribution of herbal combinations.

After we obtained the herbal combinations of each prescription and all the prescription groups in our study (i.e., four types of clinical prescriptions), we could record each herbal combination with its weight and compute the distribution of the weight of herbal combinations for each prescription with regard to the global distribution of herbal combinations of each type of clinical prescriptions. Specifically, according to the weight distribution of herbal combinations of a given clinical prescription dataset, we divided the weight range (e.g., from 1

**TABLE 2 |** The basic information of five different HCNets used for analysis.

	Outpatient	Diabetes	CHD	Blood stasis	Qi deficiency
Total number of nodes	576	492	436	439	422
Total number of edges	120,619	34,824	29,381	19,323	18,186
Average degree in network	419.82	142.56	135.78	89.64	87.39
Edge density	0.73	0.29	0.31	0.20	0.21
Average clustering coefficient	0.85	0.61	0.63	0.51	0.51

to 3,000) into four intervals of some specific value (i.e., 300 in our study). Then using the list of herbal combinations and their weights, we could further calculate the probability of herbal combinations belonging to each interval of the corresponding prescription group for a given prescription. Next, we quantified the hierarchical degree of a prescription based on the entropy measure (Shannon, 1948; Wallace et al., 2019) as follows (Eq. 4). The larger the entropy value, the stronger the hierarchical organization degree for a given prescription, which would medically mean a more systemically organized herbal prescription with hierarchical roles (i.e., tend to prescribe herbal combinations in one formula with diverse global weight ranges in each group). The higher the entropy value, the more the hierarchical organization of the prescription in terms of diverse roles.

$$E = - \sum_{i=1}^n p_i \log p_i \quad (4)$$

where  $n$  represents the number of weight intervals and is set to four in our analysis and  $p_i$  represents the probability of the herbal combinations in each interval and is calculated as follows (Eq. 5):

$$p_i = \frac{N_i}{\sum_{i=1}^n N_i} \quad (5)$$

in which  $N_i$  represents the number of herbal combinations in weight interval  $i$ .

Therefore, we could calculate entropy for all prescriptions for each type of the clinical prescriptions. Next, for each type of the clinical prescriptions, we calculate the Pearson Correlations Coefficient (PCC) between its entropy value and  $S_p$  score to evaluate the statistical correlation between hierarchical degree and molecular network interactions of the herbal combinations for each prescription group.

## RESULTS

### Herb Combination Networks

According to the clinical formulae-herb relationships in outpatient, type 2 diabetes, CHD, qi deficiency, and blood stasis, we constructed five types of herbal combination networks in which nodes represented the herbs and edges represented the cooccurrence of herbs in clinical formulae. These five HCNets were described in brief in Table 2.

### Hierarchical Organization of Herbal Combinations in Clinical Prescriptions

To investigate the hierarchical properties of herbal combination networks, we evaluate the relationship between the clustering coefficient and node degree in the network. We performed experiments on four types of clinical prescriptions, and the results were shown in Figure 3.

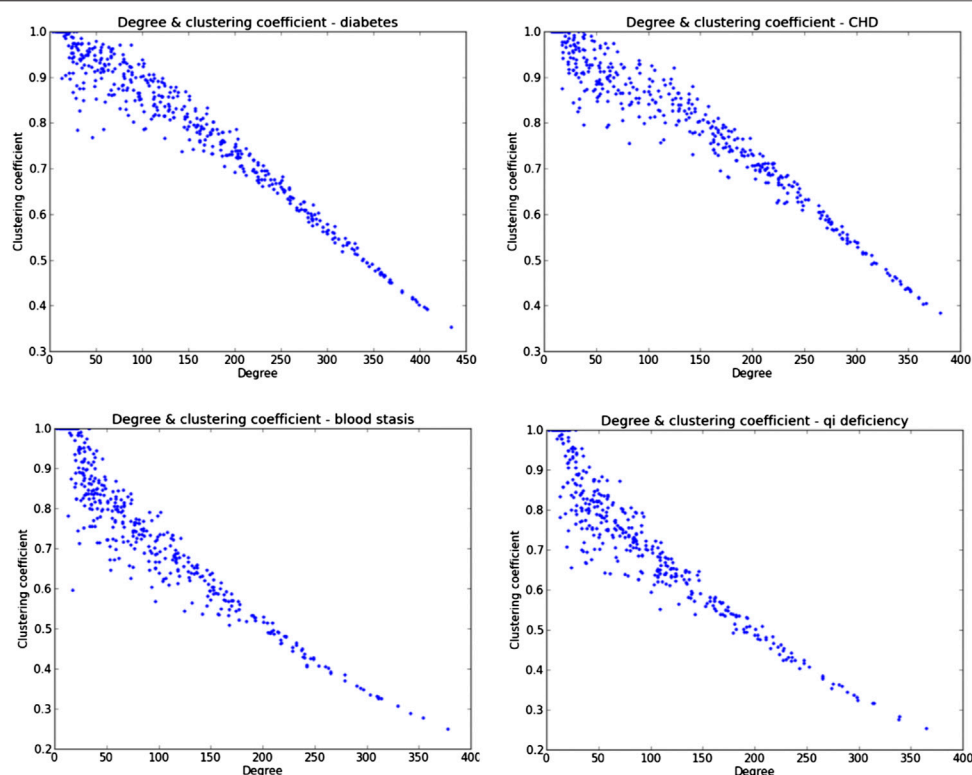

We found that it displays a clear linear negative correlation between the clustering coefficients and the degree of nodes. It was found that, in real networks, clustering coefficients decrease with the vertex degree, which has been taken as a signature of the network hierarchical structure (Soffer and Vazquez, 2005). Therefore, this indicates that hierarchical properties exist in the herbal combination networks. Next, we would further investigate the scaling properties of HCNets according to node degree and weight distribution.

### Scaling Heterogeneity of Degree and Weight Distribution

To investigate the scaling properties of HCNets, we evaluate the node degree distribution and link weight distribution in the network. It showed that herbal combinations in clinical formulae are obeying a scaling property, which has significantly departed from Poisson distribution (Figure 4). Although the node degree distribution in HCNets is not power law (this is obviously rational because the capacity of herb dictionary is fixed and thus increase of nodes is not met in HCNets), it showed a significant heterogeneous scaling for different nodes. The degrees of herb nodes scale from less than ten (e.g., 5) to several hundred (e.g., 550), whose range is much wider than the corresponding Poisson distribution.

Furthermore, it is interesting that the link weight distribution of HCNets is a clear power law, in which several herbal combinations are prescribed in high frequency while most of the other herbal combinations have very low frequency (Figure 5). This means that, in clinical practice, the prescription of herbal combinations for treatment is nonrandomly chosen and preferentially used by TCM physicians for the disease management of individualized patients.

We find that herbal combinations in four clinical formulae are obeying a scaling property (Figure 5), and it also means that the distribution of herbal combination has a hierarchical property. Next, we will calculate the degree of interaction between the targets in the context molecular network in herbal combinations and investigate whether frequently used herbal combinations hold close pharmacological effects.

**FIGURE 3 |** The relationship between clustering coefficient and node degree in HCNets. It indicated a clear linear negative correlation between the clustering coefficients and the degree of nodes.

**FIGURE 4 |** The degree distribution of herb in five HCNets. Four HCNets, namely, blood stasis, qi deficiency, CHD, and diabetes, have a similar distribution. However, the degree of outpatient HCNets obviously has a different distribution, of which most nodes have very high degrees (e.g., 500 more connections) while few nodes have low degrees (e.g., less than 20). In contrast to the real data, the node degrees in the networks derived from randomly shuffled data have a Poisson distribution for qi deficiency and blood stasis datasets, which have comparatively less clinical prescription samples.

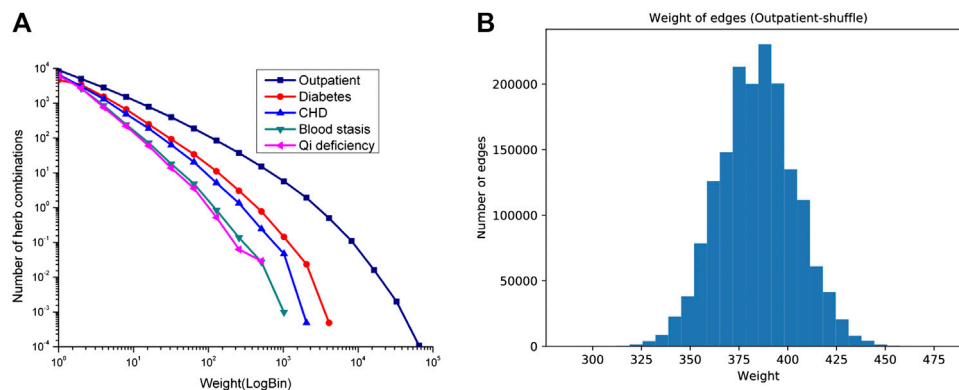

## Molecular Network Interaction Patterns of Herbal Combinations

To evaluate the underlying pharmacological mechanisms of herbal combinations in clinical prescriptions, we quantified the network correlations between the targets of the herbal ingredients of the four types of clinical prescriptions for diabetes, CHD, qi deficiency, and blood stasis (see Methods section, *Network-Based Measures of Molecular Interactions Among Herbs in Prescriptions*).

We collected the protein targets of herbs in prescriptions from HIT database (Ye et al., 2011), which is a comprehensive and fully curated database of herbs and their corresponding protein targets. Due to the lack of target information for some herbs according to HIT database, at the same time, to assure each prescription should contain at least two herbs in the analysis. Finally, we quantified the molecular network correlations of those herbs in 21,566, 9,051, 2,392, and 2,801 prescriptions from diabetes, CHD, qi deficiency, and blood stasis, respectively, in which the number of herbs containing known targets is greater than or equal to two. The mean and standard deviation (std) of  $S_p$  scores of four types of prescriptions were shown in Table 3.

In order to give a benchmark reference for the four types of clinical prescriptions, we selected the classical prescriptions of TCM, Treatise on Exogenous Febrile Disease (TEFD), for comparative experiments. The TEFD contained 113 classical prescriptions in total, of which 85

**FIGURE 5 |** Link weight distributions in HCNets. **(A)** The empirical distribution of five clinical datasets. **(B)** The distribution of random permuted samples of outpatient dataset. The empirical distributions of five real-world clinical formulae display mainly a power law. The weights of links scale from one to tens of thousands that form a wide range. However, the link weight of the corresponding random dataset of outpatient case obeys Poisson distribution with a mean weight, not more than 400. In addition, we also analyzed the random cases of the other four diseases (**Supplementary Figure S1**), the link weight of the corresponding random dataset of diabetes and CHD case obeys Poisson distribution with mean weight not more than 15, and the link weight of the corresponding random dataset of qi deficiency and blood stasis case obeys seminormal distribution with a narrow weight scale.

**TABLE 3 |** The mean and standard deviation of  $S_p$  scores of four types of clinical prescriptions and TEFD.

Type	Diabetes	CHD	Qi deficiency	Blood stasis	TEFD	Random
Mean	-0.03	-0.05	-0.09	-0.11	-0.09	0.16
Std	0.32	0.33	0.28	0.28	0.15	0.08

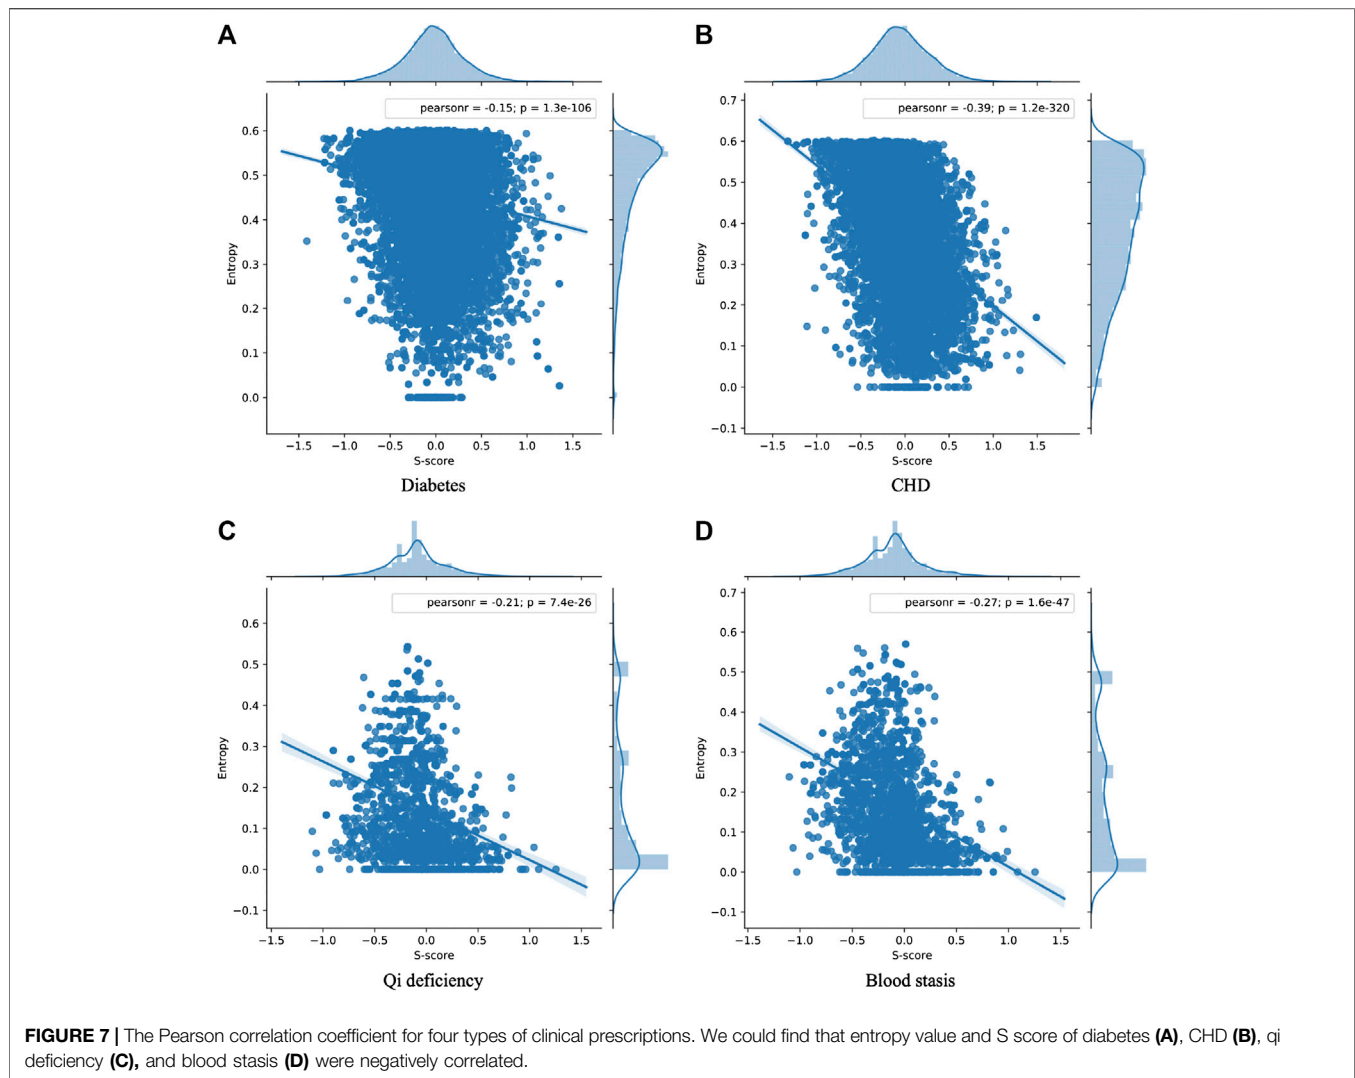

prescriptions with associated targets were selected for quantification. The number of herbs containing known targets is greater than or equal to two in 85 prescriptions. We collected the classical prescriptions from TEFD as a representative prescription benchmark with high-quality herbal combinations because most prescriptions in TEFD have been widely used in TCM clinical practice for thousands of years (Li et al., 2010a; Wang and Xiao, 2010; Zhang et al., 2010). Therefore, in

general, we will consider that the herbal combinations held in the prescriptions from TEFD give a better example than those from the above four types of clinical prescriptions.

Next, we quantified the degree of interactions between the herbal combinations in 85 prescriptions from TEFD in the context of the human PPI network (**Figure 6**). For comparison of random expectations, we reshuffled (1,000 random permutations) the herbs in each prescription by using the Fisher-Yates method (Fisher and Yates, 1948). Finally, we found that the  $S_p$  scores of prescriptions in TEFD were significantly lower than those of random prescriptions ( $p = 2.46718 \times 10^{-27}$ ). We found that 92% of real prescriptions in TEFD had lower  $S_p$  scores compared to random prescriptions, and  $S_p$  scores of 79% of real prescriptions were less than 0, but  $S_p$  scores of all random prescriptions were greater than 0. And we found that the mean  $S_p$  score in TEFD was -0.09, but the random was 0.16, indicating that the target modules of herbs in a prescription were closely related

**FIGURE 6 |** The  $S_p$  scores of prescriptions in Treatise on Exogenous Febrile Disease. We ranked the prescriptions in descending order according to the number of herbs and compared the  $S_p$  score distribution between prescriptions in TEFD and random prescriptions. The  $S_p$  scores of prescriptions in TEFD were shown as blue columnar and random prescriptions were shown as orange columnar.

to each other in the context of the molecular network. To further evaluate the quality of herbal combinations of current clinical prescriptions, with similar calculation methods, we obtained the  $S_p$  scores of each prescription in the four clinical prescriptions datasets. The results showed that the mean of  $S_p$  scores of all four clinical prescriptions was less than 0. This means that most real-world clinical prescriptions would tend to have a high degree of herbal combinations as good as those of TEFD prescriptions. It is practical and reasonable that, in TCM clinical settings, most practitioners would directly adopt the classical prescriptions or use the classical prescriptions as a basic therapeutic framework for clinical treatments (Duan et al., 2018; Chen et al., 2019).

## Molecular Correlations of Hierarchical Herbal Combinations in Clinical Prescriptions

We have found that the weights of herbal combinations scale from one to tens of thousands that form a wide range and the distribution of herbal combinations has a hierarchical

organization property in our previous analysis. Meanwhile, we also obtained the molecular measures of herbal combinations in prescriptions in terms of their molecular interactions. Next, we would expect the potential associations between these two indexes for a given prescription (see Methods section, *Hierarchical Organization Measure of Clinical Prescriptions*).

To test the assumption, we performed a Pearson correlation analysis on its entropy value and  $S_p$  score. The PCC and  $p$ -value were shown in **Figure 7**. We could find that entropy value and  $S_p$  score of clinical prescriptions were negatively correlated with PCC ranging from  $-0.15$  to  $-0.39$  (**Figure 7A**,  $p = 1.3e-106$ ; **Figure 7B**,  $p = 1.2e-320$ ; **Figure 7C**,  $p = 7.4e-26$ ; **Figure 7D**,  $p = 1.6e-47$ ) for the four clinical herbal prescriptions. This indicated that the larger the entropy value of a given prescription, the smaller the  $S_p$  score of the prescription. Therefore, it indicated that the more the hierarchical herbal combinations were involved in a prescription, the more the connected molecular networks would be found between the targets of the herbal ingredients in a given prescription. The results also reflected exactly a well-recognized principle called JCZS in TCM formula theories,

which illustrates that a well-organized formula should consist of multiple herbal ingredients with differentiated therapeutic roles for targeted disease conditions.

## DISCUSSION AND CONCLUSION

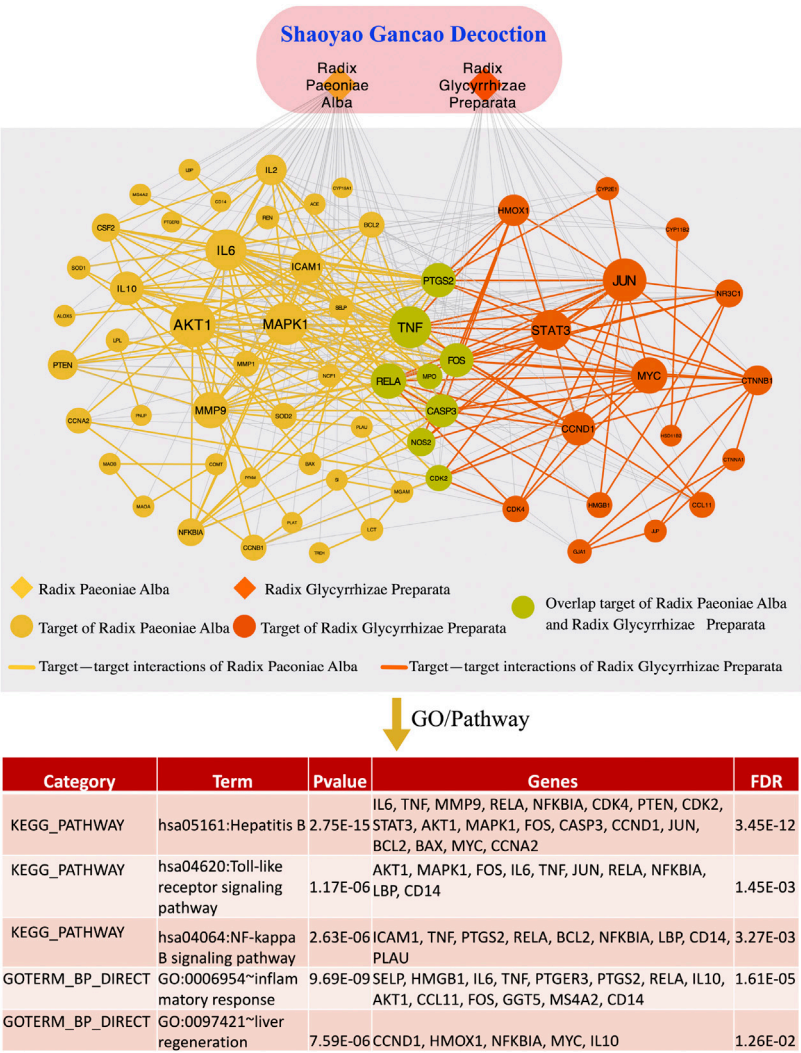

TCM herbal prescription which usually includes tens of different herbal ingredients as a single therapeutic formula is the main kind of intervention for chronic disease treatment in China (Qi et al., 2013). Typically, it is a kind of combination therapies with complicated underlying molecular pharmacological mechanisms (Chan et al., 2012). Combination therapies offer promising therapeutic solutions for complex disease treatments, from hypertension, COPD, and cancer with potential high efficacies and lower adverse effects (Yki-Jarvinen, 2001; Margulies and Hicks, 2009). However, the clinical organization principle and its underlying network mechanisms still need to be elucidated. TCM herbal prescription has been widely used as a combination therapy in clinical settings (He et al., 2012; Liu et al., 2013; Duan et al., 2018) by adhering to empirical clinical regularities, such as JCZS (He et al., 2015; Duan et al., 2018), and frequently used herbal combinations. Connecting those clinical regularities with the molecular network patterns related to the targets of herbal ingredients would potentially improve the pharmacological understanding of the empirical rules to develop more effective combination therapies.

The well-recognized principle called JCZS in TCM formula theories means that a well-organized formula should consist of multiple herbal ingredients with different therapeutic roles (Wang et al., 2008). This would imply the existence of a hierarchical organization of herbal combinations and the underlying network mechanisms of herbal ingredients for a well-established set of clinical prescriptions (e.g., the herbal prescriptions in TEFD). Here, we investigated the clinical regularities of herbal combinations involved in each prescription in terms of network topological patterns and applied a network-based measurement (Cheng et al., 2019) to quantify the molecular network interactions between herb target modules in a given herbal prescription. Our results indicate that there do exist clinical prescription rules to choose herbal combinations in a clinical prescription, which can be displayed by the scaling and hierarchical topological properties of the herbal combination network. Specifically, a clinical prescription would tend to consist of both highly used herbs or herbal combinations and less used herbs or herbal combinations as a whole formula for disease treatment. This might resemble to the well-established prescription principle (i.e., JCZS) for TCM herbal prescriptions, which implies a good prescription need include herbs with different pharmacological effects. Furthermore, we found that the network-based measure of high-quality drug combinations (Cheng et al., 2019) could be used for evaluating the molecular interaction closeness of both herbal combinations and prescriptions. For example, a classical formula in TEFD, “Shaoyao Gancan decoction” (SGD), contains two herbs: Radix Paeoniae Alba (hRPA) and Radix Glycyrrhizae Preparata (hRGP), which has been further prescribed as core herbal combinations in many classical formulae [e.g., Mahuang Shengma decoction (Fan et al., 2011), Xiaoqinglong decoction (Wang et al., 2018), Gegen

decoction (Chai et al., 2020), Chaihu Guizhi decoction (Li et al., 2019), and HuangQin decoction (Dai et al., 2018)]. According to the molecular network-based measurement, we found that the  $S_p$  score of SGD was -0.03 (the random expectation was 0.03). This means that close interactions are involved between the target modules of the two-member herbs in SGD. Actually, by identifying the herb-target associations from HIT database, we found that there are 47 and 24 potential targets of hRPA and hRGP, respectively. These two target sets each form a rather dense PPI subnetwork (we call it a module, **Figure 8A**). There are eight common targets shared by hRPA and hRGP, such as TNF, CASP3, RELA, and NOS2. Meanwhile, 75 interactions exist between the target modules of hRPA and hRGP (with 0.113 network density). We further used DAVID (Huang Da et al., 2009) to obtain the enriched GO and KEGG pathways (**Figure 8B**). The results showed that SGD enriched the inflammation-related pathways such as Hepatitis B, NF- $\kappa$ B, and TLRs (Mantovani, 2010) and liver-related GO annotations such as liver regeneration, which could partially explain the clinical effects of SGD for treating liver disorders and anti-inflammatory in clinic settings (Bi et al., 2014).

Overall, we have been working to investigate the network topological regularities and the underlying molecular network mechanisms of herbal prescriptions, and we hope that our work and findings for clinical prescriptions would give references for understanding of the principles and molecular mechanisms of multidrug combinations (Dawson and Carragher, 2014; Cheng et al., 2019; Zhang et al., 2019) after fully digging the hidden knowledge underlying the effective multiple therapies (e.g., Chinese herbal prescriptions).

This study has several limitations. First, since it is not aiming to predict the specific knowledge on pharmacological effects of specific prescriptions or drugs, unlike the study on pharmacological research of a given herbal prescription or predicting a novel target, it would be difficult for us to design a straightforward wet-lab experiment to validate the rationality of organizing herb combinations in a good clinical prescription. However, large-scale wet-lab experiments on validating the differentiated molecular patterns between high frequently used herbal combinations and rarely used herbal combinations should be designed and performed in further research to improve the reliability of the network analysis results. Second, currently, we only used HIT database as the herb-target associations for molecular network-related analysis, which would limit the number of herb-target associations and thus influence the generalization of our analysis. We would integrate other well-established network pharmacological databases, such as ETCM (Xu et al., 2019) and SymMap (Wu et al., 2019) to further validate the underlying molecular network regularities of herbal prescriptions. Third, due to the complexity of clinical conditions of individualized patients, it is important that the prescribed herbal treatments for specific patients should be evaluated by the outcomes and finally help figure out the true high-quality clinical herbal prescriptions from a large-scale clinical dataset. Therefore, we would extend the evaluation measure together with disease conditions to find good herbal prescriptions with potential effectiveness. However, without the related in vitro or in vivo experimental validations, we believe that

**FIGURE 8 |** The network molecular associations for the only two herbs, namely, Radix Paeoniae Alba and Radix Glycyrrhizae Preparata in the Shao Yao Gancao decoction, (SGD). **(A)** Target modules of the two herbs and their interactions. Yellow nodes represent the targets of Radix Paeoniae Alba, and red nodes represent the targets of Radix Glycyrrhizae Preparata, while the edges represent the interactions between the targets in the PPI network. Nodes with green color represent overlapping targets of two herbs. **(B)** The related gene ontology and pathways of target modules of the two herbs.

our current research could deliver certain potential insights for the field of network pharmacology and combination drug development. By evaluating the underlying molecular network patterns of the herbal combinations in herbal prescriptions, it would be promising to propose a novel network pharmacological approach to investigate the inherent network mechanisms (e.g., organizing of herbal combinations) of a given clinical prescription and thus help design combination therapies with better effectiveness for disease treatment.

The purpose of this study was to explore the effect of the traditional Chinese medicine Fuyou formula on precocious puberty (PP). The Fy formula may exert an effect in female rats with PP and GT-7 cells through the GPR54/GnRH signaling pathway. To confirm the effect of the Fy formula on PP through the GPR54/GnRH signaling pathway, we first treated GT1-7 cells with the Fy formula and observed changes in the expression of related genes and proteins and in GnRH secretion. Then, we randomly divided young female Sprague-Dawley rats into the control group, model group, leuporelin group and the Fy formula group. A PP model was established by injection of danazol on postnatal day 5, and the Fy formula was administered on PND15. The time of vaginal opening, the wet weights of the ovary and uterus, serum hormone levels and the expression of hypothalamic-related genes were observed. We found that the Fy formula delayed vaginal opening, decreased the wet weights and coefficients of the ovary and uterus, decreased the levels of serum hormones (E2, follicle-stimulating hormone and luteinizing hormone) and the cellular GnRH level, and downregulated the gene expression of Kiss1, GPR54 and GnRH in the hypothalamus and the gene and protein expression of GPR54 and GnRH in GT1-7 cells. In conclusion, the Fy formula may alleviate PP via the GPR54/GnRH signaling pathway.

**Keywords:** traditional Chinese medicine, Fy formula, precocious puberty, GPR54/GnRH, hypothalamic

## INTRODUCTION

Precocious puberty (PP) is one of the most common endocrine diseases in children. PP is commonly defined as puberty that starts before age eight in Chinese girls and age nine in Chinese boys (Bradley et al., 2020), before age 7.5 in African-American and Hispanic girls, and before age eight in Caucasian girls (Herman-Giddens, 2006). The age of pubertal onset based on thelarche has decreased by almost 3 months per decade from 1977 to 2013 (Eckert-Lind et al., 2020). PP is characterized by early onset of puberty, such as early development of secondary sexual characteristics, rapid maturation of bones and acceleration of growth, and early menarche, early closure of the epiphyses, which may lead to poor social adaptability, psychological stress, emotional disorders, risky behaviors, a shorter adult height and future breast and ovarian cancer

(Abbasi, 2019; Fu et al., 2020). PP can be divided into central precocious puberty [CPP, gonadotropin-releasing hormone (GnRH)-dependent] and peripheral precocious puberty (PPP, GnRH-independent). The incidence of CPP in China is approximately 1% (Luan et al., 2007). The male to female ratio of patients with PP is approximately 1:5–10 (Teilmann et al., 2005; Dong et al., 2020), and 74% of the cases in girls with CPP are idiopathic (Bradley et al., 2020; Tao et al., 2020). Although the incidence of PP in boys is low, the disorder may be caused by certain serious diseases and should be given attention (Kaplowitz and Bloch, 2016). The onset of puberty is a complex biological process involving numerous factors under the control of neuroendocrine pathways that are regulated by the hypothalamus-pituitary-gonadal (HPG) axis. Tanner stages are used to evaluate pubertal development (Carel and Léger, 2008; Tena-Sempere, 2012). The key step in puberty onset is the early activation of pulsatile GnRH secretion (Ojeda et al., 2006; Latronico et al., 2016). The timing of PP onset depends on genetic and environmental factors, and numerous studies worldwide have shown that the onset of pubertal characteristics varies with race and ethnicity, genetics, environmental conditions, exposure to certain chemicals, geographical location and nutrition (Herman-Giddens et al., 2001; Latronico et al., 2016; Abbasi, 2019). Concerns about PP in girls are extremely common and are frequently raised by parents and other guardians.

Clinical strategies for the treatment of PP in children include a gonadotropin-releasing hormone analog (GnRHa), progesterone and traditional Chinese medicines (TCMs). GnRHa, which has been used clinically for the treatment of CPP treatment for 40 years, mainly contains triptorelin and leuporelin, which can inhibit early initiation of the hypothalamus-pituitary-gonadal (HPG) axis, delay gonadal and bone development, delay epiphyseal closure and improve adult height (Kletter and Kelch, 1994; Mul and Hughes, 2008; Guaraldi et al., 2016; Fu et al., 2020). However, side effects, such as local hyperlipidemia, erythema, temporary vaginal bleeding, central obesity, body weight and bone mineral density loss, have been reported (Yu et al., 2014). Additionally, some patients require a combination of GnRHa and recombinant growth hormone (rhGH) to achieve the desired effect. However, not all patients who received combination treatment achieved satisfactory height gains (Kohn et al., 1999; Cisternino et al., 2002; Weise et al., 2004; Fu et al., 2020). CPP is diagnosed based on the GnRHa stimulation test (Carel et al., 2009). The assessment and management of this disease remain a challenge for pediatric endocrinologists (Latronico et al., 2016), and the Pediatric Endocrinology Society has suggested that the combination of GnRHa and rhGH should not be recommended as routine treatment because of its high cost and the lack of large-scale randomized clinical trials evaluating the safety and effectiveness of this combination therapy (Carel et al., 2009).

TCM formulas have played an important role in the modernization of TCM. However, there are many TCM compound preparations, which ingredients of which are complex, and most of them contain many minerals and

animal medicinal materials. Some drugs have various bad tastes and smells, such as a bitter taste, astringent taste or sour taste. Therefore, the chemical composition of TCM formulas is more complex than that of a single herbal medicine.

TCM practitioners in China have used oral herbs to treat many pediatric diseases for thousands of years. CPP is rarely reported in ancient literature, probably because it is not very common. However, some Chinese herbal formulas, such as the Nourishing (Yin) Removing (Fire) Chinese herbal mixture (Sun et al., 2010; Wang et al., 2014b; He et al., 2018), Zhi Bai Di Huang Wan (Anemarrhena, Phellodendron, and Rehmannia Pill) (Cheng et al., 2013), Jia Wei Xiao Yao San (Supplemented Free Wanderer Powder) (Yamada and Kanba, 2002), Long Dan Xie Gan Tang (Gentian Liver Draining Decoction) (He et al., 2015), Xiang Sha Liu Jun Zi Tang (Costustoot and Amonum Six Gentlemen Decoction) (Xiao et al., 2012), Cang Er Zi San (Xanthium Powder) (Yang and Yu, 2008), Wen Dan Tang (Gallbladder-Warming Decoction) (Wang et al., 2014a), and Ma Zi Ren Wan (Hemp Seed Pill) (Hu et al., 2015), have been reported to alleviate PP.

Fuyou (Fy) formula is an in-hospital preparation that clears the liver, nourishes yin and removes fire, as described by pediatric gynecologists at Beijing Children's Hospital on the basis of TCM pathogenesis and the physical characteristics of PP. The salt Anemarrhena and Radix Rehmanniae are the primary components of the Fy formula, which contains 11 TCMs that act together to clear the liver and disperse yin, nourish yin and remove fire. Our team found that clinical application over the past 20 years has suggested that the formula can control the early symptoms of PP in girls, reduce the size of the mammary glands, decrease the level of estrogen and delay the rate of bone maturation without obvious adverse reactions (Huili Liu and Liu, 2009; Pan Yu-chen and Liu, 2019).

In the present paper, we treated GT1-7 cells and young Sprague-Dawley (SD) rats with danazol-induced PP with the Fy formula and analyzed clinical data from a 1-year period. We confirmed the efficacy of the Fy formula for the treatment of PP and preliminarily identified the underlying mechanism. As children are a vulnerable group, it is not feasible to conduct randomized placebo-controlled clinical trials on these patients. Therefore, we compared clinical data before and after treatment.

## MATERIALS AND METHODS

### Chemicals and Reagents

Dulbecco's modified Eagle's medium (DMEM, 10–013-CV) and fetal bovine serum (FBS, 35–081-CVR) were obtained from Corning (NY, United States). Trypsin (0.25%) was purchased from Gibco (Grand Island, NY, United States). Isopropanol and chloroform were purchased from Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China). Penicillin/streptomycin were obtained from Sigma-Aldrich (St. Louis, MO, United States). The other reagents were of analytical grade and had a purity of 99.5% or higher. Kisspeptin-10 (kp-10, 45–54) was purchased

from Anaspec (San Jose, United States). Danazol was obtained from A&D Technology Corporation (Beijing, China). Leuporelin acetate microspheres for injection were purchased from Livzon (Zhuhai, China). Leuprolide acetate was purchased from TargetMol (MA, United States). Rabbit anti-GPR54, rabbit anti-kiss1, and rabbit anti-HSP90A antibodies were all purchased from Absin Bioscience Inc. An anti-GnRH antibody was purchased from Lifespan (LS-C294315). Rabbit anti-Erk1/2 (4,695) and anti-pErk1/2 antibodies (4,370) were purchased from CST. ELISA kits for follicle-stimulating hormone (FSH), luteinizing hormone (LH), and estradiol (E2) were obtained from Cloud-Clone Corp. A mouse GnRH ELISA kit was obtained from mlbio (ml701852). The TCM standards Mangiferin (serial number: 111607, purity: 98.1%), Paeoniflorin (serial number: 110736, purity: 97.4%) and Gentiopicrosin (serial number: 110770, purity: 98.2%) were purchased from the National Institutes for Food and Drug Control.

## Preparation of the Traditional Chinese Medicine Fuyou Formula

The Fy formula was prepared by combining the following 11 medicinal plants: 10 g each of Sheng Di Huang [*Rehmannia glutinosa* (Gaertn.) DC, *Orobanchaceae*], Yan Zhi Mu [*Anemarrhena asphodeloides* Bunge, *Asparagaceae*], Cu Bie Jia (*Trionycis carapax*, *Trionyx sinensis* wiegmann), Xia Ku Cao (*Prunellae spica*, *Prunella vulgaris* L.), Mu Dan Pi (*Paeonia x suffruticosa* Andrews, *Paeoniaceae*), and Chao Mai Ya [*Hordeum vulgare* L. (*Poaceae*), *Poaceae*]; 6 g each of Xuan Shen (*Scrophularia ningpoensis* Hemsl, *Scrophulariaceae*), Di Gu Pi (*Lycium chinense* Mill, *Solanaceae*), Long Dan Cao (*Gentiana scabra* Bunge, *Gentianaceae*), and Ze Xie [*Alisma plantago-aquatica* subsp. *Orientalis* (Sam.) Sam, *Alismataceae*]; and 3 g of Huang Bai (*Phellodendron chinense* C.K.Schneid, *Rutaceae*). The TCM compounds are listed in **Table 1**. The Fy formula dry paste powder was provided by Professor Ni Jian from Beijing University of Chinese Medicine after process optimization. The optimized process was as follows: 10 times the amount of water in the whole formulation was added, vinegar turtle was added for 30 min, the remaining 10 TCMs were added, the solution was extracted 3 times for 1 h each, the three decoctions were

combined, and the extract was concentrated (at 60 °C) to obtain a dry paste powder. Powdered Fy (40 mg) was dissolved in 1 ml of distilled water and subjected to for ultrasonic treatment for 30 min (power: 250 W, frequency: 40 KHz). The solution was filtered with a 0.22 µm microporous filter membrane, and a sample was used to treated cells. The main components of the Fy formula were determined by high performance liquid chromatography (HPLC).

## Animals

At postnatal day (PND)3, female SD rats and their mothers were obtained from SPF Biotechnology Co., Ltd. [Beijing, license no: SYXK (Beijing) 2016–0038]. The SD rats were housed at a constant temperature (23 ± 2°C) on a 12-h light:12-h dark cycle in an SPF animal room. The animals were provided food and water ad libitum and acclimated for three days before the experiment. All animal experiments were performed in strict compliance with Chinese guidelines, including the standards for Laboratory Animals (GB14925–2001) and the Guideline on the Humane Treatment of Laboratory Animals (MOST 2006), and all animal procedures were approved by the Beijing Administration Office for Laboratory Animals (approval number: SCXK-Beijing-2014-0004).

## Animal Grouping and Drug Administration

The animals were randomly divided into four groups: the control group, model group, positive control (leuporelin) group, and Fy formula (Fy) group. At PND5, the rats in the three groups were given a single subcutaneous injection of 300 µg/25 µL danazol (ethylene glycol: ethanol = 1:1, v/v) except the rats in the control group, which were given a subcutaneous injection of 25 µL of glycol/ethanol (Morishita et al., 1993; Ju et al., 2019). The rats in the leuporelin group were subcutaneously injected with 100 µg/kg leuporelin. The rats in the Fy group were given dry ointment powder solution by intragastric administration every day, and the rats in the control and model groups were given the same amount of normal saline. The vaginal opening was observed at PND20, and the vaginal exfoliated cells of the rats that exhibited vaginal opening were examined by smear. The rats that exhibited vaginal opening were sacrificed at diestrus after a complete estrous cycle, while the remaining rats were sacrificed at

the same time point. All rats were anesthetized by intraperitoneal injection of 2% pentobarbital sodium. Blood samples were collected from the abdominal aorta before execution, and the serum was separated after centrifugation (3,500 rpm, 20 min, 4°C) and preserved at -80°C for analysis of the serum hormone level. After the rats were sacrificed, the hypothalamus was removed, frozen in liquid nitrogen and stored at -80°C for further analysis. The uterus and ovaries were weighed to assess the organ coefficients (expressed as mg/100 g body weight) and fixed in formalin for hematoxylin and eosin (H&E) staining.

The Fy formula dose was calculated according to the clinical dosage administered to 6-year-old girls according to the following formula:

$$d_B = d_A \times R_B / R_A \times (W_A / W_B)^{1/3}$$

with  $d_B$  representing the animal/human body weight dose,  $d_A$  representing the known human/animal body weight dose,  $W_A$  and  $W_B$  representing known human and animal weights, respectively, and  $R_A$  and  $R_B$  representing known human/animal body shape coefficients, respectively. Every two days, the animals were weight, and the dose was recalculated.

## Hormone Assay

The serum concentrations of FSH, LH and E2 were measured by kits for ELISA, which is a competitive inhibition enzyme immunoassay technique, purchased from Cloud-Clone Corp. (Wuhan, China). The samples were measured in duplicate, and all the samples were measured together. The minimum detectable concentration of FSH was less than 1.11 ng/ml, and the intra-assay and inter-assay coefficients were less than 10 and 12%, respectively. The minimum detectable concentration of LH was less than 37.59 pg/ml, and the intra-assay and inter-assay coefficients were less than 10 and 12%, respectively. The minimum detectable concentration of E2 was less than 4.45 pg/ml, and the intra-assay and inter-assay coefficients were less than 10 and 12%, respectively.

## GT1-7 Cell Culture and Maintenance

Mouse GnRH-producing hypothalamic GT1-7 neurons (provided by Pamela L. Mellon, University of California San Diego) were cultured in complete fresh DMEM (Corning) containing 10% (v/v) heated-inactivated FBS and 1% antibiotics (100 U/ml penicillin/streptomycin) (Liu et al., 2018) under humidified conditions at 37°C in a 5% CO<sub>2</sub>-containing atmosphere. The medium was changed every 3 days, and the cells were passaged at 90% confluency for subsequent experiments. The cell line was confirmed to be free of *mycoplasma* contamination by PCR and culture. When the cells reached approximately 85% confluence, they were washed twice with PBS, digested with 0.25% trypsin-EDTA and resuspended in a single-cell suspension. Then,  $1.0 \times 10^6$  cells were seeded in a 6-well plate in 2 ml of medium containing 10% FBS for 24 h, and  $2.0 \times 10^4$  cells were seeded in a 96-well Corning plate in 100 µL of medium containing 10% FBS for 24 h. Then, the cells were

administered different treatments in serum-free medium (SFM) for 24 h depending on the experiment.

## Cell Counting Kit-8 Assay

Cell counting kit-8 (CCK-8) was purchased from MCE. To assess the toxicity of the Fy formula, GT1-7 cells were seeded in 96-well tissue culture plates at a density of  $2.0 \times 10^4$  cells per well in 100 µL of medium. After overnight incubation, the cells were incubated with 1.25, 2.5, 5, 10, 20, or 40 µg/ml Fy formula in SFM for 24 h at 37°C, and then 10 µL of CCK-8 solution (MCE, HY-K0301) was added to the cells. Following an incubation period of 1–4 h, the optical density (OD) was measured at 450 nm using an ELISA plate reader.

## RNA Extraction and Quantification

Total RNA was extracted from frozen GT1-7 cells and hypothalamic tissue using TRIzol reagent (Invitrogen, United States). Purified total RNA was solubilized in diethylpyrocarbonate (DEPC)-treated water (Beyotime, China), and the concentration was determined using a Biodrops BD-2000 spectrophotometer (OSTD Beijing Co., Ltd., China) at 260/280 or 260/230 nm. Two micrograms of total RNA was used as a template for reverse transcription using a cDNA synthesis kit (TransGen Biotech, AT311, TransScript One-Step gDNA Removal and cDNA Synthesis SuperMix), and the synthesized first-strand cDNA was stored at -80°C until use. The expression of each gene was quantified by real-time PCR (TransGen Biotech, AQ141, TransScript Tip Green qPCR SuperMix) using the following protocol: 1 cycle at 94°C for 30 s followed by 45 cycles at 94°C for 5 s, 60°C for 15 s and 72°C for 10 s. Briefly, the  $\Delta C_t$  value of each sample normalized to the internal control was calculated using the following equation:  $\Delta C_t = C_t(\text{gene}) - C_t(\beta\text{-actin})$ . To assess differences in expression between experimental and control conditions  $\Delta\Delta C_t$  was calculated with the following formula:  $\Delta\Delta C_t = \Delta C_t(\text{sample}) - \Delta C_t(\text{control})$ . The results are expressed as fold change in expression calculated by the  $2^{\Delta\Delta C_t}$  method, and the levels of the of transcripts were normalized to the level of  $\beta$ -actin.

Single-stranded oligodeoxynucleotide primers for amplification of each gene were designed based on PubMed searches and were synthesized by Invitrogen (Beijing, China). The sequences of these primers are listed in Table 2.

## GnRH mRNA Expression

GT1-7 cells were plated in 6-well plates at a density of  $1.0 \times 10^6$  cells per well in 2 ml of complete medium and incubated overnight. Then, the medium was replaced with SFM, and the cells were treated with kp-10 at final concentrations of  $10^{-11}$ ,  $10^{-9}$ ,  $10^{-8}$ ,  $10^{-7}$ ,  $10^{-6}$  or  $10^{-5}$  M for four or 24 h. The optimal concentration and duration for GnRH activation were determined. Cells were co-incubated with the Fy formula and the optimal concentration of kp-10, and the effect of the Fy formula on the GnRH gene was investigated.

## GnRH Secretion

GT1-7 cells were plated into 96-well plates, and after 24 h, the cells were treated with kp-10 at final concentrations of  $10^{-11}$  to

$10^{-5}$  M for four or 24 h. To study the effects of the Fy formula in the presence of kp-10, cells were treated with 5 or 10  $\mu$ g/ml Fy formula and  $10^{-9}$  M kp-10 for 24 h. Then, the 96-well plate was centrifuged (1,000 rpm, 10 min), and the supernatant was transferred to a new 96-well plate for the determination of GnRH levels. RIPA lysis was added to the cells to adjust the protein concentration.

## Protein Extraction and Western Blot Analysis

Western blot analysis was performed as previously described (Wang et al., 2017). To assess protein levels, GT1-7 cells were plated into 6-well culture plates at a density of  $1.0 \times 10^6$  cells per well in 2 ml of SFM and incubated overnight. Then, the GT1-7 cells were incubated with noncytotoxic Fy formula concentrations for 24 h. Then, they were lysed in RIPA lysis buffer supplemented with protease and phosphatase inhibitor cocktail (Appligen Technologies, Inc., China), and the BCA assay was used for quantitative analysis. Equal amounts of protein samples were separated by electrophoresis on 10% sodium dodecyl sulfate polyacrylamide gels and transferred to polyvinylidene fluoride membranes. The membranes were blocked with 5% BSA in Tris-buffered saline containing 0.05% Tween 20 (TBS) for 1 h at room temperature and then incubated with primary antibody at 4°C in blocking buffer. The membranes were washed three times for 10 min with TBST and then incubated for 1 h at room temperature with a horseradish peroxidase-labeled secondary antibody (1:2,000, ZSGB-BIO, Inc., China). An enhanced chemiluminescence detection system was used to visualize the signal. Protein band densities were analyzed by Gel-Pro Analyzer 3.1 software, and the protein expression of  $\beta$ -actin was used as an internal standard.

## Histopathological Evaluation of the Uterus

Uteri harvested from female rats were fixed in 4% paraformaldehyde, embedded in paraffin, and cut into 4-

mm slices using a slicing machine. The degree of pathological improvement in the uterus was evaluated by H&E staining.

## Statistical Analysis

All results are presented as the means  $\pm$  SDs. Differences were analyzed by one-way ANOVA, and the data were plotted with GraphPad 7 (GraphPad Software, San Diego, CA). Differences were considered statistically significant when  $p < 0.05$ .

## RESULTS

### Multicomponent Quantification of the Fuyou Formula High Performance Liquid Chromatography

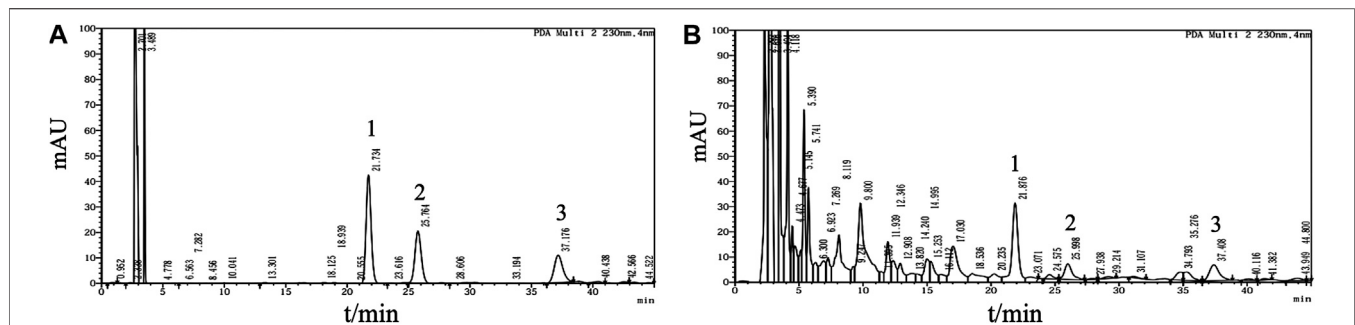

Analyses were performed using the LC Solution Chromatography workstation (Shimadzu Corporation, Kyoto, Japan). Chromatography was carried out at 30°C on an Agilent Zorbax C18 column (4.6 mm  $\times$  150 mm, 5  $\mu$ m; Agilent Technologies, Santa Clara, CA, United States). The mobile phase consisted of acetonitrile and 0.2% (v/v) acetic acid-water solution (v/v = 9:91) for isocratic elution at a flow rate of 1.0 ml/min. The signal was monitored at wavelengths of 258 and 230 nm. The chromatograms of the standard mixture and Fy formula are presented in **Figure 1**.

### The Fuyou Formula Delays Vaginal Opening in Female Rats With Precocious Puberty

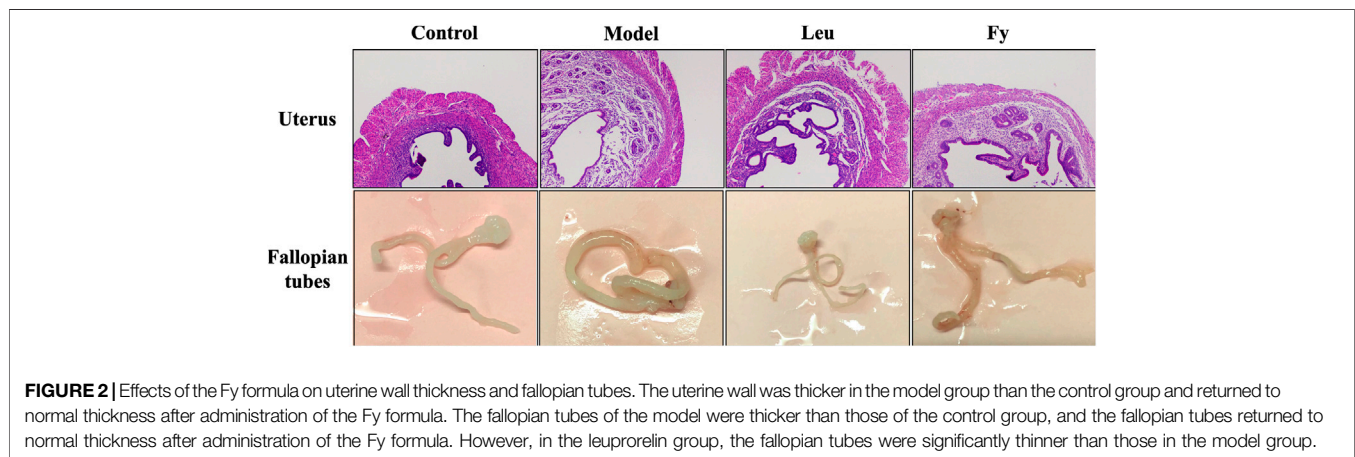

In the model group, vaginal opening was observed at PND21 and was completed vaginal opening by PND26. Vaginal opening occurred at PND25 and PND23 in the leuprorelin and Fy groups, respectively. Complete vaginal opening occurred in six rats in the leuprorelin group, six rats in the Fy group, one rat in the control group and all rats in the model group. The mean time of vaginal opening in the Fy group ( $25.7 \pm 2.1$ ) was obviously delayed compared to that in the model group ( $22.9 \pm 1.7$ ,  $p < 0.05$ , **Figure 2A**).

### The Fuyou Formula Inhibits Sex Organ Development in Rats with Danazol-Induced Precocious Puberty

As shown in **Table 3**, the wet weights of the uterus and ovaries, organ coefficients and uterine wall thickness in the model group were obviously lower than those in the control group, while the wet weights of the organs, organ coefficients and uterine wall thickness were significantly lower in the leuprorelin and Fy groups than the model group (**Figure 3**). We found that the fallopian tubes of the model group were obviously thicker than those of the control group and that the thickness of the fallopian tubes became more similar to that of the control group after administration of the Fy formula. The fallopian tubes of the leuprorelin group were thinner than those of the model group

**FIGURE 1 |** Multicomponent quantification of the Fy formula. **(A)** Chromatogram of the mangiferin, paeoniflorin and gentiopiricin standard mixture. Peak one corresponds to gentiopiricin, peak two corresponds to mangiferin, and peak three corresponds to paeoniflorin. Mangiferin (1.5 mg), paeoniflorin (3 mg) and gentiopiricin (9 mg) were accurately weighed and placed in a 20 ml volumetric flask. The mixture was diluted with methanol to the mark on the flask and shaken to obtain a mixed standard mother liquor. Then, 1.5 ml of the mixed standard mother solution was added to a 5 ml volumetric flask and diluted with methanol to the mark on the flask to obtain the reference solution. **(B)** HPLC profile of the Fy formula. The powered compound extract (0.5 g) was accurately weighed and placed in a stoppered conical flask. Then, 25 ml of methanol was added, and the flask was tightly stoppered and weighed. The compound was subjected to ultrasonic treatment for 30 min, methanol was added until the original weight was obtained, and the compound was shaken well and filtered.

**FIGURE 2 |** Effects of the Fy formula on uterine wall thickness and fallopian tubes. The uterine wall was thicker in the model group than the control group and returned to normal thickness after administration of the Fy formula. The fallopian tubes of the model were thicker than those of the control group, and the fallopian tubes returned to normal thickness after administration of the Fy formula. However, in the leuporelin group, the fallopian tubes were significantly thinner than those in the model group.

**TABLE 3 |** Uterine and ovarian wet weights, organ coefficients and uterine wall thickness (n = 8–10).

Group	Wet weight of the uterus (g)	Organ coefficient of the uterus ( $10^{-4}$ )	Wet weight of the ovary (g)	Organ coefficient of the ovary ( $10^{-4}$ )	Uterine wall thickness (mm)
Control	0.0962 ± 0.0230	10.81 ± 2.62	0.0406 ± 0.0053	4.58 ± 0.66	4.62 ± 2.10
Model	0.1841 ± 0.0496 <sup>###</sup>	19.88 ± 5.21 <sup>###</sup>	0.0508 ± 0.0069 <sup>##</sup>	5.53 ± 1.08 <sup>#</sup>	7.35 ± 1.98 <sup>#</sup>
Leu	0.0402 ± 0.0083 <sup>***</sup>	4.33 ± 0.67 <sup>***</sup>	0.0149 ± 0.0023 <sup>***</sup>	1.62 ± 0.26 <sup>***</sup>	3.28 ± 1.90 <sup>***</sup>
Fy	0.1363 ± 0.0253 <sup>*</sup>	15.00 ± 3.09 <sup>*</sup>	0.0391 ± 0.0059 <sup>**</sup>	4.30 ± 0.66 <sup>*</sup>	4.84 ± 1.27 <sup>*</sup>

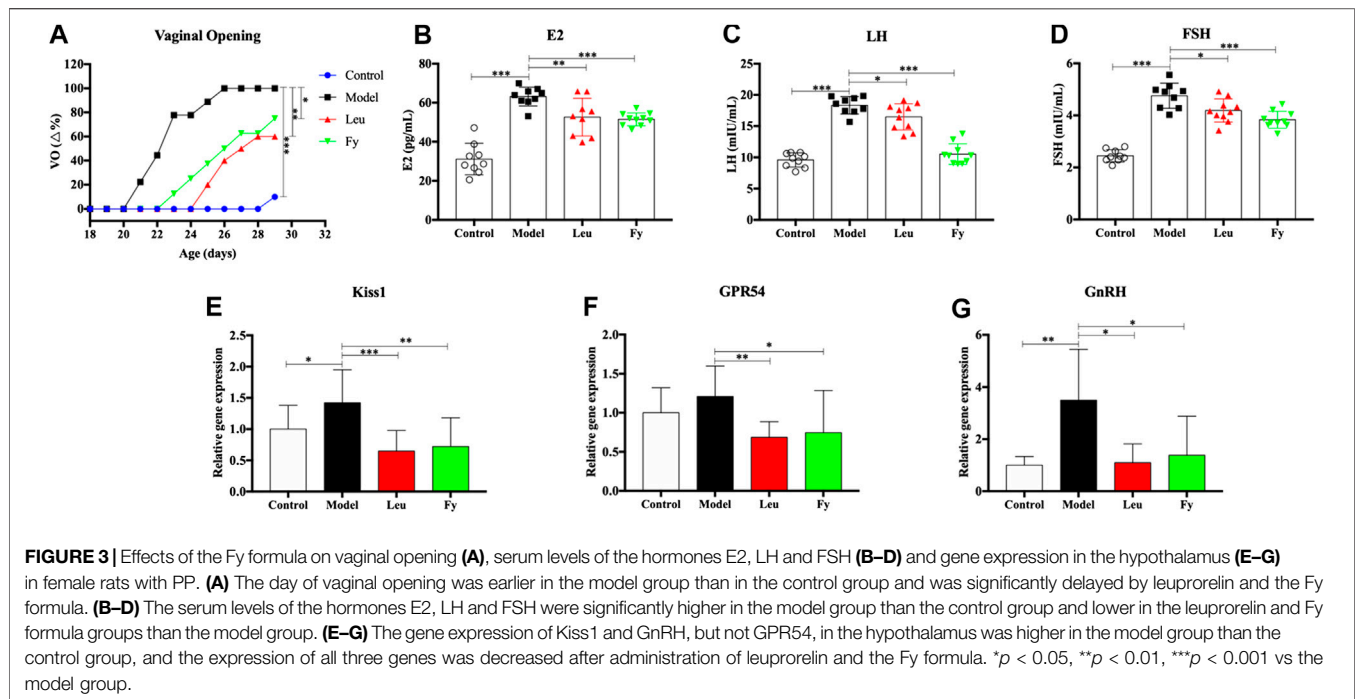

(Figure 3), indicating that leuporelin affects the normal development of rats and should be combined with growth hormone, as described in the literature (Weise et al., 2004).

## The Fuyou Formula Decreases Blood Hormone Levels and Inhibits GPR54 Expression in Rats with Danazol-Induced Precocious Puberty

ELISA was employed to evaluate the serum levels of the hormones E2, LH and FSH in PP rats. The results suggested that the levels of hormones E2, LH and FSH were higher in the model group than in the control group ( $p < 0.001$ ). However, the levels of E2, LH and FSH in the leuporelin and Fy formula groups were obviously lower than those in the model group (Figures 2B–D).

We observed that the gene expression of kiss1, GPR54 and GnRH was obviously lower in the hypothalamic of SD rats with danazol-induced PP than in the hypothalamic of control rats and that the Fy formula and leuporelin significantly reduced the expression of kiss1, GPR54 and GnRH genes compared with that in the model group (Figures 2E–G). However, there was no significant difference in GPR54 gene expression between the control and model groups.

## The Fuyou Formula Downregulates the Expression and Secretion of GnRH in Hypothalamic GT1-7 Neurons

The effect of the Fy formula on the viability of GT1-7 cells was compared with that of vehicle treatment. The maximum noncytotoxic concentration of the Fy formula was 10  $\mu\text{g}/\text{ml}$  (Supplementary Figure S1). To ensure that the Fy formula was administered at a sufficient concentration to exerts the desired effects, the final treatment concentrations for all subsequent experiments in GT1-7 cells were 5 and 10  $\mu\text{g}/\text{ml}$ . Changes in GnRH mRNA expression in GT1-7 cells after treatment with different concentrations of kp-10 for 4 or 24 h were evaluated by RT-PCR. The expression of GnRH mRNA was the highest when GT1-7 cells were treated with kp-10 at a concentration of  $10^{-9}$  M for 24 h (Supplementary Figure S2).

To further evaluate the mechanism by which the Fy formula affects the release of GnRH in GT1-7 cells via the GPR54/GnRH signaling pathway, the gene expression of GPR54, GnRH, estrogen receptor  $\alpha$  (Era) and estrogen receptor  $\beta$  (Er $\beta$ ) in GT1-7 cells treated with kp-10 was detected by RT-PCR. The RT-PCR results showed that compared with vehicle treatment, treatment with  $10^{-9}$  M kp-10 for 24 h significantly upregulated the gene expression of GPR54, GnRH, Era and Er $\beta$  (Figures 4A–D) in GT1-7 cells. Additionally, the expression of GnRH, GPR54, and Er $\beta$  in the Fy + kp-10 groups, except for Era expression in the Fy + kp-10 group, was significantly lower than that in the kp-10 group.

To evaluate the effect of the Fy formula on GnRH secretion, GT1-7 cells were treated with five or 10  $\mu\text{g}/\text{ml}$  Fy formula. Kp-10 significantly elevated GnRH secretion; however, compared with

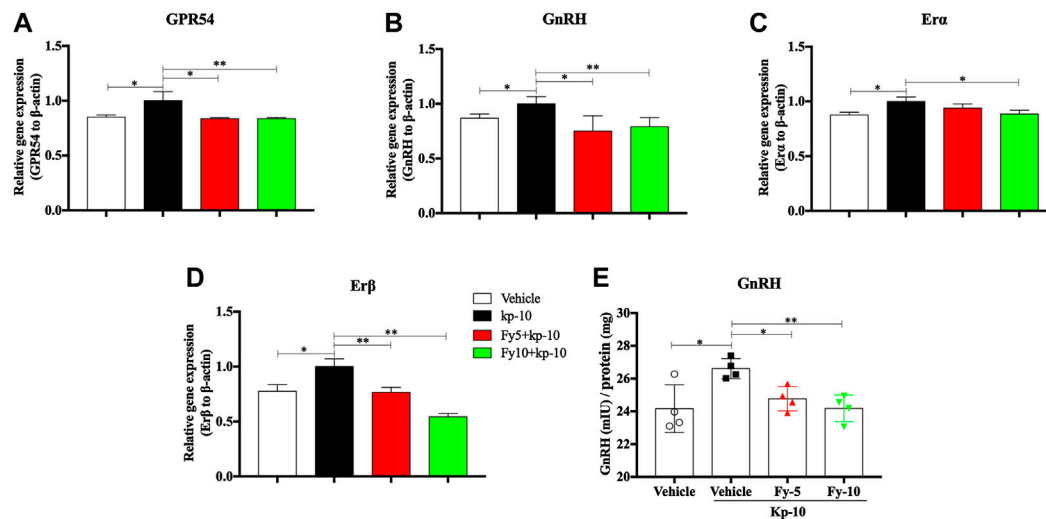

kp-10, the Fy formula significantly decreased GnRH secretion in a concentration-dependent manner (Figure 4E).

## The Fuyou Formula Inhibits the GPR54/GnRH Pathway in GT1-7 Hypothalamic Neuronal Cells

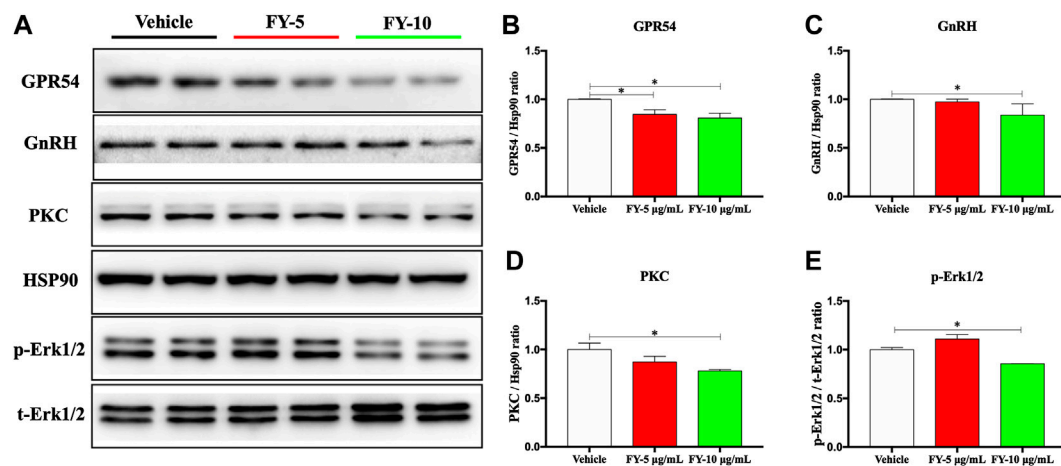

To additionally investigate the potential molecular mechanism underlying the effect of the Fy formula on the release of GnRH via the GPR54/GnRH signaling pathway, western blot analysis of the protein expression of GPR54, GnRH, PKC and pErk1/2 was conducted in GT1-7 cells treated with the Fy formula (5 or 10  $\mu\text{g}/\text{ml}$ ). GT1-7 cells expressed the GPR54 protein, as previously reported (Novaira et al., 2009b). We also performed western blot analysis of total and phosphorylated PKC and pErk1/2, as phosphorylation of these proteins is considered to be the main cellular signaling event in GPR54/GnRH activation. The protein levels of GnRH and PKC and the phosphorylation of Erk were decreased by incubation with Fy (10  $\mu\text{g}/\text{ml}$ ), as shown in Figures 5C–E. Compared with the vehicle, Fy formula at concentrations of 5 and 10  $\mu\text{g}/\text{ml}$  decreased the protein expression of GPR54 (Figure 5B).

## DISCUSSION

PP is defined as puberty that occurs before the age of 8 years in girls and before the age of 9 years in boys. PP has a far-reaching influence on children's growth, development and mental health. Chinese herbal medicines have been proven to be effective in regulating the development of puberty, but their mechanisms are still unclear (Wang et al., 2014b; Yu et al., 2014). The GPR54/

**FIGURE 4 |** Effects of the Fy formula on GnRH mRNA expression (A–D) and secretion in GT1-7 cells (E). GT1-7 cells were divided into the vehicle group (untreated GT1-7 cells), kp-10 group (GT1-7 cells treated with kp-10), and Fy + kp-10 group (GT1-7 cells treated with 5 or 10 μg/ml Fy formula and kp-10 for 24 h). (A–D) The gene expression of GPR54, GnRH, Era and Erβ was higher in the kp-10 group than the vehicle group and lower in the Fy formula group than the vehicle group. (E) Cells treated with kp-10 (24 h) exhibited increased secretion of GnRH and decreased secretion when coincubated with the Fy formula. \**p* < 0.05, \*\**p* < 0.01, \*\*\**p* < 0.001 vs. the kp-10 group.

**FIGURE 5 |** Effects of the Fy formula on GPR54, GnRH, PKC and pErk1/2 expression. (A) Representative images of western blots for GPR54, GnRH, PKC and pErk expression in GT1-7 cells after treatment with the Fy formula (5 or 10 μg/ml) for 24 h (B–E) Statistical analysis of GPR54, GnRH, PKC and pErk1/2 expression. \**p* < 0.05 vs. the vehicle group.

GnRH signaling pathway plays an important role in puberty development. The purpose of this study was to investigate the effects of the Fy formula on the GPR54/GnRH signaling pathway in GT1-7 cells and female rats with PP.

Danazol, an isoxazole derivative of 17α-ethynyl testosterone, has a variety of effects on the reproductive system, high affinity for androgen receptors, moderate affinity for glucocorticoid receptors and poor affinity for estrogen receptors. This study showed that subcutaneous injection of 300 μg of danazol into PND5 female rats accelerated the onset of sexual development, increased the weights of the uterus and ovary, increased the release of GnRH from the hypothalamus and accelerated HPG

axis activation in rats, thus hastening sexual maturity without increasing the body of the rats (Morishita et al., 1993; Sun et al., 2010). These findings suggest that the rat hypothalamus is immature at birth, hypothalamic maturation may occur from 1 to 10 days after birth, and subcutaneous injection of danazol into newborn rats may quicken the maturation of the hypothalamus-pituitary axis and induce true PP (Sun et al., 2007).

Vaginal opening is a sign of puberty in female rats (Sun et al., 2007). Our experiment showed that the time of vaginal opening was significantly advanced in the model group compared with the control group (*p* < 0.001). After administration of leuporelin and the Fy formula, vaginal opening was significantly delayed

compared with that in the model group ( $p < 0.05$ , **Figure 2A**). The wet weights and organ coefficients of the uterus and ovary in the model group were significantly higher than those in the control group ( $p < 0.05$ ) and were decreased after leuporelin and Fy formula treatment ( $p < 0.05$ , **Table 3**). The fallopian tubes were thicker in the model group than the control group and returned to normal thickness after administration of the Fy formula. However, the fallopian tubes were significantly thinner in the leuporelin group than the model group (**Supplementary Figure S2**), suggesting that leuporelin affects the normal development of sex organs and should be combined with growth hormone (Benabbad et al., 2018). The Fy formula and leuporelin decreased the serum levels of the hormones E2, LH and FSH compared with those in the model group, suggesting that the Fy formula can significantly delay puberty onset in female rats.

Although the physiological structure of humans is different from that of rodents, the Fy formula was shown to have therapeutic effects in both PP patients and a rat model of danazol-induced PP. As an in-hospital formula of Beijing Children's Hospital, the Fy formula has been used for the management of PP for more than twenty years. These findings confirm the clinical benefits of the Fy formula, which is an advantageous therapeutic approach in our country due to its low cost. We enrolled patients who were treated for more than one year. The clinical data revealed that the Fy formula markedly reduced the serum levels of estrogen in patients, significantly decreased mammary gland size, and delayed bone maturation in girls with PP (**Supplementary Table S1**). Moreover, several Chinese reports also indicated that the Fy formula of Chinese herbs has a good intervention effect on girl's ovarian cysts complicated with PP, causing most ovarian cysts to disappear (Pan Yu-chen and Liu, 2019). The clear clinical efficacy of the Fy formula is enough to prove its effective role in the treatment of PP in children. However, the physiological structure and function of humans and rats are different, so more evidence is needed to prove the mechanism of the Fy formula.

The research in humans and mice has shown that mutations or deletions in GPR54 lead to puberty failure and infertility, which suggests that the kisspeptin-GPR54 signaling pathway is absolutely essential for fertility (De Roux et al., 2003; Seminara et al., 2003; Clarkson, 2013). Subsequent research has shown that the loss of Kiss1 gene function in mice and humans results in pubertal disorders and infertility symptoms similar to GPR54 knockout (Topaloglu et al., 2012). Studies in the last decade have shown that kisspeptin and GPR54 are important regulators of GnRH activity. During puberty maturation, the increased expression of kiss1 mRNA and kisspeptin peptide in the hypothalamus is an important in promoting the full activation of GnRH nerve cells, and plays an important role in adolescent maturation and adult reproductive physiology (Clarkson, 2013). Therefore, kisspeptin mainly regulates reproductive events, such as precocious puberty, primarily by activating the GPR54 receptor indicated by GnRH neurons in the hypothalamus.

To further explore the role of GPR54/GnRH in the effects of the Fy formula on PP, gene expression was analyzed. Our results showed that kiss1, GPR54 and GnRH mRNA expression was higher in the model group than in the control group. One of our

most obvious findings was that compared to vehicle, the Fy formula significantly downregulated the gene expression of the Kiss1, GPR54 and GnRH in the hypothalamus of female rats with PP (**Figures 2E–G**). Previous studies have shown that the Kiss1 gene is involved in the development of sexual maturity during early puberty in normal female rats (Sun et al., 2007; Sun et al., 2010) and that kisspeptin administration into the hypothalamus of immature female rats can significantly advance vaginal opening, significantly increase uterine weight (Navarro et al., 2004), and induce precocious activation of the HPG axis and PP development (Plant et al., 2006; Trevisan et al., 2018). These findings suggest that the Fy formula may inhibit the expression of the kiss1 gene, weaken the binding between kisspeptin and GPR54, and ultimately reduce the pulsed secretion of GnRH, weakening the activation of downstream pituitary and gonadal development and thus alleviating PP.

Kisspeptin and its cognate receptor GPR54 are major regulators of the HPG axis (Szereszewski et al., 2010). Kisspeptin is a neuropeptide encoded by the kiss1 gene and secreted in the hypothalamus. Kisspeptin has a highly conservative region at the C-terminal sequence, consisting of 10 amino acids, named kisspeptin-10 (Pasquier et al., 2014). GPR54 couples to the  $G_{q/11}$  protein when kisspeptin-10 stimulates GPR54, and  $G_{q/11}$  activates phospholipase C and hydrolyzes PIP2 to produce the second messengers IP3 and DAG. IP3 stimulates the endoplasmic reticulum (ER), increasing the levels of intracellular  $Ca^{2+}$  and activating Ca-dependent signaling pathways in GnRH neurons, and DAG activates protein kinase C (PKC), activates extracellular signal-regulated kinases one and two in GnRH neurons, and promotes hypothalamic secretion of GnRH (Kotani et al., 2001; Harter et al., 2018; Trevisan et al., 2018). The function of kisspeptin in GnRH neurons also requires the activation of additional signaling mechanisms in the family of MAPKs, which have a strong continuous stimulation effect on the phosphorylation of MAPK extracellular signal-regulating kinases Erk1 and Erk2 (Chianese et al., 2016). Kisspeptin is produced by two main groups of neurons located in the hypothalamus, namely, neurons in the rostral periventricular area of the third ventricle (RP3V) and neurons in the arcuate nucleus (ARC). Kisspeptin produced in the ARC is generally considered to be the generator of GnRH. GPR54 is mainly expressed in the hypothalamus, specifically the POA (Herbison et al., 2010), and is expressed by most GnRH-secreting neurons. Human GPR54 is highly expressed in the placenta, anterior pituitary, pancreas, liver, adipose tissue and spinal cord, suggesting that it plays a role in the regulation of endocrine function (Kotani et al., 2001; Ohtaki et al., 2001). In humans and rats, the onset of puberty is caused by an increase in GnRH pulsed secretion. True PP is mediated by a premature increase in GnRH secretion and should be treated with a potent GnRHa (Tian et al., 2005). The administration of exogenous kisspeptin can advance the puberty of immature rodent (rats) and primates (monkeys) (Plant et al., 2006), on the contrary, administration of kisspeptin antagonist delayed puberty in rats and monkeys (Skorupskaite et al., 2014; Li et al., 2020). These findings show that kisspeptin plays an important role in the regulation of HPG axis.

Therefore, kisspeptin mainly regulates reproductive events, such as precocious puberty, primarily by activating the GPR54 receptor indicated by GnRH neurons in the hypothalamus. In the present study, we designed a series of experiments to investigate the mechanism of the Fy formula. First, we determined that kisspeptin at a concentration of  $10^{-9}$  M had a direct effect on GT1-7 cells and upregulated the expression of the GPR54, GnRH, *Era* and *Erβ* genes (Figure 4; Supplementary Figure S2). These results are consistent with previous reports showing that which kisspeptin can promote the GnRH system (Clarkson et al., 2008; Novaira et al., 2009a). Kisspeptin binds to GPR54 and stimulates hypothalamic neurons to release GnRH, leading to the secretion of gonadotropins (LH and FSH) and sex steroids, which in turn act on the gonads to produce gametes, by the pituitary gland (Trevisan et al., 2018). The Fy formula (10 μg/ml) decreased the gene expression of GPR54, GnRH, *Era* and *Erβ*, which was increased by kisspeptin in GT1-7 cells (Figures 4A–D). Kisspeptin-10 not only upregulated the expression of the GnRH gene but also increased the secretion of GnRH in GT1-7 cells (Figure 4E), which is consistent with previous results (Lehnert and Khadra, 2019). However, after administration of the Fy formula, the

secretion of GnRH was significantly decreased (Figure 4E). To confirm the effect of the Fy formula on the GPR54/GnRH signaling pathway in GT1-7 cells, we investigated its effects on related proteins and found that the Fy formula significantly downregulated the protein expression of GPR54, PKC and GnRH and the phosphorylation of Erk1/2 (Figure 5). These results indicate that the Fy formula inhibits Kiss1 gene expression, reduces the expression of kisspeptin, reduces the binding of GPR54 to Gq/11, inhibits the hydrolysis of PIP2 and the Erk1/2 signaling pathway, decreases the secretion of hypothalamic GnRH, weakens the stimulation of the pituitary gland, reduces the secretion of the gonadotropins LH and FSH and sex steroids, inhibits gonadal gamete production and alleviates the symptoms of PP (Figure 6) (Roseweir and Millar, 2009; Trevisan et al., 2018).

In this study, the therapeutic effect of the Fy formula on PP was studied in GT1-7 cells and in a rodent model. Additionally, it has also been observed clinically that the Fy formula can reduce the estrogen level in girls with PP, significantly decreased mammary gland size, and delayed bone maturation. However, because the clinical sample size in this study was small, the data may have been slightly skewed. Therefore, it is necessary to increase the clinical sample size and evaluate clinical indicators at a later stage to more comprehensively assess the curative effect of the Fy formula.

## CONCLUSION

In summary, the Fy formula reduced blood hormone levels, downregulated the gene expression of kiss1, GPR54 and GnRH in female rats with danazol-induced PP and downregulated GnRH gene and protein expression and hormone secretion induced by kp-10 in GT1-7 cells. The GPR54/GnRH signaling pathway may be involved in the effects of the Fy formula on PP. The potential mechanism of action of the Fy formula needs to be further revealed to provide support for its clinical application.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Ethics Committee of Beijing Children's Hospital (IEC-C-008-A08-V.05.1). Written informed consent to participate in this study was provided by the participants' legal guardian/next of kin. The animal study was reviewed and approved by Animal Ethics Committee of Capital Medical University (AEEI-2020-084). Written informed consent was

obtained from the individual(s), and minor(s)' legal guardian/next of kin, for the publication of any potentially identifiable images or data included in this article.

## AUTHOR CONTRIBUTIONS

GB performed the investigation and wrote the paper. KH, YH, XW, LL and HC participated in the collection and preparation of rat samples. MZ, CG and JL participated in the collection of patients data. LZ, ZS, XW, and XN designed the study and revised the paper. All authors reviewed and approved the final manuscript.

Paeonol Protects Against Myocardial  
Ischemia/Reperfusion-Induced Injury  
by Mediating Apoptosis and  
Autophagy Crosstalk.  
Front. Pharmacol. 11:586498.  
doi: 10.3389/fphar.2020.586498

Many studies have shown that crosstalk exists between apoptosis and autophagy, despite differences in mechanisms between these processes. Paeonol, a major phenolic compound isolated from Moutan *Cortex Radicis*, the root bark of *Paeonia × suffruticosa* Andrews (Paeoniaceae), is widely used in traditional Chinese medicine as an antipyretic, analgesic and anti-inflammatory agent. In this study, we investigated the detailed molecular mechanisms of the crosstalk between apoptosis and autophagy underlying the cardioprotective effects of paeonol in rats subjected to myocardial ischemia/reperfusion (I/R) injury. Myocardial I/R injury was induced by occlusion of the left anterior descending coronary artery (LAD) for 1 h followed by 3 h of reperfusion. Paeonol was intravenously administered 15 min before LAD ligation. We found that paeonol significantly improved cardiac function after myocardial I/R injury and significantly decreased myocardial I/R-induced arrhythmia and mortality. Paeonol also significantly decreased myocardial infarction and plasma LDH activity and Troponin-I levels in carotid blood after I/R. Compared with vehicle treatment, paeonol significantly upregulated Bcl-2 protein expression and significantly downregulated the cleaved forms of caspase-8, caspase-9, caspase-3 and PARP protein expression in the I/R injured myocardium. Myocardial I/R-induced autophagy, including the increase of Beclin-1, p62, LC3-I, and LC3-II protein expression in the myocardium was significantly reversed by paeonol treatment. Paeonol also significantly increased the Bcl-2/Bax and Bcl-2/Beclin-1

ratios in the myocardium after I/R injury. The cardioprotective role of paeonol during I/R injury may be due to its mediation of crosstalk between apoptotic and autophagic signaling pathways, which inhibits apoptosis and autophagic cell death.

**Keywords:** apoptosis, autophagy, paeonol, myocardial ischemia/reperfusion injury, crosstalk

## INTRODUCTION

Recent studies have shown that cardiomyocyte death is the main reason for the poor prognosis of patients with ischemic heart disease (Chiong et al., 2011; Teringova and Tousek, 2017). The most appropriate clinical strategy to limit myocardial infarct size, preserve cardiac function and improve both quality of life and survival in patients with ischemic heart disease is to minimize myocardial ischemia/reperfusion (I/R) injury-induced cardiomyocyte death, such as necrosis, apoptosis, or autophagy (Tian et al., 2013). Necrosis is marked by defective plasma membrane integrity, cellular and organellar swelling, and marked inflammation. Apoptosis and autophagy differ from necrosis, in that neither apoptosis nor autophagy exhibit myocardial inflammation and they share many death signals that regulate cell death, which may be important signaling pathways in myocardial I/R injury (Oerlemans et al., 2013). Apoptosis, characterized by chromatin condensation, nuclear fragmentation, cell shrinkage and production of apoptotic bodies, is a major mechanism of regulated cell death during myocardial I/R injury (Xia et al., 2016). Autophagy is activated in order to remove damaged organelles and stimulate phagocytic clearance of apoptotic cells (Zou et al., 2012). Evidence suggests that autophagy is beneficial during ischemia, functioning as a protein quality controller and cellular homeostasis keeper; however, excessive autophagic activity degrades essential proteins and organelles, leading to progressive consumption of proteins or organelles and autophagic cell death during I/R (Zeng et al., 2016). Even if the mechanisms differ between autophagy and apoptosis, some proteins modulate both autophagy and apoptosis. It is well documented that the crosstalk between autophagy and apoptosis is mediated by the functional and structural interactions between Beclin-1 and Bcl-2. Beclin-1, the mammalian orthologue of yeast Atg6, is part of the class III phosphatidylinositol 3-kinase (PI3K) complex that induces autophagy. Bcl-2 is not only an important regulator in apoptosis, but also an anti-autophagic protein via its inhibitory interaction with Beclin-1 (Pattingre et al., 2005). Notably, after interacting with Bcl-2, Beclin-1 is sequestered away from the Vps34/class III PI3K complex and autophagy is inhibited, whereas Bcl-2 maintains anti-apoptotic potential (Levine et al., 2008; Ciechomska et al., 2009). Evidence has shown that the interplay between autophagy and apoptosis is closely related to I/R injury, so recent studies have therefore focused on the crosstalk between these cell death processes (Li M. et al., 2016; Dong et al., 2019).

Paeonol, a major phenolic constituent extracted from Moutan *Cortex Radicis*, the root bark of *Paeonia × suffruticosa* Andrews (Paeoniaceae), and the root of *Paeonia lactiflora* Pall, is widely

used as a nutrient supplement and as an antipyretic, analgesic and anti-inflammatory agent in traditional Chinese medicine. Paeonol is associated with a wide range of biological effects, including antiplatelet aggregation (Koo et al., 2010), antioxidative (Ding et al., 2016) and anti-inflammatory activity (Lei et al., 2016). Paeonol also demonstrates antiatherosclerotic activity via the upregulation of autophagy and inhibition of vascular smooth muscle cell proliferation (Wu et al., 2017), and prevents oxidized low-density lipoprotein (ox-LDL)-induced injury to vascular endothelial cells by inhibiting excessive autophagy, increasing miR-30a levels and reducing Beclin-1 protein expression (Li et al., 2018). Furthermore, paeonol decreases cerebral infarction and neurological deficits in rats subjected to focal cerebral I/R injury (Hsieh et al., 2006; Liao et al., 2016) and has proven cardioprotective effects in rats subjected to myocardial I/R injury, improving hemorrheology indexes, decreasing oxidative injury and repairing endothelial function (Yang et al., 2010). Paeonol has also demonstrated activity against cardiotoxicity induced by epirubicin, a chemotherapeutic agent, by upregulating epirubicin-induced reductions in miR-1 expression and suppressing the phosphatidylinositol 3-kinase (PI3K)/AKT and the mammalian target of rapamycin (mTOR) signaling pathways, and NF- $\kappa$ B signaling pathways (Wu et al., 2018).

None of these previous reports has determined whether the crosstalk between apoptosis and autophagy may play a role in the cardioprotective effect of paeonol. Our investigation is the first to examine the molecular mechanisms involved in the crosstalk between apoptosis and autophagy that underlie the cardioprotective effects of paeonol in rats subjected to myocardial I/R injury.

## MATERIALS AND METHODS

### Methods

All study protocols were performed in accordance with those in the *Guide for the Care and Use of Laboratory Animals* published by the National Research Council (United States) Committee (National Academies of Sciences, 2011). All efforts were taken to reduce the numbers of sacrificed animals and to minimize animal suffering.

### Animals

All experiments and postoperative animal care were reviewed and approved by the Institutional Animal Care and Use Committee of Chung Shan Medical University (IACUC-1772). We used male Sprague-Dawley rats (LASCO Co., Charles River Technology, Taipei, Taiwan) weighing 250–350 g. The animals were housed in a room under controlled temperature ( $24 \pm 1^\circ\text{C}$ ) and humidity

(55 ± 5%) conditions and subjected to a 12:12 h light-dark cycle. They were allowed free access to food and water.

## Surgical Procedure

Myocardial I/R injury was induced by temporary occlusion of the left anterior descending coronary artery (LAD), as per previously described procedures (Wang et al., 2016). Briefly, the rats were anesthetized with a single intraperitoneal injection of urethane (1.25 g/kg) and then placed on a heated, small animal operating table. After tracheotomy, the intubated animals were ventilated with room air through a respirator for small rodents (Model 131, NEMI, United States) with a stroke volume of 15 ml/kg body weight and rate of 60 strokes/min. The jugular vein was cannulated to administer drugs and polyethylene catheters (PE-50) were inserted into the common carotid artery with a Statham P23 XL transducer to continuously monitor heart rate (HR) and arterial blood pressure (BP). A standard 1-lead ECG recorded heart rhythm via silver electrodes attached to the extremities and the adequacy of anesthetic depth. Data were acquired with a MP35 physiological recorder (BIOPAC Systems, Inc., United States).

The heart was exposed via left thoracotomy and the fourth and fifth ribs were sectioned approximately 2 mm to the left of the sternum. The heart was rapidly externalized and inverted. A 6/0 silk ligature was then placed around the left main coronary artery. The heart was repositioned in the chest and the animal was allowed to recover for 15 mins. Animals that developed arrhythmia or sustained a decrease in mean BP to less than 70 mmHg during the procedure were not included in the study. A small plastic snare from a Portex P-270 cannula was threaded through the ligature and placed in contact with the heart. The left coronary artery was then occluded by tightening the ligature and reperfusion was achieved by releasing the tension applied to the ligature (operated groups). Successful ligation of the coronary artery was validated by decreased arterial pressure and ECG changes (increase in R wave and ST segment elevation), which are indicators of ischemia. Sham-operated animals underwent the same surgical procedure, except that the silk ligature that was placed around the left coronary artery was not tied. Changes in HR, BP, and ECG were simultaneously recorded using a personal computer with waveform analysis software (AcqKnowledge, Biopac System, Goleta, CA, United States) before and during the ischemia and reperfusion periods. To evaluate antiarrhythmic effects of paeonol during myocardial I/R injury, we occluded the coronary artery for 1 h and then subjected it to reperfusion for 3 h. The ventricular ectopic activity was evaluated according to the diagnostic criteria advocated by the Lambeth Conventions (Curtis et al., 2013). Incidence and duration of ventricular tachyarrhythmias, including ventricular tachycardia (VT) and ventricular fibrillation (VF), were determined in the surviving rats and in the rats that eventually died. In rats with irreversible VF, the duration of VF was recorded until mean BP was <15 mmHg. To evaluate the effect of paeonol on cardiac function during myocardial I/R injury, a Millar catheter was inserted into the left ventricular cavity via the right common carotid artery and changes in the left ventricular systolic pressure (LVSP), left ventricular diastolic pressure (LVDP), maximal slope

of systolic pressure increment (max dP/dt) and diastolic decrement (min dP/dt) were continuously recorded using a Transonic Scisense Pressure Measurement system (SP200, Transonic Scisense Inc., Ontario, Canada).

## Experimental Groups

Most research has shown that the effective dose range for paeonol cardioprotection is 2.5–100 mg/kg by intragastric or intraperitoneal administration (Yang et al., 2010; Li et al., 2012; Ma et al., 2015; Li H. et al., 2016; Wu et al., 2018). However, recent data indicate that paeonol has higher bioavailability by intranasal and intravenous administration routes in rats compared with the intragastric route (Chen et al., 2010; Adki and Kulkarni, 2020). We therefore investigated the cardioprotective effects of 0.1 and 1 mg/kg paeonol by intravenous administration in rats subjected to myocardial I/R injury. In this study, the solution of paeonol (purity ≥ 98%, Cat. sc-205787, Santa Cruz, Dallas, TX, United States) was freshly prepared and intravenously administered 15 mins before LAD ligation. The rats were randomly assigned to one of five groups: 1) Sham-vehicle: rats underwent all surgical procedures except LAD occlusion and were treated with vehicle (0.1% dimethyl sulfoxide [DMSO] in normal saline); 2) Sham-P-1: rats underwent all surgical procedures except LAD occlusion and were treated with paeonol (1 mg/kg); 3) I/R-Control: rats were treated with vehicle and underwent myocardial I/R injury; 4) I/R-P-0.1: rats were treated with paeonol (0.1 mg/kg) and underwent myocardial I/R injury; or 5) I/R-P-1: rats were treated with paeonol (1 mg/kg) and underwent myocardial I/R injury.

## Estimation of Myocardial Infarct Size and Myocardial Damage

The sizes of both the ischemic zone and infarct zone in the rats' hearts were determined by previously described procedures (Wang et al., 2016). Evaluation of the infarct zone and collection of myocardium samples for further analyses were carried out in rats that survived 1 h of ischemia and 3 h of reperfusion. At the end of the experiment, the coronary artery was reoccluded, and 2.0 ml of 0.1% Evans blue solution was intravenously injected to stain non-ischemic myocardium and determine the area at risk. The heart was then excised and the atria were removed. Ventricular tissues were sliced into 2 mm sections and incubated in tetrazolium dye (2% 2,3,5-triphenyltetrazolium chloride [Sigma, United States] in normal saline) at 37 °C for 30 mins in darkness. The sections were placed in a solution of 10% formaldehyde in saline for 1 day before excision of infarcted (white) tissues. The weight of the infarcted tissues is expressed as a percentage of the total ventricle or the area at risk. In addition, arterial blood collected from the carotid catheter in rats that survived after 1 h of ischemia and 3 h of reperfusion was centrifuged at 3,000 g for 10 mins to isolate plasma and determine *in vivo* heart injury. Myocardial cellular damage was determined using automated clinical analyzers to measure plasma activities of lactate dehydrogenase (LDH) (ADVIA 1800; Siemens Healthcare Diagnostics Inc., NY,

United States) and the levels of Troponin-I (Centaur, Siemens Healthcare Diagnostics Inc., NY, United States).

## Western Blot

For reducing the number of animal sacrifices in this study, the effective dose of paeonol 1 mg/kg was applied to investigate the underlying mechanism involved in the cardioprotective effect of paeonol. Protein expression was evaluated by Western blot, as per previously described procedures (Su et al., 2019). The hearts of rats with myocardial I/R injury were homogenized in T-PER Tissue Protein Extraction Reagent (Thermo Scientific, United States) containing protease Inhibitor Cocktail (Thermo Scientific, United States). The homogenates were centrifuged at 10,000 g for 10 mins at 4 °C. Protein concentration was determined with protein assay kits (BioRad, United States) using bovine serum albumin (BSA) as the standard. Samples were mixed with an equal volume of loading buffer (62.5 mM Tris-HCl, pH 6.8, 10% [v/v] glycerol, 2% SDS, 5% [v/v] 2-mercaptoethanol and 0.05% [w/v] bromophenol blue) and heated for 10 min at 95 °C. The mixture was subjected to SDS-PAGE and transferred electrophoretically to nitrocellulose membranes at a constant current of 70 V for 120 mins. Membranes were blocked with 5% (w/v) non-fat milk in PBS containing 0.1% (v/v) Tween 20 (PBST) for 1 h at room temperature. Membranes were reacted with primary antibodies at 37 °C for 1 h. Membranes were washed three times with PBST and HRP-conjugated secondary antibody (1:10,000 dilution) was added and incubated at 37 °C for 1 h to detect primary bound antibody. Reactive proteins were detected by enhanced chemiluminescence (T-Pro Biotechnology, Taiwan R.O.C.) and the density of specific immunoreactive bands was quantified by densitometric scanning.

## Antibodies

### Primary Antibodies

Anti-caspase 3, anti-caspase 9, anti-caspase 8, anti-PARP (Cell Signaling, Danvers, MA, United States), anti-mTOR (Spring Bioscience, Pleasanton, CA, United States), anti-phospho mTOR (Santa Cruz, Dallas, TX, United States), anti-Bcl-2, anti-Bax (Abcam, Cambridge, MA, United States), anti-p62, anti-Beclin-1, anti-light chain 3 (LC3) and anti-GAPDH (Novus Biologicals, Littleton, CO, United States).

### Secondary Antibodies

HRP-conjugated goat anti-mouse IgG (H + L) antibody and HRP-conjugated goat anti-rabbit IgG (H + L) antibody (Jackson ImmunoResearch Laboratories, United States).

## Statistical Analysis

All results are presented as the mean  $\pm$  the standard error of the mean (S.E.M.). Statistical analyses of differences were assessed by analysis of variance (ANOVA) for combined data and followed by the Student-Newman-Keuls test. The difference in the percentage incidence of VT, VF and mortality was analyzed with a  $\chi^2$  test.  $p < 0.05$  was considered to be statistically significant.

## RESULTS

### Hemodynamic Changes

The hemodynamic parameters did not significantly differ among the four experimental groups in the pre-ischemic period. Intravenous injection of paeonol did not change HR (Figure 1A) or mean BP (Figure 1B) in rats before and during myocardial I/R injury. No significant differences were recorded in LVSP,  $+dp/dt_{max}$  or  $-dp/dt_{max}$  values before the LAD ligation, amongst the sham, control and paeonol-treated groups. However, the administration of 1 mg/kg paeonol ameliorated the myocardial function of rats, as reflected by the increase in LVSP (Figure 1C) and  $\pm dp/dt_{max}$  (Figures 1D,E) during myocardial I/R injury and significantly increased  $+dp/dt_{max}$  (Figure 1D) after myocardial I/R injury.

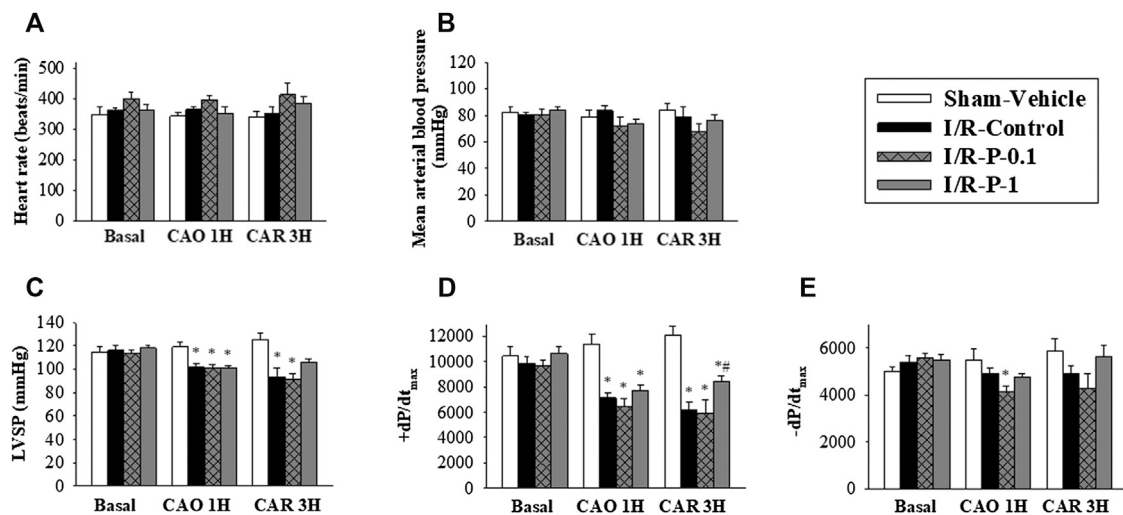

### Myocardial I/R Injury-Induced Rhythm Disturbances

The effects of paeonol on arrhythmias and mortality elicited by myocardial I/R injury in anesthetized rats are shown in **Supplementary Table S1**. Jugular vein injection of vehicle or paeonol had no induced VT and VF, and none of them died in sham-operated animals. In the control group, severe ventricular arrhythmias occurred at 6–7 mins and peaked at 8–12 mins after LAD ligation. Among the 12 rats in the control group, all animals (100%) exhibited VT ( $75.44 \pm 12.80$  s in duration) and 11 rats (92%) exhibited VF ( $134.36 \pm 27.66$  s in duration). Administration of paeonol at the dose of 1 mg/kg significantly decreased the incidence of VF (17%), as well as the duration of each (VT:  $13.33 \pm 6.06$  s; VF:  $2.00 \pm 1.60$  s). The mortality rate from myocardial I/R injury was significantly rescued from 50% to 0% in rats treated with paeonol 1 mg/kg.

### Myocardial Infarct Size and Myocardial Damage

The effects of paeonol on myocardial infarct size are shown in **Figures 2A–C**. There was no significant difference in the AAR between the control and paeonol-treated groups, indicating that in each group, a similar amount of tissue was at risk from myocardial ischemia (Figure 2B). In the control group, the infarct size was  $25.20 \pm 1.12\%$  of the AAR. Paeonol 1 mg/kg significantly rescued the infarct size to  $18.92 \pm 0.76\%$  of the AAR (Figure 2C).

Plasma LDH activity and Troponin-I levels were used as diagnostic biomarkers for acute myocardial infarction. The effects of paeonol on LDH activity and Troponin-I levels after myocardial I/R injury are shown in **Figures 2D,E**. Low LDH activity and Troponin-I levels in the plasma were recorded in the sham-operated animals, whereas both biomarkers were dramatically increased in the control group after myocardial I/R injury. Paeonol 1 mg/kg significantly reduced plasma LDH activity (Figure 2D) and Troponin-I levels (Figure 2E) compared with values in the control group during the same period. These results are consistent with the findings of myocardial infarction.

**FIGURE 1 |** Effect of paeonol on hemodynamic parameters in rats subjected to myocardial I/R injury. **(A)** heart rate, **(B)** mean arterial blood pressure, **(C)** left ventricular systolic pressure (LVSP) **(D)** maximum rates of pressure change in the LV (+dP/dt<sub>max</sub>) and **(E)** minimum rates of pressure change in the LV (-dP/dt<sub>max</sub>) were recorded by physiological parameters during myocardial I-R injury (Basal, pre-ischemic period; CAO1H, 1 h after LAD coronary arterial occlusion; CAR3H, 3 h after LAD coronary arterial reperfusion). Values are means ± S.E.M.; (n = 10–11 per group); \*p < 0.05 compared with the sham vehicle-treated group; #p < 0.05 compared with the I/R-control group.

## Apoptosis and Autophagy Protein Expression

Under the sham-operated non-I/R condition, Bcl-2, the cleaved forms of caspase-3, caspase-8, caspase-9 and PARP protein expression in the myocardium did not differ significantly between the groups. Myocardial I/R injury often leads to apoptosis of cardiomyocytes. In this study, we found that myocardial I/R injury significantly reduced the protein expression of Bcl-2 and the ratio of Bcl-2 to Bax, and significantly increased the cleaved forms of caspase-8, caspase-9, caspase-3 and PARP protein expression in the myocardium, compared with the sham-vehicle-treated group. Paeonol treatment significantly reversed changes in protein expression induced by myocardial I/R injury (**Figure 3**). These results indicate that paeonol attenuates apoptotic cell death in I/R-injured myocardium.

We also investigated the role of autophagy in the cardioprotective effects of paeonol in rats subjected to myocardial I/R injury (**Figure 4**). We found that myocardial I/R injury significantly increased the levels of Beclin-1, p62, LC3-I and LC3-II protein expression in the myocardium in the control group compared with the sham-vehicle-treated group. Paeonol treatment significantly reversed the changes in protein expression induced by myocardial I/R injury. This suggests that paeonol reduced autophagy in the myocardium after I/R injury.

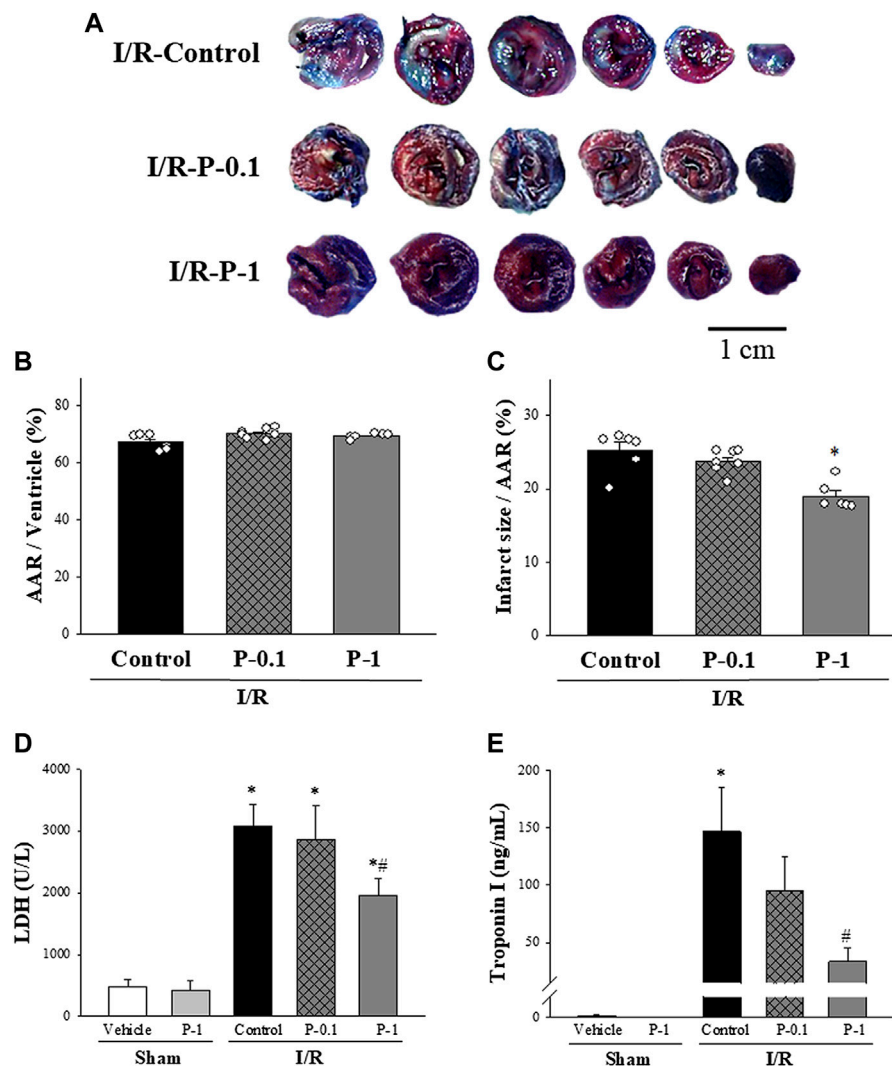

The autophagy induction pathway of Beclin-1 is considered harmful during myocardial I/R injury (Ma et al., 2015). In this study, we found that myocardial I/R injury significantly decreased the ratio of Bcl-2 to Beclin-1 protein expression and significantly increased the ratio of cleaved form of caspase-3 to Beclin-1 protein expression in the control group compared with the sham-vehicle-treated group. Paeonol treatment reversed the

protein expression ratio changes induced by myocardial I/R injury. We found that paeonol significantly increased the ratio of Bcl-2 to Beclin-1 protein expression, but without changing the ratio of cleaved-caspase 8 and cleaved-caspase 3 to Beclin-1 protein expression after myocardial I/R injury compared with the control group (**Figure 5**). Finally, paeonol significantly decreased the expression of Beclin-1 protein in the myocardium in the paeonol-treated group compared with the control group.

## DISCUSSION

In this study, we provide evidence showing that paeonol protects the heart against myocardial I/R injury by improving cardiac function, reducing myocardial extrinsic and intrinsic apoptosis and attenuating autophagy.

Paeonol is a major phenolic compound of Moutan *Cortex Radicis* that is widely used as a nutrient supplement and in traditional Chinese medicine to regulate human disorders by removing blood stasis, promoting blood flow, attenuating inflammatory responses, relieving pain and eliminating heat (Fu et al., 2012). Yang et al. reported that paeonol improves blood hemorrheology, reduces oxidative injury and repairs endothelial function, and acts as an effective cardioprotective agent in a rabbit model of myocardial ischemia induced by intravenous administration of pituitrin (Yang et al., 2010). Our results suggest that administration of paeonol 1 mg/kg significantly suppressed the incidence of VF, shortened the durations of VT and VF, and completely prevented mortality during myocardial I/R injury. In addition, pretreatment with paeonol significantly reduced cardiac infarction size and protected against cardiomyocyte injury, as indicated by the

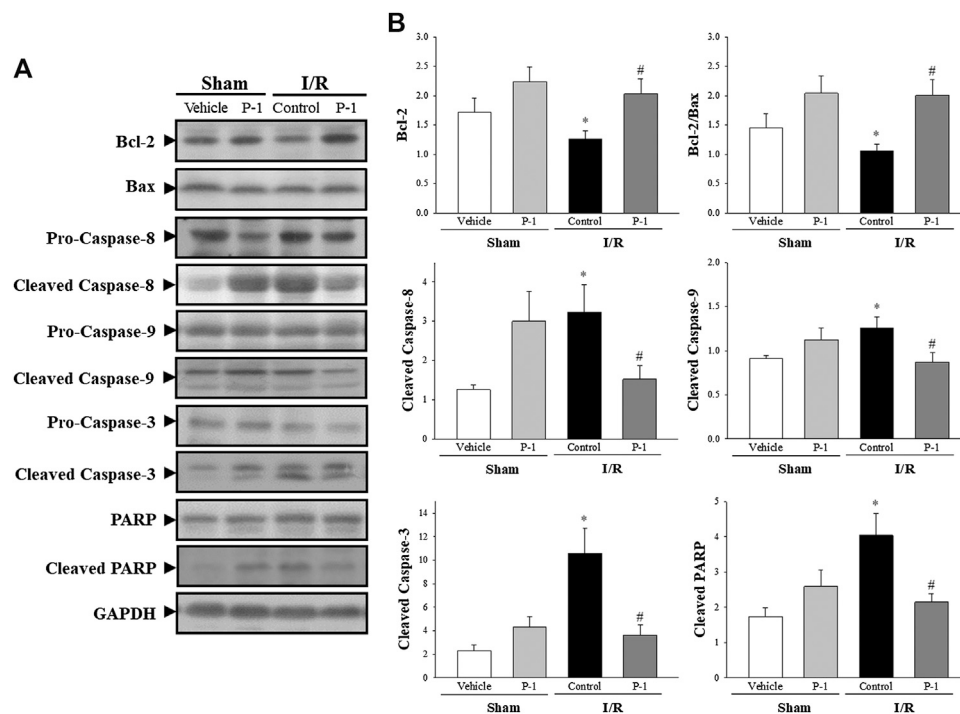

**FIGURE 2 |** Effect of paeonol on I/R induced myocardial damage in rats. **(A)** Representative Evans blue/TTC staining of heart sections from the control group and different paeonol dose groups (0.1 and 1 mg/kg) after 1 h of ischemia and 3 h of reperfusion. The perfused area is seen in blue; the area at risk (AAR) is seen in red and white. Infarction is seen in white. Quantitative analysis of the AAR/Ventricle % (ratio of non-blue area to total area) **(B)**, and the risk zone infarcted % (ratio of white area to AAR) **(C)** in control and paeonol-treated rats, plasma lactate dehydrogenase (LDH) activity **(D)**, and plasma Troponin-I levels **(E)** in the sham-operated and I/R-operated groups. The results are shown as means  $\pm$  S.E.M. ( $n = 10-11$  per group); \* $p < 0.05$  compared with the sham vehicle-treated group; # $p < 0.05$  compared with the I/R-control group.

decreasing carotid blood Troponin-I levels and LDH activity, which serve as indicators of cellular damage, in rats subjected to cardiac ischemia for 1 h and reperfusion for 3 h. Our results indicate that paeonol is a potent cardioprotective agent in rats with myocardial I/R injury.

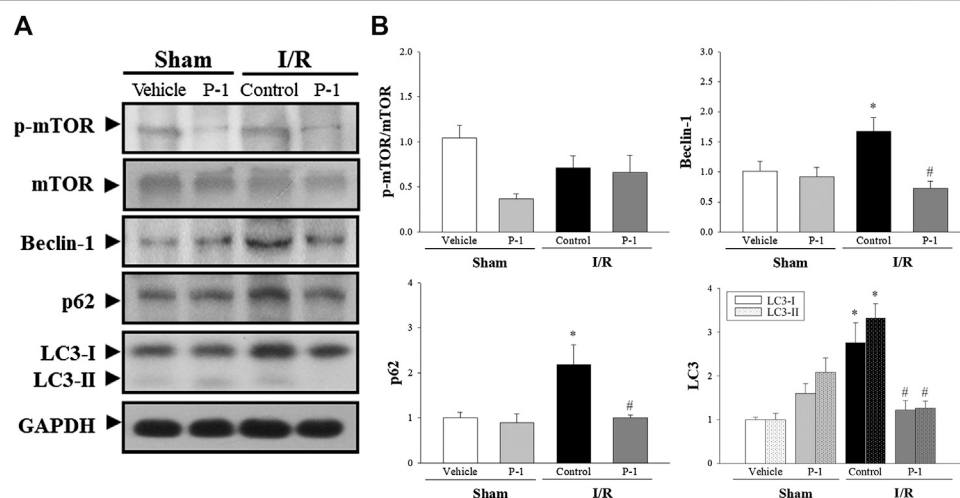

Among the many underlying mechanisms of myocardial I/R injury, apoptosis is one of the most important (Xia et al., 2016). Apoptosis is a form of programmed cell death that is positively and negatively regulated by the Bcl-2 family, which includes both pro- and antiapoptotic proteins. The ratio of proapoptotic to antiapoptotic molecules helps determine the susceptibility of cells to a death signal (Gross et al., 1999). In this study, we found

that compared with vehicle treatment, paeonol significantly increased the ratio of Bcl-2 to Bax in the myocardium after ischemia for 1 h and reperfusion for 3 h. Much evidence suggests that suppressing apoptosis may protect the heart against myocardial I/R injury (Wang et al., 2015; Wu et al., 2015). We found that paeonol treatment significantly reduced the protein expression levels of cleaved forms of caspase-8, caspase-9, caspase 3 and PARP, when compared with vehicle treatment. These results illustrate that paeonol upregulates Bcl-2 levels and suppresses apoptosis to protect the heart from I/R injury in rats through inhibition of both intrinsic and extrinsic apoptotic pathways.

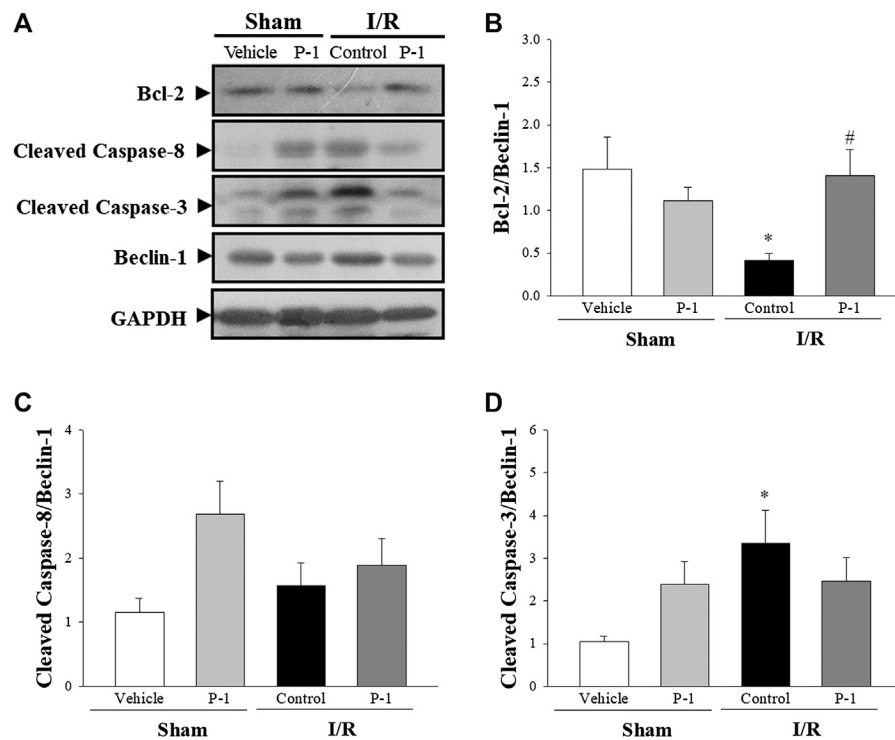

**FIGURE 3 |** Paeonol decreased apoptosis after myocardial I/R injury. **(A)** Representative images of Western blot results in heart tissue. **(B)** Graphs represent the quantitative differences between vehicle- and paeonol-treated groups in sham- and myocardial I/R-operated animals. GAPDH was used as a loading control for the blots. Data are normalized with the mean expression from the sham vehicle-treated group. \* $p < 0.05$  compared with the sham vehicle-treated group; # $p < 0.05$  compared with the I/R-control group. Values are expressed as means  $\pm$  S.E.M. ( $n = 6$ ).

**FIGURE 4 |** Paeonol decreased autophagy after myocardial I/R injury. **(A)** Representative Western blot images show the expression levels of *p*-mTOR, mTOR, Beclin-1, p62, LC3-I, LC3-II and GAPDH in heart tissue. **(B)** Graphs represent the quantitative differences between vehicle and paeonol-treated groups in sham and myocardial I/R-operated animals. GAPDH was used as a loading control for the blots. Data are normalized with the mean expression from the sham vehicle-treated group. \* $p < 0.05$  compared with the sham-vehicle group; # $p < 0.05$  compared with the I/R-control group. Values are expressed as mean  $\pm$  S.E.M. ( $n = 6$ ).

Besides apoptosis, autophagy may also contribute to myocardial I/R injury (Matsui et al., 2007). Evidence indicates that autophagy plays dual roles in myocardial I/R injury; at low

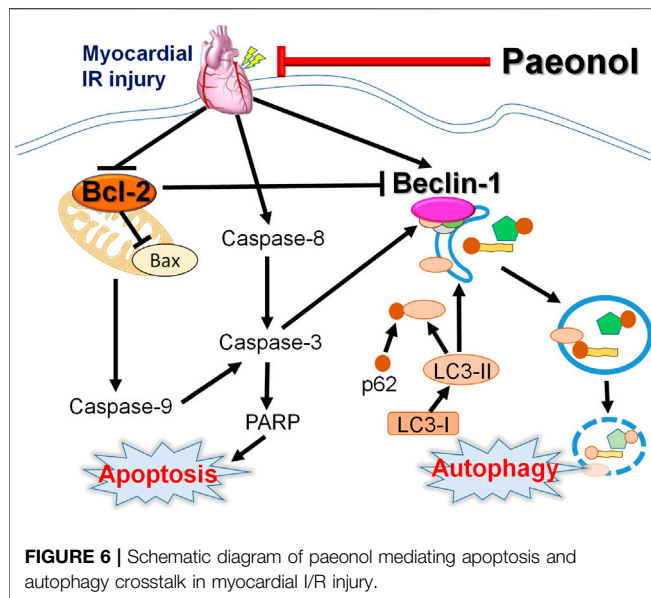

levels, autophagy is protective, by degrading damaged mitochondria and protein aggregates, whereas excessive autophagy such as during myocardial I/R may be deleterious

**FIGURE 5 |** Effect of paeonol on crosstalk between apoptosis and autophagy after myocardial I/R injury in rats. **(A)** Representative images of the Western blots results in heart tissue. Graphs represent the quantitative differences of **(B)** the ratio of Bcl-2 to Beclin-1 **(C)** the ratio of cleaved caspase-8 to Beclin-1 **(D)** the ratio of cleaved caspase-3 to Beclin-1 between vehicle and paeonol-treated groups in sham- and myocardial I/R-operated animals. GAPDH was used as a loading control for the blots. Data are normalized with the mean expression from the sham-vehicle-treated group. \* $p < 0.05$  compared with the sham-vehicle group; # $p < 0.05$  compared with the I/R-control group. for cardiac function, due to overwhelming degradation of essential proteins and organelles (Li M. et al., 2016; Wang et al., 2017). It is known that Beclin-1-dependent autophagy mediates autophagic cell death during myocardial I/R injury (Peng et al., 2013). Beclin-1 is a key autophagic protein that plays a vital role in autophagy in myocardial I/R and therefore serves as a marker for autophagy. Elevated Beclin-1 protein expression induces high levels of autophagy, while inhibition of Beclin-1 protein expression correlates with decreased autophagy and reduced cardiac myocyte death induced by myocardial I/R injury (Matsui et al., 2007). In our studies, we found that paeonol significantly decreased Beclin-1 expression in the occluded zone of rats subjected to myocardial I/R injury. In addition to inhibiting Beclin-1 expression, paeonol also attenuated myocardial I/R injury by dramatically reducing p62, LC3-I and LC3-II expression. Both LC3 and p62 are routinely used as biomarkers to monitor autophagic levels. During autophagy initiation, cytosolic-associated protein LC3-I is converted to the membrane-bound LC3-II form and then binds to the adaptor protein p62, facilitating the autophagic degradation of ubiquitinated protein aggregates in autolysosomes (Aghaei et al., 2019). Our results suggest that paeonol decreases autophagic cell death during myocardial I/R injury.

In this study, we focused on investigating the underlying mechanisms through which the crosstalk between apoptosis and autophagy was involved in the cardioprotective effect of paeonol on rats subjected to myocardial I/R injury. Both apoptosis and autophagy are two highly regulated biological processes with complex protein networks that play a vital role in tissue homeostasis, development, and disease. Autophagy is inhibited downstream of apoptosis induction due to Beclin-1 cleavage by caspases, most prominently caspase-3 (Fairlie et al., 2020). Recent evidence indicates that active caspase-8, a death receptor effector, can be degraded by autophagy, suggesting the existence of a feedback mechanism that cross-regulates autophagy and apoptosis (Hou et al., 2010). However, we found that paeonol did not affect the ratios of cleaved-caspase 8 and cleaved-caspase 3 to Beclin-1 protein expression after myocardial I/R injury compared with those ratios in the control group. It also appears that several inducers of apoptosis, such as p53 and Bcl-2, can activate autophagy. Phosphorylation of p53 is known to inhibit the activity of mTOR through AMPK activation (Mendieta et al., 2019). In this study, we found that paeonol treatment did not change the protein expression of mTOR in rats after myocardial I/R injury, which means that p53 phosphorylation is not involved in the cardioprotective effects of paeonol. Mitochondria-associated

proteins are responsible for interactions between autophagy and apoptosis. Bcl-2 is an anti-apoptotic protein that interferes with Beclin-1 at the mitochondrial outer membrane, resulting in dual regulation of apoptosis and autophagy. In this study, we found that paeonol (1 mM) significantly increased cell viability against OGD/R insult in H9c2 cells, and the protective effect is reversed by Bcl-2-selective inhibitor ABT199 (**Supplementary Figure S2**). The specific Bcl-2 inhibitor, ABT199, is a selective small-molecule B-cell lymphoma 2 Homology 3 (BH3) mimetic, has been shown to disrupt the BH3 dependent Bcl-2/Beclin-1 interaction, thereby induce apoptosis and autophagy (Chiang et al., 2018; Folkerts et al., 2019). Therefore, we suggest that the cardioprotective effects of paeonol against I/R injury may mediated by Bcl-2/Beclin-1 interaction. It is generally believed that Beclin-1-mediated autophagy is not only regulated by its own expression, but is also promoted by the binding of Beclin-1 and Bcl-2 (Marquez and Xu, 2012). Previous studies have shown that the balance between Bcl-2 and Beclin-1 protein expression affects the levels of autophagy (Yi et al., 2020). We therefore explored the association between Bcl-2 and Beclin-1 protein expression in the crosstalk between apoptosis and autophagy in rat heart after I/R injury. Our data verified that compared with vehicle treatment, treatment with paeonol significantly upregulates the expression of Bcl-2 and downregulates the expression of Beclin-1, increasing the ratio of Bcl-2 to Beclin-1 in the I/R-injured myocardium. Upregulation of Bcl-2 and downregulation of Bax, Beclin-1, LC3, and p62 following paeonol treatment suggests that crosstalk exists between apoptosis and autophagy processes during myocardial I/R. Thus, the cardioprotective effects of paeonol against I/R injury may involve upregulation of Bcl-2 that inhibits apoptosis and prevents autophagic cell death.

## CONCLUSION

Our results provide valuable insights into the signaling pathways involved in programmed cell death, including crosstalk between apoptosis and autophagy, in paeonol-induced amelioration of myocardial I/R injury in rats (**Figure 6**). Paeonol shows potential as a preventive treatment for ischemic heart diseases or post-coronary revascularization.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by The Institutional Animal Care and Use Committee of Chung Shan Medical University.

## AUTHOR CONTRIBUTIONS

C-FT and S-SH designed research and provided funding. K-MC, H-HS, J-ML, Y-TY, Y-HW, Y-HC, MW, Y-CC, and S-SH completed animal experiments, conducted molecular biology experiments and analyzed data. C-FT, Y-CC, Y-HW, and S-SH wrote the paper. All authors read and approved the final manuscript.

## FUNDING

This work was supported financially by research grants from Chung Shan Medical University Hospital (CSH-2017-C-021 and CSH-2018-C-031), and the Ministry of Science and Technology (MOST 107-2320-B-040-025) of Taiwan to C-FT and S-SH.

## ACKNOWLEDGMENTS

We would like to thank Iona J. MacDonald from China Medical University for her English language revision of this manuscript.

Hepatic fibrosis (HF) represents the excessive wound healing where an excess amount of connective tissues is formed within the liver, finally resulting in cirrhosis or even hepatocellular carcinoma (HCC). Therefore, it is significant to discover the efficient agents and components to treat HF, thus restraining the further progression of hepatopathy. *Astragalus membranaceus* (Fisch.) Bunge [also called *Astragali Radix* (AR)] is a famous herb in traditional Chinese medicine (TCM), which possesses a variety of biological activities and exerts good therapeutic effects in the treatment of HF. Flavonoids account for the major active ingredients related to the AR pharmacological effects. Total AR flavonoids have been proved to exert inhibitory effects on hepatic fibrosis. This study aimed to further undertake network pharmacology analysis coupled with experimental validation and molecular docking to investigate the effects and mechanism of multiple flavonoid components from AR against liver fibrosis. The results of the network pharmacology analysis showed that the flavonoids from AR exerted their pharmacological effects against liver fibrosis by modulating multiple targets and pathways. The experimental validation data showed that the flavonoids from AR were able to suppress transforming growth factor beta 1 (TGF- $\beta$ 1)-mediated activation of hepatic stellate cells (HSCs) and reduce extracellular matrix deposition in HSC-T6 cells via regulating the nuclear factor kappa B (NF- $\kappa$ B) signal transduction pathway. The results of the molecular docking study further showed that the flavonoids had a strong binding affinity for I $\kappa$ B kinase (IKK $\beta$ ) after docking into the crystal structure. The above results indicated that, flavonoids possibly exerted the anti-inflammatory effect on treating HF by mediating inflammatory signaling pathways. The potential mechanism of these flavonoids against liver fibrosis may be related to suppression of the NF- $\kappa$ B pathway through effective inhibition of IKK $\beta$ . This study not only provides a scientific basis for clarifying the effects and mechanism of AR flavonoids against liver fibrosis but also suggests a novel promising therapeutic strategy for the treatment of liver fibrosis.

**Keywords:** flavonoids, *Astragalus membranaceus* (fisch) bunge, liver fibrosis, anti-inflammation, network pharmacology

## INTRODUCTION

Hepatic fibrosis (HF) is a pathological event where connective tissues abnormally proliferate in liver, which is associated with a variety of factors, causing excess extracellular matrix (ECM) deposition within liver (Trautwein et al., 2015). When there is acute injury, liver can recover the structural integrity of liver, in the meantime of sustaining the unfavorable chronic injury-derived stimuli, resulting in liver parenchymal distortion (Parola and Pinzani, 2019). For HF, its pathogenic mechanisms are chronic virus infection, nonalcoholic steatohepatitis (NASH), alcoholic liver disease (ALD), together with toxin-related stimuli (such as drugs and alcohol), autoimmune hepatitis, hereditary metabolic disease and cholestatic diseases (Fan et al., 2019). Such injury to liver parenchyma will activate the hepatic stellate cells (HSCs), the cells responsible for storing vitamin A and are involved in HF occurrence (Huang et al., 2017). Upon activation, HSCs gradually transform into myofibroblasts, a heterogeneous cell population with proliferating, migrating, and fibrotic characteristics. This transformation causes a continuous accumulation of alpha smooth muscle actin ( $\alpha$ -SMA), ECM, and a large amount of type I and type III collagen, leading to scar deposition (Parola and Pinzani, 2019). In addition, HSCs can produce the transforming growth factor beta 1 (TGF- $\beta$ 1) to induce a fibrotic response, as well as the subsequent connective tissue proliferation (Xu et al., 2020). Cirrhosis is the end-stage disease of HF, and it stands for a major reason for the morbidity and mortality in the world (Scaglione et al., 2015). At present, liver transplantation (LT) remains the unique effective way to treat cirrhosis patients; as a result, it is significant to discover the efficient agents and components to treat HF, thus restraining the further progression of hepatopathy and preventing death. HF or even the early cirrhosis, is suggested to be reversible (Friedman et al., 2000). Certain herbs in the traditional Chinese medicine (TCM) are utilized in clinical treatments for a long history due to the efficient therapeutic effect and usability, particularly in treating hepatopathy (Xie et al., 2013). As a result, applying TCM herbs may serve as the efficient way to prevent and treat HF.

*Astragalus membranaceus* (Fisch.) Bunge is also called *Astragali Radix* (AR), and it accounts for an extensively used TCM herb in China, with a usage history of more than 2,000 years. Traditionally, AR is frequently applied to treat various diseases, including weakness, anemia, fever, chronic fatigue, wounds, loss of appetite, multiple allergies, and uterine bleeding (Guo et al., 2019). For these bioactive functions, AR has been widely used as a kind of health food additive supplemented in various drinks or in additional food forms for the effective body immunity reinforcement (Bai et al., 2018). Modern pharmacological experiments have indicated that AR has different biological activities, like antioxidation, immunomodulation, anticancer and anti-inflammation, which has been extensively utilized in treating nephritis, diabetes and cancers (Xu et al., 2006; Guo et al., 2019). AR has also been recognized to significantly protect from injuries to intestine, heart, liver, lung, kidney, and brain (Shahzad et al., 2016). Beyond that, AR is commonly used in Chinese herb

prescription to treat HF in Chinese clinical practice (Ding et al., 2011; Xu et al., 2015). Modern pharmacological studies has also confirmed that AR can effectively suppress HF (Liang and Yuan, 2013; Zhou et al., 2016; Wang et al., 2019). So far, over 200 components are separated in AR. Typically, flavonoids represent the leading ingredients related to the efficacy and pharmacological effects (Guo et al., 2019). The total flavonoids from AR have been proved to exert inhibitory effects on HF (Liu et al., 2005; Li et al., 2019). However, the specific AR flavonoid components responsible for inhibition on HF, as well as the precise molecular mechanisms, are not completely understood.

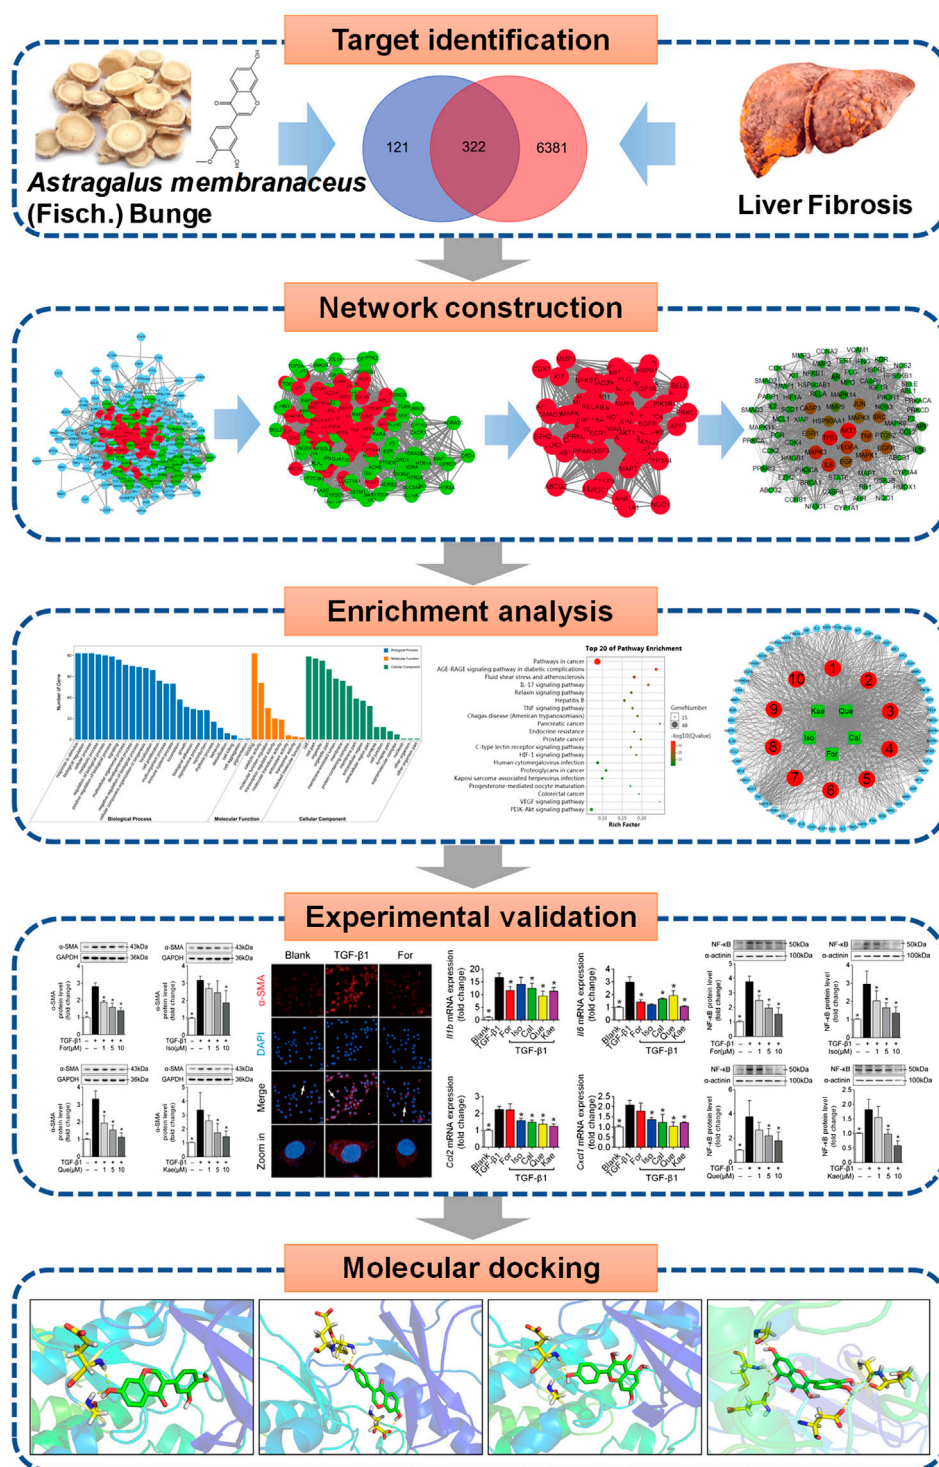

TCM herbs are the effective herbal medicines adopted for treating a variety of disorders, which exert pivotal parts in healthcare in the history of China or even numerous other countries. However, it is difficult to elucidate the effects of TCMs because of their multiple targets, multiple pathways, and multiple mechanisms of action. The above features have severely restricted the internationalization and modernization of herbal medicines (Gan et al., 2019). Recently, network pharmacology has been developed to be the effective approach for observing the interactions and impacts of different drugs on disease network (Li and Zhang, 2013; Hao and Xiao, 2014). It integrates chemoinformatics, bioinformatics, network biology, network analysis, and traditional pharmacology (Berger and Iyengar, 2009). Therefore, network pharmacology provides a novel and effective tool that can combine the TCM target database in a variety of disorders and verify at molecular level, thus providing evidence regarding the molecular targets as well as possible underlying mechanisms of herbal medicines (Gan et al., 2019).

Therefore, the present work applied network pharmacology in combination with experimental validation for clarifying the activities and possible mechanisms of flavonoids derived from AR to treat HF (**Figure 1**). The main objectives of the present study were 1) to screen the active flavonoid compounds of AR, to predict the potential targets of these flavonoids against liver fibrosis, and to analyze the potential mechanism of the flavonoids against liver fibrosis by using network pharmacology; 2) to employ TGF- $\beta$ 1 to stimulate HSC transdifferentiation into myofibroblasts to investigate the antifibrotic activity of the flavonoids; 3) to elucidate the potential influence of the flavonoids on HSC activation from the aspect of the inflammatory signaling pathway; and 4) to study the binding ability between flavonoids and key target genes by using molecular docking. Our results may help to understand the mechanisms of AR against liver fibrosis and suggest a novel promising therapeutic strategy for its treatment.

## MATERIALS AND METHODS

### Screening for Active Flavonoid Compounds in AR

According to ADME (absorption, distribution, metabolism, excretion) parameters (Xu et al., 2012), the active flavonoid compounds of AR were screened by searching the Traditional Chinese Medicine Systems Pharmacology

**FIGURE 1** | Flowchart showing the systems pharmacology approach for determining the pharmacological effects and mechanism of *Astragalus Radix* (AR) in the treatment of liver fibrosis by integrating target identification, network construction, enrichment analysis, experimental validation and a molecular docking study.

(TCMSP, <https://tcmispw.com/tcmispsearch.php>) (Ru et al., 2014), the Encyclopedia of Traditional Chinese Medicine (ETCM, <http://www.ehbio.com/ETCM/>), and the Integrative Pharmacology-based Research Platform of Traditional

Chinese Medicine (TCMIP, <http://www.tcmip.cn>) databases (Xu et al., 2019). Oral bioavailability (OB) > 30%, along with drug similarity (DL) > 0.18, was used for screening (Li et al., 2015).

## Prediction of the Targets of the Active Ingredients in AR

The target prediction for the main active compounds was performed by searching the TCMSP (Ru et al., 2014), PubChem (<https://pubchem.ncbi.nlm.nih.gov/>) (Zhu et al., 2019), STITCH (<http://stitch.embl.de/>) (Zhu et al., 2019), SuperPred (<http://prediction.charite.de/>) (Nickel et al., 2014) and Swiss Target Prediction (<http://www.swisstargetprediction.ch/>) (Gan et al., 2019) databases with the “*Homo sapiens*” species setting. All targets were combined and identified using the UniProt database (<https://www.uniprot.org/>) (Gan et al., 2019). Duplicates of the validated and predicted targets were eliminated, and the targets of the active ingredients were screened. Finally, a visual compound-target network was established with Cytoscape v3.7.2, the open-source software utilized to visualize the complicated networks and integrate all attribute data (Shannon et al., 2003).

## Screening of Potential Targets for Liver Fibrosis

The GeneCards (<https://www.gene-cards.org/>) (Safran et al., 2003) and DisGeNET (<http://www.disgenet.org/web/DisGeNET/menu/home>) (Ren et al., 2019) databases were searched with the keywords “HF” or “liver fibrosis” to identify targets related to HF.

## Network Construction

The common targets of the flavonoid ingredients and liver fibrosis were collected. The STRING database (<https://string-db.org/>) was utilized to construct the measurable targets of the protein-protein interaction (PPI) network for those main components to treat HF (Szklarczyk et al., 2015). Additionally, Cytoscape was adopted for visualizing and integrating those topological parameters in PPI network regarding the main components to treat HF. The key biological targets were acquired based on the Cytoscape degree.

## Enrichment Analysis

OmicShare tools (<http://www.omicshare.com/tools>), the freely accessible online platform to analyze data, was utilized for Gene Ontology (GO) as well as Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis for the key targets. GO annotation was classified into three distinct categories, namely, biological process (BP), cell component (CC), and molecular function (MF), and such method was adopted for identifying those potential mechanisms based on the high-throughput transcriptome and genome data (Ashburner et al., 2000). In addition, the KEGG database (<https://www.kegg.jp/>) was used to identify the systematic functions and biological relevance of candidate targets (Chen et al., 2015). In the current study, the top 20 enriched KEGG pathways were displayed, and only terms with an FDR < 0.05 were selected for analysis. Finally, according to results of KEGG analysis, Cytoscape v3.7.2 was applied in constructing a compound-target-pathway network. The characteristics of multiple components, multiple targets and

multiple pathways of the active ingredients against liver fibrosis were revealed through the construction of a network.

## Chemicals and Reagents

Formononetin (For, A0232), isorhamnetin (Iso, A0514), kaempferol (Kae, A0129), calycosin (Cal, A0190), and quercetin (Que, A0083) (purity ≥ 98%) were provided by Chengdu Must Biotechnology Co., Ltd. (Chengdu, China), which were mixed with dimethyl sulfoxide (DMSO, 0.1%, v/v; Sigma, St. Louis, MO, United States). In the meantime, the HEK293-derived recombinant human TGF-β1 (100-21) was purchased from PeproTech (New Jersey, United States). The anti-α-SMA (14395-1-AP) and anti-GAPDH (6004-1-Ig) antibodies, together with the HRP-labeled AffiniPure goat anti-mouse IgG antibody (H + L) (SA00001-1), were provided by Proteintech (Wuhan, China). The HRP-labeled goat anti-rabbit IgG antibody (H + L) (BS13278) was provided by Bioworld Technology (St. Paul, MN, United States). The Alexa fluor 568-conjugated goat anti-rabbit IgG (H + L) antibody was purchased from Abcam (Cambridge, MA, United States). The enhanced BCA protein assay kit (P0010), RIPA lysis buffer (P0013) and DAPI staining solution (C1005) were provided by Beyotime Institute of Biotechnology (Shanghai, China).

## Cell Culture and Treatment

HSC-T6, a rat HSC line, was kindly presented by Zhejiang Cancer Hospital (Zhejiang, China) and cultured in DMEM (Thermo Fisher Scientific, MA, United States) containing 10% fetal bovine serum (FBS, Thermo Fisher Scientific, MA, United States), 100 µg/ml streptomycin and 100 U/ml penicillin. Afterward, cells were subjected to incubation under 37°C and 5% CO<sub>2</sub> conditions. When cells reached confluence, PBS was used to wash cells for two times and the serum-free medium was used for further cell culture prior to subsequent experiment.

## Cell Viability Assay

Cellular viability was detected with a CCK-8 assay kit (GLPBIO, California, United States). The HSC-T6 cell line was planted into the 96-well culture plate, followed by 24 h of exposure to various doses of For, Iso, Cal, Que and Kae (0.1–200 µM). Thereafter, 10 µl CCK-8 solution was placed into all wells to incubate for 1 h, and the microplate reader (Thermo Varioskan LUX, MA, United States) was used to measure the absorbance (OD) value at 450 nm.

## Quantitative Real-Time Polymerase Chain Reaction (RT-qPCR)

The total pulmonary or cellular RNA was extracted using the TRIzol reagent (Accurate Biotechnology, Human, China) in accordance with specific instructions. Then, 1 ng RNA was used to synthesize cDNA via the *Evo M-MLV* RT Kit as well as the gDNA Clean to carry out RT-qPCR (Accurate Biotechnology, Human, China). We performed RT-qPCR for each cDNA sample in triplicate using the SYBR Green Premix *Pro Taq* HS qPCR kit (Accurate Biotechnology, Human, China) and gene-specific primer pairs for *Gapdh*, *Acta2*, *Fn1*, *Col1a1*, *Col3a1*,

*Rela*, *Jun*, *Il1 $\beta$* , *Il6*, *Tnfa*, *Ifng*, *Ccl2*, *Cxcl2*, *Cox2*, *Mmp1*, *Mmp2*, and *Mmp9* (Table 1). A QuantStudio 5 Real-Time PCR instrument (Thermo Fisher Scientific, MA, United States) was applied in PCR amplification under the conditions below: 30 s of enzyme activation under 95°C, 5 s of denaturation under 95°C, followed by 40 cycles of 30 s of annealing and extending under 60°C. In this study, those semi-quantitative RT-qPCR data of every target gene were expressed as  $2^{-\Delta\Delta C_t}$  relative expression compared with endogenous GAPDH, and the error bar represented standard error of the mean (SEM) from three independent experiments.

## Western Blot Analysis

Cell lysates were produced within the RIPA buffer that contained the fresh phosphatase and protease inhibitors. Following 15 min of centrifugation at 13,000 rpm and 4°C, we collected supernatants to a new tube, followed by boiling within the 1% SDS loading buffer for obtaining samples. Afterward, the resultant samples were added onto the 10% SDS-PAGE, and the protein were transferred onto the NC membranes, followed by 2 h of incubation with 5% nonfat skim milk (FUJIFILM Wako Pure Chemical Corporation, Fuji, Japan) supplemented within the Tris-buffered saline that contained 0.1% Tween. Later, the

membranes were incubated with anti- $\alpha$ -SMA and anti-p50 antibodies (1:800) overnight, washed, and further incubated by the HRP-labeled anti-rabbit or anti-mouse IgG secondary antibodies (1:10,000). ECL-enhanced chemiluminescence (Yeasen, Shanghai, China) was used to develop bands, whereas Image-ProPlus 6.0 (Rockville, MD, United States) was utilized for visualization.

## Immunofluorescence Assay

The HSC-T6 cell line was exposed to 10 ng/ml TGF- $\beta$ 1 for 24 h in the presence or absence of 10  $\mu$ M diverse compounds. Thereafter, all cells were rinsed by the cold PBS, followed by 20 min of 4% paraformaldehyde fixation. Later, 0.2% Triton X 100 was used to permeabilize cells, followed by 5% BSA incubation for blocking the nonspecific staining as well as incubation using  $\alpha$ -SMA antibody staining under 4°C overnight within the humid chamber. Then, cells were rinsed repeatedly before further 1 h of incubation using Alexa fluor 568-conjugated goat anti-rabbit IgG (H + L) antibody (1:200) under 37°C. Finally, PBS was used to rinse cells for two times, followed by 15 min of incubation with DAPI under 37°C. Images were viewed by confocal scanning microscopy (Leica TCS SP8, Leica, Germany) at an excitation wavelength of 568 nm.

## Molecular Docking

Nuclear factor kappa B (NF- $\kappa$ B) proteins are a crucial family of transcription factors in the signal transduction cascade of inflammatory signaling (Hoesel and Schmid, 2013). NF- $\kappa$ B activation is determined by I $\kappa$ B kinase (IKK $\beta$ )-mediated I $\kappa$ B $\alpha$  phosphorylation, as well as the later p50-p65 subunit nuclear translocation of NF- $\kappa$ B, finally inducing the expression of pro-inflammatory cytokines (Hoesel and Schmid, 2013). Therefore, the IKK $\beta$  selective inhibitor might be used as the candidate drug to resist inflammation. Accordingly, to further analyze the way in which the flavonoids of AR inhibit the inflammatory NF- $\kappa$ B pathway, the interactions between the flavonoids and IKK $\beta$  were further measured by AutoDock Vina software. The X-ray crystallographic structure of IKK $\beta$  was retrieved from the Protein Data Bank (PDB ID: 3RZF) (Xu et al., 2011). The 3D structures of the AR flavonoids taken as ligands were retrieved from the PubChem database. The grid box for IKK $\beta$  used centers of 92.23, -25.49, and 53.01 Å with corresponding sizes of 60, 60, and 60 (x, y, and z positions, respectively) for comprising each amino acid residue of the protein simulated. The other detailed docking procedures were performed as previously described (Ruan et al., 2020). After docking, the flavonoid ligands with the lowest affinity score for the receptor IKK $\beta$  were selected for further analysis. All the structure-based features were visualized by using PyMOL software.

## Data Analysis

Values were presented in the manner of mean  $\pm$  SD from three independent replicates. GraphPad Prism 7.0 (San Diego, CA, United States) was used for all statistical analyses. Significant differences were analyzed by single-factor ANOVA and two-tailed Student's *t*-test between the samples and their respective

**FIGURE 2 |** Screening for active flavonoid compounds in AR and their targets. **(A)** Molecular formulas of the five flavonoids, including For, Iso, Cal, Que, and Kae. **(B)** Compound target network (C-T network). controls. Differences were considered statistically significant at  $p$ -values of  $<0.05$ .

## RESULTS

### Active AR Flavonoid Compounds

A total of 87 reported active ingredients of AR were retrieved by searching the TCMSP database. A total of 27 reported active ingredients of AR were retrieved by searching the ETCM and TCMIP databases. In this study, we mainly focused on the active flavonoid compounds, and in line with the  $OB \geq 30\%$  and  $DL \geq 0.18$  thresholds, five active flavonoids were selected: For, Iso, Cal, Que, and Kae (Figure 2A; Supplementary Table S1). These five flavonoids were used for the subsequent network pharmacology analysis and experimental validation.

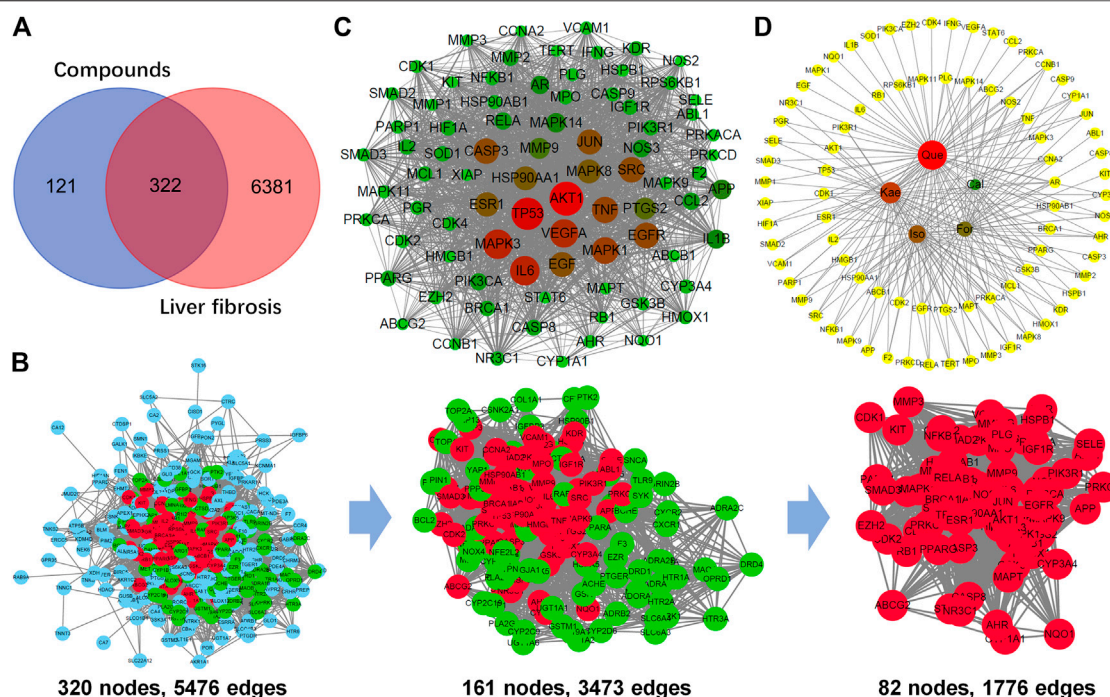

### Target Prediction and Analysis

In this process, we conducted target fishing on the five flavonoids based on the TCMSP, PubChem, STITCH, SuperPred and Swiss Target Prediction databases, obtaining 443 related targets, among which there were 141 for Cal, 144 for Iso, 167 for For, 212 for Kae and 315 for Que (Figure 2B). All of these targets were combined

and identified using the UniProt database. By searching the GeneCards and DisGeNET databases for related research reports, 6,703 targets were obtained, which are closely related to the occurrence and development of “HF” or “liver fibrosis.” Three hundred and twenty-two targets that matched the related targets of the five flavonoids and HF were then collected as the potential targets of the five flavonoids against HF (Figure 3A). Then, the PPI network of those 322 targets was established in the database String. There were 320 nodes and 5,476 edges in total.

Afterward, the topological feature analysis of the PPI network was conducted with the Cytoscape software platform based on three major parameters: degree, betweenness, and closeness. Those targets greater than the median were chosen to be key targets, then, hub nodes were established from those five anti-HF flavonoids. In the initial screening, the thresholds were set at degree  $\geq 28$ , betweenness  $\geq 0.00115124$ , and closeness  $\geq 0.47399703$ . At last, 3,473 edges and 161 hub nodes were screened. Thereafter, those 161 key targets were subjected to secondary screening, at the thresholds of degree  $\geq 43$ , betweenness  $\geq 0.00312659$ , and closeness  $\geq 0.51203852$ . The second screening ended with 82 large hub nodes and 1,776 edges (Figure 3B). Then, Cytoscape was adopted for visualizing and integrating those PPI network-involved

**FIGURE 3 |** Analysis of the key targets of the flavonoids for the treatment of liver fibrosis. **(A)** Venn diagram summarizing the differential targets of the flavonoids and liver fibrosis. **(B)** The process of topological screening for the protein-protein interaction (PPI) network. Finally, 82 candidate targets were predicted. **(C)** The PPI network of the 82 nodes. Different colors represent nodes of different sizes. The red nodes represent the large hub nodes and the green nodes represent the small hub nodes. The node size is proportional to the target degree in the network. **(D)** Compound target network (C-T network) of the flavonoids and 82 key targets.

topological parameters for those 82 screened key targets. The crucial biotargets were obtained and visualized, which included AKT1, TP53, MAPK3, IL6, TNF, JUN, MAPK1, and EGFR, etc (Figure 3C). Finally, based on 82 key targets, a large hub node-compound network was further constructed according to the five flavonoids. It was observed that Cal held relevancy to 23 key targets, For was related to 34 key targets, Iso was connected to 41 key targets, Kae was related to 50 key targets, whereas Que was associated with 72 key targets (Figure 3D).

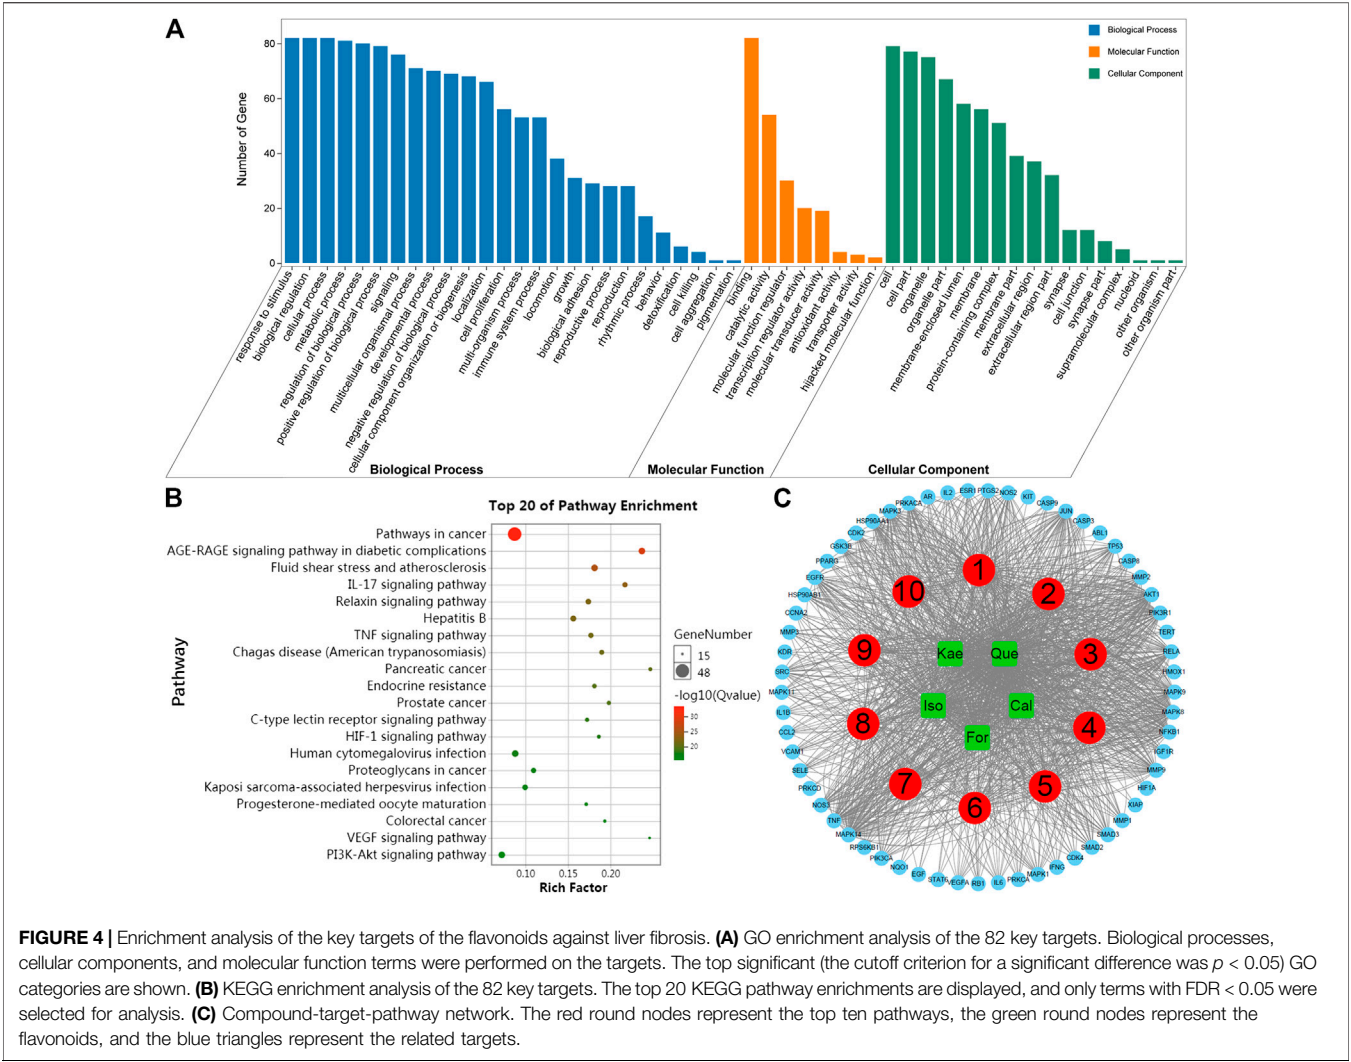

## GO Biological Process and KEGG Pathway Enrichment Analysis

The top significant (cutoff criterion with a significant difference of  $p < 0.05$ ) GO categories are shown in Figure 4A. In biological processes (BPs), the common targets were mainly enriched in cellular response to chemical stimuli (GO: 0070887), response to oxygen-containing compounds (GO: 1901700), response to organic substances (GO: 0010033), cellular response to oxygen-containing compounds (GO: 1901701), cellular response to organic substances (GO: 0071310), etc. In molecular functions (MFs), the common targets were mainly associated with enzyme binding (GO: 0019899), identical protein binding (GO: 0042802), protein kinase activity (GO: 0004672), kinase binding (GO: 0019900), and protein kinase binding (GO: 0019901), etc. In addition, cellular component (CC) analysis showed that the common targets were the membrane-enclosed

lumen (GO: 0031974), organelle lumen (GO: 0043233), intracellular lumen (GO: 0070013), nucleoplasm (GO: 0005654), and cytoplasmic part (GO: 0044444), etc.

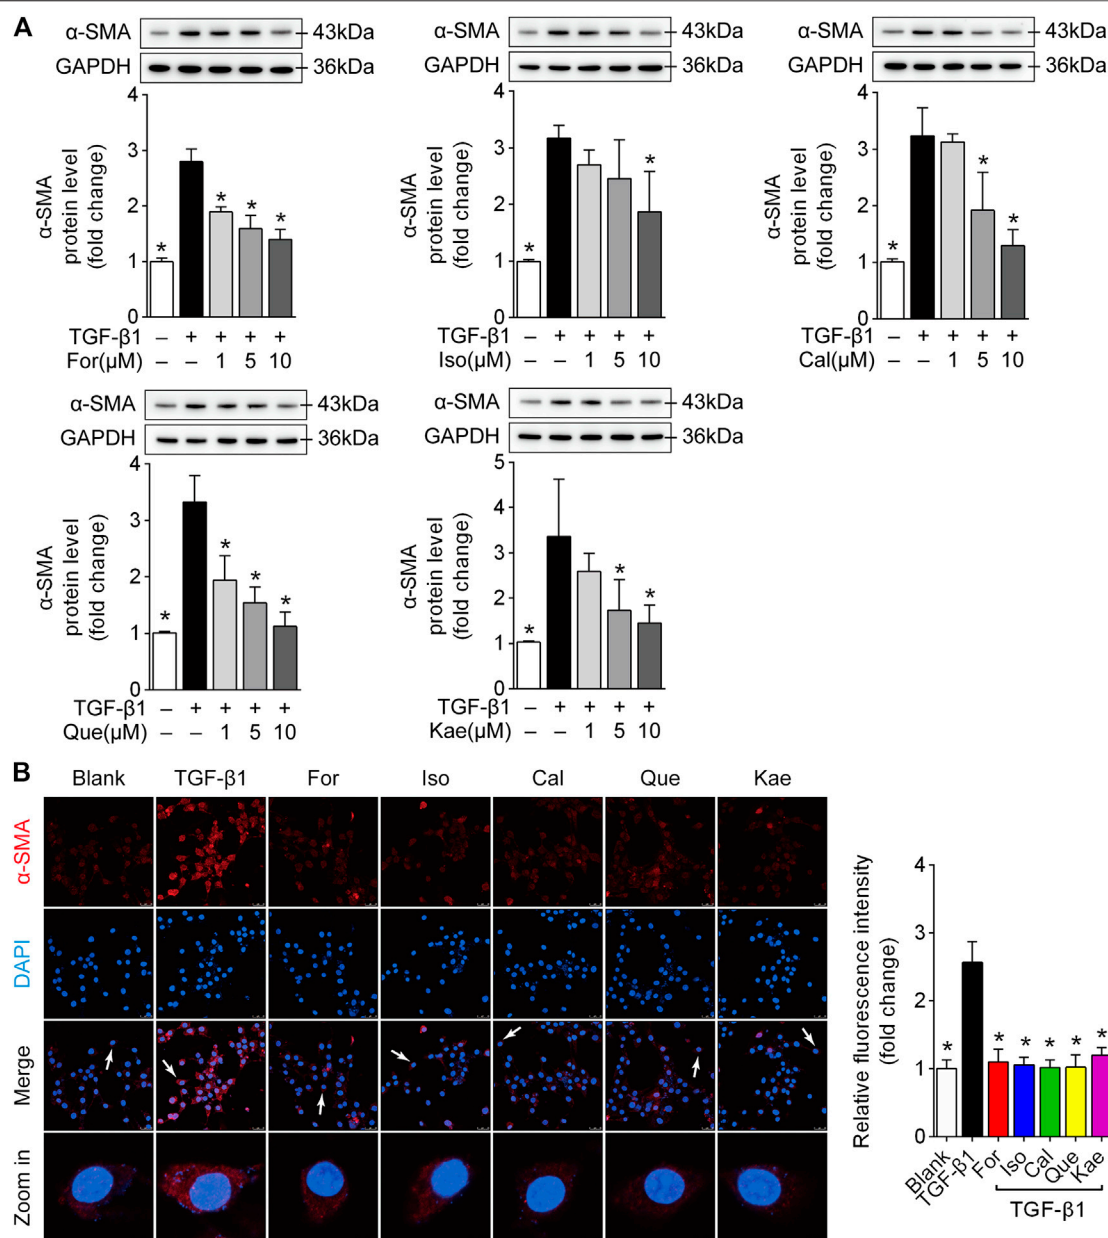

To further reveal the potential mechanism of the five flavonoids against HF, KEGG analysis was carried out on those 82 key targets. The top 20 KEGG pathway enrichments were displayed based on the threshold of FDR < 0.01; for instance, AGE-RAGE signal transduction pathway in diabetes-related complications (ko04933), pathways in cancer (ko05200), fluid shear stress and atherosclerosis (ko05418), pancreatic cancer (ko05212), IL-17 signal transduction pathway (ko04657), hepatitis B (ko05161), relaxin signal transduction pathway (ko04926), TNF signaling pathway (ko04668), Chagas disease (American trypanosomiasis) (ko05142), and endocrine resistance (ko01522), etc (Figure 4B). Moreover, those 10 most significant KEGG pathways were used to construct the compound-target-pathway network (Figure 4C). The characteristics of multiple components, multiple targets and multiple pathways of the active ingredients against liver fibrosis were revealed through the construction of a network. Further analysis revealed that the molecular mechanisms were mainly concentrated in immune and inflammatory pathways, with the main pathway being the classical IL-17 signaling pathway (Supplementary Figure S1). The key targets of the IL-17 signaling pathway mainly include NF- $\kappa$ B, AP-1, IL-6, IL-1 $\beta$ , TNF $\alpha$ , IFN- $\gamma$ , CCL2, COX2, MMP1, MMP3, and MMP9.

**FIGURE 4 |** Enrichment analysis of the key targets of the flavonoids against liver fibrosis. **(A)** GO enrichment analysis of the 82 key targets. Biological processes, cellular components, and molecular function terms were performed on the targets. The top significant (the cutoff criterion for a significant difference was  $p < 0.05$ ) GO categories are shown. **(B)** KEGG enrichment analysis of the 82 key targets. The top 20 KEGG pathway enrichments are displayed, and only terms with FDR  $< 0.05$  were selected for analysis. **(C)** Compound-target-pathway network. The red round nodes represent the top ten pathways, the green round nodes represent the flavonoids, and the blue triangles represent the related targets.

**FIGURE 6 |** The five flavonoids were able to suppress HSC activation. HSC-T6 cells were stimulated with TGF- $\beta$ 1 (10 ng/ml) for 24 h and prepared for further experiments. **(A)** Alpha-SMA protein expression in TGF- $\beta$ 1-induced HSC-T6 cells ( $n = 3$ ). **(B)** Confocal scanning images and quantified data of  $\alpha$ -SMA in HSC-T6 cells stimulated with TGF- $\beta$ 1 (10 ng/ml) for 24 h ( $n = 3$ ), scale bar = 50  $\mu$ m for 400 $\times$ . Data are expressed as the mean  $\pm$  SD. \* $p < 0.05$  vs. TGF- $\beta$ 1 treatment.

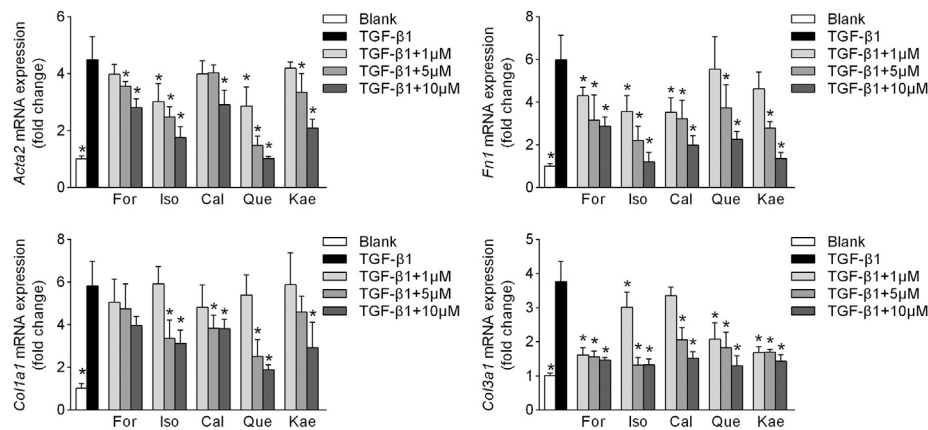

## The Five Flavonoids of AR Did Not Show Cytotoxicity to HSCs

To elucidate the efficacy of the five flavonoids against HF, the first step should be to investigate the cellular toxicity of these compounds against HSCs. The results showed that in resting cells, a concentration of 20  $\mu$ M Iso produced a significant effect on cell viability in HSC-T6 cells ( $p < 0.05$ ), whereas 0.1–10  $\mu$ M flavonoids had no toxicity. Thus, the five flavonoids at concentrations of 1, 5, and 10  $\mu$ M were chosen for the

following experiments, excluding the possibility that these five flavonoids inhibited HSC activation *via* cytotoxicity (Figure 5).

## The Five Flavonoids Were Able to Suppress HSC Activation

In order to further study the effects of the five flavonoids on HSC transdifferentiation, the expression of  $\alpha$ -SMA, a hallmark in the process of HSC activation (31258636), was detected in

**FIGURE 7 |** HF phenotypes were improved by the five flavonoids of AR. HSCs were stimulated with TGF-β1 (10 ng/ml) for 24 h and prepared for RT-qPCR experiments. Illustrations are shown for the HF phenotypes of *Acta2* (upper left panel,  $n = 4$ ), *Fn1* (upper right panel,  $n = 4$ ), *Col1a1* (lower left panel,  $n = 4$ ), and *Col3a1* (lower right panel,  $n = 4$ ). Data are expressed as the mean  $\pm$  SD. \* $p < 0.05$  vs. TGF-β1 treatment.

TGF-β1-challenged HSC-T6 cells. As suggested by Western blotting, those five flavonoids significantly decreased  $\alpha$ -SMA protein level within HSC-T6 cells induced by TGF-β1 (Figure 6A;  $p < 0.05$ ). Additionally, visualization by confocal microscopy and the quantified data confirmed the functional role of the five flavonoids in reducing  $\alpha$ -SMA overexpression induced by TGF-β1 (Figure 6B;  $p < 0.05$ ). These data revealed that the five flavonoids of AR impeded HSC activation, possibly contributing to the prevention of liver fibrosis.

## The Five Flavonoids Regulated the Phenotypes of HF

In the process of HSC transdifferentiation into myofibroblasts, increasing amounts of  $\alpha$ -SMA, collagen, fibronectin, and other ECM proteins induced by TGF-β1 eventually give rise to HF (Parola and Pinzani, 2019). The results showed that TGF-β1 stimulation remarkably increased *Acta2*, *Fn1*, *Col1a1* and *Col3a1* mRNA expression approximately 4–6-fold ( $p < 0.001$ ) in HSC-T6 cells, whereas these effects were significantly reversed by For in a dose-dependent manner (Figure 7;  $p < 0.05$ ). Similar results were noted for other flavonoid treatments ( $p < 0.05$ ). These results demonstrated that the five flavonoid interventions increased the resistance of liver stellate cells to TGF-β1-induced fibrogenic responses.

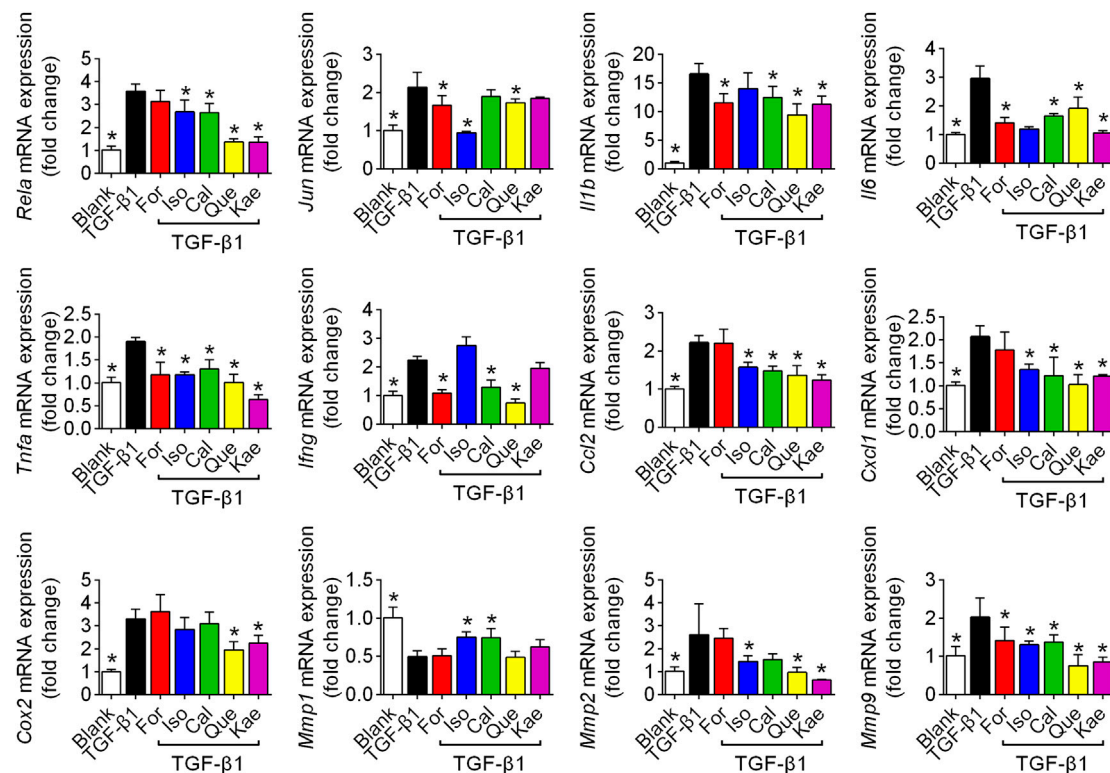

## The Inflammatory Pathway Might Be Involved in the Antifibrotic Effects of the Five Flavonoids

Based on the enrichment analysis by using network pharmacology, we noted a number of differentially expressed genes and proteins associated with the inflammatory process, including the inflammatory cytokines IL-1β, IL-6, tumor necrosis factor alpha (TNF-α), and interferon gamma (IFNγ); chemokines CCL2 and CXCL1;

the enzyme COX2; and matrix metalloproteinases (MMPs) MMP1, MMP2, and MMP9. We detected these factors by utilizing the RT-qPCR method. The results showed that TGF-β1 stimulation increased the mRNA expression of *Rela*, *Jun*, cytokines *Il1b*, *Il6*, *Tnfa*, and *Ifng*, chemokines *Ccl2*, and *Cxcl1*, the related enzyme *Cox2*, and MMP family members *Mmp2*, and *Mmp9* from ~2 to ~17-fold ( $p < 0.05$ ), whereas the five flavonoids could effectively reverse these effects in HSC-T6 cells ( $p < 0.05$ ). The protein MMP1 was able to degrade ECM in HSCs, especially type I and type III collagen. As Figure 8 shows, the five flavonoids could effectively elevate *Mmp1* expression ( $p < 0.05$ ); however, there was no significant difference after treatment with For, Que, or Kae. Collectively, these compounds were shown to significantly suppress the inflammatory process (Figure 8).

## The Five Flavonoids of AR Exhibited Anti-Inflammatory Effects via the NF-κB Signaling Pathway

The results from KEGG enrichment showed that the IL-17 pathway, mainly including NF-κB, AP-1 and various related inflammatory factors, might be involved in the treatment of the five flavonoids against liver cirrhosis. Accordingly, it needs to be confirmed whether these flavonoids exhibit antifibrotic effects via the regulation of NF-κB or AP-1. Although the five flavonoids showed regulation in AP-1 at the transcriptional level to a certain extent (Figure 8), the protein level had no marked change. Moreover, it was found that there were higher protein levels of NF-κB after TGF-β1 treatment than in the flavonoid treatment groups. Moreover, Western blot analysis and the semiquantitative illustration demonstrated that all five flavonoids could decrease NF-κB protein levels in a dose-dependent manner (Figure 9;  $p < 0.05$ ). These data suggested that the anti-inflammatory effects of the flavonoids involved NF-κB, indicating that these active flavonoids repressed HSC activation via the NF-κB signaling pathway.

**FIGURE 8 |** Inflammatory factors were involved in the process of flavonoid inhibition of HSC activation. HSCs were stimulated with TGF- $\beta$ 1 (10 ng/ml) for 24 h and prepared for RT-qPCR experiments. The figures show the mRNA expression of different inflammatory factors with or without interference with For, Iso, Cal, Que, or Kae in TGF- $\beta$ 1-induced HSC-T6 cells ( $n = 4$ ). Data includes *Rela*, *Jun*, *Il1b*, *Il6*, *Tnfa*, *Ifng*, *Ccl2*, *Cxcl1*, *Cox2*, *Mmp1*, *Mmp2*, and *Mmp9*. Data are expressed as the mean  $\pm$  SD. \* $p < 0.05$  vs. TGF- $\beta$ 1 treatment.

## Analysis of Molecular Docking Results

The docking results of the five flavonoids with the target protein IKK $\beta$  are shown in **Figure 10**. The residues docked with the molecular ligands are shown as yellow sticks. Amino acid residues Glu100 and Gly102 in the crystal structure of IKK $\beta$  formed hydrogen bonds with Cal (**Figure 10A**). For could bind to the residues Cys99, Glu100, and Asp166 in the IKK $\beta$  crystal structure by hydrogen bonds (**Figure 10B**). Both Iso and Kae could bind to the residues Glu100 and Gly102 of the IKK $\beta$  crystal structure by hydrogen bonds (**Figures 10C,D**). Amino acid residues Gly22, Thr23, Glu97, Cys99, and Gly102 in the crystal structure of IKK $\beta$  formed hydrogen bonds with Que (**Figure 10E**). The docking scores for the five flavonoids (Cal, For, Iso, Kae, and Que) with the IKK $\beta$  crystal structure were  $-8.5$ ,  $-8.7$ ,  $-8.4$ ,  $-8.4$  and  $-8.2$  kcal/mol, respectively (**Figure 10F**). The docking score represents the binding affinity, and when the score is lower, the binding affinity is stronger. An affinity  $< -7$  indicates strong binding activity (19,499,576). Our results indicate that the flavonoids have a strong binding affinity for IKK $\beta$ .

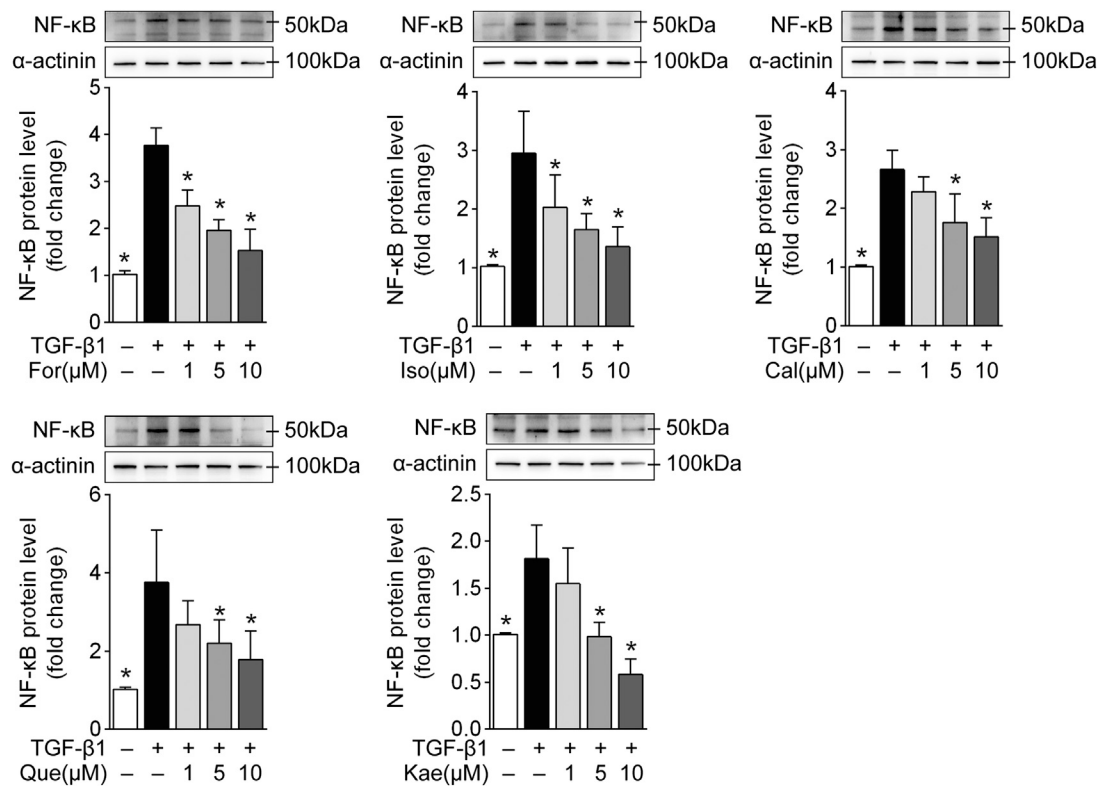

## DISCUSSION

Liver cirrhosis severely decreases the quality of life of patients. It is of great significance to seek an effective therapeutic strategy to

restrain liver disease deterioration. AR, a well-known traditional Chinese medicine, has been reported to be therapeutically effective against liver cirrhosis. However, the molecular mechanism has yet to be completely deciphered. Flavonoids are the main bioactive compounds involved in the functions of AR. Thus, in the current study, investigation into the effects and mechanism of the flavonoids from AR against liver fibrosis was conducted based on a network pharmacology approach coupled with experimental validation and molecular docking analysis. These results expand our knowledge pertaining to the basis of the effects and mechanism of AR-induced anti-liver fibrosis.

The use of TCMs, including AR, in the prevention and treatment of liver fibrosis has increased worldwide due to their privileged properties. However, it is difficult to elucidate the effects of AR because of its multiple compounds, multiple targets, multiple pathways, and multiple mechanisms of action (Guo et al., 2019), which greatly restrict the processes of modernization and internationalization of AR. In recent years, along with the generalization of systems biology, network pharmacology, which integrates chemoinformatics, bioinformatics, network biology, network analysis and traditional pharmacology, has emerged as a powerful tool to analyze the mechanism of the complex components of TCMS (Berger and Iyengar, 2009; Li and Zhang, 2013; Hao and Xiao, 2014). Thus, this study is the first to comprehensively screen the

**FIGURE 9 |** The five flavonoids might exhibit antifibrotic effects via the NF-κB signaling pathway. HSC-T6 cells were stimulated with TGF-β1 (10 ng/ml) for 24 h and prepared for protein level analysis. The diagrams show the NF-κB protein level with or without interference with For, Iso, Cal, Que, and Kae in TGF-β1-induced HSC-T6 cells ( $n = 3$ ). Data are expressed as the mean  $\pm$  SD. \* $p < 0.05$  vs. TGF-β1 treatment.

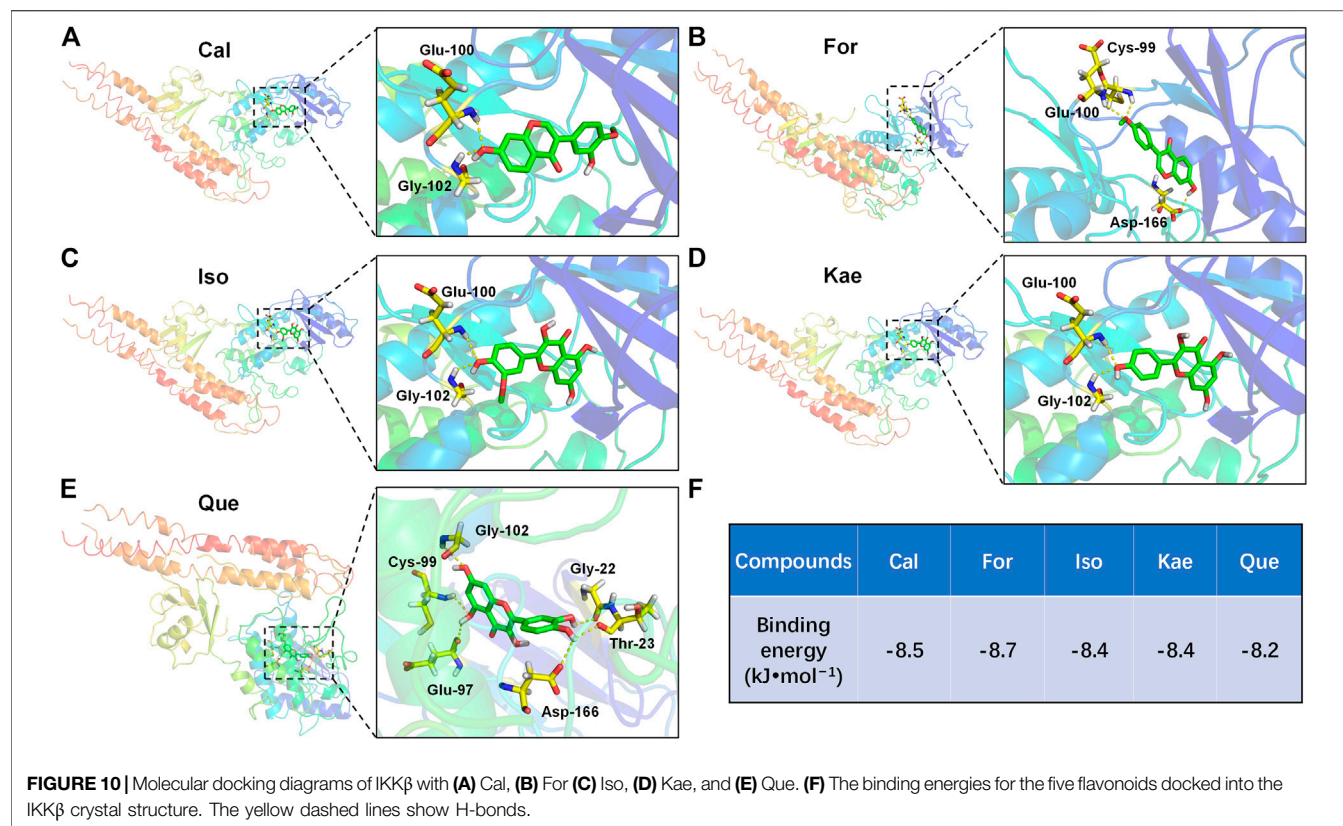

active ingredients of AR, predict the targets of these active ingredients and the genes related to liver fibrosis and analyze the potential mechanism of AR against liver fibrosis by using a network pharmacology approach.

After screening AR for OB  $\geq 30\%$  and DL  $\geq 0.18$ , a total of 87 reported active ingredients of AR were retrieved by searching the TCMSP database. Modern pharmacological studies indicate that flavonoids are the leading favorable compounds related to different AR pharmacological effects and efficacy (Guo et al., 2019). However, whether the flavonoids of AR can exert inhibitory effects on HF is not yet completely understood. There is little information regarding how flavonoids contribute to the treatment of HF by AR. There is an urgent need for systematic evaluation of the flavonoid components in AR to determine the definite bioactive component responsible for the activity of AR against HF. Thus, five potential bioactive flavonoids were selected: For, Iso, Cal, Que, and Kae (Figure 2A; Supplementary Table S1), for subsequent network pharmacology analysis and experimental validation. Then, the PPI network of candidate targets for flavonoids in the treatment of liver fibrosis was established based on the flavonoid and liver fibrosis target networks with 322 overlapping genes (Figures 2B,3A).

Afterward, the topological feature analysis of the PPI network was conducted according to those three main parameters, namely,

degree, closeness and betweenness. A total of 82 targets greater than the median were screened to be the key targets for those five anti-HF flavonoids (Figures 3B,C). It was apparent that most of these targets, including AKT1, TP53, MAPK3, IL6, TNF, JUN, MAPK1, EGFR, and many other inflammation-related proteins, were closely involved in the inflammation process. It was also observed that Que was linked to the greatest number of key targets, followed by Kae, Iso, For, and Cal (Figure 3D), suggesting that Que could be the most significant compound in AR against liver fibrosis.

Next, crucial target-related enrichment analyses of the GO and KEGG pathways were performed. GO enrichment analysis, which was based on three different terms, including BP, CC, and MF terms, was used to identify the biological mechanisms of key targets in disease (Ashburner et al., 2000). Based on the GO terms, it was proposed that the pharmacological effects of AR against liver fibrosis occurred by simultaneously activating various biological processes, cellular components, and molecular functions (Figure 4A). KEGG database can be adopted to identify potential target biological relevance and systematic functions (Chen et al., 2015). After KEGG enrichment analysis, it was found that the five flavonoids could potentially suppress liver fibrosis through multiple pathways, including pathways in cancer, the AGE-RAGE signal transduction pathway in diabetes-related complications, fluid shear stress

and atherosclerosis, the IL-17 signal transduction pathway, the relaxin signal transduction pathway, hepatitis B, and the TNF signaling pathway, etc (Figures 4B,C). Further analysis revealed that the molecular mechanisms were mainly concentrated in the immune and inflammatory pathways, with the main pathway being the classical IL-17 signaling pathway (Supplementary Figure S1). The key targets of the IL-17 signaling pathway include NF-κB, AP-1, IL-6, IL-1β, TNFα, IFN-γ, CCL2, COX2, MMP1, MMP3, and MMP9, which all exert vital parts in HF development (Tan et al., 2020; Zhou et al., 2020). Accordingly, in addition to the network pharmacology analysis, we next performed experimental validation to clarify the potential inflammatory mechanism of the flavonoids against liver fibrosis.

HSCs are pericytes found in the perisinusoidal space of the liver. Stellate cells are the major cell type involved in liver fibrosis, which is the formation of scar tissue in response to liver damage (Tsuchida and Friedman, 2017). Based on this, we used HSCs for subsequent biological verification experiments. To determine the effects of the five flavonoid compounds screened by network pharmacology on HSCs, the first step was to explore whether these compounds had cellular toxicity. Figure 5 shows that except for the Que panel, the cell survival rate of all treatments was higher than 70% in the concentration range of 0.1–200 μM. The cell viability was greater than 70% in the 40 μM group of HSCs treated with Que. However, in all flavonoid intervention groups, a concentration less than or equal to 10 μM compound did not decrease the survival rate of HSCs, indicative of the nontoxicity of the five flavonoids for further experiments.

Liver fibrogenic responses are characterized by the differentiation of HSCs into myofibroblasts, and excessive ECM deposition is a major consequence of myofibroblast activation. HSCs activation to the proliferating fibrogenic myofibroblasts has been extensively recognized to be a pivotal factor of HF in human or experimental liver damage (Parola and Pinzani, 2019). Myofibroblasts are important but transient mediators of normal wound contraction and are characterized phenotypically by their high levels of α-SMA. Therefore, α-SMA is often used as a marker of myofibroblast formation (Peng et al., 2019). In the present study, we applied multiple biological methods for evaluating those flavonoid effects on α-SMA expression within the HSC-T6 cells treated with TGF-β1. As indicated, the five flavonoids had a remarkable inhibitory effect on the transdifferentiation of HSCs (Figure 6). Upon HSC activation, formative myofibroblasts secrete large amounts of ECM. Once secreted, the formative myofibroblasts then aggregate with the existing matrix, which eventually leads to liver fibrosis. Collagens are the most abundant protein in the ECM, especially type I collagen (Col-I) and type III collagen (Col-III). Collagen fibers are connected to cells by fibronectins in the ECM (Ricard-Blum, 2011). Hence, these fibrogenic factors are good indicators of the severity of HF. In Figure 7, we detected all of these related HF phenotypes, and the RT-qPCR analysis showed that the main flavonoids of AR could counteract the effects induced by TGF-β1 in HSC-T6 cells. Given the critical role of α-SMA and ECM deposition in HSC activation and differentiation, these results indicated that the main flavonoids from AR restrained HF by inhibiting HSC activation, an effect

likely resulting from interference with the inflammatory process when the KEGG map was taken into account.
