Inflammatory pathways are associated with numerous diseases. The scientific evidence and KEGG results from our work suggested that the IL-17 pathway, mainly NF- $\kappa$ B and its associated inflammatory factors, accounts for an evolutionarily conservative pathway that can regulate HF (Luedde and Schwabe, 2011). NF- $\kappa$ B is suggested to regulate the liver fibrogenesis mainly in three diverse cell fractions, including regulating hepatocyte injury, inflammatory signals, and fibrogenic responses of HSCs. Among these, there is growing evidence that NF- $\kappa$ B acts as a key mediator of fibrosis in the transdifferentiation of HSCs to myofibroblasts (Friedman, 2004). The potential mechanisms appear through direct fibrogenic effects, anti-apoptotic effects, and secretion of macrophage-recruiting chemokines. NF- $\kappa$ B participates in down-regulating members of the miR-29 family within HSCs, thereby increasing the levels of all collagens together with additional ECM proteins within HSCs (Roderburg et al., 2011). Since NF- $\kappa$ B is primarily composed of the p50 and p65 subunits, we investigated different subunits at different biological levels. In this study, we confirmed that there was a remarkable elevation in NF- $\kappa$ B mRNA (*Rela*) and protein (p50) levels in the process of HSC activation, and all five flavonoids reversed these effects in response to TGF- $\beta$ 1 stimulation in HSC-T6 cells. As shown in **Figures 8, 9**, Que demonstrated the optimal effect among the five flavonoids.

Activation of NF- $\kappa$ B also promotes the secretion of various inflammatory mediators. Indeed, in the network pharmacology study, we identified several related inflammatory factors, including cytokines, chemokines, enzymes, and the MMP family. Cytokines, the small proteins with the molecular weight of 5–20 kDa, play vital roles in cell signaling. Of these cytokines, IL-1 $\beta$  can directly trigger the synthesis of collagen together with the proliferation of myofibroblasts (Kähäri et al., 1987). IL-6, IFN- $\gamma$ , and TNF- $\alpha$  are secreted by T cells, biliary cells, and Kupffer cells, respectively, which contributes to HSC activation (Bataller and Brenner, 2005). As **Figure 8** shows, Que and Kae might have better inhibitory effects on these cytokines than the other flavonoids. In addition to cytokines, the increased secretion of chemokines such as CCL2 and CXCL1 results in inflammatory cell influx, like the macrophages, and they show interactions with HSCs and have certain effect on HSC activation as well as wound healing (Seki et al., 2007). In this study, we found that all five flavonoids could downregulate chemokine expression induced by TGF- $\beta$ 1.

Furthermore, we analyzed a vital inducible sensor, COX-2, which exerts a vital part in liver fibrogenesis development. COX-2 is a rate-limiting enzyme responsible for catalyzing arachidonic acid in converting to thromboxane and inflammatory prostaglandins (Yang et al., 2020). Despite the controversial relationship between COX-2 and TGF- $\beta$ 1, we observed a marked increase in *Cox2* mRNA expression after TGF- $\beta$ 1 induction, and this elevation was reversed after flavonoid treatment. Accompanying cellular activation, ECM constituents change from the matrix with abundant laminin and collagen IV to the concentrated interstitial ECM, which suggested the possible occurrence of proteolytic degradation

for altering sinusoid microenvironment and HSCs fate (Han, 2006). As a matter of fact, members in MMP family are rapidly expressed via HSCs to respond to a variety of hepatic toxins. Depending on timing and other reasons, MMPs play dual roles in liver fibrosis. It has been reported that MMP2 and MMP9 are expressed in human fibrotic injury, while MMP1 can degrade ECM in HF (Takahara et al., 1997; Jimuro et al., 2003). Our work not only confirmed this phenomenon but also noted that Kae showed better MMP family regulatory ability than the other flavonoids. However, MMPs have different functions during the different processes of HF, and more in-depth experiments are needed. Besides, the antifibrotic effects of the five flavonoids should be further demonstrated using pathway inhibitors *in vitro* and animal model *in vivo*. Transgenic animal experiments have been conducted to clarify the exact mechanism(s).

Finally, the potential mechanism of AR flavonoids against liver fibrosis was further validated by using molecular docking. Molecular docking is a quick and effective method of predicting the binding affinity between TCM ingredients and their targets based on the spatial structure of ligands and receptors (Gan et al., 2019). Molecular docking analysis was conducted by using AutoDock Vina software, which may serve as the AutoDock successor docking analysis, due to its effect on apparently improving performance and accuracy in comparison with those of Lamarckian Genetic Algorithm (Kist et al., 2018). Based on results of network pharmacology, it was known that flavonoids can possibly suppress liver fibrosis by inhibiting the IL-17 signaling pathway, which includes NF- $\kappa$ B, AP-1, IL-6, IL-1 $\beta$ , TNF $\alpha$ , IFN- $\gamma$ , CCL2, COX2, MMP1, MMP3, and MMP9. The experimental validation results further confirmed that the flavonoids could exhibit potent inhibitory activity against liver fibrosis *via* suppression of NF- $\kappa$ B and its various downstream inflammatory factors. NF- $\kappa$ B represents the key transcription factor related to the inflammatory signaling cascade (Hoesel and Schmid, 2013). Normally, NF- $\kappa$ B can be found in cytoplasm, which can be inactivated by the I $\kappa$ B inhibitors. The NF- $\kappa$ B inflammatory activation is dependent on the IKK $\beta$ -mediated I $\kappa$ B protein phosphorylation, as well as p50–p65 subunit nuclear translocation in NF- $\kappa$ B, thus inducing the expression of proinflammatory cytokines (Hoesel and Schmid, 2013). As a result, specifically inhibiting IKK $\beta$  is a reasonable way to more effectively treat inflammatory disorders, like HF (Baig et al., 2018). The results of molecular docking showed that the flavonoids had high affinity for IKK $\beta$  (**Figure 10**), suggesting that the mechanism of the flavonoids against liver fibrosis may be related to suppression of the NF- $\kappa$ B pathway through effective inhibition of IKK $\beta$ .

## CONCLUSION

This study aimed to undertake network pharmacology analysis coupled with experimental validation and molecular docking to investigate the effects and mechanism of AR flavonoids against liver fibrosis. The network pharmacology analysis findings showed that the flavonoids from AR exerted their pharmacological effects against liver fibrosis by modulating

multiple targets and pathways. The experimental validation results suggested that flavonoids might play an anti-inflammatory role in the treatment of liver fibrosis by mediating inflammation signaling pathways. Our molecular docking study results also indicated that the mechanism of the flavonoids against liver fibrosis may be related to suppression of the NF- $\kappa$ B pathway through effective inhibition of IKK $\beta$ . These findings not only provide a scientific basis for clarifying the mechanism of action of AR in the treatment of liver fibrosis but also suggest a novel promising therapeutic strategy for the treatment of liver fibrosis. However, as this study was based on data mining and experimental validation, further clinical validation studies should be undertaken to determine the role of AR in liver fibrosis.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding authors.

## AUTHOR CONTRIBUTIONS

JW and LA designed the experiments and wrote the manuscript. LA, YFL, MK, LL and YML carried out the experiments and analyzed the data. JW and ZL supervised and corrected the manuscript.

## GLOSSARY

**Acta2** alpha smooth muscle actin

**$\alpha$ -SMA** alpha smooth muscle actin

**AR** *Astragalus membranaceus* (Fisch.) Bunge

**BP** biological process

**Cal** calycosin

**CC** cellular component

**Ccl2** C-C motif chemokine two

**Col-I** type I collagen

**Col-III** type III collagen

**Col1a1** type I collagen

**Col3a1** type III collagen

**Cox2** prostaglandin G/H synthase two

**Cxcl1** growth-regulated alpha protein

**DL** drug similarity

**ECM** extracellular matrix

**Fn1** fibronectin

**For** formononetin

**Gapdh** glyceraldehyde-3-phosphate dehydrogenase

**GO** gene ontology

**HF** hepatic fibrosis

**HSCs** Hepatic stellate cells

**Ifng** interferon gamma

**Il1 $\beta$**  interleukin-1 beta

**Il6** interleukin-6

**Iso** isorhamnetin

**Jun** transcription factor AP-1

**Kae** kaempferol

**KEGG** encyclopedia of genes and genomes

**MF** molecular function

**Mmp1** matrix metalloproteinase one

**Mmp2** matrix metalloproteinase two

**Mmp9** matrix metalloproteinase nine

**NF- $\kappa$ B** nuclear factor kappa B

**OB** oral bioavailability

**PPI** protein to protein interaction

**Que** quercetin

**Rela** nuclear factor kappa B subunit p65

**TCMs** traditional Chinese medicines

**TCMSP** traditional Chinese medicine systems pharmacology

**TGF- $\beta$ 1** transforming growth factor beta one

**Tnfa** tumor necrosis factor

Zhao X and Zhou L (2021) The Efficacy  
and Mechanism of Chinese Herbal  
Medicines in Lowering Serum Uric Acid  
Levels: A Systematic Review.  
Front. Pharmacol. 11:578318.  
doi: 10.3389/fphar.2020.578318

**Background.** Chinese herbal medicines are widely used to lower serum uric acid levels. However, no systemic review summarizes and evaluates their efficacies and the underlying mechanisms of action. **Objectives.** To evaluate the clinical and experimental evidences for the effectiveness and the potential mechanism of Chinese herbal medicines in lowering serum uric acid levels. **Methods.** Four electronic databases PubMed, Web of Science, the Cochrane Library and Embase were used to search for Chinese herbal medicines for their effects in lowering serum uric acid levels, dated from 1 January 2009 to 19 August 2020. For clinical trials, randomized controlled trials (RCTs) were included; and for experimental studies, original articles were included. The methodological quality of RCTs was assessed according to the Cochrane criteria. For clinical trials, a meta-analysis of continuous variables was used to obtain pooled effects. For experimental studies, lists were used to summarize and integrate the mechanisms involved. **Results.** A total of 10 clinical trials and 184 experimental studies were included. Current data showed that Chinese herbal medicines have promising clinical efficacies in patients with elevated serum uric acid levels (SMD:  $-1.65$ , 95% CI:  $-3.09$  to  $-0.22$ ;  $p = 0.024$ ). There was no significant difference in serum uric acid levels between Chinese herbal medicine treatments and Western medicine treatments (SMD:  $-0.13$ , 95% CI:  $-0.99$  to  $0.74$ ;  $p = 0.772$ ). Experimental studies revealed that the mechanistic signaling pathways involved in the serum uric acid lowering effects include uric acid synthesis, uric acid transport, inflammation, renal fibrosis and oxidative stress. **Conclusions.** The clinical studies indicate that Chinese herbal medicines lower serum uric acid levels. Further studies with sophisticated research design can further demonstrate the efficacy and safety of these Chinese herbal medicines in lowering serum uric acid levels and reveal a comprehensive picture of the underlying mechanisms of action.

**Keywords:** Chinese herbal medicine, serum uric acid, serum urate, efficacy, mechanism

**Abbreviations:** Abbreviations can be referred to **Tables 3, 4**. FABP1, fatty acid-binding protein; HPRT1, hypoxanthine-guanine phosphoribosyl transferase; APOB, apolipoprotein B; FOS, one subunit of activator protein-1; FN1, fibronectin1; MIP-1 $\alpha$ , MIP-1  $\beta$ , serum proinflammatory cytokines; TXNIP, thioredoxin interacting proteins; PTEN, phosphate and tension homology deleted on chromosome ten; NALP1/6, NACHT, LRR and PYD domains-containing protein one and six; ADAMTs, a family of metalloproteinases with thrombospondin motifs; TIMP, tissue inhibitor of metalloproteinase; CD2AP, CD2-associated protein.

## INTRODUCTION

Hyperuricemia refers to an abnormally high concentration of serum uric acid (sUA), typically defined as >7 mg/dL in men and >6 mg/dL in women. The data from the National Health and Nutrition Examination Survey (NHANES) 2007–2016 showed that the prevalence rates of hyperuricemia were 20.2% among men and 20.0% among women between 2015 and 2016 in the United States (Chen-Xu et al., 2019). A cross-sectional survey in China showed that the prevalence of hyperuricemia was 8.4% among Chinese adults from 2009 to 2010 (Liu et al., 2014a). Hyperuricemia and gout remain as a considerable burden, which not only adversely affect patients' health and quality of life (Burke et al., 2015; Gamala and Jacobs, 2019), but also cast an economic burden in the society (Rai et al., 2015). SUA is associated with cardiovascular diseases, such as hypertension (Kuwabara et al., 2018) and atrial fibrillation (Tang et al., 2014). Elevated sUA can lead to decreased renal function, which in turn reduces the excretion of UA in urine, resulting in an increased risk of hyperuricemia or gout (Sato et al., 2019). Elevated sUA may also contribute to the pathogenesis of metabolic syndrome (Battelli et al., 2018; Battelli et al., 2019), non-alcoholic fatty liver disease (Xu et al., 2015), diabetes (Kim et al., 2015). Urate-lowering therapy is a therapeutic strategy for controlling gout, chronic kidney disease, metabolic syndrome and many other diseases. Current interventions for elevated sUA include xanthine oxidase inhibitors, uricosuric agents and anti-inflammatory drugs. Although both febuxostat and allopurinol are effective in reducing sUA, allopurinol may produce a mild skin rash and severe cutaneous reactions (Strilchuk et al., 2019), while febuxostat has a higher risk of all-cause and cardiovascular mortality (White et al., 2018). Benzbromarone is a uricosuric drug which is widely used, but studies have reported possible complications such as hepatotoxicity (Strilchuk et al., 2019). Although these drugs are clinically used, their efficacies are unsatisfactory, and are usually coupled with adverse side effects in the long-term use (Dalbeth et al., 2016).

Hyperuricemia belongs to the arthromyodynia disease category in traditional Chinese medicine. Chinese herbal medicine has been used to treat hyperuricemia for a long time and has significant clinical efficacy (Lin et al., 2016). Chinese herbal medicines with high efficacy and low incidence of adverse reactions have drawn increasing attention from scholars. Studies have compared Chinese herbal medicine with Western medicine for their efficacies in lowering sUA levels. However, these studies differ in their treatment protocols and evaluation methodologies, which greatly limit their clinical applicability. In addition, the mechanism of Chinese herbal medicine in lowering sUA levels is still being explored. Some herbs such as *Phellodendri Chinensis* Cortex, *Atractylodes Lancea* (Thunb.)Dc. (Chen et al., 2015b), *Smilacis Glabrae Rhizoma* (Liu et al., 2015), reduce UA intake and/or increase UA excretion by regulating various physiological and cellular pathways. Some herbs like bergenin (Chen et al., 2020a), *alpinia oxyphylla* seed extract (Lee et al., 2019b) and *rhizoma smilacis glabrae* extracts (Liang et al., 2019), promote renal and gut uric acid excretion in hyperuricemia models and also decrease the serum levels of inflammatory cytokines. Most

Chinese herbal medicines act on multiple targets to achieve their sUA lowering effects. Therefore, the aim of this systematic review is to evaluate the evidence for the efficacy of Chinese herbal medicines in lowering sUA levels in patients with hyperuricemia, compared to no intervention, placebo or urate-lowering agents, and to comprehensively summarize the mechanisms underlying the sUA lowering effects reported from experimental studies.

## MATERIALS AND METHODS

### Data Source and Search Strategy

Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (Moher et al., 2009) was used to construct the report of the current study and the completed checklist is provided in Supplementary material, **Supplementary Table S1**. The electronic databases PubMed, Web of Science, the Cochrane Library and Embase were systematically searched by three researchers (Liqian Chen, Zhengmao Luo and Ming Wang). For any discrepancies between researchers, consensus was reached through discussion. We reviewed literatures published from 1 January 2009 to 19 August 2020 on elevated sUA that had been treated with Chinese herbal medicines. The following combination of terms were used as search keywords: (Traditional Chinese Medicine OR Herbal Medicine OR Chinese Herbal Drugs OR Chinese Plant Extracts OR (Plants, Medicinal) OR Phytochemicals OR herb\* OR natural product) combined with (gout OR pain paralysis OR hyperuricemia OR uric acid). The full search strategy in PubMed was provided in Supplementary material, **Supplementary Table S2**. The search did not exclude articles based on language. To look for additional relevant studies, references of all potentially relevant articles were also retrieved, and authors of studies that met the inclusion criteria but lacked data would be contacted. Abstracts, meeting proceedings, and personal communications were not used for the purpose of this study.

### Study Selection

The articles in this review included clinical trials and *in vivo* and *in vitro* studies. When screening clinical trials, the followings are the inclusion criteria:

- A). Types of trials: All randomized controlled trials (RCTs) investigating the use of Chinese herbal medicine in lowering sUA will be eligible for inclusion.
- B). Types of participants: In accordance with the NHANES-III laboratory definition, hyperuricemia is typically defined as >7 mg/dL in men and >6 mg/dL in women (Choi et al., 2020). All adult patients (18 years and older, no upper age limit) with a diagnosis of hyperuricemia will be considered for this review.
- C). Types of interventions: According the General guidelines for methodologies on research and evaluation of traditional medicine from WHO, herbal medicines are defined as materials or products derived from plants that have medical or other beneficial effects on human health, including herbs, herbal materials, herbal products,

finished herbal products that contain parts of plants or other plant materials or compositions as active ingredients, as well as materials of inorganic or animal sources. The interventions included in this study include Chinese herbal medicine in various prescriptions, such as herbal formulas, herbal extracts, active ingredients of herbs. Clinical trials comparing Chinese herbal medicine with no intervention, placebo or urate-lowering agents were included in our study. Chinese herbal medicine plus placebo or combined with urate-lowering agents compared to the same medications was also included. We do not limit the formulations or administration of herbal preparations for clinical use.

- D). Types of outcome measures: Outcome measures should include at least one essential outcome, such as change in sUA levels after treatment and the overall efficacy.

When screening *in vivo* or *in vitro* experimental studies using the herbs, the following conditions should be met before inclusion: A) Original article investigating the use of Chinese herbal medicine in lowering sUA will be eligible for inclusion. B) Studies using experimental models of mice, rats, rabbits or cell cultures will be considered. All models used should present corresponding pathological symptoms. C) The model should only be treated with Chinese herbal medicine before or after intervention. If medication other than herbs were being used, both the treatment group and the control group must be administered. D) Outcome measures should include change in sUA after treatment.

## Data extraction

The data were extracted by three researchers (Jingru Cheng, Fei Li and Hanqi Lu) independently to obtain the following information: A) the design of study; B) characteristics of trial participants (including sample size, age, period); C) type of intervention (including dose regimen, duration); D) type of outcome measure (including the level of sUA). The reported mean (standard deviation [SD]) or risk estimates and 95% confidence intervals (CIs) of sUA were also extracted.

## Quality Assessment

The quality assessment of the studies was performed independently by three researchers (Qiuxing He, Yanting You and Xinghong Zhou), and all discrepancies between researchers were resolved through discussion. The methodological quality of RCTs was assessed according to the Cochrane Handbook for Systematic reviews of Interventions. The scores for each bias domain and the final score of risk of systematic bias were graded as low, high or unclear risk. The overall level of evidence was considered “strong” if there were consistent findings among multiple high quality RCTs, and “moderate” if findings were consistent among multiple low-quality RCTs and/or one high-quality RCT. Level of evidence was “conflicting” if findings were inconsistent across the studies, and “no evidence from trials,” if there were no RCTs.

## Statistical Analysis

Statistical analysis was performed with the software STATA version 16.0. The  $d$  index and the standard deviation ( $SD_d$ )

values of sUA for each RCT were calculated before using STATA. The  $d$  index and  $SD_d$  values of sUA were continuous, standard mean difference (SMD) with 95% confidence interval (95% CI) was calculated. The overall effect was calculated by a Z-test, and  $p < 0.05$  (2-tailed) was deemed statistically significant. Potential heterogeneity was assessed by  $I^2$  statistics. A fixed effects model was chosen if  $I^2 \leq 50\%$ , otherwise, a random effects model was applied. Subgroup analysis was performed to illuminate the heterogeneity according to the study characteristics, such as interventions other than Chinese herbal medicine. A ‘leave-one-out’ sensitivity analysis was carried out to test the reliability of the results. Potential publication bias was evaluated by the Egger’s test and Begg’s test. When the geometric mean and CIs were reported, tools provided in the Cochrane Handbook were used to convert the geometric mean and CIs to arithmetic mean and SD of the raw data.

## RESULTS

### Literature Flow

The initial electronic search of the literature yielded 4981 potentially relevant citations. After duplicate removal and title/abstract screening, 374 full-text articles were retrieved for detailed assessment. Of these studies, 180 articles did not meet the inclusion criteria. Finally, 194 articles were included in the review with 10 clinical trials, 169 *in vivo* experiments, 0 *in vitro* experiments, and 15 that were a combination of both *in vitro* and *in vivo* experiments (Figure 1).

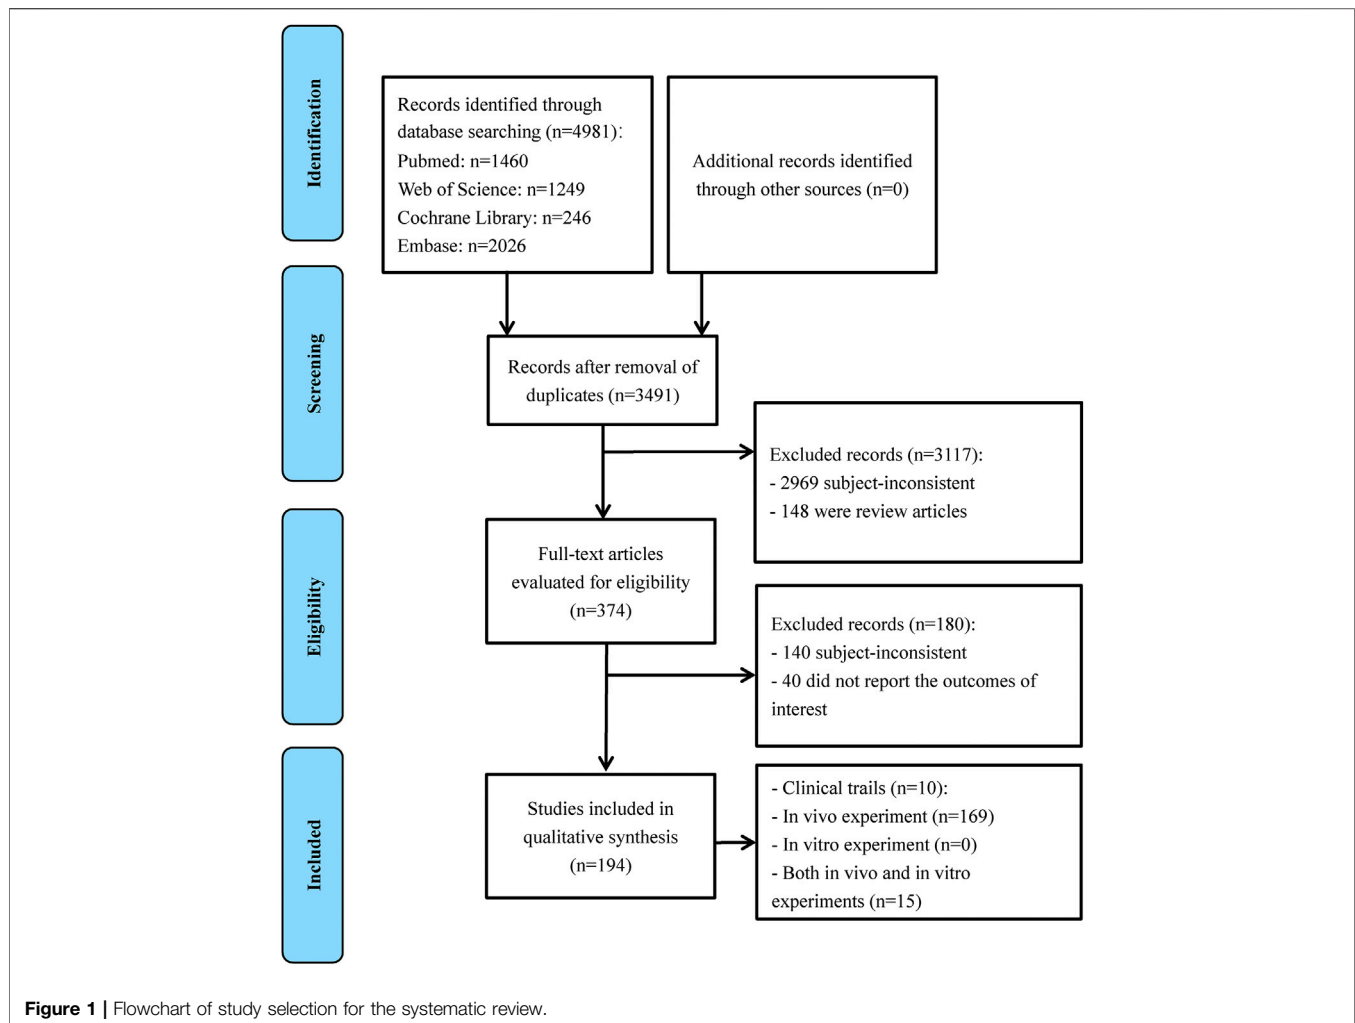

### Results of clinical trials

#### Study Characteristics

The specified characteristics of the included clinical trials as well as their study populations were summarized in Table 1. All clinical trials included were RCTs which mainly explored the effects of Chinese herbal medicine on patients with elevated sUA levels such as hyperuricemia and gout. In order to objectively observe the therapeutic effects of herbs on lowering sUA levels, the changes of sUA levels before and after treatment in 10 clinical trials were listed in Supplementary material, Supplementary Table S3. Of the 10 included trials, nine were treated with herbal formula, and the remaining one was treated with a combination of herbal extracts and active ingredients. In the subgroup analyses of intervention, two studies compared the therapeutic effects of Chinese herbal medicine and placebo (Rozza et al., 2016; Xie et al., 2017), three studies compared Chinese herbal medicine and Western medicine (Zhang et al., 2009; Zhou et al., 2013; Wang et al., 2014), two studies compared Chinese herbal medicine, Western medicine and placebo or no intervention (Zhang et al., 2011; Wang et al., 2019b), one compared two kinds of Chinese herbal medicine and Western medicine (Yu et al., 2018), and two compared Chinese herbal medicine combined Western medicine and Western medicine (Chen et al., 2009; Xiang et al., 2009).

### Meta-Analysis

In order to investigate the efficacy of Chinese herbal medicine in lowering sUA, we performed a subgroup analysis based on

interventions. A random effects model was used for the analysis because  $I^2 = 96.4\%$ .

### Chinese Herbal Medicine vs Placebo or No Intervention

Four RCTs were analyzed. The subgroup meta-analysis showed that all of them were statistically significant differences between Chinese herbal medicine and placebo or no intervention. The combined SMD was  $-1.65$  with a 95% CI of  $-3.09$  to  $-0.22$  ( $p = 0.024$ ). Therefore, there was a significant difference between the Chinese herbal medicine and placebo or no intervention in the reduction of sUA (**Figure 2**).

### Chinese Herbal Medicine vs Western Medicine

Seven RCTs were analyzed. On subgroup meta-analysis, the combined SMD was  $-0.13$  with a 95% CI of  $-0.99$  to  $0.74$  ( $p = 0.772$ ), indicating no significant difference between the Chinese herbal medicine and Western medicine in the reduction of sUA (**Figure 2**).

### Chinese Herbal Medicine Plus Western Medicine vs Western Medicine

Two RCTs were analyzed. Subgroup meta-analysis (**Figure 2**) showed no statistical significance between the Chinese herbal

medicine plus Western medicine and Western medicine in the reduction of sUA (SMD  $-2.27$ , 95% CI:  $-5.84$  to  $1.31$ ,  $p = 0.214$ ).

### Meta-regression Analyses

The meta-regression showed that samples size, duration of treatment, type of diseases and intervention other than Chinese herbal medicine did not influence these results (all  $p$  values  $>0.05$ ) (**Supplementary Figure S1**).

### Quality Assessment

RCT was assessed according to the Cochrane Handbook for Systematic reviews of Interventions (**Table 2**). Generally, the methodological quality was assessed to be moderate. Most of the studies (8/10, 80%) have details on the random grouping of patients, but only half of the studies (5/10, 50%) fully reported the scheme of concealment allocation. Only four trials (4/10, 40%) had their subjects and investigators blinded during the study, and four trials (4/10, 40%) had all the subjects, investigators and outcome evaluators blinded.

### Sensitivity Analysis

Sensitivity analysis was conducted to confirm the efficacy Chinese herbal medicine in lowering sUA. The pooled SMDs were

repeated by sequentially removing one of the included studies with a random-effects model (**Supplementary Figure S2**). None of the studies changed the overall effect.

Publication Bias

There was no evidence of publication bias according to the Begg’s test ( $p = 0.428$ ) and Egger’s test ( $p = 0.344$ ) for the meta-analysis of Chinese herbal medicine on lowering sUA (**Supplementary Figure S3**).

Results of experimental studies

We categorized 184 *in vivo* and *in vitro* experiments into three groups: 56 active ingredients (**Table 3**), 78 natural products

(**Table 4**), and 52 herbal formulas (**Table 5**). Among them, one article described two active ingredients (Lin et al., 2018), and one article (Su et al., 2014) studied one active ingredient and one natural product concurrently. To assure the quality of the studies included, detailed information on herbs (including source, concentration, quality assessment, chemical analysis, and compound purity) was summarized in Supplementary material, **Supplementary Tables S4–S6**.

Active Ingredients That Lower Serum Urate *in vivo* and *in vitro* Studies

Active ingredient is a single ingredient and studies have shown that it plays an important therapeutic role in

**TABLE 3 |** Active ingredients on lowering serum uric acid based on *in vivo* and *in vitro* studies.

HUA, hyperuricemia; PO, potassium oxonate; MSU, monosodium urate; SLC2A9, solute carrier family 2, facilitated glucose transporter member; PPAR- $\gamma$ , peroxisome proliferator-activated receptor  $\gamma$ ; IL, interleukin; TNF- $\alpha$ , tumor necrosis factor;  $\alpha$ -SMA, alpha-smooth muscle actin; TGF- $\beta$ , transforming growth factor beta-1; NLRP3, the NOD-like receptor P3 inflammasome; XO/XOD, xanthine oxidase; URAT1, urate transporter one; GLUT9, glucose transporter nine; OAT1/3, organic anion transporter one and three; Smad3, mothers against decapentaplegic homolog three; Src, proto-oncogene tyrosine-protein kinase Src; STAT3, signal transducer and activator of transcription three; FOXO3 $\alpha$ , forkhead box O3 alpha; SIRT1, silent information regulator one; NF- $\kappa$ B, nuclear factor-kappa B; MCP-1, monocyte chemoattractant protein-1; JAK2, Janus kinase two; SOCS-1/3, suppressor of cytokine signaling 1/3; MDA, malondialdehyde; SOD, superoxide dismutase; ABCG2, adenosine triphosphate (ATP)-binding cassette transporter two; XDH, xanthine dehydrogenase; OCT1/2, organic cation transporter; ALP, alkaline phosphatase; OCTN1/2, organic cation/carnitine transporter one and two; ROS, reactive oxygen species; NR-1, N-methyl-D-aspartic acid receptor one; p38, phosphorylated p38 mitogen-activated protein kinase; ERK, phosphorylated extracellular regulated protein kinase; ADA, adenosine deaminase; TLRs, toll-like receptors; IRAK, IL-1R-associated kinase; TRAF6, TNF receptor associated factor 6; I $\kappa$ B, inhibitor of NF- $\kappa$ B; IKK $\alpha$ , inhibitor of nuclear factor kappa-B kinase; TAK1, transforming growth factor beta-activated kinase one; OATP1A1, organic anion transporting polypeptide 1A1; OIT3, oncoprotein-induced transcript 3; PRPS, phosphoribosyl pyrophosphate synthetase; HGPRT, hypoxanthine-guanine phosphoribosyl transferase; PRPPAT, phosphoribosyl pyrophosphate amino-transferase; MMP-9, matrix metalloproteinase nine; TRAP, tartrate-resistant acid phosphatase; COX-2, cyclooxygenase-2; PGE2, prostaglandin E2; NO, nitric oxide; ASC, the apoptosis-associated speck-like protein containing a caspase recruitment domain; RST, renal-specific transporter; MRP4, multidrug resistance protein 4. N/A, not available.

reducing sUA. Among the active ingredients with potential of lowering sUA (Table 3), 25 of which act on uric acid synthesis, 28 target uric acid transporter, 19 resolve inflammation, nine possess kidney protective function, and four regulate the oxidative stress.

### Natural Products That Lower Serum Urate *in vivo* and *in vitro* Studies

Natural products include herbs and relatively complex extracts derived from herbs. Among the natural products with potential of lowering sUA (Table 4), 40 of which act on uric acid synthesis, 29 target uric acid transporter, 17 resolve inflammation, eight

possess kidney protective functions, and three regulate the oxidative stress.

### Herbal Formulas That Lower Serum Urate *in vivo* and *in vitro* Studies

Herbal formula is a combination of a variety of herbs. The composition of the herbal formula included in the current study were listed in Supplementary material, **Supplementary Table S7**. Among the herbal formula with lowering sUA effects (Table 5), 18 of which act on uric acid synthesis, 15 target uric acid transporter, 15 resolve inflammation, seven possess kidney protective functions, and five regulate the oxidative stress.

## DISCUSSION

### The efficacies of Chinese herbal medicines lowering Serum uric Acid levels

This systematic review compares the efficacies of the Chinese herbal medicines and the Western medicine in lowering sUA levels by analysing 10 RCTs with a total of 1,060 patients. The meta-analysis has three important findings. First, there is a significant difference between the Chinese herbal medicine, placebo or no intervention in the reduction of sUA levels. Second, the efficacies of Chinese herbal medicines in lowering sUA levels are comparable to that of Western medicine. Third, the efficacies of Chinese herbal medicines plus Western medicine in lowering sUA levels are comparable to that of Western medicine. The heterogeneity of the meta-analysis was high. To investigate the source of heterogeneity in our analysis, we conducted a sensitivity analysis, removing one study at one time from the primary analysis did not change the main finding. In addition, our findings were confirmed by the lack of publication bias and effect modifiers according to the Begg's test, Egger's test and meta-regression analysis.

The results indicate that the efficacies of Chinese herbal medicines in lowering sUA levels are comparable to that of Western medicine, which is consistent with the analysis result of Lin et al. (Lin et al., 2016). Compared with the study of Lin et al., our study is more comprehensive, because we also compared the sUA lowering efficacy between Chinese herbal medicine and placebo or no intervention, and between Chinese herbal medicine plus western medicine and western medicine. In addition, we have summarized the underlying mechanisms of herbs in lowering sUA. It should be noted that among the 10 RCTs included, a total of six RCTs used one or several components of Simiao Pills, which is a famous formula in traditional Chinese medicine, including *Cortex Phellodendri Chinensis*, *Atractylodes Lancea* (Thunb.) DC., *Coix lacrym-jobi L. var. ma-yuen* (Roman.) Stapf (Yi Yi), *Cyathula officinalis Kuan* (Xiang et al., 2009; Zhang et al., 2009; Zhang et al., 2011; Zhou et al., 2013; Xie et al., 2017; Yu et al., 2018). The specific doses of herbs in each study have been listed in the **Supplementary Tables S4–S6**. According to the Pharmacopoeia of the People's Republic of China revised by the Food and Drug Administration in 2015, except for the use of *Cortex Phellodendri Chinensis*, *Atractylodes Lancea* (Thunb.) DC.,

*Cyathula officinalis Kuan* in one RCT (Xiang et al., 2009) exceeded the recommended dosage, the dosages of these four herbs in the remaining five RCTs were within the recommended dosage range. Except for the RCT in which the dosage exceeded the recommended dosage (Xiang et al., 2009), the dosage of these four herbs in the remaining five RCTs were all at the high level or even reached the critical value within the recommended range. Despite the high dosage, the three RCTs describing the adverse reactions in the six RCTs showed that the incidence of adverse reactions was either lower than that of the placebo group or was not statistically significant compared with the control group.

In addition to clinical studies, experimental studies have also suggested the urate lowering effects of Simiao Pills, which act on xanthine oxidase (XO), uric acid transport-related proteins urate anion transporter 1 (URAT1) and glucose transporter 9 (GLUT9), and also modulate the inflammation, oxidative stress and other processes (Hu et al., 2010; Hua et al., 2012; Shi et al., 2013; Pan et al., 2014; Ma et al., 2015; Lin et al., 2020). The finding suggests that Chinese herbal medicines are mostly multi-targeted or have interplay with other signaling pathways to lower sUA levels. In contrast, conventional Western medicines used to lower sUA levels include allopurinol, probenecid and benzbromarone, which generally act on specific targets. Allopurinol competitively inhibits xanthine oxidase (Strilchuk et al., 2019). Probenecid and benzbromarone are typical urate-promoting drugs target at URAT1 (Azevedo et al., 2019). These may partly explain why the combination of Chinese and Western medicine can improve the index of renal function while lowering sUA levels in patients with hyperuricemia (Chen et al., 2009; Xiang et al., 2009).

Nevertheless, several limitations of the meta-analysis are worth considering. Due to limited reports, participants with elevated sUA levels in this meta-analysis included patients with hyperuricemia and gout, and most participants were from China. These facts indicate that the current meta-analysis could have potential bias. Further trials need to be carried out in a larger comprehensive population to demonstrate the efficacy of Chinese herbal medicines in lowering sUA. In addition, long-term tracking of sUA is necessary to determine whether Chinese herbal medicine can effectively control sUA. However, long-term follow-ups were not available in the current included studies. The incidence of adverse reactions is an important indicator to compare the efficacy and

Abbreviations can be referred to **Tables 3, 4**. FABP1, fatty acid-binding protein; HPRT1, hypoxanthine-guanine phosphoribosyl transferase; APOB, apolipoprotein B; FOS, one subunit of activator protein-1; FN1, fibronectin1; MIP-1 $\alpha$ , MIP-1  $\beta$ , serum proinflammatory cytokines; TXNIP, thioredoxin interacting proteins; PTEN, phosphate and tension homology deleted on chromosome ten; NALP1/6, NACHT, LRR and PYD domains-containing protein one and six; ADAMTs, a family of metalloproteinases with thrombospondin motifs; TIMP, tissue inhibitor of metalloproteinase; CD2AP, CD2-associated protein.

safety of Chinese herbal medicine and Western medicine in lowering sUA levels. However, of the six included studies comparing Chinese herbal medicine and Western medicine, only 2 has reported the adverse reaction events in details. Thus, we cannot evaluate the safety of Chinese herbal medicine vs. western medicine in lowering sUA levels. Moreover, the standardization of the methodologies and the small number of the included trials may lead to an overestimation of the overall efficacy of Chinese herbal medicine. Therefore, studies with high quality are needed to confirm the efficacy and safety of Chinese herbal medicine in lowering sUA levels.

## The mechanisms of Chinese herbal medicines in lowering Serum uric Acid

In current review, 186 *in vivo* and *in vitro* experiments with 56 active ingredients (**Table 3**), 78 natural products (**Table 4**), and 52 herbal formulas (**Table 5**) are included to explore the common mechanism of Chinese herbal medicine in lowering sUA levels. According to the summary of the targets of Chinese herbal medicine in lowering sUA, it is clearly revealed that most Chinese herbal medicine lowers sUA by acting on multiple targets or multiple pathways. The therapeutic mechanism of

Chinese herbal medicine included in this study mainly involved the UA synthesis, UA transport, inflammation, renal fibrosis and oxidative stress.

Uric acid, produced primarily in the liver, is the final product of diet and endogenous purine metabolism. Problems with key enzymes involved in UA production can cause abnormal UA levels, including phosphoribosyl pyrophosphate (PRPP) synthetase, purine nucleoside phosphorylase, xanthine oxidase, hypoxanthine-guanine phosphoribosyl transferase (HGPRT) (Cammalleri and Malaguarnera, 2007; Maiuolo et al., 2016). In the circulation, UA exists mainly in the form of urate anion under physiologic pH. The saturation level of monosodium urate in human plasma is limited. Hence, UA must be excreted continuously to prevent its accumulation and reduce the toxicity. The primary scavenger of urate is the kidney, which expels about 75% of urate every day (Chaudhary et al., 2013). In recent years, studies have revealed the complex interaction of transporters involved in urate metabolism (Wright et al., 2010). Several transporters involved in urate metabolism have been identified, including URAT1, GLUT9, organic anion transporters (OAT1/3), and adenosine triphosphate (ATP)-binding cassette transporter 2 (ABCG2) (Enomoto et al., 2002; Lipkowitz, 2012; Mandal and Mount, 2015). Previous studies have found that inflammation, oxidative stress, mitochondrial

dysfunction and other factors cause abnormalities in these critical proteins, and thus lead to the disorders in UA metabolism (Lanaspa et al., 2012; Zhou et al., 2018b). On the contrary, abnormal UA levels can also lead to the release of some cytokines, such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), nuclear factor-kappa B (NF- $\kappa$ B), the NOD-like receptor P3 (NLRP3) inflammasome, interleukin-6 (IL-6), interleukin-1 $\beta$  (IL-1 $\beta$ ), and so on (Major et al., 2018; Singh et al., 2019).

### Herbs Lower Serum Uric Acid by Targeting Uric Acid Synthesis

The substrate for UA synthesis is ribose-5-phosphate which can be converted to PRPP via PRPP synthase and then to inosine monophosphate. This intermediate compound produces adenosine monophosphate and guanosine monophosphate, which subsequently release adenosine and guanosine molecules, respectively. Adenosine deaminase converts adenosine to inosine, while guanosine to free guanine. Inosine is degraded to hypoxanthine via purine nucleoside phosphorylase. Xanthine oxidase, one of the key enzymes involved in UA synthesis, converts hypoxanthine to xanthine which then converts to UA. Guanine is directly converted to xanthine, which subsequently to UA by XO. On the other hand, hypoxanthine and guanine enter a salvage pathway through the activity of HGPRT, which converts these purine into their respective nucleotides (Lipkowitz, 2012; Lima et al., 2015; Maiuolo et al., 2016). Thus, PRPP synthase, XO and HGPRT are all key enzymes that can cause abnormal sUA levels. PRPP gene mutations have been implicated in a number of human diseases. Overexpression of PRPP results in the enhanced activity of phosphoribosyl pyrophosphate synthetase-I, which can lead to excessive production of purine. Patients with active phosphoribosyl pyrophosphate synthetase-I may result in UA over production (Mittal et al., 2015). Lesch-Nyhan disease is caused by a wide variety of mutations in the HGPRT gene and is one of the models of gout caused by the increased production of UA (Fu et al., 2014; Harris, 2018). Lack of HGPRT can lead to Kelley-Seegmiller syndrome, which is characterized by hyperuricemia, hyperuricosuria, gouty arthritis and urolithiasis (Chavarriga et al., 2019). Among these key enzymes, XO is the most commonly studied enzyme. 3,5,2',4'-tetrahydroxychalcone significantly inhibits the activities of XO in liver, and the decreased content of PRPP in liver will suppress the UA production (Niu et al., 2018). In our review, nearly half of the studies (83/186, 45%) confirm that herbs regulate XO synthesis and activity. For example, pallidifloside D, a saponin glycoside constituent from the total saponins of *Smilax riparia*, enhances the hypouricemic effect of allopurinol by regulating XO activity. The combination of allopurinol and Pallidifloside D significantly up-regulates HGPRT expression and down-regulates the expressions of PRPP in PC12 cells (Li et al., 2016).

### Herbs Lower Serum Uric Acid by Targeting Uric Acid Transporter

About two-thirds of UA is excreted by the kidneys, and the remaining is excreted via the gastrointestinal tract. Renal

excretion of UA consists of four steps: 1) glomerular filtration, 2) presecretory reabsorption, 3) secretion and 4) post-secretory reabsorption (Maiuolo et al., 2016). Urate is filtered through the glomerulus, so the reabsorption and secretion of UA after glomerulus play an important role in regulating the excretion of UA. Most of the urate (99%) filtered through the glomerulus is reabsorbed in the early S1 segment of the proximal tubule (presecretory reabsorption). Uric acid is then secreted in the S2 segment of the proximal tubule to return approximately 50% of the filtered urate into the tubule lumen. Post-secretory reabsorption occurs primarily in the distal S3 segment of the proximal tubule, followed by about 10% of the secreted urate in the urine (Diamond and Paolino, 1973; Mandal and Mount, 2015). Urate transporters such as URAT1, OAT1, OAT3, GLUT9, ABCG2 play important roles in regulating sUA, and their dysfunction may cause abnormal urate transport. URAT1, the main urate-anion exchanger in the luminal membrane of the proximal tubules, can be inhibited by the uricosuric agents, likes probenecid, benzbromarone and losartan (Enomoto et al., 2002). URAT1 mutations have been found in patients with familial hypouricemia and UA levels below 1 mg/dL, and the UA transport is inactivated when this mutant transporter is expressed in *xenopus* oocytes (Dinour et al., 2011). Clinical studies have shown that inhibition of URAT1 effectively reduces sUA levels and resolves the gout symptoms (Lee et al., 2019a). URAT1 is a branch of the organic anion transporter (OAT). OAT1 and OAT3 exchange urate with bivalent anions, suggesting that they are suitable for basolateral entry of urate during urate secretion (Mandal and Mount, 2015). Among the 14 members of the GLUT family transport glucose or other monosaccharides, GLUT9 does transport essentially urate (Caulfield et al., 2008). GLUT9 mediates urate transport, which is independent of sodium, chlorine and anions, but voltage-dependent (Anzai et al., 2008). Compared with the mutation in URAT1, the complete loss of GLUT9 results in the net secretion of urate (Preitner et al., 2009). ABCG2 is a multidrug resistance transporter that is also implicated as an important urate transporter. Its gene variation has become the main cause of elevated sUA levels (Dehghan et al., 2008). ABCG2-mediated loss or reduction of renal urate secretion will lead to increased renal urate reabsorption (Woodward et al., 2009).

In our review, more than one-third of the studies (72/186, 39%) show that Chinese herbal medicines target uric acid transporters. *Alpinia oxyphylla* seed extract enhances UA excretion in the kidney by reducing URAT1 and up-regulating OAT1 (Lee et al., 2019b). Wuling San down-regulates mRNA and protein levels of URAT1 and GLUT9, as well as up-regulates OAT1 in the kidney of hyperuricemic mice. Moreover, Wuling San also up-regulates organic cation/carnitine transporters which are associated with impaired renal function, leading to kidney protection (Ding et al., 2013). Gypenosides, natural saponins extracted from *Gynostemma pentaphyllum*, significantly lower sUA levels by reducing XO and increasing in urate excretion through regulating URAT1, GLUT9, and OAT1 (Pang et al., 2017).

## Herbs Lowering Serum Uric Acid Resolve Inflammation

Uric acid belongs to the damage-associated molecular patterns, altered metabolites of necrotic or stressed cells that the innate immune system sees as an alarm signal (Patel, 2018). Elevated UA levels alters the physiology, boosting the expressions of inflammatory proteins by triggering complex pro-inflammatory cascades that damage cells and tissues (Chen and Lan, 2017). Clinical trials have shown that serum levels of IL-6 and TNF- $\alpha$  are significantly higher in hyperuricemia patients than in healthy people, and that of IL-6 and TNF- $\alpha$  are significantly increased as sUA levels increase (Zhou et al., 2018b). SUA above 9 mg/dl is associated with a gouty arthritis incidence of 4.9%. The accumulation of monosodium urate (MSU) crystals induce a mass of inflammatory cells (such as neutrophils and monocytes) to infiltrate into the site of MSU crystal deposits in patients, resulting in an acute inflammatory response, manifested as acute gout flares (Dalbeth et al., 2016). IL-1 released from these immune cells further triggers the release of various pro-inflammatory cytokines and chemokines, such as IL-8, IL-6 and TNF- $\alpha$ , which can further enhance neutrophil recruitment (El Ridi and Tallima, 2017). Inflammatory cytokines, especially IL-1 $\beta$ , are the key mediators of gouty inflammation. A phase III, international safety study of patients with acute gout arthritis treated with rilonacept (an IL-1 blocker) for 16 weeks shows that rilonacept significantly reduces the risk of gout attacks by 70.3% (Sundy et al., 2014). In experimental studies included in this review, 37 articles (11 active ingredients, 13 natural products, and 13 herbal formulas) describe the effects of these herbs on IL-1. It is worth mentioning that these herbs not only act on IL-1, but also as XO, UA transporter, other inflammatory factors such as IL-6, IL-8, TNF- $\alpha$ , NF- $\kappa$ B, NLRP3, caspase 1, etc.

There are 16 herbs included in this review that interfere with the NLRP3 inflammasome. Consistent with reported studies, elevated UA can be effectively reduced by regulating NLRP3 inflammasome - IL-1 pathway (Dhanasekar and Rasool, 2016; Szekecz et al., 2019). Acute gout is an inflammatory response to MSU crystals. Innate immune pathways are essential in the pathogenesis of gout, particularly the activation of NLRP3 inflammasome, which leads to the release of IL-1 $\beta$  and other pro-inflammatory cytokines (So and Martinon, 2017). MSU crystals must first be coated with serum proteins and then interact with articular cell's surface membrane directly or via receptors, to stimulate a cytosolic molecular platform involved in innate immunity and promote the assembly and activation of the NLRP3 inflammasome (El Ridi and Tallima, 2017). NLRP3 inflammasomes are formed by the recruitment of the apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC), and subsequent recruitment of caspase-1. Caspase-1 activates pro-inflammatory cytokines IL-1 $\beta$  and IL-18 by cleaving their respective precursor proteins, pro-IL-1 $\beta$  and pro-IL-18 (So and Martinon, 2017). Neutrophils are recruited and activated in response to the spillover of IL-1, producing ROS, proteolytic enzymes, pro-inflammatory chemokines, cytokines and so on, which recruit and activate macrophages (El Ridi and Tallima, 2017). Thus, the release of IL-1 $\beta$  mediated by inflammasome and the rapid recruitment of

neutrophils lead to acute inflammatory episodes in gout patients. It is noteworthy that hyperuricemia may stimulate inflammatory leukocytes through epigenetic modification such as histone methylation, even without MSU crystals, thereby increasing production of IL-1 $\beta$ , IL-6, and TNF- $\alpha$  (Wasilewska et al., 2012; Zhou et al., 2018b).

The activation and maturation of IL-1 $\beta$  in response to endogenous and exogenous stimuli are also involved in the NF- $\kappa$ B pathway (Chen and Lan, 2017). In our review, there are 13 articles focused on NF- $\kappa$ B signaling pathway, showing the inhibitory effect of herbs on NF- $\kappa$ B activation under elevated sUA levels. It has been proved that NF- $\kappa$ B can be activated by UA (Spiga et al., 2017). Its activation transcribes a large number of pro-inflammatory genes. In a resting state, NF- $\kappa$ B combines with I $\kappa$ B $\alpha$  (inhibitor of NF- $\kappa$ B kinase subunit  $\alpha$ ) form a dimer in the cytoplasm, after I $\kappa$ B $\alpha$  kinase is activated, it phosphorylates I $\kappa$ B $\alpha$ . Subsequently, NF- $\kappa$ B is transferred from the cytoplasm to the nucleus, leading to the transcription and expression of genes related to inflammation. Studies have shown that inhibition of NF- $\kappa$ B restrains inflammation and improves hyperuricemia or gout conditions (Chen et al., 2019a; Wang et al., 2019c). Interestingly, studies focused on NF- $\kappa$ B activity is also related to NLRP3. NF- $\kappa$ B is essential for the initiation, assembly and activation of NLRP3 inflammasome, which is also a key step in the release of inflammatory cytokines in MSU crystal-induced inflammation (So and Martinon, 2017). P38 mitogen-activated protein kinase (MAPK) is also involved in the inflammatory cascade of NF- $\kappa$ B. Uric acid activates NF- $\kappa$ B through MAPK signal pathway, thus leading to the release of inflammatory factors such as TNF- $\alpha$  (Tang et al., 2017).

## Herbs Lowering Serum Uric Acid Protect Against Renal Fibrosis

Evidence suggests that UA levels can be used to predict the prognosis of chronic kidney disease and end-stage kidney disease. Elevated sUA level is an independent risk factor for kidney disease and lead to renal fibrosis (Fan et al., 2019). Mice with systemic GLUT9 knockout showed moderate hyperuricemia, excessive hyperaciduria and obstructive nephropathy, along with progressive inflammatory fibrosis (Preitner et al., 2009). Once UA exceeds the maximum amount the kidneys can excrete, it gets deposit in the kidney and firstly causes direct pathological damage to the kidney. Secondly, the deposition of UA in the kidney results in the accumulation of neutrophils and monocytes as well as the release of inflammatory factors, which lead to glomerulosclerosis and interstitial fibrosis and aggravate renal injury (Ye et al., 2018). Prevention and treatment of renal fibrosis is the best treatment for kidney diseases caused by elevated sUA. However, at present, modern medical treatments are not effective in reducing renal fibrosis and preventing the progression of diseases.

A total of 24 studies included in this review are focused on hyperuricemic nephropathy, suggesting that herbal medicines improve renal injury induced by elevated sUA levels by regulating renal fibrosis-related signal pathways. Fibrosis is

usually associated with strong inflammatory reactions and immunocyte infiltration. Therefore, inhibition of inflammatory cytokines might be a potential method to prevent fibrosis. Vaticaffinol, one of the herbs included in this review, markedly down-regulates NLRP3, ASC, caspase-1, IL-1 $\beta$ , IL-18, IL-6 and TNF- $\alpha$  in hyperuricemic mice, thus significantly decreases sUA levels and improves kidney function (Chen et al., 2017b). Transforming growth factor- $\beta$ 1/Mothers against decapentaplegic homolog 3 (TGF- $\beta$ 1/Smad3) signaling is the most potent fibrogenic factor in the regulation of renal interstitial fibrosis process (Loeffler and Wolf, 2015). Pterostilbene, also mentioned in this review, suppresses the activation of TGF- $\beta$ 1/Smad3 and proto-oncogene tyrosine-protein kinase Src/Signal transducer and activator of transcription 3 (Src/STAT3) signaling pathway as to decrease sUA level and alleviate renal fibrosis in hyperuricemic mice (Pan et al., 2019). These findings highlight the fact that herbal medicines may be the potential antifibrotic therapeutics for hyperuricemic nephropathy treatment.

### Herbs Lowering Serum Uric Acid Modulate Oxidative Stress

In addition to the inflammatory process, oxidative stress is one of the early events related to the elevated sUA. Uric acid entering cells can rapidly induce oxidative stress (Ko et al., 2019; Yin et al., 2019). This state of oxidative stress is governed by the balance between ROS production and their elimination by antioxidants. Since the cell membrane is impermeable to urate anion, cellular concentration of urate depends on the specific transporter of urate and xanthine oxidoreductase (XOR). In mammals, this enzyme exists in two forms, xanthine dehydrogenase (XDH) and XO. XDH transfers electron to NAD<sup>+</sup> and generates NADH, and XO transfers electron to O<sub>2</sub> and generates oxidative stress (Isaka et al., 2016). In addition, XOR may lead to the production of the superoxide anion and nitric oxide, especially under low pH or hypoxia conditions (Godber et al., 2000; Battelli et al., 2019). It can be seen that the generation of UA mediated by XO is closely related to the production of ROS. On the other hand, antioxidant enzymes that scavenge ROS are ubiquitous, including superoxide dismutase, glutathione peroxidase and catalase, the changes of these enzymatic activities may lead to oxidative stress. However, in inflammatory diseases including hyperuricemia, the production of the superoxide anion is often faster than its removal by superoxide dismutase (Zamudio-Cuevas et al., 2015).

There is an increasing interest in using herbs to resolve the inflammatory conditions, including hyperuricemia, because they play an anti-inflammatory role by inhibiting the production of ROS, such as procyanidins, Shizhifang, Zisheng Shenqi decoction, quercetin, Modified Simiao decoction and other herbs included in this review. Antioxidants like quercetin inhibits inflammation in rat models of chronic MSU-induced arthritis by decreasing inflammatory mediators such as IL-1 $\beta$  (Huang et al., 2012). Other herbs mentioned above also show significant antioxidant

effects. For example, Shizhifang effectively suppresses the NLRP3-ASC-caspase-1 axis through accommodating the ROS pathway, thereby alleviates potassium oxonate - induced hyperuricemia (Wu et al., 2017). In summary, the herbs that possess anti-oxidant effects may be developed as anti-inflammatory agents to treat inflammatory diseases such as gout and hyperuricemia.

### Limitations and Perspectives From the Experimental Studies

As shown in Tables 3–5, there are fewer studies on the active ingredients of herbs than on the herbal extracts and herbal formulas. Aside from herbal formula, there can be hundreds of active ingredients in a single-flavored herb, making it difficult to identify the ones that actually mediate the therapeutic effects. This partly explains why multiple signaling pathways are involved in herbal treatments. Extraction of components that mediate the therapeutic effects is difficult. In general, safe and effective single-flavored herb can be screened out from literatures or experimental studies, and its effective active ingredients can be separated by pharmacological methods. Then, the mechanism of action of the drug can be explored based on the identified active ingredients from the herbs. In recent years, there are new approaches to identify the active ingredients of herbs and predict their targets, such as Systems Pharmacology. Researchers used Systems Pharmacology as a basis to screen out active ingredients from herbal formulas or herbs, and predict the targets of active ingredients, and finally verify them through *in vivo* and *in vitro* experimental studies (Zhou et al., 2016; Hong et al., 2017; Zhao et al., 2019). It really opens up new ideas for the studies of herbs and shortens the time to find out the mechanisms of action underlying the therapeutic effects of the herbs. However, with the increasing number of herbal studies using Systems Pharmacology, we can find that it also has disadvantages, such as limited Systems Pharmacology databases, data not updated, limited prediction results and so on. In view of this, it is still necessary to explore how to efficiently screen out the active ingredients of the herbs and identify their molecular targets.

## CONCLUSION

In conclusion, the results of meta-analysis indicate that Chinese herbal medicines have potent therapeutic effects in lowering sUA levels. The signaling pathways involved in the sUA lowering effects include UA synthesis, UA transport, inflammation, renal fibrosis and oxidative stress. Further studies with sophisticated research design can further demonstrate the efficacy and safety of these Chinese herbal medicines in lowering sUA levels. Identification of the active ingredients and delineation of the underlying mechanisms of action can facilitate the clinical translation and application of these ingredients.

## AUTHOR CONTRIBUTIONS

All the authors contributed sufficiently for their participation in the study, as follows: XZ and LZ conceived, designed, and

supervised the study; LC, ZL, MW, JC, FL, and HL conducted the literature search, data extraction, data analysis and interpretation; QH, YY, and XZ appraised the articles; LC, ZL, and MW wrote the paper, HK modified the paper. All authors have read and approved the final manuscript.

## FUNDING

This work was supported by the Key Project of National Natural Science Foundation of China (No. 81830117), the National Science Foundation of China (Nos. 81774212,

81760821, 81703952), the Natural Science Foundation of Guangdong Province, China (Nos. 2017A030313722, 2018A030313375, 2019A1515010400), and the Science & Technical Plan of Guangzhou, Guangdong, China (No.201903010069).

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2020.578318/full#supplementary-material>.

Green tea extract (GTE) is popular in weight loss, and epigallocatechin gallate (EGCG) is considered as the main active component. However, GTE is the primary cause of herbal and dietary supplement-induced liver injury in the United States. Whether there is a greater risk of liver injury when EGCG is consumed during dieting for weight loss has not been previously reported. This study found for the first time that EGCG could induce enhanced lipid metabolism pathways, suggesting that EGCG had the so-called “fat burning” effect, although EGCG did not cause liver injury at doses of 400 or 800 mg/kg in normal mice. Intriguingly, we found that EGCG caused dose-dependent hepatotoxicity on mice under dietary restriction, suggesting the potential combination effects of dietary restriction and EGCG. The combination effect between EGCG and dietary restriction led to overactivation of linoleic acid and arachidonic acid oxidation pathways, significantly increasing the accumulation of pro-inflammatory lipid metabolites and thus mediating liver injury. We also found that the disruption of Lands’ cycle and sphingomyelin-ceramides cycle and the high expression of taurine-conjugated bile acids were important metabolomic characteristics in EGCG-induced liver injury under dietary restriction. This original discovery suggests that people should not go on a diet while consuming EGCG for weight loss; otherwise the risk of liver injury will be significantly increased. This discovery provides new evidence for understanding the “drug-host” interaction hypothesis of drug hepatotoxicity and provides experimental reference for clinical safe use of green tea-related dietary supplements.

**Keywords:** green tea extract, epigallocatechin gallate, hepatotoxicity, combination effect, lipid metabolism, metabolomics, herbal and dietary supplements

## INTRODUCTION

Green tea is a beverage that has been brewed for thousands of years and has been widely popular across the world for hundreds of years. It is rich in catechin compounds with antioxidant effect, and epigallocatechin gallate (EGCG) is the most important component of green tea extract (GTE). It is popularly believed to have a wide range of health benefits, including preventing cancer, lowering cholesterol, reducing inflammation, and delaying aging (Li et al., 2019). In recent years, GTE and its principal component EGCG have been reported to have the so-called “fat-burning” weight loss effect (Chen et al., 2016), which makes it one of the most popular herbal and dietary supplement (HDS) in the world. However, in contrast to these health benefits, the number of drug-induced liver injury (DILI) cases when GTE is used for weight loss has consistently increased, with GTE being the leading cause of HDS-DILI in the United States (Navarro et al., 2017). GTE accounts for more than 50% of the suspected HDS products that cause DILI (Navarro et al., 2013). In severe cases, there is risk of acute liver failure or mortality. According to clinical observational research results, individuals who fasted or lost significant weight seemed to be more prone to liver injury, or liver injury was more severe when consuming GTE (Pillukat et al., 2014; Zheng et al., 2016). Although the hepatotoxicity of GTE and its main component EGCG has been reported (Emoto et al., 2014; Wang et al., 2015), it is not clear why there are more reports of liver injury when GTE is used for weight loss.

The “fat-burning” functions of EGCG were considered to include promoting energy consumption and fatty acid

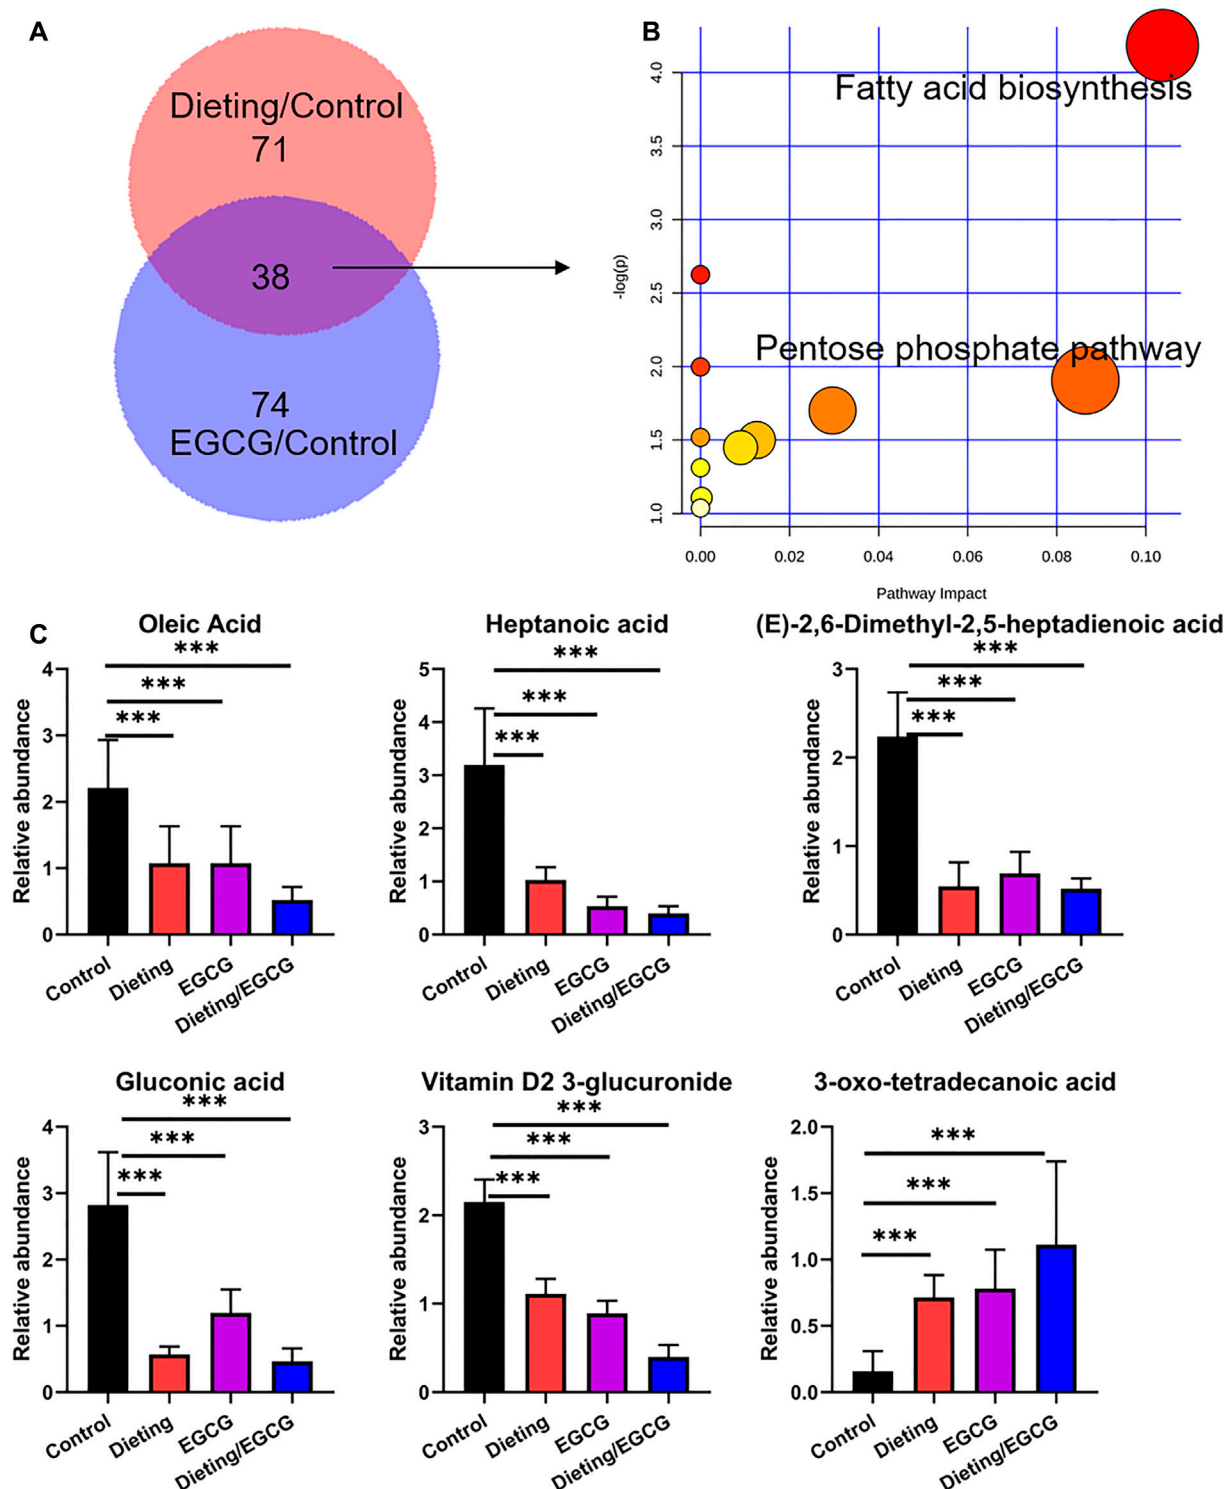

oxidation, inhibiting fatty acid synthesis, and reducing nutrition absorption (Wolfram et al., 2006; Rains et al., 2011; Yamashita et al., 2018). Some studies have shown that the process of weight loss through dieting (calorie restriction) is also accompanied by the remodeling of fatty acid metabolic pathways, such as decomposing more fatty acids to provide calories, thus achieving the effect of fat loss (Bruss et al., 2010; Lee et al., 2015; Collet et al., 2017; Green et al., 2019). Dieting while consuming EGCG can enhance the catabolism of fatty acids, which may increase the effect of fat loss. However, there is no experimental evidence as to whether this superposition of fatty acid metabolism regulation may be involved in the occurrence process of EGCG liver injury, thereby increasing the risk of EGCG-induced liver injury. In this regard, we try to characterize the metabolic alterations induced by EGCG and the dietary restriction in mice plasma using metabolomics approach and investigate the potential liver injury due to EGCG and dietary restriction alone or in combination, so as to provide experimental reference for rational use of GTE products for weight loss.

## MATERIALS AND METHODS

### Animal Grouping and Administration

Healthy female C57BL/6J mice, SPF grade, weighing 22–24 g, were purchased from SPF Experimental Technology Co., Ltd (License No.: SCXK (BJ) 2018-0010). Mice were provided with

**Figure 1 |** EGCG simulates the effect of dieting on fat loss. **(A)** The differential metabolites amount between dieting and control is displayed as pink, while that between EGCG and control is displayed as purple. The Venn diagram shows the shared metabolites between EGCG and dieting. **(B)** Pathway enrichment of 38 common metabolites. **(C)** Relative abundance of fat loss biomarkers. \*\*\* $p < 0.001$ .

food and water and kept at  $25 \pm 2^\circ\text{C}$ , 50–60% humidity, with 12 h/12 h light and dark cycles, in separate cages in the experimental animal center of the Fifth Medical Center of the Chinese PLA General

Hospital. All animal experiments were approved by the Center for Laboratory Animal Welfare and Ethics of the Fifth Medical Center of the Chinese PLA General Hospital and followed the Animal Research

Guidelines of National Institutes of Health. Epigallocatechin gallate (EGCG, purity  $\geq 98\%$ ) was purchased from Chengdu Preferred Biotech Co., Ltd.

The mice were adaptively fed for 7 days, during which their food intake was monitored to obtain the average daily food intake per cage. The basic feed composition has crude protein ( $\geq 180$  g/kg), crude fat ( $\geq 40$  g/kg), total amino acids ( $\geq 76.6$  g/kg), and various vitamins and micronutrients. The mice were then fed in the following two ways at 17:00 every day for 6 days: 1) free diet and 2) fixed diet, that is, 50% of the average daily food intake (limited less than 2 g each mouse 1 day). On the sixth day, the mice on the free diet were randomly divided into a control group (control), low-dose EGCG group (400 mg/kg), and high-dose EGCG group (800 mg/kg). Meanwhile, the mice on the fixed diet were randomly divided into three groups: dieting group, dieting/low-dose EGCG group (400 mg/kg), and dieting/high-dose EGCG group (800 mg/kg). The four administration groups were treated with intragastric EGCG of the corresponding dose at the same time. The control group and the dieting group were given equal volume of normal saline through intragastric means. There were eight mice in each group. After 24 h, the animals were sacrificed, blood was collected, and plasma was centrifuged at 4°C and frozen at -80°C. Fresh mice liver tissues were washed with normal saline and soaked in 4% neutral paraformaldehyde solution.

## Evaluation of Blood Biochemistry and Liver Histology

The frozen plasma was returned to room temperature, and alanine aminotransferase (ALT) and aspartate aminotransferase (AST), glutathione S-transferase (GST) activity, and total bile acid (TBA) concentration were measured and calculated according to the kit instructions. ALT kit (No.: C009-2), AST kit (No.: C010-2), GST kit (No.: A004), and TBA kit (No.: E003-2-1) were purchased from Nanjing Jiancheng Bioengineering Institute.

The liver tissues of mice were collected, and routine histological sections were stained with hematoxylin and eosin (HE). Then, the pathological sections were photographed under a microscope. Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) was used to detect and analyze the apoptosis of hepatocytes. Image-Pro Plus 6.0 software was used to label and calculate the apoptosis rate.

## Metabolomics Analysis

We selected plasma from the control, dieting, high-dose EGCG (800 mg/kg), and dieting/high-dose EGCG (800 mg/kg) groups as metabolomics test samples. The mice samples stored at -80°C refrigeration were thawed to 4°C, and 50  $\mu$ l of each sample was pipetted into the 1.5 ml EP tube; three times the volume of precooled methanol was added, vortexed for 30 s, and kept standing at 4°C for 30 min. It was then centrifuged at 14,000 rpm for 15 min in a precooled 4°C centrifuge; 100  $\mu$ l of supernatant was pipetted and dried with nitrogen. 75% methanol of the same volume was added to reconstitute the sample to be tested. Meanwhile, 10  $\mu$ l of each sample was taken and mixed

evenly and used as the quality control (QC) sample. For plasma metabolite chromatographic separation conditions and non-targeted metabolomics mass spectrometry detection conditions, please see the **Supplementary Material**.

Using MassHunter Qualitative Analysis software (version B06.00, Agilent, United States), LC-MS raw data was converted into visual data. MZmine software (version 2.5) was used for peak extraction, data correction, chromatographic deconvolution, and comparison. The raw data was displayed on the MetaboAnalyst webpage (<https://www.metaboanalyst.ca/>) and normalized and compared between groups, and metabolites with group differences were screened by calculating the fold change (FC) values and significant differences ( $p$  value) between groups. The criteria for differences between groups were as follows: FC was greater than 1.5 or less than 0.67, and  $p$  value was less than 0.05. At the same time, the obtained data matrix was imported into SIMCA-P software (version 14.1, Umetrics AB, Umea, Sweden) for principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA). Under the OPLS-DA model, the important variable (VIP)  $> 0.5$  and  $|p(\text{corr})| \geq 0.5$  were used as the screening criteria for metabolites with inter-group differences. These metabolites were then identified using the Metlin database (<http://www.metlin.scripps.edu/>) and HMDB (<http://www.hmdb.ca/>) (mass error limited to 30 ppm). Pathway analysis based on the identified metabolites was conducted using MetaboAnalyst according to the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway database ([www.genome.jp/kegg/](http://www.genome.jp/kegg/)). MS/MS spectra of mainly representative metabolites were in **Supplementary Figure S4**.

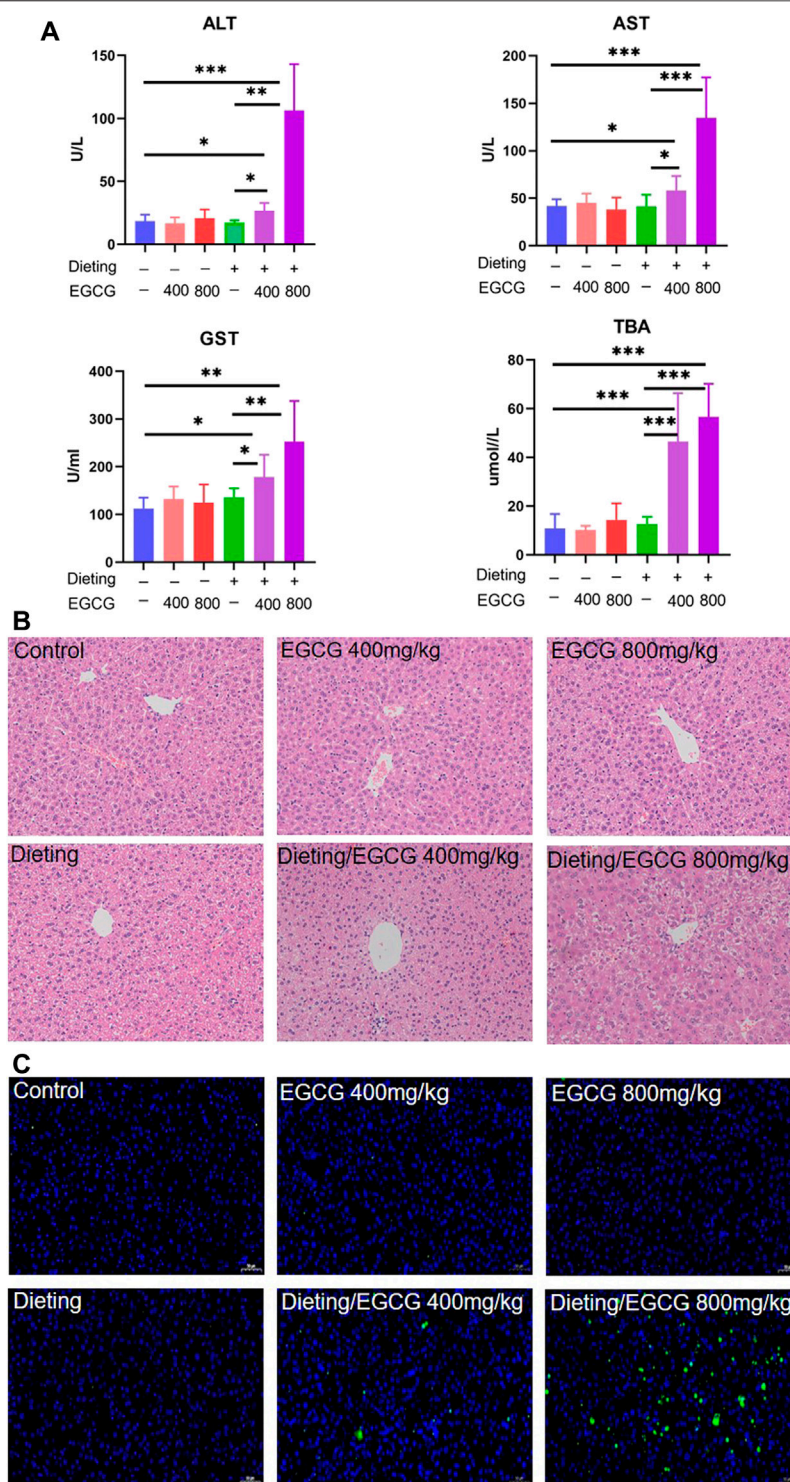

## Statistical Analysis

The experimental data was expressed as mean  $\pm$  SD. GraphPad Prism software version 8 was used for statistical analysis, Student's  $t$ -test was used for inter-group comparison, and analysis of variance (ANOVA) was used for one-way ANOVA.  $p < 0.05$ ,  $p < 0.01$ , and  $p < 0.001$  were considered to be statistically significant.

## RESULTS

### EGCG Simulates Dieting Effects for Lipid Metabolism

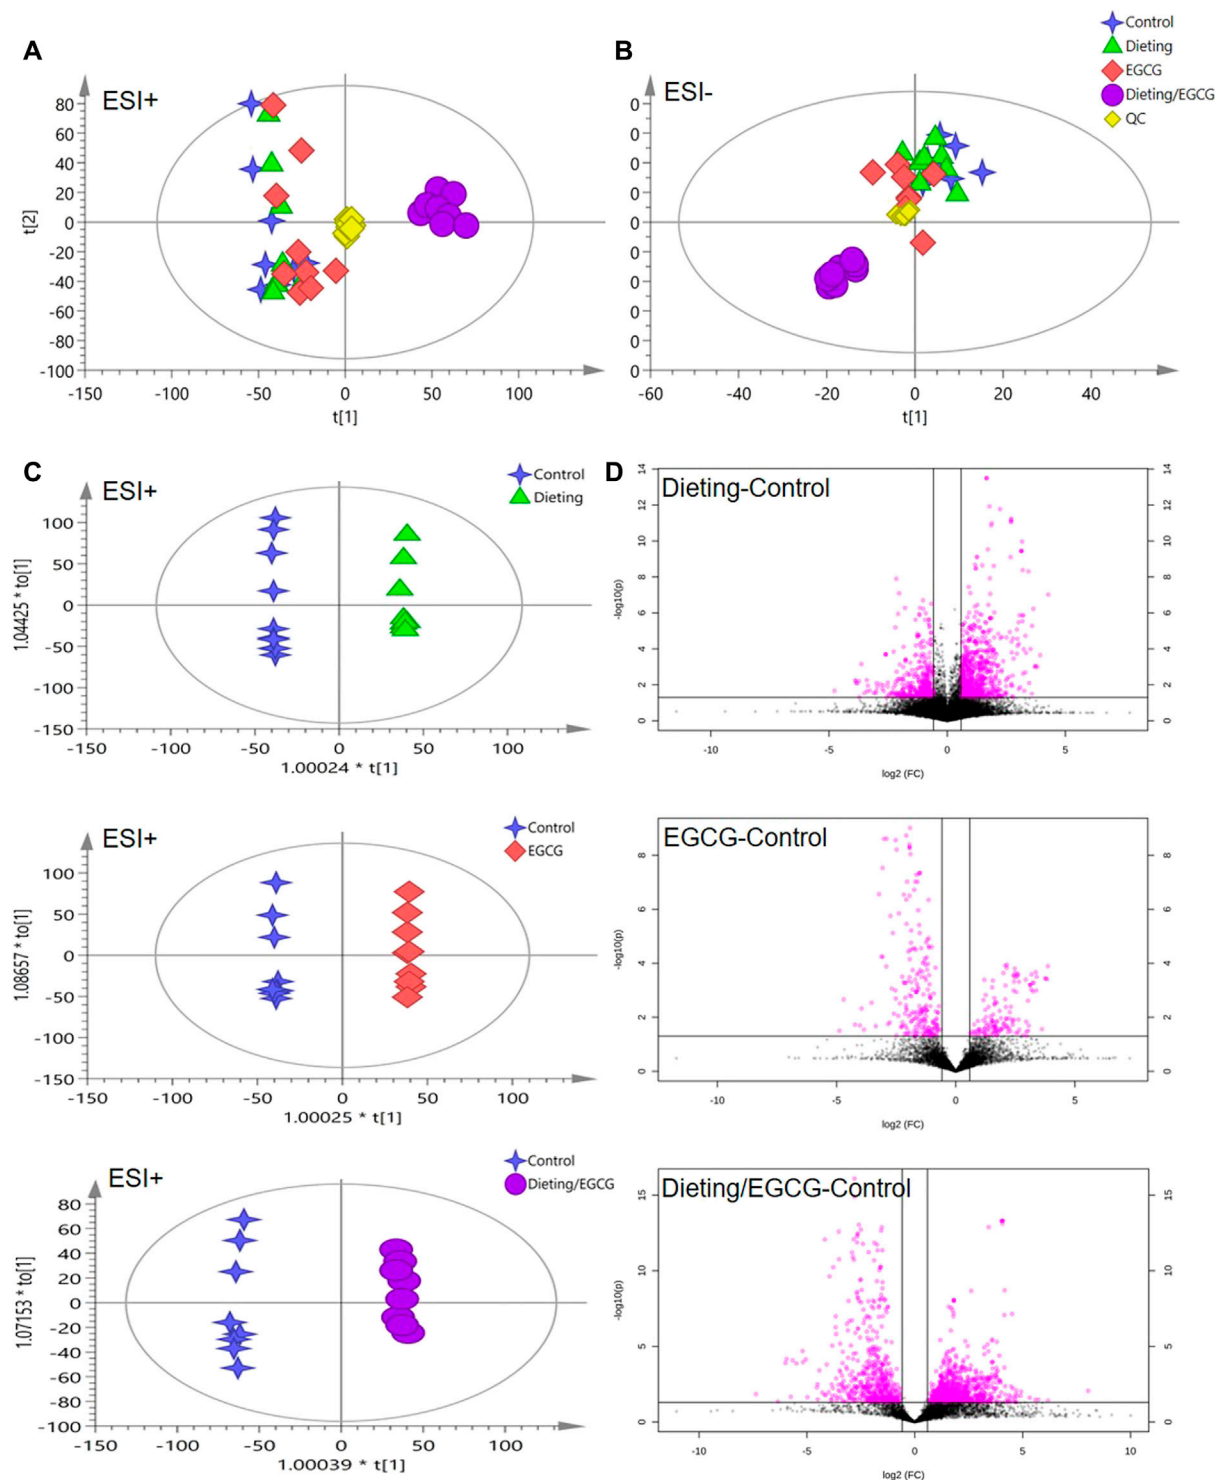

We screened and identified differential metabolites to study the metabolic changes caused by EGCG and diet on the mice. EGCG and diet coregulated metabolites as shown in the Venn diagram in **Figure 1A**. The pathways altered by EGCG and dieting mainly focused on fatty acid biosynthesis and pentose phosphate pathway (**Figure 1B**). Biomarkers included gluconic acid, oleic acid, heptanoic acid, (E)-2, 6-dimethyl-2, 5-heptadienoic acid, vitamin D2 3-glucuronide, and 3-oxotetradecanoic acid. The corresponding abundance changes were shown in **Figure 1C**, and the specific identification information was shown in **Supplementary Table S1**. We found that dietary restriction could slow down fatty acid synthesis, which could explain the fat loss effect caused by dieting. EGCG could also slow down fatty acid synthesis, which was consistent with its claimed weight loss effect. At

**Figure 2 |** Dieting exacerbates EGCG hepatotoxicity in mice. **(A)** Plasma ALT; AST; GST; TBA. the same time, we found that, in the dieting/EGCG group, the content of related biomarkers decreased further, but the excessive metabolic changes brought about by this

combination may also cause adverse results. Therefore, we compared the liver injury induced by EGCG with that induced by EGCG under dietary restriction *in vitro* and *in vivo*.

## Dietary Restriction Exacerbates EGCG Hepatotoxicity *In Vivo*

The experimental animal results (Figure 2A) showed that, compared with the control group, there were no statistical differences in biochemical indexes between dieting group and each EGCG single administration group ( $p > 0.05$ ). However, there were significant increases on ALT, AST, GST, and TBA in the combination groups of dieting with EGCG ( $p < 0.01$ ). The liver injury indicators in the high-dose (800 mg/kg) EGCG with dieting group were higher than those of the low-dose combination group (400 mg/kg).

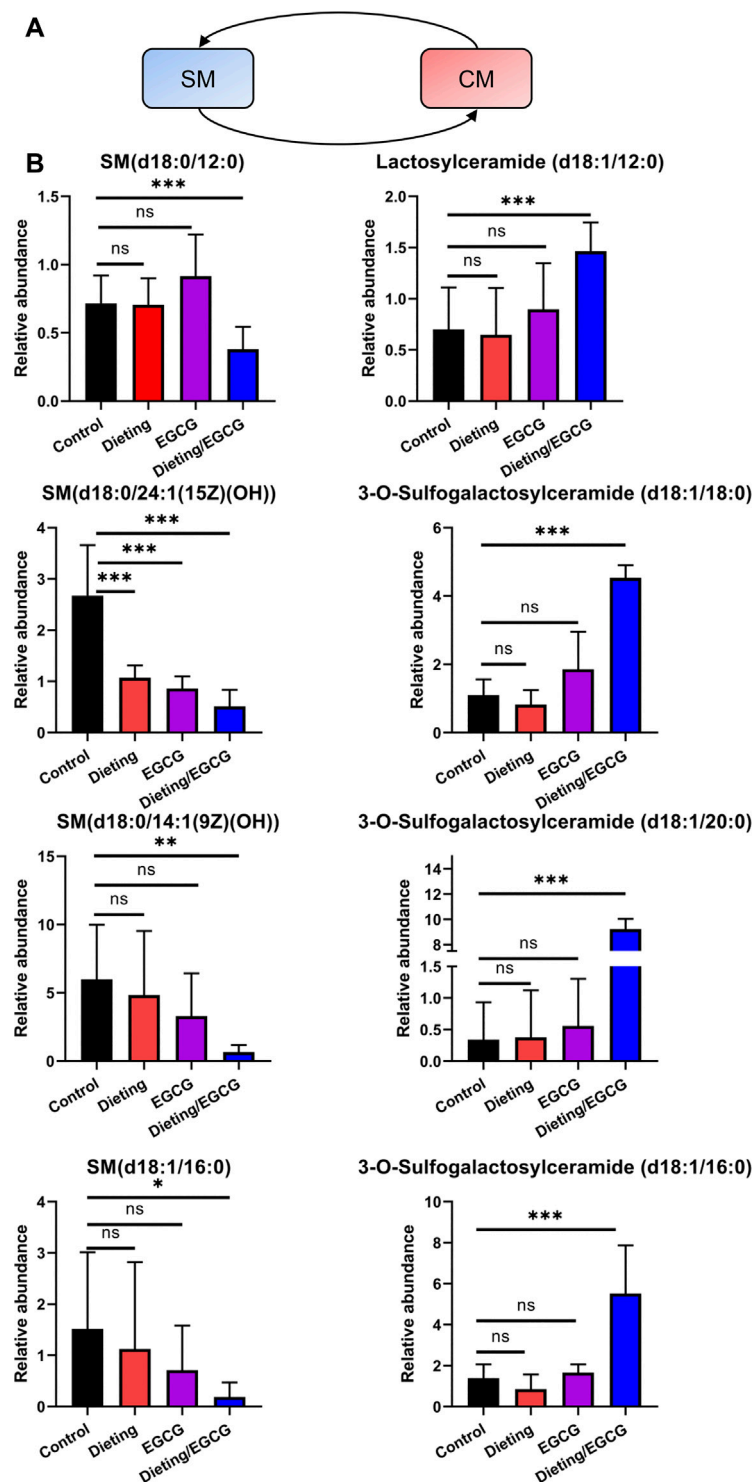

The results of HE staining (Figure 2B) showed that the hepatocytes in the control, EGCG, and dieting groups represented with normal morphology. By contrast, obvious histological changes occurred in the diet combined with EGCG treatment group, including a decrease in the number of hepatocytes and some vacuolar degeneration, accompanied by infiltration of inflammatory cells. In the TUNEL staining results (Figure 2C), there were basically no green fluorescence positive cells in the visual field of the single administration group compared with the control group, and there was no statistical difference in the calculated apoptosis rate. Under dietary restriction conditions, green fluorescence positive cells were scattered in the visual field of 400 mg/kg EGCG administration group, and the apoptosis rate was significantly different from that of the control group ( $p < 0.05$ ). There was more hepatocyte apoptosis in the visual field of 800 mg/kg EGCG combined

with diet, and the apoptosis rate was significantly different from that in the control group ( $p < 0.01$ ) (Supplementary Figure S1). The above results indicate that EGCG can cause increased hepatocyte apoptosis under dietary restriction.

## Metabolomics Analysis of Dietary Restriction Exacerbating EGCG Hepatotoxicity

PCA and OPLS-DA analysis were carried out on the data in positive and negative ion modes using SIMCA-P. Figures 3A,B displayed the scattered point plots of PCA of all samples in positive ion and negative ion modes. It could be seen that QC samples were concentrated in the middle of the score matrix projection plot, which indicated that the instrument remained stable during the analysis process. In addition, in positive ion mode, control, EGCG, and dieting groups were distributed on the left side of the first principal component, while dieting/EGCG group was located on the right side of the first principal component and was far away from control, EGCG, and dieting groups, suggesting that the metabolic profile of the dieting/EGCG group had obviously changed, which was consistent with the experimental phenotype of liver injury caused by EGCG under dietary restriction.

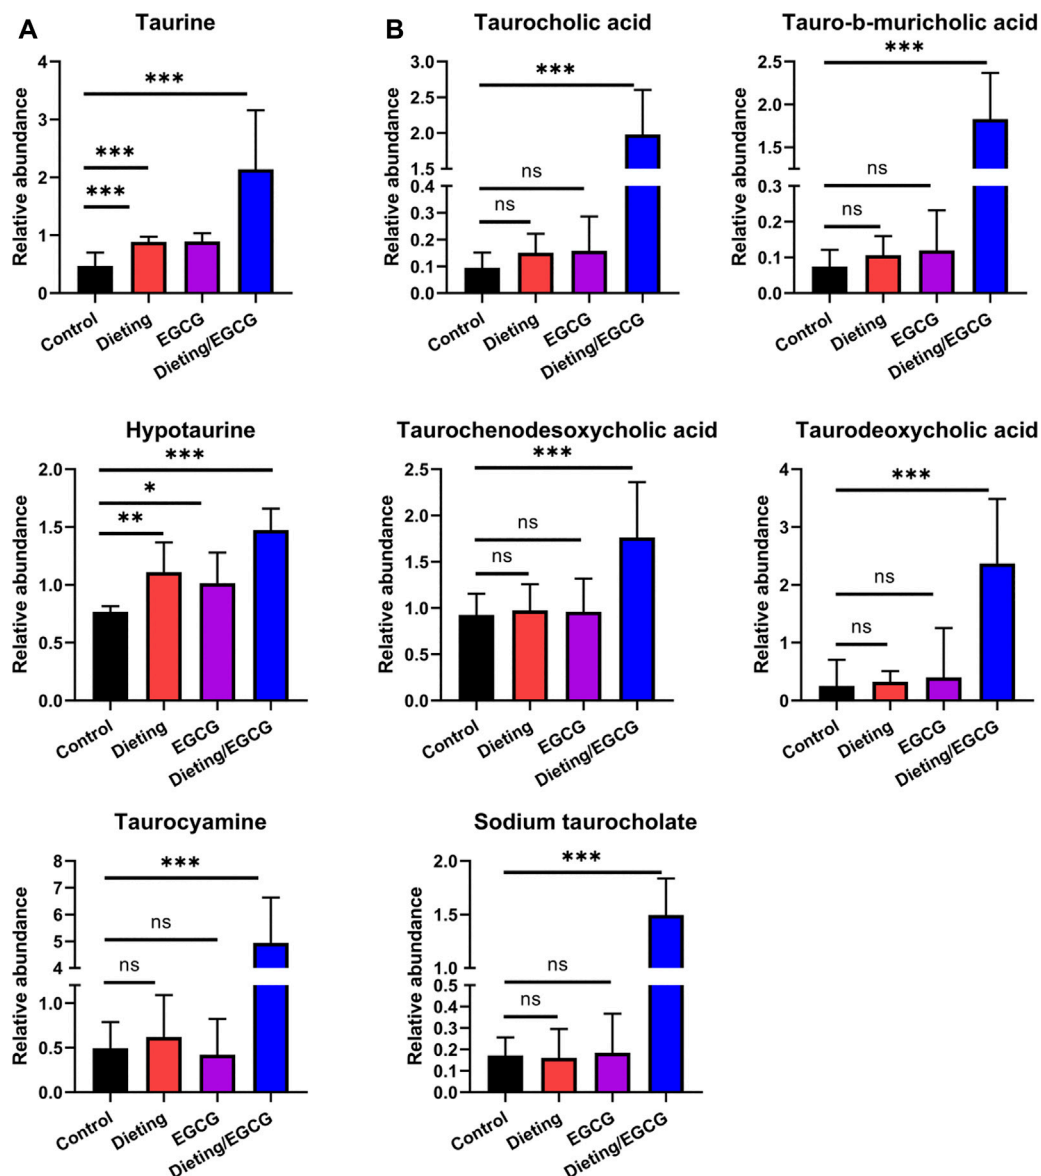

In order to further obtain the differences between groups and different compounds, OPLS-DA modeling and analysis were carried out. In the positive ion mode, dieting and control,

**Figure 6 |** Dieting exacerbating EGCG hepatotoxicity disrupts SM-CM cycle. **(A)** SM-CM cycle. Blue represents downregulation and red represents upregulation. **(B)** Relative abundance of metabolites in SM-CM cycle. \* $p < 0.05$ , \*\* $p < 0.01$ , and \*\*\* $p < 0.001$ ; CM, ceramides; ns, no significance; SM, sphingomyelin.

EGCG and control, dieting/EGCG and control groups were located on both sides of the ordinate and were completely separated. Volcanic plots showed the metabolic changes in mice induced by dieting, EGCG, or dieting/EGCG (Figures 3C,D for positive

ion and Supplementary Figure S2 for negative ion). Further, we used dieting/EGCG and control to screen the metabolic pathways related to liver injury. We found that some important pathways were alteration, including linoleic acid metabolism,

**Figure 7 |** Dieting exacerbating EGCG hepatotoxicity increases taurine metabolites and taurine-conjugated bile acids. **(A)** Relative abundance of taurine, hypotaurine, taurocyamine. **(B)** Relative abundance of taurine-conjugated bile acids. \* $p < 0.05$ , \*\* $p < 0.01$ , and \*\*\* $p < 0.001$ ; ns, no significance.

glycerophospholipid metabolism, sphingolipid metabolism, taurine, and hypotaurine metabolism (Supplementary Figure S3).

### Dietary Restriction Exacerbating EGCG Hepatotoxicity Was Associated With Increased Production of Pro-Inflammatory Metabolites Through Arachidonic Acid and Linoleic Acid Metabolism

Unsaturated fatty acid catabolism was significantly enhanced, which may be an important marker of lipid peroxidation; the plasma levels of arachidonic acid (Figure 4A) decreased significantly in the dieting/EGCG group, while the levels of its derived eicosanoid acids including 15-deoxy-delta12, 14-PGJ2, leukotriene D4, and thromboxane A2

significantly increased (Figure 4B). We also found that linoleic acid metabolism (Figure 4C) was disrupted, and the level of linoleate in dieting/EGCG group was significantly reduced. Its downstream metabolites including 9(10)-EpOME, 9,10-DHOME, 12(13)-EpOME, 12,13-DHOME showed different degrees of upregulation in the combined treatment group (Figure 4D). The above specific identification information is shown in Supplementary Tables S2, S3.

### Dietary Restriction Exacerbating EGCG Hepatotoxicity Disrupts Lands' Cycle

Metabolic remodeling is an important manifestation of the liver's stress response, wherein the dynamic transition between phosphatidylcholine (PC) and lysophosphatidylcholine (LPC)

(Lands' cycle) is the key regulatory pathway (**Figure 5A**). We found that dieting/EGCG group significantly upregulated PC, while LPC, a precursor for synthesizing PC, significantly decreased; for example, LPC (20:3) is converted to PC (20:3/18:1) by lysophosphatidylcholine acyltransferases (LPCAT) using oleoyl-CoA (18:1-CoA). We identified 12 groups of LPC to PC transformations (**Figure 5B**) and eight phospholipid metabolites with no corresponding relationship. The specific identification information was shown in **Supplementary Table S4**. As can be clearly seen from **Figure 5B**, the LPCs tended to decrease in the EGCG and dieting groups and further decreased in the dieting/EGCG group. We could see that the length of the carbon chain affected by liver injury ranged from 14 to 22, including both saturated and unsaturated chains, indicating that this metabolic change did not have anything to do with the length of fatty acid side chain and the number of double bonds, but was only related to the formation of PC corresponding to the addition of a fatty acid side chain on LPC. It could be seen that the changes in phospholipid component were extensive and not specific to a specific phospholipid component. The changes of these biomarkers showed that dietary restriction exacerbating liver injury induced by EGCG could cause metabolic abnormalities in Lands' cycle.

### Dietary Restriction Exacerbating EGCG Hepatotoxicity Disrupts SM-CM Cycle

The dynamic conversion between sphingomyelin (SM) and ceramides (CM) is another crucial regulatory pathway in the process of liver's stress response (**Figure 6A**). Through metabolomics analysis, we found that the SM-CM cycle was broken during liver injury, which is manifested in the following: multiple sphingomyelins, including SM (d18:0/24:1 (15Z) (OH)), SM (d18:0/14:1 (9Z) (OH)), SM (d18:1/16:0), and SM (d18:0/12:0), were significantly downregulated in the dieting/EGCG group; at the same time, several ceramide metabolites, including lactosylceramide (d18:1/12:0), 3-O-sulfogalactosylceramide (d18:1/18:0), 3-O-sulfogalactosylceramide (d18:1/20:0), and 3-O-sulfogalactosylceramide (d18:1/16:0), were significantly upregulated in the dieting/EGCG group (**Figure 6B**). The specific identification information is shown in **Supplementary Table S5**. These results showed that the metabolic transition from SM to CM was one of the important characteristics of dieting exacerbating liver injury induced by EGCG.

### Dietary Restriction Exacerbating EGCG Hepatotoxicity Increases Taurine Metabolites and Taurine-Conjugated Bile Acids Levels

In addition to the above metabolic characteristics, we also found that the levels of taurine and taurine-conjugated bile acids increased significantly. Taurine and its metabolites, hypotaurine and taurocyamine, were significantly higher in the dieting/EGCG group than in the dieting or EGCG group (**Figure 7A**). Taurine-conjugated bile acids, including taurodeoxycholic acid, tauro-b-muricholic acid, taurocholic acid, sodium taurocholate, and taurochenodesoxycholic acid,

were not significantly different between the dieting and EGCG groups but increased more than three times in the dieting/EGCG group (**Figure 7B**). Specific identification information is shown in **Supplementary Table S6**.

## DISCUSSION

With increasing obesity globally, there has been a steady increase in the consumption of GTE for weight loss. EGCG is the main component of GTE, and its big selling point is fat burning. However, the potential mechanism of such claimed weight loss effect of EGCG has not been fully characterized. Thus, we used metabolomics to reveal the effects between EGCG and dietary restriction on mice. The results showed that either EGCG treatment or dieting could regulate lipid metabolism, pentose phosphate pathway and other metabolic pathways, to inhibit fatty acid synthesis and to enhance the oxidation of fatty acid in mice. In addition, either EGCG or dietary restriction could reduce gluconic acid, indicating that pentose phosphate pathway may be inhibited, and nicotinamide adenine dinucleotide phosphate (NADPH), an important raw material for fatty acid elongation, could be reduced, which in turn would lead to the slowdown of fatty acid synthesis. These results suggested that EGCG could simulate the fatty acid consumption effect caused by dieting and had the so-called "fat-burning" effect.

However, the reports of adverse reactions related to HDS for weight loss, especially the liver injury caused by GTE, have increased significantly to a leading cause of HDS-DILI in recent years. It has been shown that a single large dose of EGCG (1,500 mg/kg) can cause liver injury in normal mice (Lambert et al., 2010). As known, drug-induced liver injury is affected by drugs, the host and the environment, of which the host's state could be an important risk factor (Fontana, 2014). In this study, we observed for the first time that 400 mg/kg EGCG (equivalent to four times the common daily dose) could cause significant increase of transaminase and hepatocyte damage on a dietary restriction mice model; however, in normal mice, the same dose of EGCG did not cause liver injury. The above results suggested that dieting could increase the risk of EGCG-induced liver injury, with the characterization of combined toxicity potentiation. This is the first time that dieting has been proved to be a risk factor for EGCG hepatotoxicity by experimental evidence.

We further investigated the metabolic underlying mechanism wherein dietary restriction could increase the risk of EGCG-induced liver injury. We found that enhancement of fatty acid peroxidation pathway was caused by combining EGCG treatment and dietary restriction. It generated excessive oxidative pro-inflammatory lipid metabolites (9(10)-EpOME, 9,10-DHOME, 12(13)-EpOME, 12,13-DHOME) of linoleic acid. Moreover, the levels of eicosanoid oxidative metabolites (15-deoxy-delta12, 14-PGJ2, leukotriene D4, and thromboxane A2) in the downstream of arachidonic acid increased, which have been shown to promote inflammation and cell damage (Hall et al., 2017). It could be seen that liver injury caused by EGCG and dieting may be related to the increase of pro-inflammatory lipid peroxidation products,

which further mediates tissue inflammation and injury. Except for the overlap of metabolic pathways regulation, other mechanisms could lead to the rising risks of EGCG administration during diet. For example, the blood concentration of EGCG increased more than 3.5-fold in the fasting condition that the EGCG exposure of liver tissue lifted in Beagle dogs, thus exacerbating the risk of liver injury (Kapetanovic et al., 2009).

We also characterized some metabolic features related to EGCG treatment plus dietary restriction-induced liver injury. Among them, the disturbances of Lands' cycle, SM-CM cycle, and bile acids are crucial. Firstly, we observed the significant decrease of LPC and increase of its corresponding PC components in dieting/EGCG group. This feature of disturbance in Lands' cycle has been reported as an important metabolic feature of various liver injuries such as steatohepatitis or alcoholic liver disease (Matsubara et al., 2011), which illustrated the liver injury phenotype found in our experiment. Similarly, the second metabolic feature—SM level decrease and CM level increase—reflects the disturbance of SM-CM cycle. Notably, the conversation of LPC-PC cycle and SM-CM cycle is controlled by LPCAT and sphingomyelin phosphodiesterase (SMPD, also known as sphingomyelinase), respectively. Such two key metabolic enzymes' overexpression has been demonstrated as important features of hepatocytes in response to chemical toxin-induced liver injury (Liu et al., 2014). In addition, due to the combined inhibition of EGCG and dietary restriction on fatty acid synthase (FASN) and carnitine palmitoyl transferase-1 (CPT-1), cytoplasmic fatty acyl CoA accumulates and condenses with serine to produce 3-ketosphinganine and is then metabolized by ceramide synthetase to produce CM (Khiewkamrop et al., 2018). CM is a functional sphingolipid, and the upregulation of CM is an important signal for the activation of apoptosis cascade increasing the expression of pro-apoptotic protein Bcl2 and inducing apoptosis of various cells (Siskind et al., 2010). The high abundance of CM could promote ROS production by directly acting on mitochondrial respiratory electron chains (Abadie et al., 2001). It was indicated that increased CM may not only be a metabolomic characteristic of EGCG liver injury, but also participate in the process of liver injury. Last but not least, dysregulated taurine-conjugated bile acids are suggested to play roles in several diseases, which may be related to the high expression of bile acid transporter induced by hepatocyte injury signal.

Taken together, the disturbances of Lands' cycle, SM-CM cycle, and taurine-conjugated bile acids may be the metabolomic characteristics of EGCG and dieting-induced liver injury, and some active metabolites may also be partially involved in the liver injury process. These metabolic characteristics could be utilized in clinical monitoring of the incidence risk of EGCG hepatotoxicity. Though this paper fully characterizes the metabolic alteration reflecting *in vivo* biological processes, further causality relationship and mechanism researches are worthy explored.

It is worth pointing out that few reports of liver injury were a result of the consumption of green tea in China, which is significantly different from the situation in the United States.

Green tea is mainly used as a beverage in China, with 2–3 g of natural tea leaves soaked in water each time, where the average EGCG content is 0.7% in the natural tea beverage (James et al., 2018). However, in the United States, HDS products using GTEs are made up of complete polyphenols extracted from tea leaves with further purified EGCG or artificially added EGCG, and the EGCG content in some GTE products exceeds 90% (Hopley, 2005). The dose of tea polyphenols ingested when consuming tea is very low and obviously lower than that of GTE products in the United States, which means that we take the daily GTE product containing 800 mg of EGCG as the dosage comparable to drinking 114 g of green tea in one day. In addition, tea is traditionally consumed as a beverage in China; its extracts are not concentrated and used for weight loss, nor is it used for dieting, and people often drink tea before or after meals, so it can be explained from one aspect that green tea does not cause liver injury in China.

## CONCLUSION

To summarize, low dose of EGCG can increase fatty acid decomposition and inhibit fatty acid synthesis to a certain extent, which simulates the effect of dietary restriction on fatty acid metabolism and has certain fat loss effect. However, consuming EGCG while dieting could excessively disturb lipid metabolic pathways and lead to liver injury in mice, which indicates that dietary restriction could increase the risk of liver injury caused by EGCG. This happens to be a dilemma for people who plan to lose weight, as dieting and consuming EGCG concurrently may speed up weight loss, but it also leads to a higher risk of liver injury.

*Portulaca oleracea* L., known as the “vegetable for long life,” is an annual succulent herb that is widely distributed worldwide. Many clinical and experimental studies have demonstrated that purslane seed (MCXZ) can be used as an adjunctive and alternative therapy for the treatment of diabetes mellitus (DM). However, the underlying active constituents and pharmacological mechanisms through which MCXZ exerts effects in DM remain unclear. In the present study, we confirmed that MCXZ treatment resulted in hypoglycemic activity, lowering the fasting blood glucose and glycated hemoglobin levels in streptozotocin-induced diabetic mice. Then, ultra-high-pressure liquid chromatography coupled with linear ion trap-Orbitrap tandem mass spectrometry was used to systematically analyze the chemical profile of MCXZ, resulting in the identification of 84 constituents, including 31 organic acids and nine flavonoids. Finally, the Integrative Pharmacology-based Research Platform of Traditional Chinese Medicine was employed to analyze the key active components of MCXZ and the molecular mechanisms through which these components acted in DM. Ten key active compounds were identified based on the topological importance of their corresponding putative targets within the known DM-associated therapeutic target network of known MCXZ putative targets. Functionally, these candidate targets play critical anti-hyperlipidemia, anti-hyperglycemia, immunity regulation, and inflammatory roles involving DM-related pathways, such as the vascular endothelial growth factor (VEGF) signaling pathway and Fc gamma R-mediated phagocytosis, which indicated that MCXZ exhibited anti-diabetic activity through multi-faced actions.

**Keywords:** purslane seed, diabetes mellitus, UHPLC-LTQ-orbitrap, TCMIP v20, molecular network

## INTRODUCTION

Diabetes mellitus (DM) represents a major public health issue, causing serious economic burdens for both developed and developing countries (Papatheodorou et al., 2018). The International Diabetes Federation (IDF) reported that approximately 463 million individuals had diabetes worldwide in 2019, including 116 million patients in China, which was ranked first in the world (International Diabetes Federation (IDF), 2019). Persistent hyperglycemia and long-term metabolic disorders may lead to the development of nephropathy, retinopathy, neuropathy, and cardiovascular disease (Zhang H. et al., 2018). Currently, the drugs used to treat DM include biguanide, sulfonylureas,  $\alpha$ -glycosidase inhibitors, benzoin acid, and derivative secretagogues, most of which aim to control blood glucose levels and must be used long-term. Gradual increases in the required doses of these drugs can lead to liver and kidney dysfunction, which can be associated with various complications, in addition to those resulting from the disease process (Moukette et al., 2017). Therefore, the development of safer, more effective drugs, especially those derived from natural products, which can provide improved management for blood glucose and diabetes-associated complications, has long been the focus of DM studies.

Traditional Chinese medicine (TCM) is practiced as a form of holistic and personalized medicine and has been shown to effectively lower blood glucose levels, control diabetic complications, and cause fewer side-effects than western medicines, based on syndrome differentiation and treatments (Zhang, 2014) that are multi-component, multi-pattern, and multi-target. As a result, increasing research has focused on the TCM-based treatment of DM. In TCM theory, DM belongs to the category of “Xiao-Ke-Zheng,” which was first recorded in the classical medical text “Huangdi Neijing” over a thousand years ago. Purslane is an annual succulent herb best known as the “vegetable for long life” and is distributed throughout diverse geographical environments worldwide. Purslane seed (MCXZ) has been used as both food and medicine for thousands of years in China (Aberoumand, 2009). Clinically, MCXZ, as an adjuvant combined with other treatments, has been shown to alleviate DM symptoms, including reduced inflammation and improved liver function (El-Sayed, 2011; Dehghan et al., 2016). Chemically, a wide variety of compounds have been identified in MCXZ, including flavonoids, polysaccharides, fatty acids, proteins, glutathione, antioxidants, and vitamins (El-Sayed, 2011). Pharmacologically, MCXZ has been associated with various biological activities, including hypoglycemic (A. Mohamed et al., 2019), hypocholesterolemic (Movahedian et al., 2007), anti-oxidative (Guo et al., 2016), diuretic, antipyretic, analgesic, and anti-inflammatory (Daniel, 2006) processes. Currently, MCXZ is used as an adjuvant treatment for DM to improve glucose tolerance, lipid metabolism disorders, liver functions, and insulin sensitivity and reduce hyperinsulinemia (Mohanapriya et al., 2006; El-Sayed, 2011). However, the potential active components and molecular mechanisms through which MCXZ acts and that may be applied to the direct treatment of DM remain unclear, which limits the clinical applications of MCXZ.

In the current study, an integrative pharmacology approach was used to investigate the active constituents and the underlying pharmacological mechanisms through which MCXZ acts during the treatment of DM. This study combined high-throughput chemical analysis, target prediction, and network construction and analysis, which was performed by following a three-step analytical process (Figure 1). 1) Chemical information databases, including the Encyclopedia of Traditional Chinese Medicine (ETCM) and other electronic databases, were searched for the constituents of purslane. 2) Ultra-high-pressure liquid chromatography coupled with linear ion trap-Orbitrap tandem mass spectrometry (UHPLC-LTQ-Orbitrap) was performed to rapidly characterize the preliminary chemical profile of MCXZ. 3) The TCMIP V2.0 platform was utilized to predict MCXZ putative targets, construct a drug target-disease-gene network based on predicted interactions among MCXZ putative targets and known therapeutic targets associated with DM-related diseases, and identify potential active constituents correlated with the candidate MCXZ targets during the treatment of DM.

## MATERIALS AND METHODS

### Chemicals and Materials

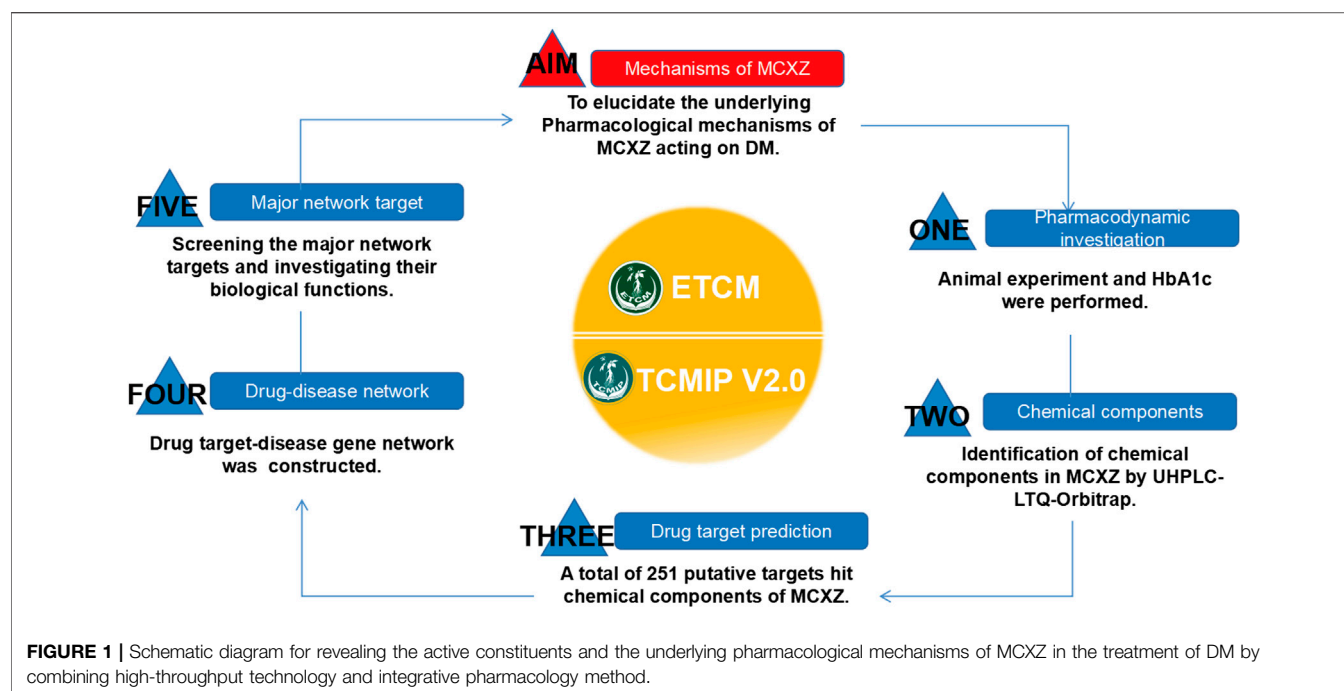

Mass spectrometry-grade methanol, acetonitrile, and formic acid were acquired from Fisher Scientific Co. (Loughborough, United Kingdom). Purified water was prepared by a Milli-Q system (Millipore, Billerica, MA, United States). Other reagents used in the experiment were of analytical grade. MCXZ was supplied by Guangzhou Zhongda Pharmaceutical Development Co., Ltd. (Batch NO. 180201; Guangzhou, China). This drug was identified as a dry, mature seed from *Portulaca oleracea* by the pharmacist Yan Jin (research assistant at the China Academy of Chinese Medical Sciences).

### Animals and Experimental Design

Healthy specific-pathogen-free (SPF)-grade male Balb/c mice (body weight: 18.0–21.0 g) were purchased from the Department of Experimental Animal Science, Department of Medicine, Peking University (Beijing, China). The project identification code was 20160010. All animal experiments were approved by the Committee on Animal Care and Use of the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences. Before the experiment began, all animals were placed in a standard laboratory environment, during which they were provided free access to food and water. The experiment did not begin until the animals had adapted to the environment for 3 days.

Dried MCXZ was ground into a powder with 80 mesh by a high-speed multi-function grinder (JP-500C, Yongkang Jiupin Industry and Trade Co., Ltd.). Before administration, the powder was dissolved in normal saline containing 0.5% carboxymethyl cellulose sodium to prepare 54.17, 108.33, and 216.67 mg/ml suspensions (Liu, 2018).

Streptozotocin (STZ, 60 mg/kg, dissolved in 0.1 M sodium citrate buffer, pH 4.5) was injected intraperitoneally, continuously for 5 days to induce DM in mice (Goodarzi

et al., 2019). To establish the normal control group, 12 healthy mice were injected intraperitoneally with an equal volume of sodium citrate buffer. One week after the last injections, the mice were fasted for 5 h, after which blood was collected from the tail vein, and the fasting blood glucose (FBG) levels were measured using a blood glucose monitor (GT-1980, Aikelai Medical Electronics (Pinghu) Co., Ltd.). Mice with FBG levels greater than  $11.1 \text{ mmol} \cdot \text{L}^{-1}$  were considered to be successful DM model mice. All successfully modeled DM mice were randomly divided into five groups according to body weight and FBG: Model (STZ) group, Met (metformin hydrochloride) group, and MCXZ low-, medium-, and high-dose groups ( $n = 12$  for each group). The dose of metformin hydrochloride used was  $130 \text{ mg/kg}$  body weight (BW)/day; the low, medium, and high doses of MCXZ powder were 812.5, 1,625, and  $3,250 \text{ mg/kg}$  BW/day, respectively. The normal control group and model group were administered an equivalent volume of 0.9% NaCl. All groups were treated through intragastric administration for four consecutive weeks.

FBG (fasted for 5 h) was detected every 2 weeks for 4 weeks. At the end of the experiment, the mice were fasted for more than 12 h, and then eye blood samples were collected. Blood samples were collected in blank sterile tubes and allowed to coagulate at room temperature for 1 h. Then, whole blood was centrifuged at 3,500 rpm for 15 min. The serum was separated and stored at  $-80^{\circ}\text{C}$  for further studies.

### Measurement of Glycated Hemoglobin (HbA1c)

A specific enzyme-linked immunosorbent assay (ELISA) kit (Cusabio, batch number: M03033575) was used to quantify

HbA1c from serum samples. This assay employs the competitive inhibition enzyme immunoassay technique. The experiment was performed according to the manufacturer's instructions.

### Histopathological Evaluation of Liver and Kidney Tissues

The liver and kidney tissues were removed and immersed in 4% formalin for 72 h at  $4^{\circ}\text{C}$ . To analyze the histopathological changes that occurred in the liver and kidney, sections from paraffin-embedded tissues were stained with hematoxylin and eosin and captured under a light microscope (Olympus, BX51, Japan).

### Chemical Information Database for the Compounds Found in Purslane

The chemical compound database information associated with purslane primarily included chemical name, molecular formula, molecular weight, structural formula, and other information. The chemical components associated with purslane were collected from existing databases, using "*Portulaca oleracea*" as the keyword. These databases included the Encyclopedia of Traditional Chinese Medicine (ETCM, <http://www.nrc.ac.cn:9090/ETCM/>), which contains information about a total of 7,274 herbal ingredients (Xu et al., 2019). Other resources included electronic databases such as PubMed (<https://pubmed.ncbi.nlm.nih.gov/>, update on 2019) and CNKI (China Journals of Full-text database; <https://www.cnki.net/>, update on 2019). Detailed information regarding the identified compounds in purslane is presented in **Supplementary Table S1**.

## Preparation of Sample Solutions

MCXZ was ground into a powder with 40 mesh, and 1 g of powder was accurately weighed. The powder was dissolved in 10 ml 70% methanol and submitted to ultrasonic extraction for 40 min. The extracts were centrifuged for 12 min (at 12,000 rpm), and the supernatant was separated. The sample solution was subjected to 0.22-mm nylon membrane filtration and analyzed directly by UHPLC-LTQ-Orbitrap.

## LC System

Sample analysis was performed using the Thermo Accela UHPLC system (Thermo Fisher Scientific, San Jose, California, United States). Chromatographic separation was performed on a maintained reverse-phase column Waters HSS T3-C18 (2.1 × 100 mm, 1.8 μm). The mobile phase was a mixture of methanol (A) and 0.1% formic acid in water (B). The following elution gradient was used: 0–5 min, 3%–10% A; 5–25 min, 10%–40% A; 25–35 min, 40%–60% A; 35–45 min, 60%–80% A; 45–50 min, 80%–95% A; 50–60 min, 95% A. The flow rate was set to 0.3 ml/min, and the injection volume was 1 μL.

## Mass Spectrometry and Data Processing

For LC-ESI-MS<sup>n</sup> experiments, the samples were detected in the positive and negative ion modes by electrospray ionization (ESI) source and were scanned in one-stage and multi-stage modes separately. The parameters for the ESI source were as follows: ion source voltage, 3.5 kV; capillary temperature, 350°C; sheath and auxiliary gas pressure, 0.24 and 0.07 MPa, respectively; ion source temperature, 350°C. The sheath and auxiliary gas was nitrogen in both cases. The mass axis of MS was calibrated using an external standard method (the mass error was less than 5 ppm); mass calibration positive ion selection: 74.09643, 3.06037, 195.08465, 262.63612, 524.26496, and 1,022.00341; negative ion selection: 230.10174, 249.15299, and 407.28030. The MS<sup>1</sup> was fully scanned and acquired in the range of 50–1,500 m/z, with a resolution of 30,000. The MS<sup>2</sup> uses a data-dependent scan (DDS). The three peaks with the highest abundance were selected for collision-induced dissociation to obtain MS<sup>2</sup> data.

Mass Frontier 6.0 (Thermo Fisher Scientific) software and Xcalibur 2.1 (Thermo Fisher Scientific) software were employed for data analysis. The accuracy error threshold was fixed at 10 ppm.

## Prediction of Putative MCXZ Targets

According to the results of MCXZ component recognition, the corresponding targets were obtained through target prediction and functional analyses of TCM (including prescriptions) using the Integrative Pharmacology-based Research Platform of Traditional Chinese Medicine (TCMIP V2.0 <http://www.tcmip.cn/TCMIP/index.php>) (Xu H. Y. et al., 2017). The principle underlying target prediction is the use of MedChem Studio (version 3.0) software to search DrugBank for the structural similarities between the two-dimensional structures of chemical components and the certified drug (Approved), followed by scoring the similarity using the Tanimoto coefficient. When the similarity score was ≥0.8 (moderate-high similarity), the potential targets for the MCXZ chemical components were obtained.

## Prediction of Known Therapeutic Genes Acting on DM

The candidate therapeutic genes associated with DM were collected from the TCMIP V2.0 database using “Diabetes Mellitus” as the keyword. The platform integrates HPO, OMIM, TTD, Drugbank, DisGeNET, ORPHANET, and other drug, biological, and symptom databases.

## Protein–Protein Interaction Data

Protein–protein interactions (PPIs) were obtained by importing putative MCXZ targets and DM-related genes into the STRING database (<http://string-db.org/>, version 11.0). To ensure the accuracy of the results, the species was set to “Homo sapiens,” and the confidence was set to 0.4.

## Network Analysis and Visualization

To scientifically explain the complex relationships between putative MCXZ targets and known DM-related genes and to identify key nodes, Cytoscape software (version 3.7.1, Boston, MA, United States) was used to create an interaction network between identified components, putative targets, and known DM-related genes. This complex network analysis method includes data integration, analysis, and visualization. The Network Analyzer in Cytoscape software was then used to calculate the three topological parameters of each node gene, including “degree,” “betweenness,” and “closeness.” The core nodes of the interaction network between MCXZ and DM-related targets were obtained by selecting those targets with degree values greater than 2-fold the median value and the key core target network through which MCXZ acts on DM was acquired by selecting nodes that meet all three topological parameters simultaneously. These three topological parameters are typically used to evaluate the topological importance of nodes in molecular interaction networks. The higher the center of a node, the more important that the node was to the network (Mao et al., 2019).

## Pathway Enrichment Analysis

To elucidate the biological functions of putative MCXZ targets, the targets were introduced into DAVID (<https://david-d.ncifcrf.gov/>, version 6.7), and pathway enrichment analysis was conducted on targets within the network using the Kyoto Encyclopedia of Genes and Genomes database (KEGG, <http://www.genome.jp/kegg/>). Relevant pathways with *p*-values < 0.05 were selected as significant pathways.

## Quantitative Real-Time Reverse Transcriptase-Polymerase Chain Reaction (qRT-PCR)

Total RNA was isolated from pancreatic tissue using RNAiso Plus (TaKaRa, Tokyo, Japan). The PCR reaction procedures were performed as follows. Stage 1: Pre-denaturation, one cycle at 95°C for 5s. Stage 2: PCR reaction, 40 cycles at 95°C for 10s and 60°C for 30s. Stage 3: 1 cycle heating from 60°C–95°C, at 0.05°C/s. The relative expression levels of vascular endothelial growth

**FIGURE 2 |** MCXZ alleviates the symptoms of the mice with DM. **(A)** MCXZ reduce the FBG of the mice with DM. **(B)** MCXZ downregulated the level of HbA1c in the serum of mice with DM. MCXZ-L, MCXZ low dose group 812.5 mg/kg; MCXZ-M, MCXZ middle dose group 1625 mg/kg; MCXZ-H, MCXZ high dose group 3250 mg/kg. Data are mean  $\pm$  SD. \*\*\* $p$  < 0.001, \*\* $p$  < 0.01 vs. Control; #### $p$  < 0.0001, ## $p$  < 0.01, # $p$  < 0.05 vs. the model group;  $n$  = 8–12 animals per group.

factor (*VEGF*), erb-b2 receptor tyrosine kinase 2 (*ErbB2*), androgen receptor (*AR*), and protein kinase B (*Akt1*) were calculated using the  $2^{-\Delta\Delta C_t}$  method.  $\beta$ -actin (*ACTB*) was used as the internal control. All quantitative real-time reverse transcriptase-polymerase chain reaction (qRT-PCR) experiments were repeated three times. The primer sequences used in this study were as follows: *VEGF*-F, 5'-CCT GGG AAA TGT GCC TGT GA-3' and *VEGF*-R, 5'-ATT CGC ACA CGG TCT GT-3'; *ErbB2*-F, 5'-ATT GGC TCT CAT TCA CCG CA-3' and *ErbB2*-R, 5'-CCA AGC CCT CAA GAC CAC AT-3'; *Akt1*-F, 5'-GAT AAC GGA CTT CGG GCT GT-3' and *Akt1*-R, 5'-CGG CCA CAC ATC TCG TA-3'; androgen receptor (*AR*)-F, 5'-GCC CGA ATG CAA AGG TCT TC-3' and *AR*-R, 5'-CCC AGA GCT ACC TGC TTC AC-3'; *ACTB*-F, 5'-AGG GAA ATC GTG CGT GAC AT-3' and *ACTB*-R, 5'-AAC CGC TCG TTG CCA ATA GT-3'.

## Statistical Analysis

All data were analyzed by SPSS 25.0 software (SPSS Inc., Chicago, IL, United States). Data were expressed as the mean  $\pm$  standard error of the mean (SEM). The results were presented using GraphPad Prism 7.0 software (GraphPad Software, San Diego, CA, United States). Significant differences between normally distributed gene expression data were determined by one-way analysis of variance (ANOVA). The FBG and HbA1c data, which were not normally distributed, were analyzed using the nonparametric Kruskal-Wallis test.  $p$  < 0.05 was considered significant.

## RESULTS

### Effects of MCXZ on FBG and HbA1c Levels in DM Model Mice

As shown in Figure 2A, the FBG concentrations were significantly increased in diabetic model mice (model group) compared with those in normal mice (control group), whereas the MCXZ and Met groups showed significantly reduced FBG concentrations compared with that in the model group.

Meanwhile, to further examine the effects of MCXZ on DM, HbA1c levels were detected using an ELISA kit. HbA1c is currently considered the gold standard for glucose monitoring in patients with DM and has been increasingly adopted as a criterion for DM diagnosis. HbA1c levels were substantially increased in the diabetic model mice (model group) compared with those in normal animals (control group). Compared with the model group, mice treated with MCXZ showed significantly decreased HbA1c levels (Figure 2B). Surprisingly, the hypoglycemic effect observed in the low-dose MCXZ group was better than those observed in the medium- and high-dose groups.

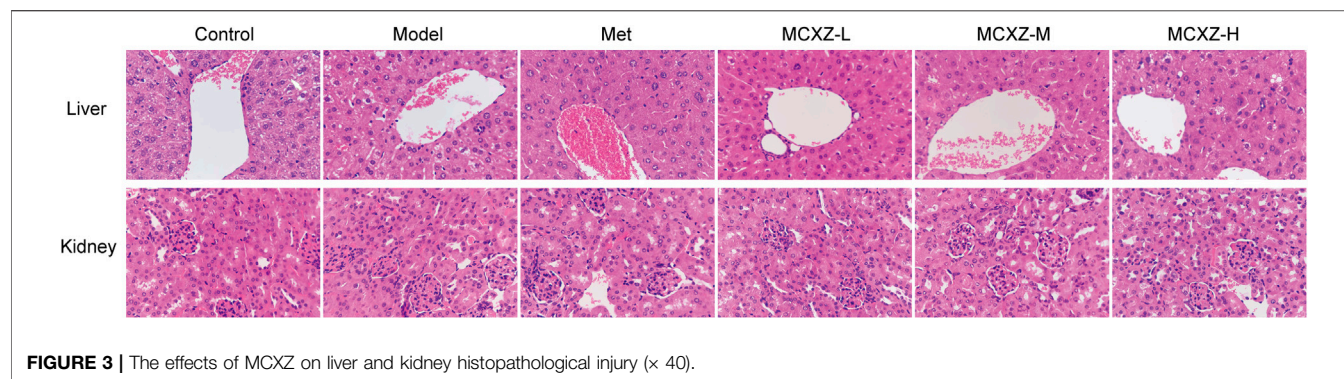

### Effects on Liver and Kidney Tissue Histopathology

As shown in Figure 3, compared with the control group, the structures of the liver and kidney tissues were not significantly altered in any of the experimental groups, including the Model, Met, MCXZ-L, MCXZ-M, and MCXZ-H groups.

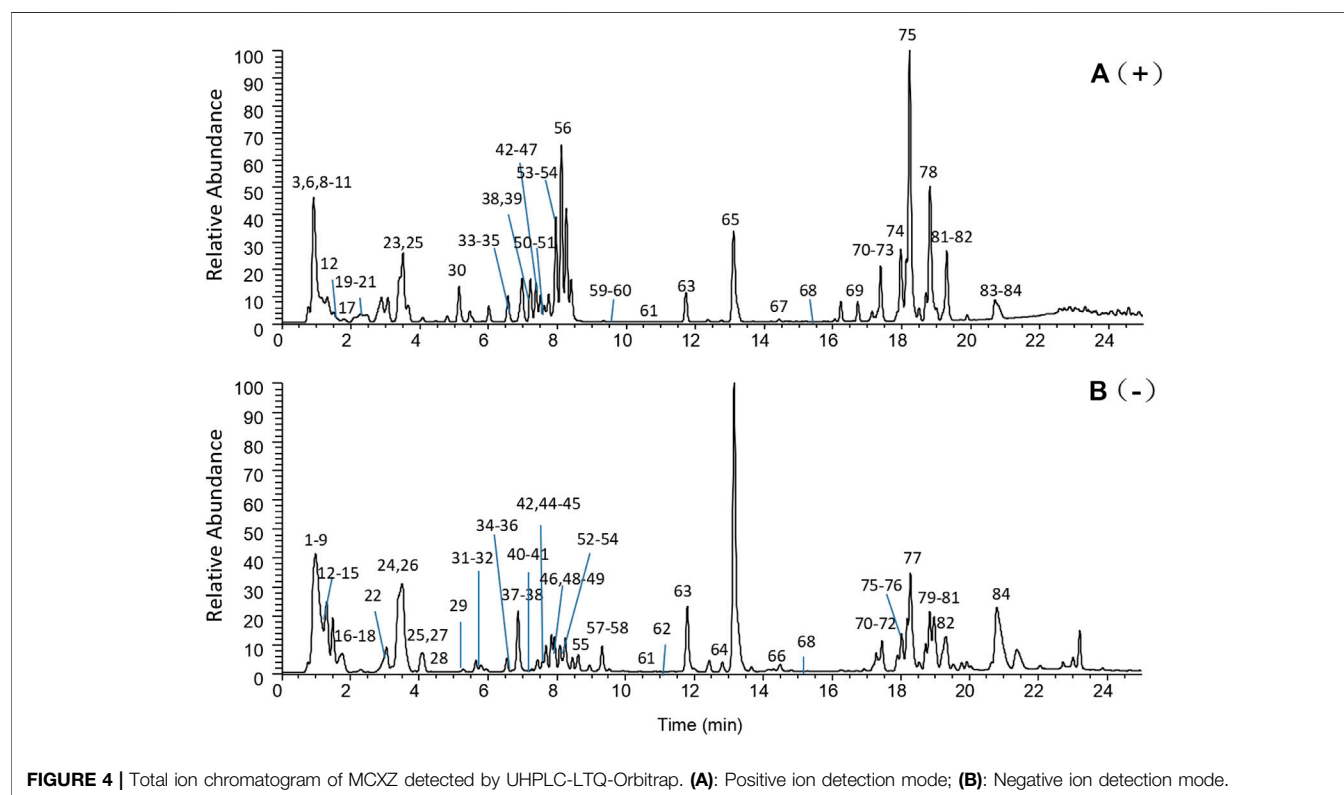

### Identification of the Primary Compounds Found in MCXZ Using UHPLC-LTQ-Orbitrap

The systemic characterization of chemical profiles is an important precondition for determining the pharmacological mechanisms through which TCM agents exert their effects. To perform this characterization in MCXZ, the UHPLC-LTQ-Orbitrap method, together with the ETCM database, was initially applied for the rapid and high-throughput identification of MCXZ compounds (both known and unknown) in the present study. The UHPLC-LTQ-Orbitrap method combines efficient separation and strong structural characterization abilities to achieve the high-resolution acquisition of parent and daughter ion data, both quickly and simultaneously, to obtain multi-stage mass spectrometry fragment information, which can significantly improve the ability to rapidly identify and analyze the chemical components of complex systems, such as those used in TCM (Wang et al., 2015). The ETCM contains 7,274 herbal ingredients. Any identified molecular formulas that are not included in the

**FIGURE 3 |** The effects of MCXZ on liver and kidney histopathological injury ( $\times 40$ ).

**FIGURE 4 |** Total ion chromatogram of MCXZ detected by UHPLC-LTQ-Orbitrap. (A): Positive ion detection mode; (B): Negative ion detection mode.

purslane chemical components database may represent either known compounds that have not previously been associated with purslane or new compounds; compounds can be searched in his database and confirmed against various types of information. The total ion chromatograms (TIC) of MCXZ were presented in **Figure 4**, corresponding to the positive and negative signals.

During the identification process, the compounds were first analyzed and identified in positive ion mode, and then further analyzed and verified in negative ion mode. Compounds in MCXZ were identified or tentatively characterized according to their retention times and  $MS^n$  data, which are summarized in **Table 1**. The specific method used Xcalibur 2.1 to extract molecular ion peaks from first-order, high-resolution, mass spectrometry data, which were then matched with the high-precision excimer ions in the purslane chemical compound

database (the collected compounds were calculated by  $[M-H]^-$ ,  $[M + CH_3COO]^-$ ,  $[M]^+$ ,  $[M + H]^+$ , and  $[M + Na]^+$ ). All possible compounds were obtained with a mass error of 5.0 ppm. The  $MS^n$  information could also be compared against the precise relative molecular mass, fragmentation patterns, and pathways reported in the related literature to identify compounds (Sun et al., 2014; Yu et al., 2016). Using the described sample treatment methods and analytical conditions, a total of 84 compounds were analyzed and identified in MCXZ using both positive and negative ion modes, including 31 organic acids, 22 alkaloids, nine flavonoids, eight coumarins, et al.

For example, flavonoids respond in both positive and negative ion modes, and molecular ions exist in  $(M + H)^+$ ,  $(M + Na)^+$ , and  $(M-H)^-$  form during primary mass spectrometry. High-precision quasi-molecular ions for Compound 68 were obtained in both

positive and negative ion modes, at m/z 255.0659 and 253.0862, respectively, which was identified as daidzein (C<sub>15</sub>H<sub>10</sub>O<sub>4</sub>) based on comparisons with the chemical composition database. Meanwhile, in positive ion mode, the MS<sup>n</sup> information showed that the (M + H)<sup>+</sup> ion of daidzein at m/z 255 was fragmented by the continuous loss of 28 Da (-CO) at m/z 227 and 56 Da (-2CO) at m/z 199 (Figures 5A,B). In negative ion mode, the MS<sup>n</sup> information

showed that the (M-H)<sup>-</sup> ion of daidzein at m/z 253 was fragmented by the loss of 44 Da (-CO<sub>2</sub>) at m/z 209 and 56 Da (-2CO) at m/z 197 (Figures 5C and 5D), which was consistent with the results of previous studies (Fang et al., 2013). The above fragmentation pathways provide insights that enable us to speculate on the structures of other flavonoids and their derivatives, such as genistein and kaempferol.

## Putative Targets and the Potential Molecular Basis of the Traditional Efficacy Observed During MCXZ Treatment

The TCMIP V2.0 integrated the ETCM database with a series of authoritative algorithms, including the calculation of physicochemical properties, target prediction, network analysis, and visualization. The TCMIP V2.0 had been used as a powerful platform to construct multi-dimensional correlations for in-depth studies of the molecular mechanisms of TCM (Xu H. Y. et al., 2017). In this study, TCMIP V2.0 was used to perform target prediction for MCXZ.

A total of 84 compounds were identified in MCXZ, which were introduced into TCMIP V2.0 to perform target prediction, resulting in a total of 251 putative predicted targets. Detailed information regarding the identified putative MCXZ targets can be found in **Supplementary Table S2**. The functional enrichment analysis of the predicted MCXZ targets was performed using the KEGG database, the pharmacological effects of the pathways were determined by consulting the literature, and the relationships between pharmacological effects and traditional efficacy were analyzed. Network analysis and visualization were performed using Cytoscape software (**Figure 6**).

According to the functional analyses performed for the putative targets and associated pathways affected by MCXZ, combined with the known therapeutic effects of MCXZ in TCM theory, the functional effects of MCXZ could be divided into two modules. The first module includes clearing the liver and improving vision, which is associated with improving endocrine/metabolic system functions (Guan et al., 2019). The second module resolves dampness, which has anti-cancer (Chen and Wang, 2010), antidiuretic (Liu et al., 2012), and sedative (Zhang, 2016) effects. Surprisingly, both functions include anti-inflammatory, anti-microbial, immunomodulatory (Shi et al., 2019), antihyperlipidemic, hypoglycemic (Feng, 2011; Guan et al., 2019), antioxidant (Qi and Li 2018; Chen, 2020), and apoptotic effects.

## Underlying Mechanisms Through Which MCXZ Acts on DM

According to the disease-related gene database in TCMIP V2.0, 239, the present study identified DM-related genes, shown in **Supplementary Table S3**. To explore the potential mechanisms through which MCXZ acts on DM, an interaction network, based on the STRING database and the putative MCXZ target-DM-related gene interactions (**Figure 7**) was constructed, and the topological network parameters were calculated. **Supplementary Table S4** provides detailed information regarding the proposed interactions between putative MCXZ targets and DM-related genes. The network consists of 420 nodes and 4,793 edges.

To determine the hub nodes, which may have high value and perform important functions, we calculated the values of the nodes within the putative MCXZ target-DM-related gene interaction network. Consequently, 78 nodes were selected as hubs due to degree values that were greater than 2-fold the

median value of all nodes in the network. Based on the direct connections between hubs, an interaction network composed of 78 hubs and 1,079 edges was established (**Supplementary Table S5**). After calculating the topological parameters (degree, betweenness, and closeness) of each hub, 75 major hub nodes were selected as key targets because the three topological parameters for them exceeded the corresponding median values. Among these hubs, 35 major hub nodes were known DM-related genes, of which 44 were putative targets of MCXZ and were considered to be candidate MCXZ targets for the treatment of DM. **Supplementary Table S6** provides details for the 44 targets presumed to be targeted by MCXZ.

The biological functions and pathways of MCXZ target candidates for DM therapy were studied using enrichment analysis, based on the KEGG database. MCXZ appears to treat DM primarily by improving the endocrine/metabolic system, in addition to exerting anti-inflammatory, anti-microbial, immunomodulatory, antihyperlipidemic, hypoglycemic, apoptotic, and other pharmacological effects. The key DM-associated KEGG pathways involved in these pharmacological activities included Type II diabetes mellitus and inflammatory and immune-related pathways such as the Fc epsilon RI signaling pathway, Fc gamma R-mediated phagocytosis, VEGF signaling pathway, T cell receptor signaling pathway, Toll-like receptor signaling pathway, and Calcium signaling pathway. It also involved multiple endocrine/metabolic system-related pathways, including Glutathione metabolism, Metabolism of xenobiotics by cytochrome P 450, Drug metabolism, and Arachidonic acid metabolism, as well as Apoptosis-related pathways, such as ErbB signaling pathway and Apoptosis (**Figure 7**).

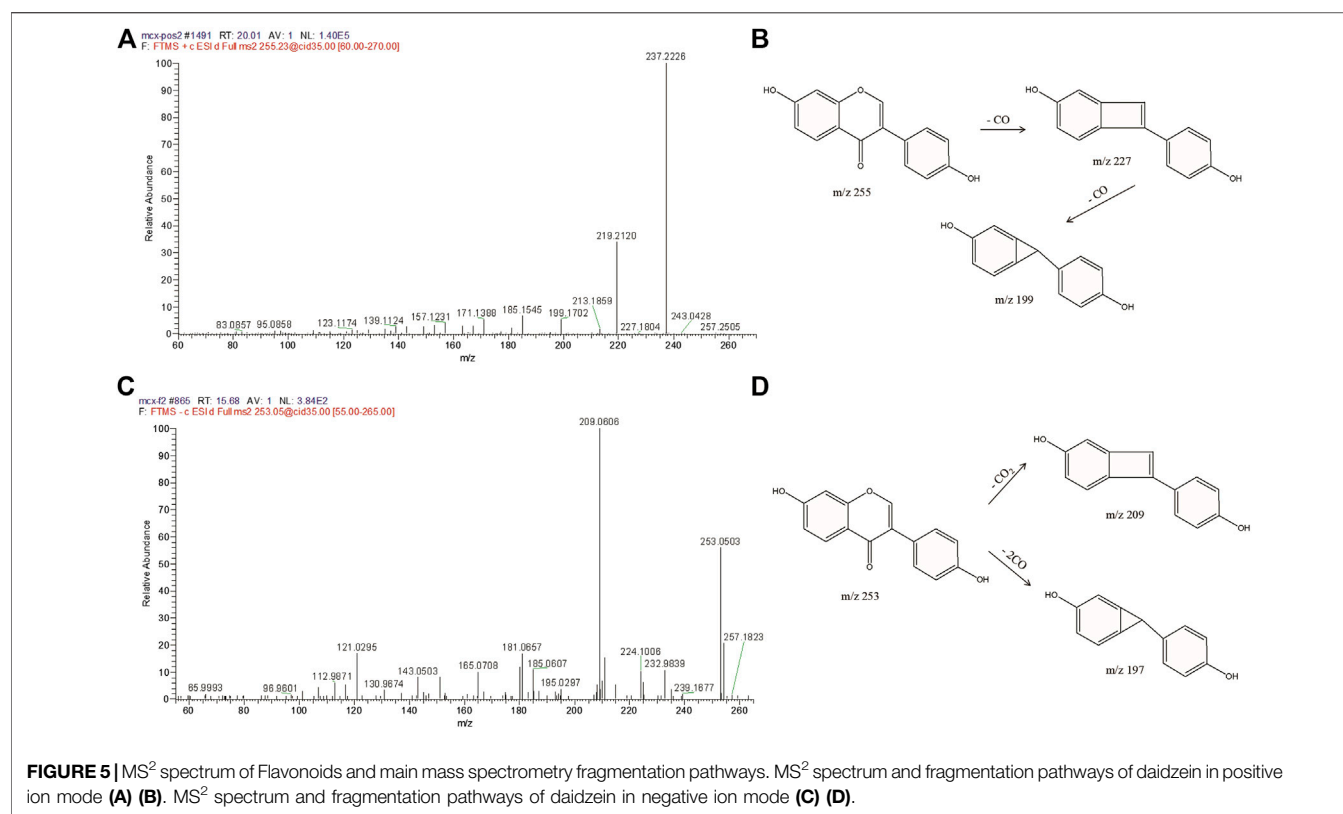

## Expression of *Akt1*, *VEGF*, *ErbB2*, and *AR* mRNA

The accuracy of network pharmacology prediction results was verified by detecting the expression levels of key genes, including *Akt1*, *VEGF*, *ErbB2*, and *AR*, which are involved in the VEGF and ErbB signaling pathway.

In the pancreatic tissue of diabetic model mice (model group), the expression levels of *Akt1*, *VEGF*, *ErbB2*, and *AR* mRNA were significantly increased ( $p < 0.05$ ) compared with those in normal mice (control group). In contrast, after 4 weeks of treatment with MCXZ, the expression levels of *Akt1*, *VEGF*, *ErbB2*, and *AR* mRNA significantly decreased compared with those in the model group ( $p < 0.05$ , **Figure 8**).

## DISCUSSION

DM has become a common and high-risk disease in modern times. Due to unhealthy lifestyles (e.g., poor diet, low physical activity, and sedentary behavior) (Mozzillo et al., 2017), patients with DM tend to be younger. According to the IDF, currently, 463 million individuals suffer from DM, a number that is expected to reach 592 million by 2035 (Liu et al., 2019). At present, the drugs

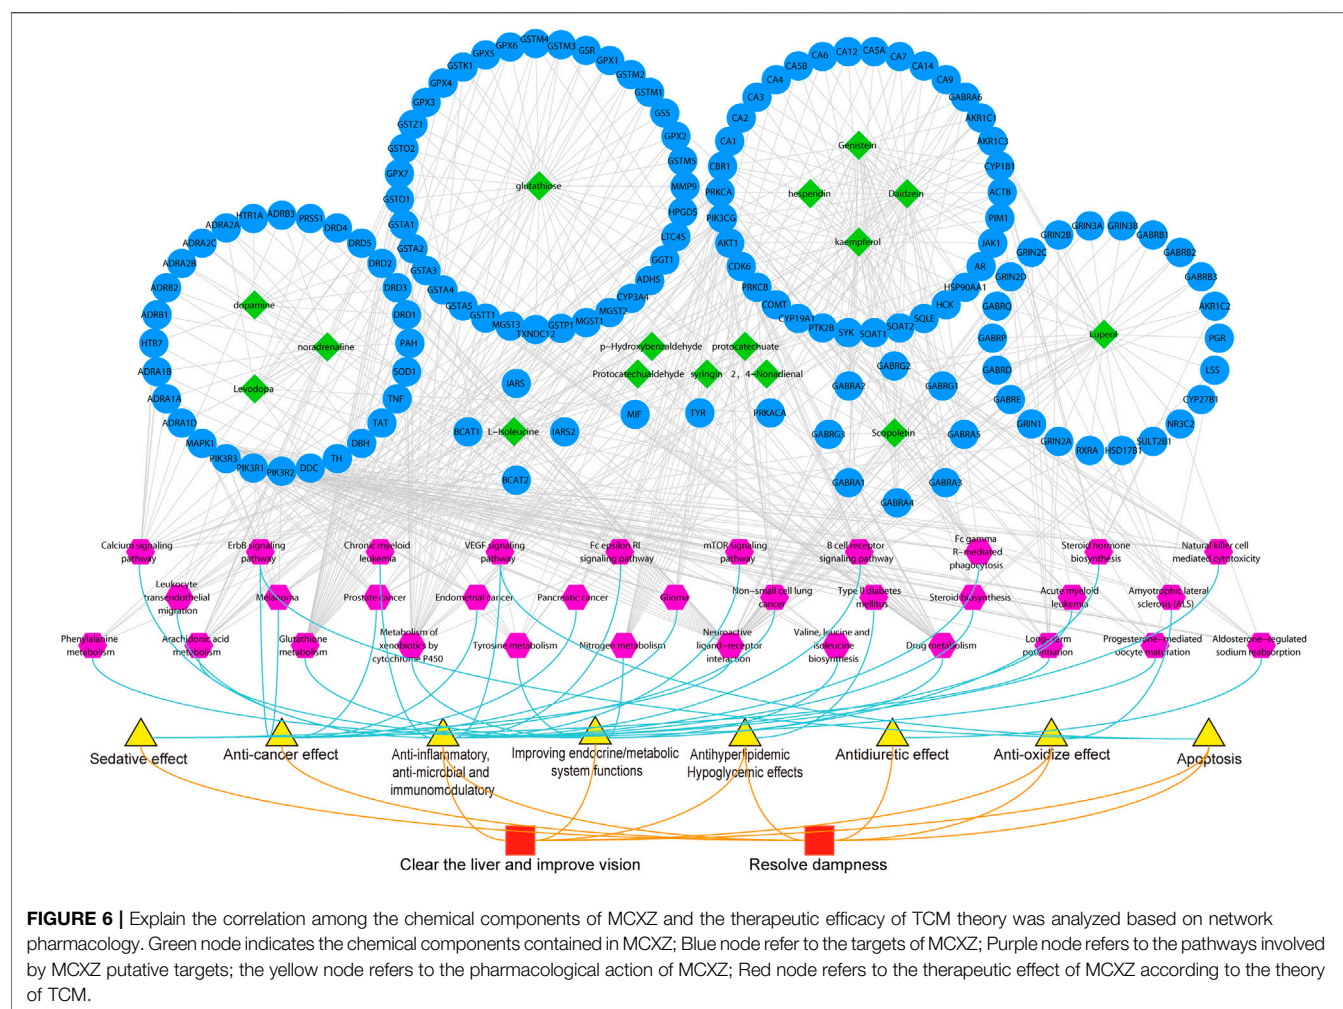

used to treat DM typically aim to control blood glucose levels, and most of these drugs lack the sufficient ability to prevent and control disease symptoms, with reduced efficacy over time (Moukette et al., 2017). Therefore, researchers have begun to search for new compounds, especially among natural products, to better control blood glucose levels and associated complications.

MCXZ is widely distributed in tropical, subtropical, and temperate regions. Due to strong adaptability to changes in environmental conditions, the germplasm resources of MCXZ are relatively abundant. Studies have shown that MCXZ could be used as an effective and safe adjuvant therapy among DM subjects (El-Sayed, 2011). In this study, we found that MCXZ alone was able to directly reduce the levels of FBG and HbA1c in STZ-induced DM model mice, and the hypoglycemic effect of the low-dose MCXZ group was found to be better than the middle- and high-dose groups, which may be attributed to lower drug concentrations being more beneficial to digestion and absorption by the gastrointestinal tract.

All experimental data indicated that MCXZ induced anti-hyperglycemic effects and no histopathological damage was observed in the liver or kidney of mice after MCXZ administration, which is consistent with the literature. Chavalittumrong et al. studied the toxicity of purslane and found no histopathological damage to the brain, heart, kidney, liver, spleen, lung, kidney, or other tissues, indicating that purslane had no obvious toxic effects on the examined internal organs (Chavalittumrong et al., 2004).

To explain the material basis and molecular mechanisms of MCXZ treatment in DM, high-throughput technology

(UHPLC-LTQ-Orbitrap) and the ETCM database were used to characterize the chemical components of MCXZ quickly and systematically. A total of 84 chemical components were identified, including 34 organic acids, 21 alkaloids, nine flavonoids, and seven coumarins. Some of these compounds have previously been used in the treatment of DM, such as genistein, levodopa, daidzein, 2,4-nonadienal, syringin, glutathione, kaempferol, dopamine, lupeol, and noradrenaline. Several studies have shown that genistein was able to improve dysfunctional hepatic gluconeogenesis in DM (Dkhar et al., 2018). Diabetic retinopathy is a common complication of DM, and clinical studies have also shown that the combined use of levodopa and carbidopa can reverse retinal dysfunction (Motz et al., 2020). Noradrenaline can promote insulin secretion by islet glands and regulate glucose metabolism, reducing and maintaining the stability of blood glucose levels (Zhang and Sun, 1991). Studies have shown that daidzein improved insulin resistance, dyslipidemia, and inflammation and was able to prevent DM and its related complications (Das et al., 2018). The anti-diabetic mechanism of kaempferol may be related to the ability of this substance to promote glucose metabolism and inhibit hepatic gluconeogenesis. (Alkhalidy et al., 2018). Syringin has been shown to treat DM by increasing glucose utilization and reducing plasma glucose levels in rats with insulin deficiency (Niu et al., 2008). Lupeol significantly reduced the level of blood glucose and oxidative stress in DM model rats, indicating that lupeol might have hypoglycemic activity and be useful for the treatment of DM (Malik et al., 2019).

A total of 251 putative MCXZ targets were identified using the TCMIP V2.0 database, and the relationships between the putative MCXZ targets and traditional efficacy were analyzed. The pharmacological effects of the predicted MCXZ targets and pathways are closely related to traditional efficacy. MCXZ exerts a hypoglycemic effect through the “clear the liver and improve vision” and “resolve dampness” functions, according to TCM theory, and the possible use of MCXZ in the treatment of DM was preliminarily analyzed (Ren et al., 2017). Furthermore, the interactions between potential MCXZ targets and DM targets were analyzed, and relevant pathways were identified by performing KEGG pathway enrichment analysis. A multi-level association network diagram, showing the “TCM-key active ingredients-core target-key pathways-pharmacological actions-disease effects” relationships were drawn to clarify the pharmacological basis and potential molecular mechanisms through which MCXZ exerts its effects in the treatment of DM.

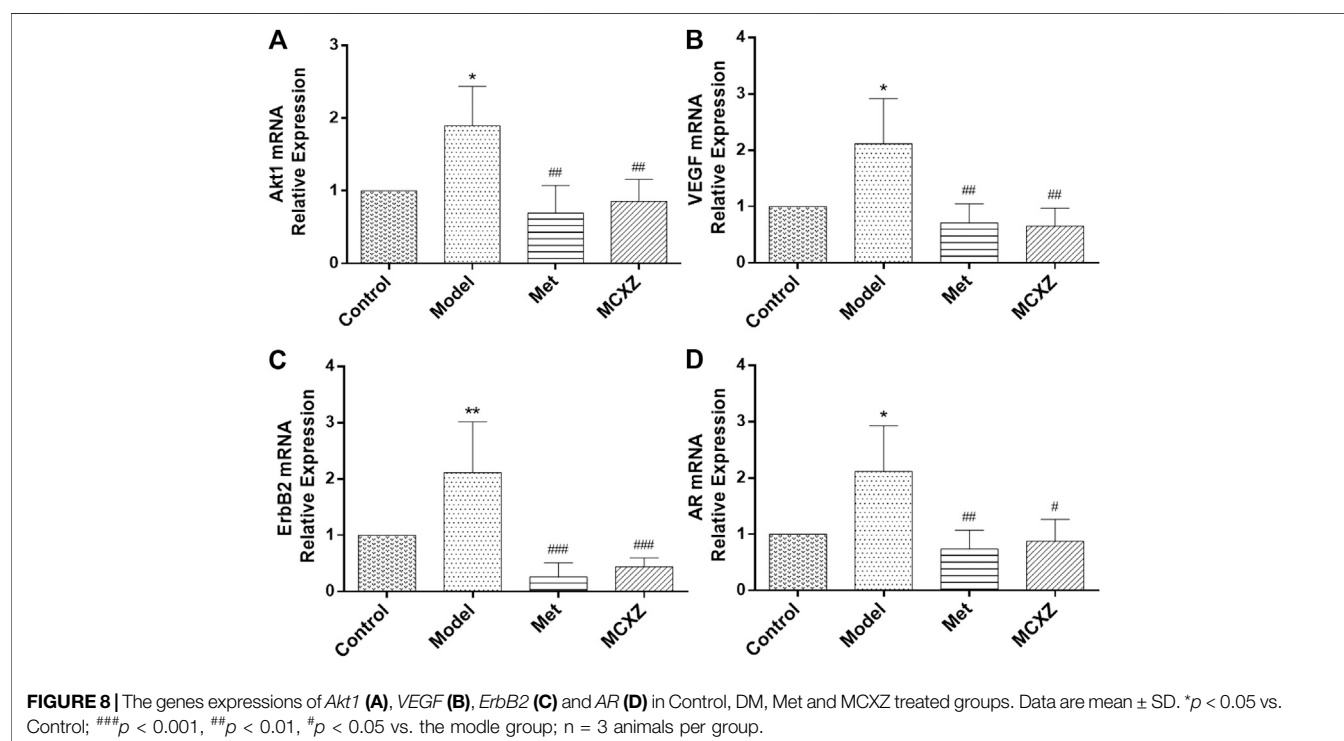

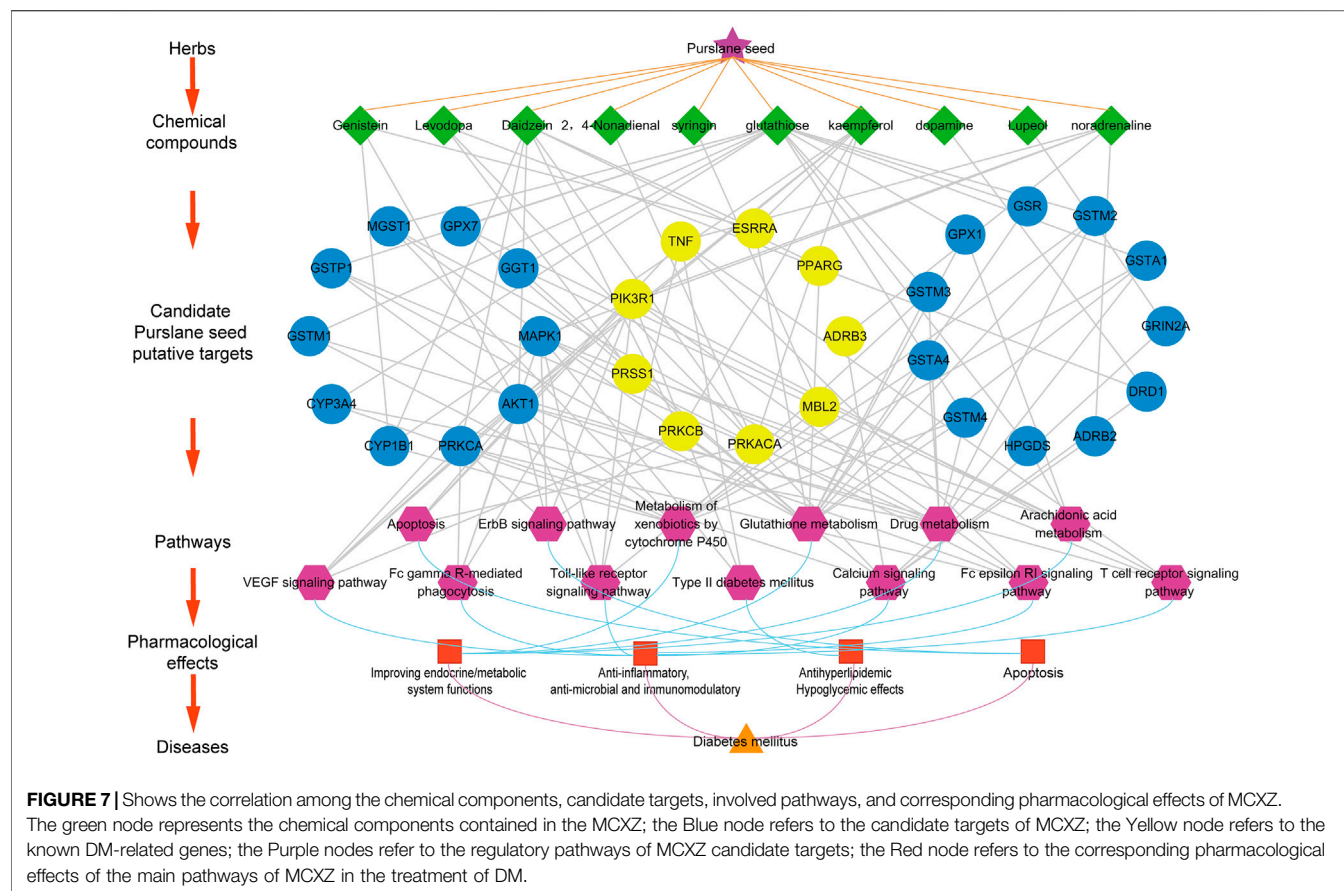

After combining data from previous publications and performing a multi-dimensional network analysis, we preliminarily determined the potential pathways and targets through which MCXZ is likely to act for the treatment of DM (Figure 7). In summary, even after excluding Type II diabetes

mellitus as a direct DM pathway, several pathways were identified that could indirectly affect DM and DM-associated complications. VEGF promotes angiogenesis, and an increasing number of studies have shown that VEGF plays an important role in the development of diabetic microvascular complications, such as diabetic retinopathy, skin ulcers, and kidney disease. The inhibition of VEGF expression, the prevention of VEGF receptor binding, and the inhibition of downstream signaling pathways can successfully inhibit the development of diabetic microvascular complications (Li et al., 2017; Zhou et al., 2017).

Fc gamma R-mediated phagocytosis, which is a classical immune regulatory process, may represent a key pathway for the prevention and treatment of DM. Experiments have shown that the activation of Fc gamma R-mediated phagocytosis affects the balance of glucose metabolism. Blocking Fc gamma R-mediated phagocytosis was shown to reduce DM occurrence (Feng et al., 2019).

DM has been associated with a high risk of developing cognitive impairment, and studies have shown that the Calcium signaling pathway affected gut microbiota, which improved cognitive impairment in patients with DM (Zhang

**FIGURE 9 |** Schematic Illustration of the main pathways of MCXZ in the treatment of DM.

et al., 2020). The primary functions of toll-like receptors include the induction of inflammatory responses and the establishment of adaptive immunity. Studies have shown that toll-like receptors play major roles in the pathogenesis of inflammation-mediated insulin resistance. Taha et al. analyzed 30 DM patients with impaired glucose tolerance and 30 healthy individuals and found a correlation between high levels of toll-like receptor four expression and DM occurrence (Taha et al., 2018).

The glutathione metabolism signaling pathway serves to present oxidative stress-induced injuries and is involved in glucose-induced insulin secretion. Increasing the glutathione concentration in plasma can improve peripheral insulin levels, reduce oxidative damage, and increase insulin sensitivity in diabetic patients (Yang, 2019). The ErbB signaling pathway functions to protect the myocardium, inhibit myocardial fibrosis, and promote angiogenesis. The activation of this pathway might be able to protect against the development of diabetic cardiomyopathy (Han et al., 2019). Other studies have shown that blocking the activation of epidermal growth factor receptor (*EGFR*) can inhibit the infiltration and oxidative stress of kidney immune cells, increase islet autophagy activity, and improve diabetic nephropathy (Li et al., 2018).

The core targets involved in these pathways include phosphoinositide-3-kinase regulatory subunit 1 (*PIK3R1*), serine protease 1 (*PRSS1*), peroxisome proliferator-activated receptor gamma (*PPARG*), protein kinase C beta

(*PRKCB*), mannose-binding lectin 2 (*MBL2*), adrenoceptor beta 3 (*ADRB3*), tumor necrosis factor (*TNF*), protein kinase cAMP-activated catalytic subunit alpha (*PRKACA*), and estrogen-related receptor alpha (*ESRRA*) (Figure 7). Notably, these nine core target proteins are all known DM candidate targets, and studies have confirmed that they play key roles in relieving major DM symptoms. Studies have demonstrated a critical role for *PIK3R1* in insulin signal transduction, which is closely related to the occurrence of insulin resistance (Karadoğan et al., 2018). Studies have confirmed that activating *PPARG* could significantly improve systemic insulin sensitivity and glucose metabolism (Yang and Chan 2016). *PPARG*, which is encoded by *PPARG*, is a transcription factor that can be activated by multiple ligands and is widely distributed in adipocytes and immune cells, where it has been shown to promote the differentiation of white adipocytes, increase the number of insulin receptors, promote the transcription of genes associated with insulin signal transduction, and enhance insulin signal transduction. Therefore, the effects of DM can be attenuated by activating *PPARG* (Gao et al., 2016). *PRKCB* is involved in the regulation of the B cell receptor signaling pathway, apoptosis induced by oxidative stress, insulin signaling transduction, and endothelial cell proliferation (Wu et al., 2019b).

*MBL2* is a member of the lectin family, which has been associated with immune dysfunction and is commonly expressed in immune

disorder-related diseases. Recently, *MBL2* has been found to play a role in the development of insulin resistance and gestational DM, and functional variations in *MBL2* can increase DM susceptibility (Muller et al., 2010). *ADRB3* is an obesity-associated gene that plays a key role in the regulation of energy balance. In many ethnic groups, the Arg64 allele in *ADRB3* is associated with the early onset of abdominal obesity and non-insulin-dependent DM (Takenaka et al., 2012). Adipose tissue is an enormously active endocrine organ that secretes various hormones and classical cytokines, such as TNF- $\alpha$  and interleukin (IL)-6. Studies have shown that the upregulation of TNF- $\alpha$  plays an important role in the induction of insulin resistance, which is associated with obesity and DM (Jaganathan et al., 2018). *PRKACA* is involved in the regulation of lipid and glucose metabolism in addition to the insulin signaling pathway (Chi et al., 2019). *ESRRA* is a key regulator of mitochondrial metabolism, able to regulate the absorption of energetic substances, the production and transport of ATP on the mitochondrial membrane, and the response of the body to energy (Dufour et al., 2007). Increased *ESRRA*-activated oxidative phosphorylation in the skeletal muscle of DM patients has been shown to improve blood glucose regulation in DM patients (Mootha et al., 2004).

To verify the accuracy of the predicted network pharmacology results, we detected the expression levels of the key genes *Akt1*, *VEGF*, *ErbB2*, and *AR*, which are members of the VEGF and ErbB signaling pathways. We found that DM upregulated the expression levels of *Akt1*, *VEGF*, *ErbB2*, and *AR* in pancreatic tissue, which is consistent with other literature (Li et al., 2019; Momeny et al., 2019; Srivastava et al., 2019; Zhang et al., 2019).

The results of the present study provide mechanistic insights into the effects of MCXZ in the treatment of DM (**Figure 9**). Our findings indicated that MCXZ might play a role in the treatment of DM in a multi-component, multi-target, and multi-pathway manner, which reflects the therapeutic characteristics of TCM.

## CONCLUSION

In conclusion, this study provides evidence to support MCXZ as a promising TCM agent, which can lower blood glucose levels without being associated with negative side effects. MCXZ likely acts in DM by affecting *PIK3R1*, *TNF*, *PRKACA*, and other targets associated with insulin resistance and inflammation through the actions of various chemical components, including genistein, levodopa, and daidzein, which regulate multiple pathways, such as Type II diabetes mellitus, VEGF signaling pathway, Toll-like receptor signaling pathway, and Calcium signaling pathway. These findings were consistent with the existing literature on DM, which was able to describe the molecular mechanisms through which MCXZ acts to treat DM and its complications. This study not only elucidates the effective application of TCM from a macro point of view, but the potential molecular mechanisms of action were also able to be identified from a micro perspective, combining the advantages of

TCM theory with modern medical research. However, this study was based on predictions associated with existing research results, and these potential effects must be verified and confirmed through further research.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by All animal experiments were approved by the Committee on Animal Care and Use of the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences.

## AUTHOR CONTRIBUTIONS

JH, XZ, PW, and YQ collected the data and drafted the manuscript. LY proposed the research goal of MCXZ and provided MCXZ. JH, HX, and FL conceived of the study, participated in its design and coordination, and helped to draft the manuscript. The other authors participated in the design of the study and performed the statistical analysis. All authors read and approved the final manuscript.

## FUNDING

This work was supported by grants from the National Key Research and Development Program of China (2017YFC1702104, 2017YFC1702303), the National Natural Science Foundation of China (Grant No. 81830111 and 81774201), the Youth Innovation Team of Shaanxi Universities, and Shaanxi Provincial Science and Technology Department Project (No. 2016SF-378), the Fundamental Research Funds for the Central public welfare research institutes (ZXKT17058). The funding agencies had no role in the study design, the collection, analysis, or interpretation of data, the writing of the report, or the decision to submit the article for publication.

Characteristics of *Platycodon*  
*grandiflorum* and its Mechanism in  
Lung Cancer Treatment.  
Front. Pharmacol. 11:609825.  
doi: 10.3389/fphar.2020.609825

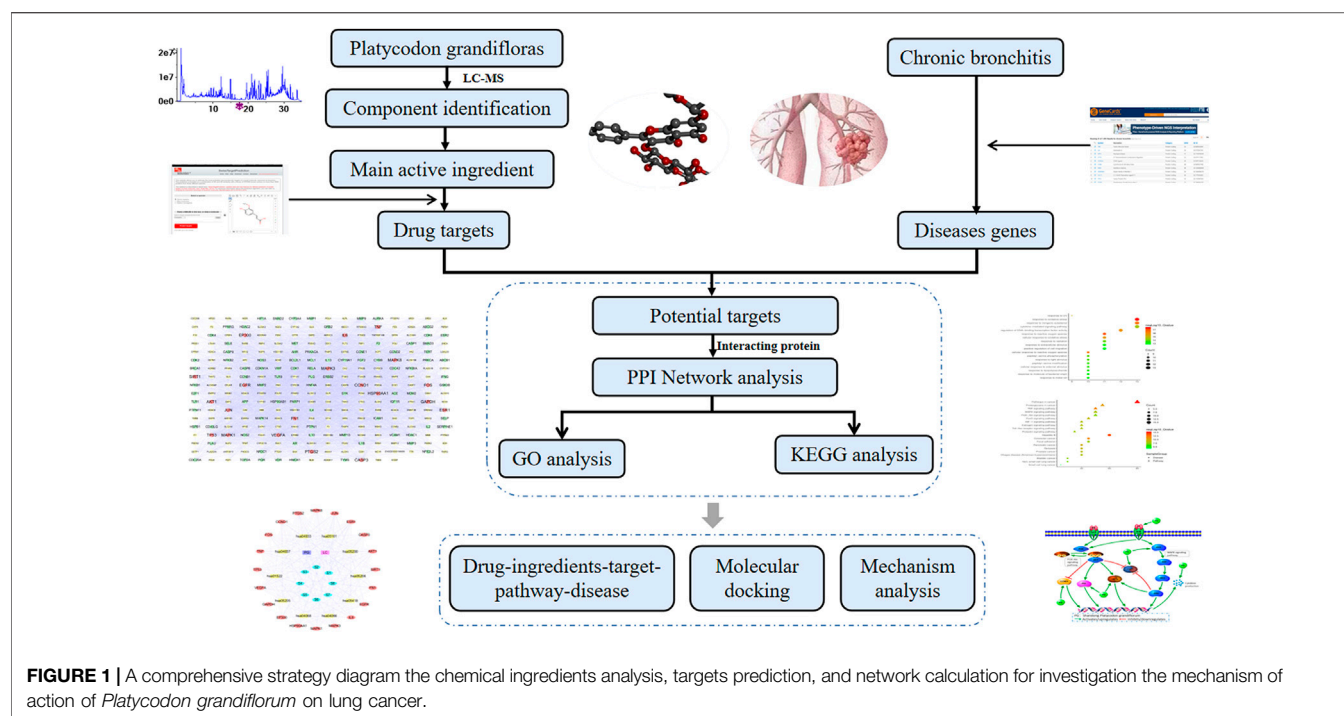

**Objective:** The technology, network pharmacology and molecular docking technology of the ultra performance liquid chromatography-quadrupole time-of-flight tandem mass spectrometry (UPLC-Q-TOF-MS/MS) were used to explore the potential molecular mechanism of *Platycodon grandiflorum* (PG) in the treatment of lung cancer (LC).

**Methods:** UPLC-Q-TOF-MS/MS technology was used to analyze the ingredients of PG and the potential LC targets were obtained from the Traditional Chinese Medicine Systems Pharmacology database, and the Analysis Platform (TCMSP), GeneCards and other databases. The interaction network of the drug-disease targets was constructed with the additional use of STRING 11.0. The pathway enrichment analysis was carried out using Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) in Metascape, and then the "Drug-Ingredients-Targets-Pathways-Disease" (D-I-T-P-D) network was constructed using Cytoscape v3.7.1. Finally, the Discovery Studio 2016 (DS) software was used to evaluate the molecular docking.

**Results:** Forty-seven compounds in PG, including triterpenoid saponins, steroidal saponins and flavonoids, were identified and nine main bioactive components including platycodin D were screened. According to the method of data mining, 545 potential drug targets and 2,664 disease-related targets were collected. The results of topological analysis revealed 20 core targets including caspase 3 (CASP3) and prostaglandin-endoperoxide synthase 2 (PTGS2) suggesting that the potential signaling pathway potentially involved in the treatment of LC included MAPK signaling pathway and P13K-AKT signaling pathway. The results of molecular docking proved that the bound of the ingredients with potential key targets was excellent.

**Conclusion:** The results in this study provided a novel insight in the exploration of the mechanism of action of PG against LC.

**Keywords:** lung cancer, molecular mechanism, network pharmacology, *Platycodon grandiflorum*, ultra performance liquid chromatography-quadrupole time-of-flight tandem mass spectrometry

## INTRODUCTION

Lung cancer (LC) is a malignant tumor with the highest morbidity and mortality worldwide, mostly in male than in female, indeed known as “the king of cancer” (Shao and Zhang, 2020). At present, surgery, chemotherapy and radiotherapy are the main treatments to combat LC, but their side effects are numerous and unavoidable and the clinical prognosis is not ideal. The development of traditional Chinese medicine (TCM) included the discovery and used of anti-cancer drugs; thus, it has attracted more and more attention. TCM adopts syndrome specific treatments, TCM combined with chemotherapy and other methods, with less toxic side effects. For this reason, TCM prescriptions achieved good results in clinical practice (Bai et al., 2017; Wang and Li, 2019). Therefore, the research and development of new TCM to combat LC would be of great significance.

*Platycodon grandiflorum* (PG) is a plant belonging to the family of campanulaceae, and the dried root is used in TCM to regulate the lung meridian. PG exerts the effect of smoothing lung, dispelling the phlegm, and expelling the pus, and represents the main treatment to cure sore throat, vomiting due to a purulent carbuncle infection in the lung, hypochondriac pain in the chest and other syndromes (Chinese Pharmacopoeia Commission, 2020). The properties of PG were first published in Shennong Materia Medica Classic. PG is mainly growing in the Northeast China, Central China and Guangdong, and the components of PG are different in different areas. Shandong is one of the authentic areas cultivating PG. The roots of PG from Shandong are longer, less bifurcated and with a high content of active components (Zhu et al., 2013). According to the TCM, PG mainly acts on the lung and its related parts, with an

antitussive and expectorant effect, and good therapeutic effect on LC (Yim et al., 2016; Li et al., 2019; Deng et al., 2020). However, its mechanism of action in the treatment of LC is not clear.

UPLC-Q-TOF-MS/MS is a high-throughput analytical technology rapidly developed in the past decade, which is widely used in medicine, drug research and other fields (Jin et al., 2018; Ren et al., 2020). Network pharmacology is a theory based on systems biology, which emphasizes the multi-pathway regulation of signaling pathways, thus in agreement with the multi-component-multi-target characteristics of TCM (Yang et al., 2019; Zhang et al., 2019; Ye et al., 2020). Therefore, in this study, the components of the PG roots cultivated in the Shandong Province were analyzed, and then the “Drug-Ingredients-Targets-Pathways-Disease” (D-I-T-P-D) network was constructed according to the relevant principles and methods of network pharmacology to explore the potential molecular mechanism used by PG to treat LC. Our aim was to identify a new drug through the development of the potential of PG to provide a theoretical basis for its clinical application. The flow chart of the approach used in this study is shown in **Figure 1**.

## MATERIALS AND METHODS

### Chemicals and Materials

Methanol, acetonitrile, and formic acid used for high performance liquid chromatography (HPLC) were purchased from ACS (Washington D.C., MD, United States). Methanol for herb extraction was purchased from Xilong Scientific Co., Ltd (Guangdong, China). Ultrapure water was obtained from a Milli-QB system (Bedford, MA, United States). PG root pieces (simply

**FIGURE 2 |** The total ion chromatograms (TICs) of *Platycodon grandiflorum* by UPLC/Q-TOF-MS/MS (A) TIC of *Platycodon grandiflorum* in positive ion mode (B) TIC of *Platycodon grandiflorum* in negative ion mode.

defined as PG pieces according to the Chinese Pharmacopoeia 2015 edition that assumes that PG is the root) were purchased from Jiangxi Jiangzhong Herbal Pieces Co., Ltd (Jiangxi, China; batch number: 181024). The original PG medicinal material was purchased from Yiyuan, Shandong province, and was identified as the dried root of *Platycodon grandiflorum* (Jacq.) A. DC. Campanulaceae from Professor Fu Xiaomei. PG decoction pieces were processed by Jiangxi Jiangzhong TCM Decoction Co., Ltd. according to the processing method of the Chinese Pharmacopoeia 2015 edition. Next, dried PG pieces were crushed into a 40 mesh powder and stored in the laboratory of the Jiangxi University of TCM.

A total of 15 pure compounds were used as reference standards (purity  $\geq 98\%$ ). Among them, deapio-platycodin D, platycodin D, polygonatoside C1, rubinin, luteolin, kaempferol, apigenin, caffeic acid, ferulic acid, adenosine, and lobetyolin were purchased from Chengdu Chroma-Biotechnology Co., Ltd (Sichuan, China). 3-O- $\beta$ -D-glucopyranosyl platycodigenin, rutin, chlorogenic acid, and linoleic acid were purchased from Sichuan Vicky Biotechnology Co., Ltd (Sichuan, China).

## Ultra-Performance Liquid Chromatography-Quadrupole-Time-Of-Flight Tandem Mass (UPLC-Q-TOF-MS/MS) Analysis

### Preparation of Standard and Sample Solutions

Ten milligrams of each reference compound (deapio-platycodin D, platycodin D, polygonatoside C1, adenosine, ferulic acid, apigenin, luteolin, chlorogenic acid, caffeic acid, kaempferol, robinin, lobetyolin, rutin, 3-O- $\beta$ -D-glucopyranosyl platycodigenin and linoleic acid) were weighed and transferred into a 10-ml volumetric flask. Methanol was added to reach the volumetric mark, and the solution was shaken well, stored at 4 °C and used as a

stock solution. Then, the appropriate amount of stock solution was transferred into a 5 ml volumetric flask, and methanol was added to reach the volumetric mark. The solutions were filtered using a 0.22  $\mu$ m microporous membrane to obtain the standard solutions.

A total of 2.0 g PG powder was accurately weighed and transferred into a round bottom flask with 50 ml 50% methanol. The solution was mixed well, incubated for 0.5 h at room temperature, and ultrasonically treated for 30 min using an ultrasonic cleaning instrument (Jiangsu, China). The extracted solution was centrifuged at 14,000 rpm for 15 min at room temperature, and filtered using a 0.22  $\mu$ m microporous membrane before qualitative analysis.

### UPLC-Q-TOF-MS/MS Conditions

The chemical analysis was performed on a connected UPLC system (Nexera X2 LC-30A, Shimadzu Corp., Japan) -hybrid triple quadrupole time-of-flight mass spectrometer (Triple TOF<sup>TM</sup> 5600<sup>+</sup>, AB Sciex, Forster City, CA, United States) with an electrospray ionization source (ESI). Acquity UPLC BEH C<sub>18</sub> column (2.1  $\times$  100 mm  $\times$  1.7  $\mu$ m) was used to perform chromatographic separation with a flow rate of 0.25 ml/min at 40 °C. The linear gradient program used in this work was composed of a mobile phase system including solvent A (100% acetonitrile, v/v) and solvent B (0.01% formic acid in water, v/v) according to this detailed composition: solvent A at 5–23% for 10 min, 23–25% for 6 min, 25% for 4 min, 25–29% for 3 min, 29–95% for 7 min, 95–5% for 2.1 min, isocratic eluted at 5% for 2.9 min.

The settings of Q-TOF-MS/MS parameters were as follows: ion source gas 1 (GSI) and gas 2 (GS2) were both set at 50 psi, curtain gas (CUR) was set at 40 psi, ion spray voltage floating (ISVF) was set at 5500 V in the positive mode while 4500 V was set in the negative mode, ion source temperature (TEM) was set at 500 °C, collision energy (CE) was set at 60 V, collision energy spread (CES) was set at 15 V, declustering potential (DP) was set

<sup>a</sup> Structures confirmed by comparison with reference standards

at 100 V, and nitrogen was used as a nebulizer and auxiliary gas. Samples were analyzed in both positive and negative ionization modes with a scanning mass-to-charge ( $m/z$ ) range from 100 to 1,250. Data were collected in the information-dependent acquisition (IDA) mode and analyzed by PeakView® 1.2 software (AB Sciex, Foster City, CA, United States).

### Identification of the Ingredients

The chemical PG ingredients were collected from existing databases, such as SciFinder (<https://scifinder.cas.org>), the Traditional Chinese Medicine Systems Pharmacology database, and the Analysis Platform (TCMSP, <http://lsp.nwu.edu.cn/tcmsp.php>) database. Then, a PG ingredients database was established,

containing the basic information, such as ingredient name and molecular formula. A total of 161 ingredients in PG were collected, and the specific information is listed in the **Schedule 1**. MS data were imported into PeakView® 1.2 to perform the ingredient analysis. Chemicals were identified according to the reference standards, chromatographic elution behavior, mass fragment pattern, and mass spectral library (Natural Products HR-MS/MS Spectral Library, Version 1.0, AB Sciex, Foster City, United States).

### Predicted and Screened Potential Targets

The prediction targets of the active PG components were obtained using the following databases: Swiss Target

**FIGURE 5 |** Cracking pathway of flavonoids.

**FIGURE 6 |** Cracking pathway of phenolic acids.

Prediction (<http://www.swisstargetprediction.ch/>) (Xu et al., 2018), Pharmmapper (<http://www.lilab-ecust.cn/pharmmapper/>) (Shen et al., 2019), Pubchem (<https://pubchem.ncbi.nlm.nih.gov/>) (Xu et al., 2018) and TCMSP (<http://lsp.nwu.edu.cn/tcmsp.php>) (Ye et al., 2020). The protein name was standardized using Uniprot (<http://www.uniprot.org/>), and the library of the targets of the active components was obtained. The known disease targets were searched in the databases of GeneCards (<https://www.genecards.org/>) (Ye et al., 2020) and DisGenet (<http://www.disgenet.org/>) (Gao et al., 2020) using “Lung cancer” as the keyword, and the LC-target database was obtained.

## Protein-Protein Interaction (PPI) Network Construction

R software was used to intersect PG related targets and LC related targets, and the overlapping targets were uploaded into STRING 11.0 (<https://string-db.org/>). The protein type was set to “*Homo sapiens*” and the minimum interaction score was 0.4. The PPI network diagram was obtained, imported into Cytoscape v3.7.1 software, and CentiScape was used to calculate the degree centrality (DC) to filter PPI network core targets.

FIGURE 7 | Cracking pathway of organic acids.

## Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) Pathway Enrichment Analysis

Metascape (<http://www.metascape.org/>) is a gene annotation tool that integrates many authoritative databases such as GO, KEGG, UniProt and DrugBank. It allows the completion of pathway enrichment analysis and biological process annotation and performs gene-related protein network analysis and drug analysis, providing comprehensive and detailed information regarding each gene (Zhou et al., 2019). Metascape perfectly fills the gap of DAVID while maintaining its advantages, and its data is frequently updated (the last update was August 14, 2019), greatly guaranteeing the timeliness and credibility of the data.

The gene symbols of the core targets were introduced into Metascape, “*Homo sapiens*” was selected to perform the enrichment analysis, which was annotated and analyzed using the KEGG database (<https://www.kegg.jp/>) and PathwayBuilderTool\_2.0 software to further explain the role of the core targets in gene function and signaling pathway.

## D-I-T-P-D Network Construction

The files related to “drug-core ingredient,” “core ingredient-core target,” “pathway-core target,” and “disease-core target” were established, and the D-I-T-P-D network was constructed using

Cytoscape v 3.7.1 to explain the multi-effect synergistic mechanism of PG.

## Molecular Docking Evaluation

Discovery Studio 2016 software (DS) is a commonly used molecular modeling and simulation software widely used in the field of drug design and optimization, protein structure and function (Zhang and Mao, 2018). The PDB format of the core target is obtained in the Uniprot database, and the X-ray crystal structure of the core target is downloaded from the RCSB database (<https://www.rcsb.org/>). Then the molecular docking function of DS software is used to perform component-target molecular docking in the LibDock module.

## RESULTS

### Composition Analysis and Identification

The typical total ion chromatogram of the non-volatile components extracted from PG, shown in Figure 2, of positive and negative ions was analyzed by Peakview<sup>®</sup> 1.2, and the composition was screened by “XIC manager”. The structural formula of the target compound was matched with the secondary fragment ion, and the compounds were further identified according to the matching degree and the law of ion bond breaking. The compounds with a matching degree greater than

TABLE 2 | Information on the 9 active ingredients in *Platycodon grandiflorum*.

80% and in accordance with the law of bond breaking were considered. According to the reference (Wang et al., 2017a; 2017b) and the data of the control quality spectrum, 47 chemical constituents were identified in the alcohol extract of PG (Table 1). Among them, deapio-platycodin D, platycodin D, polygonatoside C1, adenosine, ferulic acid, apigenin, luteolin, chlorogenic acid, caffeic acid, kaempferol, robinin, lobetyolin, rutin, 3-O- $\beta$ -D-glucopyranosyl platycodigenin and linoleic acid were compared with the reference standards. Among these 47, 24 were triterpenoid saponins, three were steroidal saponins, six

were flavonoids, three were phenolic acids, four were organic acids and seven were other components.

## Analysis of the Cracking Law of the Components

### Triterpene Saponins

Triterpenoid saponins are the largest number of components and the main components identified from PG. The main approach to cleave triterpenoid saponins is a continuous intramolecular

deglycosylation and interchain cleavage to obtain the characteristic fragment ions. In this experiment, 24 triterpenoid saponins, including platycodin D, polygalacin D and deapio-platycodin D were identified from PG. Using platycodin D as an example for the analysis, they all behave similarly by producing a molecular ion peak  $m/z$  1,223.5702 in the anion mode, and the retention time was 20.73 min. The glycosidic bond was broken under a high energy bombardment, the fragment ions  $m/z$  681.3789  $[M-H]^-$ ,  $m/z$  541.1729  $[M-H]^-$ ,  $m/z$  681.3789  $[M-H]^-$  were further removed, and the fragment ion  $m/z$  501.3189  $[M-H]^-$  was obtained. In addition, the interchain cleavage produced the fragment ions  $m/z$  469.1518  $[M-H]^-$  and  $m/z$  409.1329  $[M-H]^-$ . The specific cracking pathway of the triterpenoid saponins is shown in **Figure 3**.

### Steroidal Saponins

Three steroidal saponins were identified and their cleavage rules were similar to the ones to cleave triterpenoid saponins. The characteristic fragment ions were obtained by the cleavage of their sugar chains. Using polygonatoside C1 as an example for the analysis, the molecular ion peak  $m/z$  869.4540 was

produced in the negative ion mode, and the retention time was 13.02 min. The cleavage of the sugar chain produced the fragment ions  $m/z$  809.3746  $[M-H]^-$  and  $m/z$  707.3538  $[M-H]^-$ . The specific cracking pathway of the steroidal saponins is shown in **Figure 4**.

### Flavonoids

It is already known that flavonoids are the main components in PG (Wang et al., 2017b; Deng et al., 2020). The main components identified were flavonoids and flavonoid glycosides, and the characteristic cleavage mode was the R-DA cleavage, while glycosides followed the glycosyl cleavage. Using luteolin as an example for the analysis, the molecular ion peak  $m/z$  285.0405 was produced in the negative ion mode, and the retention time was 14.61 min the characteristic fragment ions  $m/z$  151.0087  $[M-H]^-$ ,  $m/z$  133.0303  $[M-H]^-$ , and  $m/z$  107.0166  $[M-H]^-$  were obtained, respectively, by R-DA cleavage at two different positions. In addition, the fragment ion  $m/z$  267.0299  $[M-H]^-$  was obtained by removing one molecule of  $H_2O$ , and the fragment ion  $m/z$  175.0421  $[M-H]^-$  was also obtained by alpha cracking. The specific cracking pathway of the flavonoids is shown in **Figure 5**.

## Phenolic Acids

Three phenolic acid components were identified from PG. The main cracking methods were alpha cracking, Michael rearrangement cracking, and neutral H<sub>2</sub>O molecule detachment. Using the chlorogenic acid as an example for the analysis, it generated a molecular ion peak  $m/z$  353.0878 in the negative ion mode, with

a retention time of 5.10 min. There are three main cracking methods: first, the alpha cleavage produced the fragment ion  $m/z$  191.0569 [M-H]<sup>-</sup>, and two molecules of H<sub>2</sub>O were removed to obtain the fragment ion  $m/z$  173.0479 [M-H]<sup>-</sup> and  $m/z$  155.0334 [M-H]<sup>-</sup>. Second, the cleavage by Michael rearrangement produced the fragment ion  $m/z$  189.0419 [M-H]<sup>-</sup>, and then a molecule of H<sub>2</sub>O

**FIGURE 11 |** Survival curve of the relationship between high and low expression and overall survival of patients.

was removed to obtain the fragment ion  $m/z$  171.0325  $[M-H]^-$ . Third, the alpha fragmentation produced the fragment ion  $m/z$  135.0471  $[M-H]^-$  and  $m/z$  107.0499  $[M-H]^-$ . The specific cracking pathway of the phenolic acids is shown in **Figure 6**.

### Organic Acids

The organic acid components identified in this work were mainly long-chain carboxylic acids with multiple unsaturated bonds. The characteristic cleavage method involved the Michael rearrangement cracking, alpha cracking and neutral molecule removal. Using the sanleng acid as an example for the analysis, it generated a molecular ion peak  $m/z$  329.2334 in the negative ion mode with a retention time of 26.23 min. Michel rearrangement fragmentation produced the characteristic fragment ion  $m/z$  185.1110  $[M-H]^-$ . The fragment ion  $m/z$  311.2160  $[M-H]^-$  was obtained by removing one molecule of  $H_2O$ . Another molecule of  $H_2O$  was removed from  $m/z$  311.2160  $[M-H]^-$  to obtain the fragment ion  $m/z$  293.2189  $[M-H]^-$ ; in addition,  $m/z$  311.2160  $[M-H]^-$  underwent alpha cracking to obtain the fragment ion  $m/z$  211.1344  $[M-H]^-$ . The specific cracking pathway of the organic acids is shown in **Figure 7**.

### Screening of the Active Ingredients

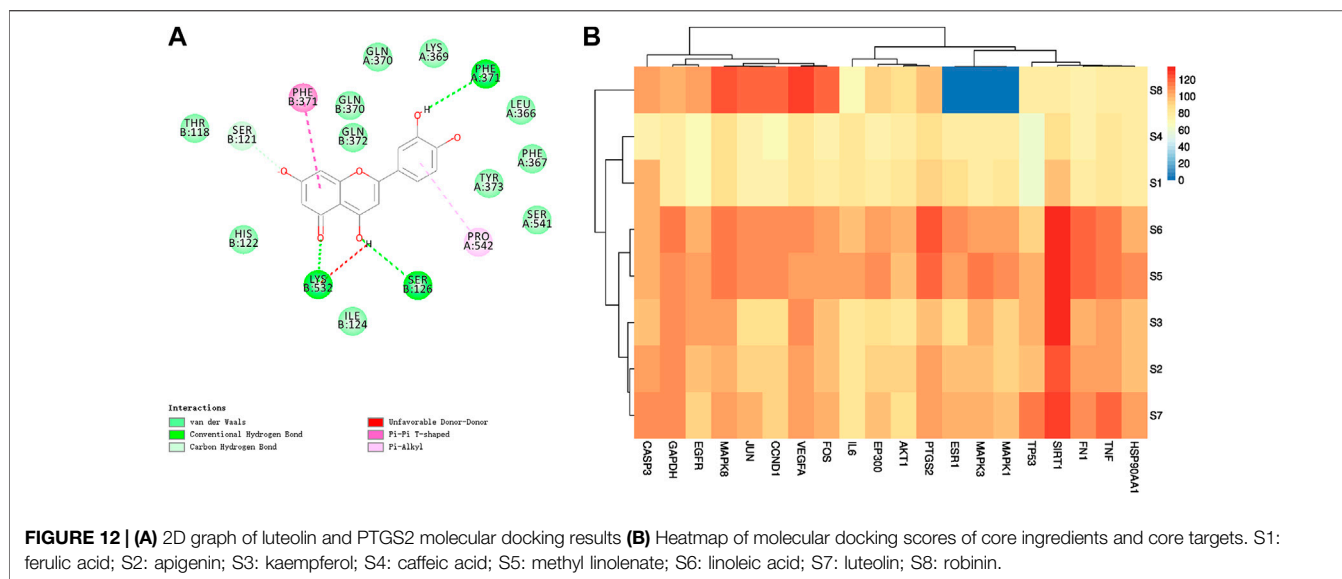

The absorption-distribution-metabolism-excretion-toxicity (ADMET) properties of the chemical constituents were predicted by DS, and apigenin, caffeic acid, kaempferol, linoleic acid, methyl linolenic acid, and ferulic acid were

selected. Although some components do not meet the DS screening criteria, they are still considered as active components in order to select the active components of PG more comprehensively. For example, luteolin and robinin were obtained from TCMSP, with oral bioavailability greater than 30% and drug-likeness greater than 0.18 despite they did not meet the DS screening criteria, so they are considered as active ingredients. Recent studies showed that platycodin D is one of the main components of PG, and has a certain preventive and therapeutic effect on LC (Zhao et al., 2015; Zhang, 2016b; Deng et al., 2020), thus platycodin D is also retained as the active ingredient. To sum up, a total of nine ingredients were selected as the active components of PG, and their detailed characteristics are listed in **Table 2**.

### PPI Network Analysis

A total of 545 targets of the selected nine active components in PG were obtained using the Swiss Target Prediction, Pubchem, TCMSP and pharmpmapper databases. A total of 2664 LC related targets were collected using GeneCards and DisGenet databases using “Lung cancer” as the keyword (**Schedules 2,3**).

The Venn diagram of drug-disease overlapping targets was obtained using the R software to intersect PG related targets and LC related targets (**Figure 8A**), revealing the existence of 285 common targets (**Schedule 4**). The interactive PPI network of common targets was obtained by introducing the 285 drug-disease common targets into STRING and the obtained

network was imported into the Cytoscape software for visualization (**Figure 8B**). No interaction was found between the target S100P and other targets, but the other 284 common targets had an interaction. The average value of DC calculated by CentiScape was 39.775, and 108 potential targets with DC values greater than 39.775 were selected. The higher the DC value, the more important the role in the network. In this study, the targets with the top 20 DC values were selected as the core targets. The red dot in **Figure 8B** represents the core target, the light green dot represents the potential target, the yellow dot represents the interactive target, and the connection between the nodes represents the interaction between the two proteins.

## GO and KEGG Pathway Enrichment Analysis

The pathway enrichment analysis of the 20 core targets was carried out using Metascape. The enrichment results were selected under the conditions of  $p < 0.01$ , minimum count 3, and enrichment factor  $> 1.5$ . A total of 849 GO biological functions and 116 KEGG enrichment items were obtained. The GO functions related to the treatment of LC included oxidative stress response (GO:0006979), active regulation of cell migration (GO:0030335), regulation of DNA binding transcription factor activity (GO:0051090), and regulation of cytokine-mediated signaling pathway (GO:0019221) (**Figure 9A**), mostly related to apoptosis, oxidative stress and energy metabolism. The 20 core targets were closely related to cancer pathway (hsa05200), TNF signaling pathway (hsa04668), MAPK signaling pathway (hsa04010) and PI3K-AKT signaling pathway (hsa04151), and are related to diseases such as hepatitis B, colorectal cancer, non-small cell LC and small cell LC (**Figure 9B**). The first 20 representative signaling pathways are listed in **Table 3**, which might represent the key pathways in the treatment of LC. It is also suggested that PG can be used in the treatment of LC. The top 10 pathways were determined in the KEGG database and annotated

using the PathwayBuilderTool\_2.0 software to integrate the potential pathways of PG in the treatment of LC (**Figure 9C**). This analysis provided a new research method for the limitations in treating LC.

## D-I-T-P-D Network Analysis

In order to explain the complex mechanism of multi-ingredient-multi-target-multi-pathway of PG in the treatment of LC, this study selected the top 10 pathways and used Cytoscape v 3.7.1 to construct a D-I-T-P-D network, as shown in **Figure 10**. In this network, the purple node represents the drug, the green node represents the core ingredient of PG, the yellow node represents the core target of PG in the treatment of LC, the red node represents the pathway, the blue node represents the disease, and the edge represents the interaction among nodes. The network consists of 40 nodes (1 drug, eight core components, 20 core targets, 10 pathways and one disease), with a total of 277 edges, which fully showed that the targets of the core ingredients of PG were distributed in different pathways, and the ingredients coordinated with each other in the body.

## Subsistence Analysis

The relationship between the top five core targets in the PPI network and the prognosis of LC patients was analyzed using the Kaplan-Meier Plotter database. The results revealed that the overall survival of LC patients with high expression of GAPDH, AKT1, TP53, IL6 and MPKA3 was significantly lower than that in patients with their low expression ( $p < 0.01$ ) (**Figure 11**).

## Molecular Docking Verification Results

The analysis of the D-I-T-P-D network showed that each core component interacted with multiple targets. Thus, the DS software was used to dock the core components with the core target molecules in order to verify the interaction among them. It is generally accepted that the higher the score of the ligand binding to the receptor, the greater the possibility of

interaction. The docking results of luteolin and protein PTGS2 docking are shown in **Figure 12A**, which might bond by hydrogen bonds, van der Waals forces and other forces. The docking score was sorted out, the highest score was obtained (**Schedule 5**), and then ImageGP was used for visual processing (**Figure 12B**). The redder the color, the better the affinity of the component to the target. The relationship between the above-mentioned core components and core targets was consistent according to the analysis of the docking scoring results.

The cluster analysis revealed that GAPDH, VEGFA, EGFR, JUN, CCND1, MAPK8, FOS and CASP3 could be included into one group, while EP300, AKT1, HSP90AA1, MAPK3, TNF, SIRT1, ESR1, PTGS2, TP53, FN1, MAPK1 and IL6 could be included in one category. SIRT1, PTGS2, CASP3, VEGFA, MAPK8 and GAPDH were the targets with strong binding ability according to the molecular docking. Linoleic acid, methyl linolenate, luteolin, apigenin and kaempferol were the core components with strong binding ability according to the molecular docking, and the docking scores of these five components with SIRT1 were greater than 120, followed by methyl linolenate, kaempferol, linoleic acid, luteolin and apigenin. This result suggested that these five components have a good binding activity with SIRT1 and might play a key role in the treatment of LC using PG.

## DISCUSSION

The etiology of LC is complex and so far, no final conclusion was obtained. It is related to smoking, air pollution, dietary factors, decreased immune function and genetic factors (Li and Wang, 2019), while TCM believes that the main cause in the development of LC is the lack of “vital qi”, since the “deficiency of vital qi” is “evil”. Professor Jia Yingjie claims that the “deficiency of vital qi and coexistence of toxin and blood stasis” is the key of the pathogenesis of LC (Yu et al., 2020). PG exerts the effect of smoothing the lung, dispelling the phlegm, and expelling the pus, which is consistent with the pathogenesis of LC. However, the mechanism of PG in the treatment of LC is still unclear due to the multi-ingredient and multi-target characteristics of TCM. Therefore, it is imperative to analyze the ingredients of PG and explore the mechanism used by PG in the treatment of LC.

In this study, 47 non-volatile ingredients were identified from the alcohol extract of PG by the UPLC-Q-TOF-MS/MS technique. According to the ADMET parameters and other basic properties of the ingredients, and combined with the results in the literature, nine main active ingredients including platycodin D and apigenin were selected. The results showed that they play an important role by affecting 285 overlapping genes involved in the treatment of LC. The PPI network showed that the DC values of GAPDH, AKT1 and TP53 were greater than 175, and they were predicted as the most relevant targets. The enrichment analysis of the GO pathway and KEGG pathway in the 20 core targets showed that most of the functional enrichment results of GO were apoptosis, oxidative stress and energy metabolism. Our hypothesis was that oxidative stress response might be the most

important biological process managed by PG in the treatment of LC. The results of the KEGG pathway enrichment analysis showed that the top 10 pathways included cancer pathway, TNF signaling pathway, MAPK signaling pathway, PI3K-AKT signaling pathway and FoxO signaling pathway. Among them, MAPK signaling pathway, PI3K-AKT signaling pathway, FoxO signaling pathway and HIF-1 signaling pathway were related to cell proliferation and apoptosis, oxidative stress and inflammation. MAPK signaling pathway is one of the most important pathways regulated by PG in the treatment of LC. Related studies showed that the MAPK signaling pathway participates in the regulation of cell cycle, apoptosis and proliferation of NSCLC cells, and inhibits the expression of P-glycoprotein (P-gp), multidrug resistance gene 1 (MDR1), TP53 and other proteins, thus inhibiting the growth of NSCLC cells, blocking cell cycle and inducing apoptosis (Liao et al., 2020; Qiao et al., 2020; Wang et al., 2020). PI3K-AKT signaling pathway is considered as the primary pathway for cancer cell survival, since it promotes tumor cell proliferation and metastasis, and inhibits apoptosis and angiogenesis. If this pathway is abnormal, it directly leads to the abnormal proliferation of cells (Ma et al., 2014; Sui et al., 2018). Therefore, the activation of the MAPK signaling pathway and the inhibition of the PI3K-AKT signaling pathway are crucial in the treatment of LC.

The D-I-T-P-D network showed that the same target could interact with many ingredients. For example, PTGS2 could bind ferulic acid, luteolin, linoleic acid, apigenin and sophorin, while CASP3 can bind methyl linolenic acid, apigenin, ferulic acid and robinin, indicating that multiple active ingredients in PG might act on the same target. In addition, our results showed that apigenin was related to CASP3, AKT1, FOS, JUN, MAPK8, TNF, VEGFA, and CCND1, and linoleic acid was related to PTGS2, TP53, ESR1, MAPK1, MAPK8 and IL6, which was consistent with the results obtained by molecular docking, suggesting that PG could act on multiple targets through the same active component. This result also explained the characteristics of multi-ingredient and multi-target synergism of PG, providing a basis in the mechanism of PG to treat LC. Our hypothesis was that PG was closely related to cell proliferation and apoptosis in the treatment of LC according to the GO pathway and KEGG pathway enrichment analysis. Several core components of PG could interact with PTGS2 and CASP3, potentially promoting cancer cell apoptosis through specific signaling pathways such as MAPK signaling pathway and PI3K-AKT signaling pathway in order to cure LC.

The survival analysis results showed that the top five core targets (GAPDH, AKT1, TP53, IL6, and MPKA3) in the PPI network were closely related to the survival of LC patients. The overall survival of LC patients with a high expression of these genes was significantly lower than that of patients with their low expression, suggesting that its overexpression is related to a poor prognosis in LC patients. Thus, they could be used as biomarkers to evaluate LC prognosis.

The results of molecular docking showed that apigenin, luteolin, linoleic acid, kaempferol and methyl linolenate might be the potential active ingredients. Some studies showed that apigenin has a cytotoxic effect on human LC cisplatin-resistant cell line A549/DDP, and indeed it effectively inhibits its growth and reverse its drug resistance (Zhao et al., 2017; Mo et al., 2020). Zhou Liang et al. found that luteolin inhibits the metastasis and proliferation of LC through the down-regulation of the PI3K/AKT signaling pathway and the improvement of the immune function in the body (Zhou et al., 2017). In addition, Li Xiaolin et al. demonstrated that luteolin effectively blocks A549/DDP cell cycle and even promotes apoptosis, and that TP53 protein is involved in this process (Li et al., 2009). In addition, some scientists found that kaempferol weakens the invasion and migration ability of NSCLC A549 cells by inhibiting the expression of estrogen-related receptor  $\alpha$  (ERR $\alpha$ ), thus providing a strong support in the study of the anti-cancer mechanism of kaempferol (Zhang et al., 2018). However, Mouradian and other scientists found that linoleic acid increases the activity of PI3K/AKT signaling pathway, promotes the proliferation of LC cells, and leads to tumor formation, with GAB1 as the main target of linoleic acid (Mouradian et al., 2014). Apigenin, luteolin, linoleic acid, kaempferol, and methyl linolenate are widely found in plants, but plants that contain all these five components are rare. Besides PG, *Panax notoginseng* (Liu, 2019) and peony seed (Zhang, 2016a) also contain these five components. However, so far, no reports are available regarding *Panax notoginseng* and peony seed anti-LC effect. Therefore, our analysis of the effect and mechanism of PG in the treatment of LC is of great significance.

## CONCLUSION

PG is one of the most commonly used TCM in clinical practice, since it has a significant therapeutic effect on lung-related diseases and has been used in China for thousands of years. In this study, the chemical constituents of PG were analyzed and identified. A total of nine active PG components and 285 overlapping targets of PG and LC were screened. PPI network, GO and KEGG enrichment analysis showed that the mechanism of PG in the treatment of LC might be related to its involvement in cancer cell apoptosis, inflammation and

oxidative stress through the MAPK signaling pathway and PI3K-AKT signaling pathway. The network pharmacological method developed in this study provided another strategy for a comprehensive understanding of the mechanism of PG in the treatment of LC.

## DATA AVAILABILITY STATEMENT

All datasets presented in this study are included in the article/Supplementary Material.

## AUTHOR CONTRIBUTIONS

YD integrated the data and wrote the manuscript; ML, YL, and KW performed the literature search; XY and YC completed the ingredient identification; HR and LX collected the prediction targets; HL and HZ completed the network analysis; ZZ improved the manuscript writing; JZ conceptualized and designed the experimental plan.

## FUNDING

This study was supported by the National Key R and D Program—Special Topics for Modernization of TCM (No. 2018YFC1707206), Key R and D Program of Jiangxi Province (No. 20192BBG70073), National Natural Science foundation of China (No. 81560651), Jiangxi Province's double first-class discipline (TCM) construction project (No. JXSYLXK-ZHYAO039/141), and Doctoral Research start-up Fund (No. 2018WBZR009).

## ACKNOWLEDGMENTS

The authors thank the Jiangxi University of TCM for the assistance in performing this study.

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2020.609825/full#supplementary-material>.

doi: 10.3389/fphar.2021.617559

Ionizing radiation damage refers to acute, delayed, or chronic tissue damage associated with ionizing radiation. Specific or effective therapeutic options for systemic injuries induced by ionizing radiation have not been developed. Studies have shown that Chinese herbal Medicine or Chinese Herbal Prescription exhibit preventive properties against radiation damage. These medicines inhibit tissue injuries and promote repair with very minimal side effects. This study reviews traditional Chinese herbal medicines and prescriptions with radiation protective effects as well as their mechanisms of action. The information obtained will guide the development of alternative radioprotectants.

**Keywords:** ionizing radiation, oxidative damage, Chinese herbal medicines, Chinese herbal prescriptions, anti-radiation, radiation protective drugs

## INTRODUCTION

Ionizing radiation is essential in clinical diagnoses and treatment. It is an effective therapeutic strategy for cancer treatment. Approximately 50% of cancer patients are administered with radiotherapy to inhibit metastasis (Begg et al., 2011). Ionizing radiation causes clustered DNA damage and leads to persistent oxidative stress injuries to cellular macromolecules (Shuryak, 2019). Radiotherapy inhibits metastasis by inducing DNA damage. However, it causes unintended damage to normal cells by enhancing DNA double-strand breaks (DSBs). Double-strand breaks can be repaired through two major pathways: the non-homologous end-joining (NHEJ) and homologous recombination (HR). The NHEJ pathway occurs during the G0/G1 phase, while the HR repair pathway is only active in the late S and G2 phases (Shibata, 2017). Severe genetic changes such as chromosomal deletions and translocations in the repair process can stimulate tumorigenesis (Shrivastav et al., 2008; Gerelchuluun et al., 2015). According to the United Nations Scientific Committee, the effects of atomic radiation include mutations due to DNA deletions (Sankaranarayanan and Wassom, 2005), and epigenetic transmissions that affect generations (Horemans et al., 2019). Oxidative damage after exposure to ionizing radiation is a crucial reason for sustained injuries (Einor et al., 2016). Approximately 70% of cellular radiation damage is indirectly caused by water dissociation and reactive oxygen species (ROS). Free radicals are triggers for a state of constant oxidative stress (Anuranjani and Bala, 2014). Inflammation, immunity, and other associated signaling pathways are involved in the regulation of cellular damage by inducing cell senescence, apoptosis, and other cell fates (Santivasi and Xia, 2014). The pathological process is as shown in **Figure 1**. Ferroptosis is a novel form of cell death that

is involved in pathological damage after irradiation (Lei et al., 2020). There is a need for the development of drugs that inhibit or repair pathological damages associated with radiation.

Current therapeutic strategies for radiation damage focus on minimizing DNA breaks, generation of antioxidants, scavenging free radicals, and inhibiting lipid peroxidation (Weiss and Landauer, 2003; Johnke et al., 2014; Smith et al., 2017). However, clinical applications of radioprotectants are limited because of its limited efficacies and severe side effects (Brizel, 2007; Citrin et al., 2010; Singh and Seed, 2019). Chinese herbal medicines have been used for thousands of years. They are widely used in clinical settings to treat various diseases, or are used in combination with western medicines to improve clinical efficacies (Li and Xu, 2011; Hao et al., 2017; Takayama and Iwasaki, 2017; Wang and Zhang, 2017; Yeh et al., 2017; Lei et al., 2019). As early as the 1960s, Chinese researchers had extended the research focused on the anti-radiation effects of Chinese herbal medicines. It has been found that *Panax ginseng* C.A.Mey., *Ganoderma Lucidum* Karst, *Angelica sinensis* (Oliv.) Diels, and other medicinal herbs exhibit varying degrees of anti-radiation effects. In addition, Chinese Herbal Prescriptions have been shown to facilitate physical recovery. Traditional Chinese medicinal herbs have complex chemical structures and biological activities. The Chinese Herbal Prescription, which is composed of more than one medicinal herb, is the embodiment of traditional Chinese

medicine's clinical applications. The Chinese Herbal Prescriptions can enhance the efficacy of a drug, reduce or neutralize the adverse effects of individual drugs and improve their therapeutic efficacies (Shen et al., 2017; Li et al., 2019b; Shi et al., 2019b). In recent years, researches on the treatment of ionizing radiation damage with Traditional Chinese Medicine are regularly emerging. The active compounds in Chinese medicinal herbs and Chinese Herbal Prescriptions exhibit significant effects on the reduction of oxidative stress and promote DNA repair. Their biological mechanisms involve the regulation of multiple signaling pathways.

In this review, we summarized recent advances that have been aimed at elucidating the functions and mechanisms of effective active ingredients of Chinese herbal medicines and prescriptions in preventing ionizing radiation associated damage. We aimed at establishing novel therapeutic avenues for the development and clinical applications of radiation protective drugs.

## ANTI-RADIATION ACTIVE COMPOUNDS OF CHINESE HERBAL MEDICINES

Active compounds in Chinese herbal medicines can scavenge for free radicals, reduce DNA damage, promote post-injury repair, and reduce cell apoptosis. Therefore, these herbs prevent

**TABLE 1 |** Effects and Mechanisms of active compounds of Chinese Herbal Medicines in ionizing radiation damage.

Names	Category	Origins	Objects (model inducer,dose)	Pharmacological action/Mechanisms	References
Ginsenoside Rb(1), Rb(2), Rc, Rd, Re and Rg(1)	Saponins	<i>Panax ginseng</i> C.A.Mey.	ICR mice (12 Gy, 6.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduce intestinal crypt cells apoptosis	Lee et al. (2006)
Gypenosides	Saponins	<i>Gynostemma pentaphyllum</i>	Male Balb/c mice (5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increase the activity of SOD and CAT in serum, interference with Nrf2 signaling pathways	Ying et al. (2018)
Eleutheroside	Saponins	<i>Eleutherococcus senticosus</i> (Rupr. & Maxim.) Maxim.	Male mice (2 Gy x rays)	Improve peripheral blood cell radiation injury	Yue et al. (2005)
Acidic polysaccharide of ginseng	Polysaccharides	<i>Panax ginseng</i> C.A.Mey.	Bms (1 Gy $^{60}\text{Co}$ $\gamma$ rays) Balb/c mice (5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Alter the phenotype of bms, increase the viability and alloreactivity of bms	Kim et al. (2007)
Acidic polysaccharide of ginseng	Polysaccharides	<i>Panax ginseng</i> C.A.Mey.	C57BL/6 mice(7 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibit p53 dependent pathway and mitochondrial apoptosis pathway activation	Park et al. (2011) and Bing et al. (2014)
Lycium Barbarum Polysaccharide	Polysaccharides	<i>Lycium barbarum</i> L.	Wistar rats (2.3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Elevate SOD levels, suppress MDA levels and restores testosterone levels	Luo et al. (2011)
Lycium Barbarum Polysaccharide	Polysaccharides	<i>Lycium barbarum</i> L.	Kunming mice (4 Gy X-rays)	Improve antioxidant capacity and cell cycle	Zhou et al. (2016)
Lycium Barbarum Polysaccharide	Polysaccharides	<i>Lycium barbarum</i> L.	Wistar rats (2.3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibit mitochondrial apoptosis	Luo et al. (2014)
Astragalus Polysaccharide	Polysaccharides	<i>Astragalus mongholicus</i> Bunge	Balb/c mice (5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibit the secretion of pro-inflammatory factors, reduce the damage of pulmonary fibrosis caused by peroxide	Liu et al. (2014)
Astragalus Polysaccharide	Polysaccharides	<i>Astragalus mongholicus</i> Bunge	Bmscs A549 cells (2 Gy X-rays)	Improve the ROS - mediated side effects of ionizing radiation via MAPK/NF- $\kappa$ B signaling pathway	Zhang et al. (2018c)
Astragalus Polysaccharide	Polysaccharides	<i>Astragalus mongholicus</i> Bunge	Human bone marrow mesenchymal stem cells (2 Gy X-rays)	Promote the self-renewal and proliferation of cells	Kongxi et al. (2020)
Astragalus Polysaccharide	Polysaccharides	<i>Astragalus mongholicus</i> Bunge	Human bone marrow mesenchymal stem cells (2 Gy $^{12}\text{C}^{6+}$ )	Down-regulates NF- $\kappa$ B signaling pathway to maintain cell DNA stability	Li-ying et al. (2018)
Ganoderma Polysaccharides	Polysaccharides	<i>Ganoderma Lucidum</i> Karst	Mice (5 Gy X-rays)	Improves the expression of biomarkers in the thymus	Kunmu et al. (2020)
Ganoderma Polysaccharides	Polysaccharides	<i>Ganoderma Lucidum</i> Karst	Kunming mice (7.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increase the survival rate, improve the phagocytosis of mononuclear macrophages and NK cell activity	Guohui et al. (2004)
Angelica sinensis polysaccharide	Polysaccharides	<i>Angelica sinensis</i> (Oliv.) Diels	Balb/c male mice (3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increase the number of bone marrow cell and protect hematopoietic system	Zhao et al. (2012)
Ginkgo flavonoids	Flavonoid	<i>Ginkgo biloba</i> L.	SD rats (800 cgy X-rays)	Inhibit lipid peroxidation and reduce the secretion of LDH and TNF- $\alpha$	Sener et al. (2006)
Houttuynia Cordata	Flavonoid	<i>Houttuynia cordata</i> Thunb.	Kunming mice (3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Improve peripheral blood cell injury	Jun and Zhenghai (2010)
Paeoniflorin	Glycosides	<i>Paeonia lactiflora</i> Pall.	EA.hy926 cell line (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Interfere with Nrf2/HO-1 pathway to reduce oxidative stress response	Yu et al. (2013)
Paeoniflorin	Glycosides	<i>Paeonia lactiflora</i> Pall.	Thymocytes (0–8 Gy $^{60}\text{Co}$ $\gamma$ rays)	Act on the expression of Bcl-2, Bax and Caspase-3, and reduce mitochondrial apoptosis	Li et al. (2007)
Paeoniflorin	Glycosides	<i>Paeonia lactiflora</i> Pall.	HSF cell line (16 Gy X-rays)	Inhibits MAPK signal pathway to revers DNA damage	Yang et al. (2015)
Astragaloside IV	Glycosides	<i>Astragalus mongholicus</i> Bunge	Balb/c mice (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Regulates cell apoptosis or cell cycle, down-regulates Bax/Bcl-2 ratio, and reduces cell cycle arrest in G0/G1 phase	Li et al. (2011)
Rhodiolide	Glycosides	<i>Rhodiola rosea</i> L.	AHH-1 cells (4, 6, 8, 10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increases the proliferative activity of lymphocytes	Tianxiang et al. (2013)
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	Swiss albino mice (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Promotes Nrf2 nuclear translocation and activates the NHEJ repair pathway	Das et al. (2017a)
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	Swiss mice (4, 6, 8, 10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces DNA strand break in leukocytes and bone marrow cells and promotes the recovery of bone marrow hematopoietic functions	Maurya and Devasagayam (2013)

(Continued on following page)

**TABLE 1 |** (Continued) Effects and Mechanisms of active compounds of Chinese Herbal Medicines in ionizing radiation damage.

Names	Category	Origins	Objects (model inducer,dose)	Pharmacological action/Mechanisms	References
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	Swiss albino mice (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces I $\kappa$ B $\alpha$ phosphorylation, and NF- $\kappa$ B nuclear translocation, improves radiation-induced inflammation	Das et al. (2014)
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	Swiss albino mice (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces lipid peroxidation and increases the activity of SOD and catalase, increases PI3K phosphorylation levels, reduces cell cycle arrest	Das et al. (2016)
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	Swiss albino mice (2.5, 5, 10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits peroxide and downstream mitochondrial apoptosis pathway activation	Das et al. (2017b)
Ferulic Acid	Phenolic acids	<i>Angelica sinensis</i> (Oliv.) Diels	SD rats (5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increases SIRT1 activity and testosterone levels in testis, and decreases oxidative stress response	El-Mesallamy et al. (2018)
Salvianic acid A	Phenolic acids	<i>Salvia miltiorrhiza</i> Bunge	L-02 cells (4 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces apoptosis and DNA damage	Juan et al. (2012)
Salvianic acid A	Phenolic acids	<i>Salvia miltiorrhiza</i> Bunge	Balb/c mice (4, 8 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects hematopoietic system	Juan et al. (2015)
Resveratrol	Polyphenols	<i>Red grapes</i>	Female SD rats (3.2 Gy $^{137}\text{Cs}$ $\gamma$ rays)	Inhibits NF- $\kappa$ B - activated inflammatory cytokines	Said et al. (2016)
Resveratrol	Polyphenols	<i>Red grapes</i>	Lymphocyte (0.5, 1 Gy X-rays)	Inhibits DNA damage	Basso et al. (2016)
Resveratrol	Polyphenols	<i>Red grapes</i>	Male C57BL/6 N mice (7 Gy $^{137}\text{Cs}$ $\gamma$ rays)	Improves intestinal morphology, reduce crypt cell apoptosis, and regulates the expression of Sirt1 and p53	Zhang et al. (2017a)
Resveratrol	Polyphenols	<i>Red grapes</i>	Male C57BL/6 mice (6 Gy $^{137}\text{Cs}$ $\gamma$ rays)	Ameliorates thymus and spleen atrophy, reduce lymphocyte count, Modulates immunosuppression	Zhang et al. (2018a)
Tea Polyphenols	Polyphenols	<i>Green tea</i>	Kunming mice (738 cGy $^{60}\text{Co}$ $\gamma$ rays)	Recovery the haematopoietic system, antioxidant potential activity and reduce inflammatory cytokines	Hu et al. (2011)
Tea Polyphenols	Polyphenols	<i>Green tea</i>	Male C57BL/6 mice (2 Gy X-rays)	Inhibits oxidative stress and mitochondrial apoptosis	Ding et al. (2015)
Ginseng oligopeptide	Oligopeptides	<i>Panax ginseng</i> C.A.Mey.	Caco-2 (2 Gy X-rays) Balb/c mice (3.5 Gy X-rays)	Attenuates immune dysfunction	He et al. (2017)
Ginseng oligopeptide	Oligopeptides	<i>Panax ginseng</i> C.A.Mey.	BALB/c mice (3.5, 8Gy $^{60}\text{Co}$ $\gamma$ rays)	Decreases inflammatory and oxidative stress	He et al. (2018)

radiation damage through different mechanisms. Below, we highlight a few representative active compounds and highlight their potential mechanisms and pharmacological activities in radioprotection (As shown in **Table 1**).

## Saponins

Saponins are the main active compounds in many Chinese herbal medicines (Yang et al., 2014), especially in *Panax ginseng* C.A.Mey. Lee et al. established that the active ingredients in *Panax ginseng* C.A.Mey such as Ginsenoside Rc, Ginsenoside Rd, and Ginsenoside Re are radioprotective (Lee et al., 2006). The administration of Ginsenoside Rd and Ginsenoside Re in mice before irradiation enhanced the formation of endogenous splenic colonies and inhibited radiation-induced apoptosis of the intestinal crypt cells (Lee et al., 2006). Ginsenosides have a wide range of biological and pharmacological properties. They have been shown to be effective against neurological diseases, infectious diseases, and tumors (Rokot et al., 2016; Arring et al., 2018; Nguyen and Nguyen, 2019). Through intestinal biotransformation, *Panax ginseng* C.A.Mey. can be

transformed into high pharmacological activity metabolites that act on multiple human tissues (Mancuso and Santangelo, 2017).

Other medicinal herbs have also been shown to contain saponins that play a role in radioprotection. Administration of Gypenoside before irradiation effectively increased serum superoxide dismutase (SOD) and CAT levels that inhibit the expression of Nrf2 and HO-1 (Ying et al., 2018). Saponins from *Eleutherococcus senticosus* (Rupr. & Maxim.) Maxim. ameliorate peripheral blood cell damage associated with radiation (Yue et al., 2005).

## Polysaccharides

Polysaccharides are widespread in animals, plants, and microorganisms. They form part of the primary substances that make up living things (Chen and Huang, 2018). *Panax ginseng* C.A.Mey. contains polysaccharides. The acidic polysaccharide of ginseng (APG) has been shown to increase IL-12 levels in bone marrow cells (BMs) of irradiated mice. Kim et al. speculated that APG contribute to the proliferation of CD4 (+) T lymphocytes and facilitate viability as well as

**TABLE 2 |** Effects and Mechanisms of Chinese Herbal Medicines in ionizing radiation damage.

Names	Familia	Objects (model inducer,dose)	Pharmacological action/Mechanisms	References
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	Outbred albino rats (4 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits carcinogenesis	Bespalov et al. (2014)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	Balb/c mice (8 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects the bone marrow and increases inflammatory factor	Song et al. (2003)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	Swiss albino mice (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects against radiation-induced hematological and biochemical alterations	Verma et al. (2011)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	Splenocytes (5 Gy $^{60}\text{Co}$ $\gamma$ rays) Balb/c mice (4.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits immunosuppression	Han et al. (2005)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	Wistar rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects against cardio-nephrotoxicity through enhancing the antioxidant activity and inhibition of endothelial dysfunction	Mansour (2013)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	C57BL/6 mice (15 Gy X-rays)	Prevents the manifestations of oxidative stress, protects against RILI	Jang et al. (2015)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	C57BL/6 mice(6.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects against radiation-induced inflammation and cancer	Koo et al. (2013)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	RAW264.7 cells (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits proinflammatory responses	Lee et al. (2014)
<i>Panax ginseng</i> C.A.Mey.	Araliaceae	RBL-2H3 cells (10, 30, 50, 70, 100 kGy $^{60}\text{Co}$ $\gamma$ rays) Balb/c mice (100 kGy $^{60}\text{Co}$ $\gamma$ rays)	Suppresses the release of $\beta$ -hexosaminidase, histamine, intracellular ROS and $\text{Ca}^{2+}$ influx induced by IgE-antigen complex, inhibits mast cell-mediated signal transduction activity, and reduces IL-4 serum levels	Kang et al. (2018)
<i>Panax quinquefolius</i> L.	Araliaceae	Human (1, 2 Gy X-rays)	Inhibits lymphocytic DNA damage after radiotherapy, Increases total antioxidant capacity	Lee et al. (2010)
<i>Zingiber officinale</i> <i>roscoe</i>	Zingiberaceae	Swiss albino mice (6–12 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits lipid peroxidation	Jagetia et al. (2003)
<i>Zingiber officinale</i> <i>roscoe</i>	Zingiberaceae	Human mesenchymal stem cells (4 Gy $^{60}\text{Co}$ $\gamma$ rays)	Induces Nrf2 nuclear translocation	Ji et al. (2017)
<i>Zingiber officinale</i> <i>roscoe</i>	Zingiberaceae	SD rats (2 Gy $^{60}\text{Co}$ $\gamma$ rays)	Improves taste, vomiting symptoms	Sharma et al. (2005)
<i>Zingiber officinale</i> <i>roscoe</i>	Zingiberaceae	Albino rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Regulates inflammatory signaling pathways	Mohamed and Badawy (2019)
<i>Zingiber officinale</i> <i>roscoe</i>	Zingiberaceae	Albino rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Suppresses inflammatory factors, enhances mitochondrial complex activity	Soliman et al. (2018)
<i>Angelica sinensis</i> (Oliv.) Diels	Apiaceae	Wistar rats (8 Gy X-rays)	Inhibits OPN, C-Jun, miRna-21 expressions, reduces TGF- $\beta$ 1 release and Tn-I levels, resistance to radiation-induced cardiac fibrosis	Ma et al. (2019)
<i>Ginkgo biloba</i> L.	Ginkgoaceae	Wistar rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits lipid peroxidation and prevents DNA damage	Ismail and El-Sonbaty (2016)
<i>Ginkgo biloba</i> L.	Ginkgoaceae	Wistar rats(1 mci of (99 m)Tc)	Anti-lipid peroxidation and anti-apoptotic	Raafat et al. (2013)
<i>Portulaca oleracea</i> L.	Portulacaceae	Albino rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Relieves lipid peroxidation in liver and kidney	Abd El-Azime et al. (2014)
<i>Lycium barbarum</i> L.	Solanaceae	Kunming mice (5 Gy X-rays)	Inhibits the expression of P53, caspase-3 and caspase-6, and accelerates the recovery of splenic functions	Duan et al. (2015)
<i>Crataegus pinnatifida</i> Bunge	Rosaceae	Lymphocytes (150 cGy $^{60}\text{Co}$ $\gamma$ rays)	Reduces micronucleus in lymphocytes	Hosseinimehr et al. (2009)
<i>Hippophae rhamnoides</i> L.	Elaeagnaceae	Swiss albino strain 'A'Male mice (10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Protects mitochondria and chromatin	Shukla et al. (2006)
<i>Hippophae rhamnoides</i> L.	Elaeagnaceae	Swiss albino mice (5Gy, 10 Gy $^{60}\text{Co}$ $\gamma$ rays)	Enhances spermatogonial proliferation, stem cell survival and reduces sperm abnormalities	Goel et al. (2006)

alloreactivity by inducing phenotypic changes in BMs (Kim et al., 2007). APG inhibits the activation of the p53-dependent pathway and the mitochondrial apoptosis pathway. It down-regulates pro-apoptotic proteins (p53, BAX, cytochrome-c, and caspase-3), thereby, promoting the proliferation of crypt cells. These effects were shown to protect the small intestines of mice from radiation damage (Park et al., 2011; Bing et al., 2014).

*Lycium barbarum* L. is commonly used in traditional medicine to nourish the liver and kidney. Its active ingredient, the Lycium barbarum polysaccharide (LBP), exhibits significant antioxidant effects. Studies have reported that after multiple consecutive local

$^{60}\text{Co}$   $\gamma$ -rays irradiation of rats' testis, LBP enhanced testicular SOD activity, inhibited malondialdehyde (MDA) levels, promoted redox balance recovery, and restored the secretion of testosterone (Luo et al., 2011). In the hematopoietic system, LBP was shown to increase the antioxidant capacity of bone marrow mononuclear cells and mitigated cell cycle arrest by interfering with adhesion molecules CD44 and CD49d (Zhou et al., 2016). In addition, by acting on Bcl-2 and Bax, LBP inhibits spermatogenic cell apoptosis by regulating mitochondrial membrane potential and inhibiting mitochondrial apoptosis (Luo et al., 2014).

**TABLE 3 |** Effects and Mechanisms of Chinese Herbal Prescription in ionizing radiation damage.

Chinese Herbal Prescription	Content	Objects (model inducer,dose)	Pharmacological action/Mechanisms	References
Siwu Tang	<i>Rehmannia glutinosa</i> (Gaertn.) DC., <i>Angelica sinensis</i> (Oliv.) Diels, <i>Conioselinum anthriscoides</i> 'Chuanxiong', <i>Paeonia lactiflora</i> Pall.	Female C57BL/6 mice (3.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Promotes hematopoietic and immune system recovery	Liang et al. (2006) and Liu et al. (2017)
BuzhongYiqi Tang	<i>Astragalus mongholicus</i> Bunge, <i>Codonopsis pilosula</i> (Franch.) Nannf., <i>Atractylodes lancea</i> (Thunb.) DC., <i>Bupleurum chinense</i> DC., <i>Actaea cimicifuga</i> L., <i>Citrus reticulata</i> Blanco, <i>Angelica sinensis</i> (Oliv.) Diels, <i>Glycyrrhiza glabra</i> L.	ICR mice (3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increases the peripheral white blood cell count, relieves platelet damage, reduces lipid peroxides and improves the hematopoietic microenvironment	Xiao-fang et al. (2013) and Xiaoling et al. (2006)
Xuebijing (XBj) injection	<i>Carthamus tinctorius</i> L., <i>Paeonia lactiflora</i> Pall., <i>Conioselinum anthriscoides</i> 'Chuanxiong', <i>Salvia miltiorrhiza</i> Bunge, and <i>Angelica sinensis</i> (Oliv.) Diels	ICR mice (2 Gy, 7.5Gy $^{60}\text{Co}$ $\gamma$ rays) Bone marrow mononucleated cells (1 Gy, 4Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces ROS in bone marrow cells	Li et al. (2014a)
Yiqi Yangyin Fang (YYF)	<i>Astragalus mongholicus</i> Bunge, <i>Panax ginseng</i> C.A.Mey., <i>Ligustrum lucidum</i> W.T.Aiton, <i>Eclipta prostrata</i> (L.) L., <i>Angelica sinensis</i> (Oliv.) Diels, <i>Atractylodes macrocephala</i> Koidz., <i>Poria cocos</i> (Schw.) Wolf, <i>Glycyrrhiza glabra</i> L.	ICR mice (2 Gy, 4Gy $^{137}\text{Cs}$ $\gamma$ rays)	Increases the number of bone marrow cells, hematopoietic progenitor cells, and hematopoietic stem cells, inhibits bone marrow suppression by reducing intracellular ROS levels	Zhang et al. (2017b)
HemoHIM	<i>Angelica sinensis</i> (Oliv.) Diels, <i>Ligusticum officinale</i> (Makino) Kitag., <i>Paeonia lactiflora</i> Pall.	Female C57BL/6 mice (5 Gy $^{137}\text{Cs}$ $\gamma$ rays)	Regulates IL-12 p70/pSTAT4 signaling pathway, accelerates the recovery of immune cells	Park et al. (2012) Park et al. (2014)
Bushen Jiedu Recipe	<i>Schisandra chinensis</i> (Turcz.) Baill., <i>Ophiopogon japonicus</i> (Thunb.) Ker Gawl., <i>Codonopsis pilosula</i> (Franch.) Nannf., <i>Astragalus mongholicus</i> Bunge	Knockout mice (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Regulates TLR4 signaling pathway, reduces white blood cell damage, and protects immune organs	Yunjing et al. (2015) and Lidan et al. (2016)
Wumai Danghuang Oral Liquid	<i>Schisandra chinensis</i> (Turcz.) Baill., <i>Ophiopogon japonicus</i> (Thunb.) Ker Gawl., <i>Codonopsis pilosula</i> (Franch.) Nannf., <i>Astragalus mongholicus</i> Bunge	Kunming mice (2 Gy, 3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increases SOD activity, degrades MDA content, repairs the immune system	Chunhong et al. (2014) and Hang et al. (2013)
Co-Herba Houttuyniae Oral Liquid	<i>Houttuynia cordata</i> Thunb., <i>Panax ginseng</i> C.A.Mey., <i>Lycium barbarum</i> L.	Kunming mice (1.5 Gy, 3 Gy $^{60}\text{Co}$ $\gamma$ rays)	Reduces the rate of chromosomal aberrations, enhances immune functions and the anti-stress ability	Lin et al. (2001) and Lin et al. (2002)
Radioprotection Formula	<i>Astragalus mongholicus</i> Bunge, <i>Ganoderma lucidum</i> Karst, <i>Lycium barbarum</i> L., <i>Poria cocos</i> (Schw.) Wolf	Kunming mice (3 Gy, 7.5 Gy $^{60}\text{Co}$ $\gamma$ rays)	Increases the survival rate, white blood cell count, thymus index, spleen index and bone marrow cell DNA content	Liming et al. (2011)
STW 5	<i>Iberis amara</i> L., <i>Melissa officinalis</i> L., <i>Matricaria chamomilla</i> L., <i>Carum carvi</i> L., <i>Mentha aquatica</i> L., <i>Angelica archangelica</i> L., <i>Silybum marianum</i> (L.) Gaertn., <i>Chelidonium majus</i> L., <i>Glycyrrhiza glabra</i> L.	Male Wistar rats (6 Gy $^{60}\text{Co}$ $\gamma$ rays)	Inhibits oxidative stress responses, lowers inflammatory factors and intestinal damage index, regulates apoptosis-related factors	Khayyal et al. (2014) and El-Ghazaly et al. (2015)
Astragalus immortal prescription	<i>Rehmannia glutinosa</i> (Gaertn.) DC., <i>Ophiopogon japonicus</i> (Thunb.) Ker Gawl. and <i>Equus asinus</i> L., <i>Astragalus mongholicus</i> Bunge	Kunming mice (8 Gy X rays)	Increases the activities of GSH-Px, SOD and reduces MDA content in the liver	Cai-qin et al. (2017)
Wuzi Yanzong Pill (WZY)	<i>Lycium barbarum</i> L., <i>Cuscuta chinensis</i> Lam., <i>Schisandra chinensis</i> (Turcz.) Baill., <i>Plantago asiatica</i> L., <i>Rubus chingii</i> Hu	Male Kunming mice (4 Gy X rays)	Increases serum testosterone and reduces MDA and oxidative stress index (OSI)	Ji et al. (2016)
Yiqi Jiedu Decoction (YQJD)	<i>Astragalus mongholicus</i> Bunge, <i>Angelica sinensis</i> (Oliv.) Diels, <i>Lycium barbarum</i> L., <i>Panax quinquefolius</i> L., <i>Paeonia lactiflora</i> Pall., <i>Crataegus pinnatifida</i> Bunge, <i>Poria cocos</i> (Schw.) Wolf, <i>Portulaca oleracea</i> L.	Male Balb/c mice (2 Gy $^{60}\text{Co}$ $\gamma$ rays)	Promotes testicular index and testicular structure recovery, decreases spermatogenic cell apoptosis, and protects spermatogenic functions by intervening in TLR5 signaling pathways	Wang et al. (2020)

*Astragalus mongholicus* Bunge is a qi-tonifying medicinal herb that is often used in qi deficiency syndromes (Li et al., 2014b). Radiation-induced lung injury is one of the most common and fatal complications of chest radiotherapy (Klein et al., 2016). After

ionizing irradiation, alveolar epithelial cells in the lung exhibit a senescence phenotype and up-regulates the transcription of pro-inflammatory factors that induce pulmonary fibrosis (Beach et al., 2017). This condition manifests itself as breathlessness. The

Astragalus polysaccharide is the active ingredient in *Astragalus mongholicus* Bunge. It inhibits thiobarbituric acid reactive substances and pro-inflammatory factors, but also activates SOD, catalase and glutathione. In addition, it reduces the damage of pulmonary fibrosis caused by peroxidation. Its mechanism of action is correlated with the expression of NF- $\kappa$ B, and this mechanism applies to radiation-induced liver injury (Liu et al., 2014).

Astragalus polysaccharide inhibits p38 phosphorylation, JNK, ERK1/2, NF- $\kappa$ B P65, and COX-2 protein expression levels. Evidence shows that it inhibits ionizing radiation-induced side effects through the ROS-mediated MAPK/NF- $\kappa$ B signaling pathway (Zhang et al., 2018c). Ionizing radiation decreases the capacity for cell proliferation. The Astragalus polysaccharide has been documented to promote self-renewal and proliferation of cells by elevating the expressions of peroxisome proliferator-activated receptor- $\gamma$  (PPAR- $\gamma$ ), CCAAT/enhancer-binding protein  $\alpha$  (C/EBP $\alpha$ ) and protecting adipogenic differentiation functions (Kongxi et al., 2020). *In vitro* studies have also revealed that Astragalus polysaccharides enhance bone marrow mesenchymal stem cell proliferation by downregulating NF- $\kappa$ B signaling pathway-related proteins and maintaining DNA stability (Li-ying et al., 2018).

*Ganoderma Lucidum* Karst has qi replenishment and nerve soothing properties. It contains various biologically active components and pharmacological activities that are important in the control of multiple diseases (Jin et al., 2016; Ahmad, 2018). The *Ganoderma lucidum* polysaccharide is the main biologically active component of *Ganoderma Lucidum* Karst. Studies have shown that *Ganoderma lucidum* polysaccharide regulates the metabolism of endogenous substances (such as L-glutamic acid, taurine, and glycerophospholipid) that enhance the expression of relevant biomarkers in mice thymus and exert radioprotective effects (Kunmu et al., 2020). Guohui et al. reported that after exposing mice to radiation, *Ganoderma Lucidum* Karst increased mice survival rates and improved the phagocytic abilities of mononuclear macrophages and NK cells (Guohui et al., 2004).

The polysaccharides of *Angelica sinensis* (Oliv.) Diels have been documented to exhibit thymus and spleen protective indices, increase the number of red blood cells (RBC), white blood cells (WBC), and bone marrow cells of mice after irradiation. Therefore, they play a role in protecting the hematopoietic system (Zhao et al., 2012).

## Flavonoids

Flavonoids are widely distributed in plants and exhibit health promoting properties (Mukai, 2018). *Ginkgo biloba* L. contains flavonols and other active compounds (Mei et al., 2017) that are responsible for its free radical scavenging ability and antioxidant properties (Evans, 2013). Therefore, *Ginkgo biloba* L. prevents ionizing radiation mediated injuries by inhibiting oxidative stress. Sener et al. have detected rat lung, liver, kidney, and ileum. They reported that the administration of *Ginkgo biloba* L. before and after irradiation attenuated malondialdehyde (MDA) content and reduced DNA damage by inhibiting lipid peroxidation (Sener et al., 2006). *Houttuynia cordata* Thunb. has shown to clearing heat and removing toxicity, reducing swelling and draining pus

(Ma et al., 2017). The flavonoid contents of *Houttuynia cordata* Thunb. have been shown to improve the state of peripheral blood cells after radiation, thereby reducing injury (Jun and Zhenghai, 2010).

## Glycosides

*Paeonia lactiflora* Pall. is an herb that nourishes the blood, restrains yin, softens the liver, and relieves pain. Paeoniflorin is a component of *Paeonia lactiflora* Pall.. Paeoniflorin increased glutathione (GSH), SOD, and reduced MDA and lactate dehydrogenase (LDH) content in an endothelial cell model. In addition, it was shown to reduce oxidative stress responses by interfering with the Nrf2/HO-1 pathway (Yu et al., 2013). Another study showed that it inhibited ROS-mediated mitochondrial apoptosis and reduced ROS accumulation as well as intracellular cytosolic Ca<sup>2+</sup> concentrations. Other than inhibiting the mitochondrial apoptotic pathway by acting on Bcl-2, Bax, and caspase-3 (Li et al., 2007), paeoniflorin also inhibited MAPK signaling pathway activation and reversed radiation-induced DNA damage (Yang et al., 2015).

Astragaloside IV is an active ingredient in *Astragalus mongholicus* Bunge that is involved in controlling apoptosis or cell cycle, down-regulation of the Bax/Bcl-2 ratio, inhibition of G0/G1 cell-cycle arrest, increasing the proliferative ability of bone marrow cells, and in protection against radiation induced damage to the hematopoietic system (Li et al., 2011).

*Rhodiola rosea* L. contains a variety of biologically active compounds with antioxidant, anti-inflammatory, and stress response properties (Amsterdam and Panossian, 2016; Nabavi et al., 2016). Glycosides in *Rhodiola rosea* L. were shown to stimulate lymphocytic cell proliferation after radiation (Tianxiang et al., 2013).

## Phenolic Acids

*Angelica sinensis* (Oliv.) Diels promotes blood nourishment and circulation and is often used to treat blood deficiency syndromes. Ferulic acid (FA) is a bioactive component of *Angelica sinensis* (Oliv.) Diels that reduces DNA damage. Studies have shown that administration of FA to mice 1 h before or after irradiation inhibited micronuclei formation in peripheral blood. FA promotes hematopoietic recovery by attenuating DSBs in white blood cells and bone marrow cells (Maurya and Devasagayam, 2013). After DNA damage, the PARP1 repair mechanism is activated and regulates inflammatory mediators (such as cytokines, chemokines, and inducible Nitric Oxide synthase) (Bai and Virag, 2012), while SIRT1 negatively regulates PARP1 (Caito et al., 2010). After the exposure of mice to ionizing radiation, it was found that PARP1 activities and intracellular calcium concentrations increased in the testis, while SIRT1 activities and expression significantly decreased. FA reversed the expression of SIRT1, maintained testosterone levels, and reduced oxidative stress, while regulating PARP1 and cytosolic calcium concentrations to ameliorate spermatogenesis disorders (El-Mesallamy et al., 2018). Accumulated ROS enhances p53 nuclear transport, expands ataxia capillaries, and activates mutant protein (ATM). Using a radiation damage mice model, Das et al. showed that FA enhanced the nuclear

translocation of nuclear factor Nrf2 and activated the NHEJ repair pathway in response to ROS-mediated oxidative stress and DNA damage (Das et al., 2017a). In addition to inhibiting DNA damage and promoting DNA repair, FA was also involved in the regulation of inflammatory pathways and related factors. It was shown to inhibit the expression of Cox-2 and inducible nitric oxide synthase 2 (iNOS-2) after irradiation, control the phosphorylation/activation of IKK $\alpha$ / $\beta$  and I $\kappa$ B $\alpha$  pathways, and regulate the downstream NF- $\kappa$ B nuclear translocation, thus ameliorating radiation-induced inflammation (Das et al., 2014).

In the intestines, FA was shown to interfere with the ROS/NF- $\kappa$ B/Nrf2/p53-caspase 3-PARP axis. In this processes, it enhanced the expression of Mn-SOD and Heme oxygenase-1 (HO-1) that inhibited peroxidation, regulated phosphatidylserine and mitochondrial membrane potential, and suppressed the activation of downstream mitochondrial apoptotic pathways (Das et al., 2017b). Therefore, FA can regulate cell cycle while inhibiting lipid peroxidation and radiation-induced cell apoptosis. Ionizing radiation activates stress marker cyclin (Cdc42) and down-regulates the activation of survival pathways by inhibiting the phosphorylation of phosphatidylinositol 3-kinase (PI3K) and serine/threonine kinase (Akt). The phosphatase gene (PTEN) is a critical molecule that regulates the survival pathway of PI3K/Akt. Ionizing radiation significantly increases the expression of PTEN that promotes cell cycle arrest and inhibits survival-related pathways. It has been demonstrated that FA lowers the overexpression of Cdc42, apoptotic proteins (p53, p21, Bax, and PTEN), and increases PI3K phosphorylation. Moreover, reduced cell cycle arrest inhibits lipid peroxidation while increasing SOD and catalase activities (Das et al., 2016). After radiation, the senescence phenotype of normal cells can be observed with the cells undergoing inflammation and fibrosis (Li et al., 2018b). Due to its antioxidant and anti-inflammatory aspects, FA has been shown to ameliorate these conditions.

*Salvia miltiorrhiza* Bunge is an alternative therapeutic option for cardiovascular and cerebrovascular diseases. It has anti-inflammatory, antioxidant, and anti-cancer biologic properties (Shi et al., 2019a). Salvianic acid A is the active compound in *Salvia miltiorrhiza* Bunge that has been shown to inhibit apoptosis and reduce ionizing radiation associated DNA damage (Juan et al., 2012). An *in vivo* assay established that salvianic acid A protects the hematopoietic system and improves survival after radiation (Juan et al., 2015).

## Polyphenols

Polyphenols exhibit antioxidant properties that inhibit DNA damage caused by peroxide free radicals (Fraga et al., 2019). Resveratrol is a vital plant antitoxin that possesses antioxidant and anti-inflammatory effects. Resveratrol inhibits NF- $\kappa$ B - activated inflammatory cytokine secretion by up-regulating the expression of peroxisome proliferation-activated receptor (PPAR-4) and SIRT1. These effects prevent ionizing radiation-induced premature ovarian failure (Said et al., 2016). *In vitro* experiments, Basso et al. demonstrated that resveratrol is involved in inhibiting DNA damage after radiation through the assessment of human lymphocyte DNA damage, repair

kinetics, and histone deacetylase activity (Basso et al., 2016). It also improves the morphology of the small intestine, reduces crypt cell apoptosis, regulates Sirt1 and acetylated p53, and has a radioprotective role (Zhang et al., 2017a). Resveratrol improves thymic and spleen atrophy, lymphocyte counts, and proliferation caused by ionizing radiation. Moreover, it inhibits serum levels of IL-2, IL-4, IL-7, and IFN- $\gamma$  thereby regulating immune functions (Zhang et al., 2018a). Green tea is also rich in polyphenols. Tea polyphenols can improve hematopoietic functions after irradiation (Hu et al., 2011), inhibit oxidative stress and mitochondrial apoptosis as well as prevent radiation induced spermatogenic cell death (Ding et al., 2015).

## Oligopeptides

The Ginseng oligopeptide (GOP) reduces the concentration of plasma diamine oxidase and LPS, and inhibits the secretion of IL-1 as well as TNF- $\alpha$ . It also protects the intestinal epithelial barrier by up-regulating the expression of tight junction proteins (ZO-1 and Occludin). It promotes intestinal repairs by suppressing the expression of apoptosis-related proteins (Bax and Caspase-3) and elevating lymphocyte (CD3 +, CD4 +, CD8 +) concentrations (He et al., 2017; He et al., 2018). He et al. reported that prophylactic administration of GOP exhibited radioprotective effects while post-treatment was beneficial for the quick repair of irradiation-induced injuries (He et al., 2017).

In summary, various radioprotective compounds occur in traditional Chinese medicines. This implies that the anti-radiation mechanisms of Chinese herbal medicines are multifaceted. However, Chinese herbal contains sophisticated compounds. If only an active compound is used to explore the effect mechanism, there may be limitations.

## CHINESE HERBAL MEDICINES AND THE ANTI-RADIATION EFFECTS

Extracts from Chinese herbal medicines have been used to comprehensively elucidate on the anti-radiation mechanisms of Chinese Herbal Medicines (Table 2).

### Roots and Rhizomes of Chinese Herbal Medicine

Studies have confirmed that *Panax ginseng* C.A.Mey. reduces the overall or local cancer rates induced by long-term exposures to radiation (Bespalov et al., 2014). Ionizing radiation causes acute myelosuppression and leads to the apoptosis of hematopoietic stem cells as well as hematopoietic progenitor cells. These pathological changes are the primary causes of death after exposure to moderate-to-high radiation doses (Shao et al., 2014). The extract of *Panax ginseng* C.A.Mey. was shown to increase bone marrow cells, spleen cells, and granulocyte-macrophage colony-forming units (CFU-GM) in mice while promoting the secretion of endogenous cytokines (IL-1, IL-6, and IL-12) to rejuvenate hematopoietic functions (Song et al., 2003). In addition, the extract inhibited the decrease in red blood cell counts, hemoglobin and hematocrit, as well as

prevented radiation induced anemic symptoms (Verma et al., 2011). The extract of *Panax ginseng* C.A.Mey. has been reported to protect the hematopoietic system from ionizing radiation by inhibiting cyclooxygenase 2 (COX-2) and down-regulating activated p38 MAPK and PI3K/Akt pathways (Koo et al., 2013). Ionizing radiation-induced changes in the cellular microenvironment affect the immune system (Frey et al., 2017). *Panax ginseng* C.A.Mey. has immune regulation properties (Lee et al., 2005). Studies have shown that *Panax ginseng* C.A.Mey. elevates the mRNA expression of Th1 and Th2 cytokines and inhibits immunosuppression after radiation by stimulating normal spleen cells in mice (Han et al., 2005). *Panax ginseng* C.A.Mey. also exerts its radioprotective effects by inhibiting the expression of IL-1 $\beta$  in macrophages while simultaneously preventing the signal cascade of CHK2 and nuclear factor kappa B (NF- $\kappa$ B) (Lee et al., 2014). By destroying the intestinal epithelial barrier, radiation therapy enhances intestinal permeability and mucosal injury. Intestinal injuries lead to high plasma lipopolysaccharide (LPS) levels and elevated pro-inflammatory cytokine secretions that trigger a series of inflammatory reactions and bowel syndrome (Romesser et al., 2019). Moreover, *Panax ginseng* C.A.Mey. was shown to improve appetite in rats and reduced anorexic symptoms after radiation (Balaji Raghavendran et al., 2012). Ionizing radiation also causes damage to other tissues and organs. Oral administration of the extract of *Panax ginseng* C.A.Mey. before irradiation inhibited the suppression of serum creatine kinase and lactate dehydrogenase levels, suppressed urea and creatinine levels and further protected against irradiation-induced cardio-nephrotoxicity by enhancing antioxidant activities and inhibiting endothelial dysfunctions (Mansour, 2013). Through its antioxidant mechanisms, *Panax ginseng* C.A.Mey. can inhibit catalase activity, increase glutathione content, suppress the expression of IL-1 $\beta$ , TNF- $\alpha$ , and alleviates inflammation in radiation-induced lung injuries (Jang et al., 2015). Ionizing radiation leads acute skin damage (Park et al., 2018). The extract of *Panax ginseng* C.A.Mey. was shown to suppress the secretion of  $\beta$ -hexosaminidase, histamine, intracellular ROS, and internal Ca<sup>2+</sup>. It was also revealed that Black *Panax ginseng* C.A.Mey. inhibited mastocyte-mediated signaling activities, suppressed IL-4 serum levels, and ameliorated the symptoms and clinical signs of post-radiation allergic dermatitis (Kang et al., 2018). These studies suggest that *Panax ginseng* C.A.Mey. may be a useful herb against radiation associated damage.

*Panax quinquefolius* L. belongs to the Araliaceae family and has yin nourishment as well as heat clearing properties. From a clinical observation study, it was suggested that *Panax quinquefolius* L. ameliorated lymphocytic DNA damage after radiotherapy, suppressed micronucleus ratios in human lymphocytes, and enhanced total antioxidant capacities after exposure to radiation (Lee et al., 2010). In addition, this herb protects genes from acute damage in a short period. Studies have established that *Panax quinquefolius* L. tea protects cellular DNA from oxidative stress damage for at least 2 h (Szeto et al., 2015).

A fresh rhizome of *Zingiber officinale* Roscoe has been reported as being able to inhibit lipid peroxidation and excessive glutathione consumption (Jagetia et al., 2003), and improve mice survival after irradiation (Jagetia et al., 2004). Ji et al. demonstrated that the extract of *Zingiber officinale* Roscoe suppresses ionizing radiation-induced overproduction of ROS and DSBs in human mesenchymal stem cells. Its antioxidant mechanisms involve the induction of NRF2 nuclear translocation and activation of its downstream cell protection genes (HO-1 and NQO-1) (Ji et al., 2017). Radiotherapy confers adverse side effects such as vomiting and nausea. These side effects have been attributed to ionizing radiation associated damage of the gastrointestinal, viscera and the vagus nerve to release serotonin that activates the brains vomiting center through serotonin receptors. Furthermore, radiation affects neural activity in the brain and activates specific sensory receptors. *Zingiber officinale* Roscoe can ameliorate nausea and vomiting. *Zingiber officinale* Roscoe inhibits the activation of related receptors, promotes neurobehavioral functions, and alleviates radiation-induced taste aversion and vomiting (Sharma et al., 2005). Besides, *Zingiber officinale* Roscoe plays a role in the regulation of inflammatory signaling pathways. Zingerone suppresses the MAPK signaling pathway, inhibits cytochrome P4502E1 as well as nicotinamide adenine dinucleotide phosphate (NADPH) oxidase, and downregulates liver enzyme activities. Further, it has been shown to regulate the expression of inflammatory markers such as TLR4, iNOS, COX-2, and MPO (Mohamed and Badawy, 2019). Negative regulation of the TLR4 pathway by zingerone alleviates radiation-induced hepatic injury (Lee et al., 2018). Epidemiological studies have indicated that adults with congenital heart diseases are exposed to low-dose ionizing radiations during cardiac surgeries. These patients have an increased risk for cancer when compared to the general population (Cohen et al., 2018). Studies have shown that prophylactic administration of zingerone regulates serum lactate dehydrogenase, creatine kinase-MB activity and suppresses the expression of TNF- $\alpha$  as well as COX-2. It also inhibits DNA fragmentation, enhances mitochondrial complex activity, and interferes with the aggravation of ionizing radiation induced heart damage (Soliman et al., 2018). The antioxidant and anti-inflammatory effects of *Zingiber officinale* Roscoe in other tissue damage models have not been established.

Chest radiotherapy induces myocardial fibrosis (Curigliano et al., 2016) while whole-body radiation can lead to osteopontin (OPN) activation. OPN is a cytokine involved in myocardial fibrosis. The extract of *Angelica sinensis* (Oliv.) Diels inhibits radiation induced cardiac fibrosis by suppressing the expression of OPN, c-jun, and miRNA-21 as well as suppressing Troponin-I (Tn-I) levels (Ma et al., 2019). The main active components in *Paeonia lactiflora* Pall. have been shown to have radioprotective properties.

## Leafy Chinese Herbal Medicines

Different parts of *Ginkgo biloba* L. in the Ginkgo family can be used as alternative medicine. *Ginkgo biloba* L. leaves have been utilized in studies of radiation-associated injuries. Ionizing

radiation induces permanent nervous cerebral defects, chronic microangiopathy, and blood-brain barrier dysfunctions. Radiation associated brain damage results in cerebrovascular abnormalities, demyelination, white matter necrosis, and cognitive impairment (Lumniczky et al., 2017). Abnormally elevated levels of catecholamine, epinephrine, norepinephrine, dopamine, and inflammatory factors are the major causes of radiation-induced brain injuries. Ismail et al. confirmed that the extract of *Ginkgo biloba* L. regulated the above mentioned indicators by suppressing lipid peroxidation (Ismail and El-Sonbaty, 2016). In addition, that the extract of *Ginkgo biloba* L. was shown to suppress the expressions of P53, Bcl-2 and inhibited apoptosis after radiation (Raafat et al., 2013).

## Whole Chinese Herbal Medicines

Biologically active compounds in *Portulaca oleracea* L. include flavonoids, alkaloids, terpenoids, and sterols. These compounds have been shown to have antioxidant, antibacterial, and anti-inflammatory properties. *Portulaca oleracea* L. extracts alleviated lipid peroxidation in the liver and kidney of irradiated rats. It also suppressed MDA levels in tissues and inhibited total cholesterol (TC), triglyceride (TG), low-density lipoprotein cholesterol (LDL-c), and maintained atherosclerosis indices (Abd El-Azime et al., 2014). From the mechanism perspective, *Portulaca oleracea* L. may also play an anti-inflammatory role by inhibiting TNF- $\alpha$  secretion, thereby preventing NF- $\kappa$ B nuclear translocation. This herb also plays an important role in regulating peroxidation (Zhou et al., 2015). *Mentha canadensis* L. from the Labiatae family inhibits radiation induced damage by scavenging for free radicals, its antioxidant, anti-inflammatory, anti-mutation activities, and enhancing DNA repair (Baliga and Rao, 2010).

## Fructus of Chinese Herbal Medicines

The antioxidant properties of the Solanaceae *Lycium barbarum* L. are important in antagonizing mitochondrial apoptosis and inhibiting DNA damage. Duan et al. documented that *Lycium barbarum* L. increases the DNA content of red blood cells and hemoglobin, effectively inhibits P53, caspase-3, and caspase-6 while accelerating the recovery of splenic functions (Duan et al., 2015). *Crataegus pinnatifida* Bunge is rich in polyphenols and total flavonoids. An extract of *Crataegus pinnatifida* Bunge has been established to reduce lymphocytic micronucleus and lowers the effects of radiation (Hosseini-mehr et al., 2009). While an extract of *Hippophae rhamnoides* L. scavenges for free radicals, prevents cell cycle arrest in the G2-M phase (Goel et al., 2003), and protects mitochondria and chromatin from radiation-induced damage (Shukla et al., 2006). Moreover, *Hippophae rhamnoides* L. protects against radiation-induced sperm injuries (Goel et al., 2006).

In conclusion, the above reviews show that a single Chinese herbal medicine can ameliorate radiation-induced damage in a variety of ways. These herbs have considerable potential as radioprotectants.

## Chinese Herbal Prescriptions in the Prevention of Radiation Damage

Traditional Chinese Medicine's clinical efficacy exerted in the form of Chinese herbal prescriptions, is based on clinical symptoms and purposefully matched different Chinese medicines. Experimental and clinical studies have verified the therapeutic effect of Chinese Herbal Prescriptions (Zhang et al., 2016; Gao et al., 2017). Compared to a single herb or active compound, Chinese Herbal Prescription contains many active compounds with multiple therapeutic targets. These Prescriptions are suitable for the prevention and treatment of multiple ionizing radiation induced systemic damage. Synergism between the different herbs enhance therapeutic effects with reduced toxicity (Zhang et al., 2018b) (Table 3).

## Hematopoietic System

The hematopoietic system is highly sensitive to radiation. Hematopoietic cells exposed to ionizing radiation degenerate quickly, and undergo necrosis as well as apoptosis. In addition, ionizing radiation decreases the number of peripheral blood cells, especially neutrophils, lymphocytes, and platelets, leading to bleeding and anemia.

Siwu Tang is a classical Chinese herbal prescription that reinforces qi and nourishes the blood. It is comprised of four Chinese herbal medicines (*Rehmannia glutinosa* (Gaertn.) DC., *Angelica sinensis* (Oliv.) Diels, *Conioselinum anthriscoides* 'Chuanxiong', and *Paeonia lactiflora* Pall.) (Sun et al., 2016). The active compounds in this prescription include fructose, paeoniflorin, and ferulic acid, among others. This Prescription promotes hematopoietic and immune system recovery after irradiation by increasing the number of peripheral white blood cells and bone marrow colony-forming units (Liang et al., 2006). Studies revealed that Siwu Tang induces the antioxidant Nrf2 pathway, partially inhibits DNA damage, prevents the activation of nuclear transcription factor activating protein-1 (AP-1) and NF- $\kappa$ B, thereby, inhibiting ionizing radiation-induced damage and oncogenesis (Liu et al., 2017).

Buzhong Yiqi Tang is a well-known Chinese herbal prescription with nearly 800 years of application. It is widely used a therapeutic option for spleen-qi deficiencies and post-illness symptoms (Hu et al., 2019; Liu et al., 2019). This prescription is composed of *Astragalus mongholicus* Bunge, *Codonopsis pilosula* (Franch.) Nannf., *Atractylodes lancea* (Thunb.) DC., *Bupleurum chinense* DC., *Actaea cimicifuga* L., *Citrus reticulata* Blanco, *Angelica sinensis* (Oliv.) Diels, and *Glycyrrhiza glabra* L.. This prescription has been shown to significantly elevate peripheral white blood cell counts in mice after irradiation and relieves platelet damage (Xiao-fang et al., 2013). Further, it suppresses lipid peroxides generated by the accumulation of free radicals and improves the hematopoietic microenvironment (Xiaoling et al., 2006).

Xuebijing (XBJ) is an injection of Chinese herbal prescription. It was approved by the National Medical Products Administration for the clinical management of septicemia. It contains *Carthamus tinctorius* L., *Paeonia lactiflora* Pall., *Conioselinum anthriscoides* 'Chuanxiong', *Salvia miltiorrhiza*

*Bunge*, and *Angelica sinensis* (Oliv.) Diels. A previous study documented that XBJ improved the survival rate of irradiated mice by suppressing ROS production in bone marrow cells and alleviated radiation induced hematopoietic cell injury (Li et al., 2014a).

In the study of Yiqi Yangyin Fang (YYF: *Astragalus mongholicus* Bunge, *Panax ginseng* C.A.Mey., *Ligustrum lucidum* W.T.Aiton, *Eclipta prostrata* (L.) L., *Angelica sinensis* (Oliv.) Diels, *Atractylodes macrocephala* Koidz., *Poria cocos* (Schw.) Wolf, *Glycyrrhiza glabra* L.), Junling Zhang et al. indicated that this prescription increased the number of bone marrow cells, hematopoietic progenitor cells, and hematopoietic stem cells. It also improved bone marrow suppression after radiation by suppressing intracellular ROS levels (Zhang et al., 2017b).

## Immune System

Ionizing radiation damages the hematopoietic system, the thymus and the spleen. Radiation inhibits tissue and cell repair after injury and induces immunosuppression. Inhibition is proportional to the radiation dose. Hematopoietic and immune dysfunctions associated with ionizing radiation elevate tissue permeability, weaken body resistance, and predisposes the body to endogenous or exogenous infections.

HemoHIM is a prescription composed of three herbs with various biological and immunological activities. HemoHIM inhibits the continuous down-regulation of Th1 immune responses after radiation by regulating the IL-12 p70/pSTAT4 signaling pathway (Park et al., 2012). This prescription has also been shown to protect hematopoietic stem cells and speeds up the recovery of immune cells (Park et al., 2014).

Bushen Jiedu Recipe is an optimized combination of Liuwei Dihuang Pills. This prescription maintains kidney tone, nourishes yin, tonifies Qi and blood, clears heat and removes toxin. Yunjing et al. documented that Bushen Jiedu Recipe interfered with the expression of NF- $\kappa$ Bp65 by regulating the TLR4 signaling pathway, suppressed white blood cell damage and protected the thymus and spleen (Yunjing et al., 2015; Lidan et al., 2016).

The Wumai Danghuang Oral Liquid is composed of *Schisandra chinensis* (Turcz.) Baill., *Ophiopogon japonicus* (Thunb.) Ker Gawl., *Codonopsis pilosula* (Franch.) Nannf., and *Astragalus mongholicus* Bunge. This prescription exhibits its anti-radiation effects by elevating SOD, degrading MDA and inhibiting the generation of free radicals (Chunhong et al., 2014). In addition, Wumai Danghuang Oral Liquid exhibits protective and repair effect on radiation induced immune injuries (Hang et al., 2013).

*Houttuynia cordata* Thunb. and its bioactive molecules have anti-inflammatory and antioxidant properties (Shingnaisui et al., 2018). Co-Herba Houttuyniae Oral Liquid contains *Houttuynia cordata* Thunb., *Panax ginseng* C.A.Mey., *Lycium barbarum* L.. This liquid suppresses the rate of radiation induced chromosomal aberrations (Lin et al., 2001). It also enhances the anti-stress ability of mice by improving immune functions. Moreover, *Panax ginseng* C.A.Mey. and *Lycium barbarum* L. improve immune functions and inhibit radiation effects by promoting the repair of damaged cells and tissues (Lin et al., 2002).

The radioprotective prescription (*Astragalus mongholicus* Bunge, *Ganoderma lucidum* Karst, *Lycium barbarum* L., and *Poria cocos* (Schw.) Wolf) has been shown to improve the survival rate, white blood cell count, thymus index, spleen index, and the DNA content of bone marrow cells thereby reducing radiation induced immune damage in mice models (Liming et al., 2011).

## Digestive System

Ionizing radiation severely damages the digestive system and causes pathological changes such as intestinal mucosal damage and liver fibrosis. These damages lead to digestive and absorptive dysfunctions, resulting in a series of clinical symptoms like diarrhea, nausea, and vomiting.

STW 5 is a herbal prescription with anti-inflammatory and antioxidant properties. This prescription inhibits oxidative stress responses, suppresses the levels of inflammation factors, and intestinal damage indices by regulating apoptosis-related factors to prevent intestinal mucosal damage after radiation (Khayyal et al., 2014). Prophylactic administration of STW 5 reduces the severity of radiation mucositis (El-Ghazaly et al., 2015).

*Astragalus* immortal prescription is composed of *Rehmannia glutinosa* (Gaertn.) DC., *Ophiopogon japonicus* (Thunb.) Ker Gawl. and *Equus asinus* L.. It is derived from Dunhuang medical papers (now stored in France, code: P.4038), and *Astragalus mongholicus* Bunge. This prescription has been shown to elevate the activities of GSH-Px and SOD while suppressing MDA levels in the liver. Furthermore, it protects the liver from radiation induced oxidative damage (Cai-qin et al., 2017).

## Reproductive System

The male reproductive system is very sensitive to ionizing radiation as it can damage the seminiferous epithelium and spermatogenic cells at all levels. These radiations can confer injuries to the reproductive system, and cause male infertility (Bates et al., 2016; Kesari et al., 2018). Radiation also causes DNA damage in spermatogenic cells, increases embryonic mortality, and offspring cancer susceptibility. It may induce hereditary changes.

Wuzi Yanzong Pill (WZYZ) is a Chinese herbal prescription that is used as a therapeutic option for male infertility. Clinically, it has significant therapeutic effects on oligospermia and asthenozoospermia. WZYZ improves sperm quality by suppressing DNA damage (Zhao et al., 2018). A double-blind randomized controlled trial confirmed that WZYZ is an excellent therapeutic option for men with low fertility who cannot be cured by conventional western medicines (Zhao et al., 2019). Pelvic exposure to radiation reduces testicular weight, sperm quality and leads to testicular oxidative stress and abnormal testicular structure. WZYZ protects against suppressed serum testosterone levels, reduces MDA levels and oxidative stress indices (OSI) in the testis. Its mechanism may be associated with up-regulation of PCNA (Ji et al., 2016).

The Yiqi Jiedu Decoction (YQJD) enhances testicular index, structural recovery of the testis, decreases the apoptotic rate of spermatogenic cells, and maintains spermatogenic functions after

irradiation. These results suggest that YQJD plays a protective role by intervening in TLR5 downstream signaling pathways (Wang et al., 2020).

## ANTI-RADIATION MECHANISMS OF CHINESE HERBAL MEDICINES

### Mitochondrial Apoptosis Pathway

Oxidative stress leads to the pathogenesis of various human diseases and the aging process. Mitochondria is the energy center in cell metabolism, it regulates redox homeostasis, and plays a central role in diseases pathogenesis (Li et al., 2019a). Oxidative stress damages the mitochondria, accelerates excessive ROS production, activates the mitochondrial apoptotic pathway and induces apoptosis (Kim and Kim, 2018). Ionizing radiation mediated overproduction of ROS is associated with mitochondrial dysfunctions. ROS acts as a signaling molecule that initiates a series of cascade reactions (Wu et al., 2019). Changes in the mitochondrial membrane potential elevates the expressions of pro-apoptotic proteins and suppresses the expression of anti-apoptotic proteins (Sun et al., 2018). These events trigger the activation of caspase-3, and initiates the mitochondrial-dependent pathway (Li et al., 2018a). As previously stated, Chinese Herbal Medicines inhibit mitochondrial apoptosis by: i. inhibiting oxidative stress responses and suppressing the generation of ROS, and ii. Interfering with the expression of pathway associated factors, regulating the pro-apoptotic protein and anti-apoptotic protein ratios, as well as by suppressing Cytochrome C and caspase-3.

### MAPK Signaling Pathway and PI3K/AKT Signaling Pathway

Mitogen-activated protein kinases (MAPK) family, including three significant members of extracellular signal-regulated kinases (ERK), p38 kinase, and c-Jun N-terminal kinase (JNK), participate in various physiological processes such as morphogenesis, cell growth, proliferation, apoptosis, and differentiation (Fang and Richardson, 2005; Lu et al., 2019). Ionizing radiation activates the classic MAPK signaling pathway, JNK, and P38 MAPK pathways. In addition, radiation-induced secreted cytokines enhance MAPK pathway responses in cells (Dent et al., 2003). Enhancement of the MAPK signal upregulates telomerase activity, initiates changes in chromatin distribution, and regulates the cell cycle (Shain et al., 2018). Activated p38 and JNK signaling pathways are involved in immune regulation (Wang et al., 2019a). After p38 activation, a mitochondrial apoptotic pathway is initiated (Choi et al., 2006; Niaudet et al., 2017). The PI3K/AKT signaling pathway is essential in the regulation of cell growth, migration, proliferation, and metabolism in mammals (Pompura and Dominguez-Villar, 2018). Activated PI3K/Akt pathway accelerates DSB repair. Ionizing radiation inhibits its activation (Toulany and Rodemann, 2015). This pathway is also involved in cell

cycle and apoptosis regulation after exposure to ionizing radiation (Chen et al., 2018). Because of the wide reach of the MAPK and PI3K/AKT signaling pathways, Chinese Herbal Medicines regulate them through multiple targets.

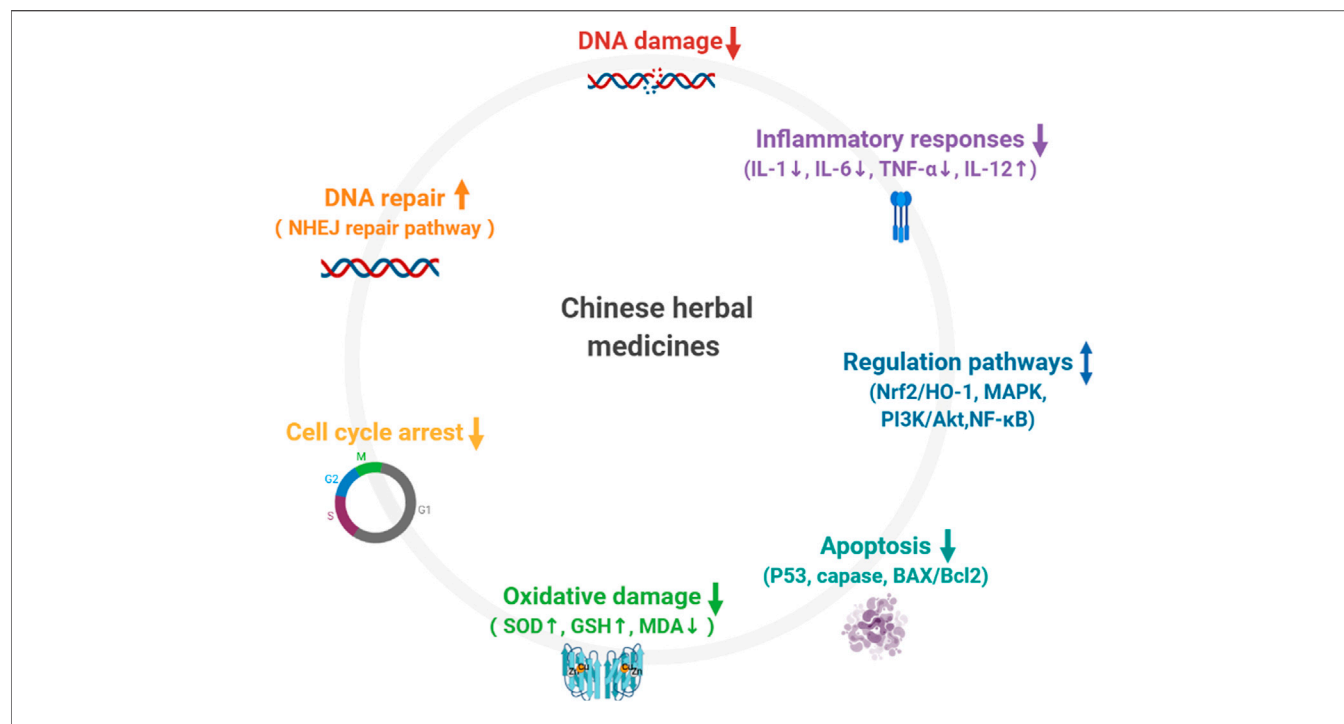

### Nrf2/HO1 Signaling Pathway

The Nrf2/HO-1 signaling pathway antagonizes tissue and organ oxidative stress injuries by regulating antioxidant, anti-inflammatory, apoptosis, pyroptosis, ferroptosis, and autophagy processes. Nrf2 is a transcription factor and the core regulator of cellular redox. It stimulates gene expression through antioxidant response elements in gene promoters and protects cells against ROS induced DNA damage (Zimta et al., 2019). When exposure to ionizing radiation occurs, Nrf2 acts as a critical transcription factor that regulates antioxidant enzymes and protects tissues from oxidative stress damage. HO-1 regulates the expression of apoptotic and inflammatory factors. In addition, it also promotes angiogenesis by preventing oxidative damage (Loboda et al., 2016). Chinese Herbal Medicines trigger Nrf2 and enhances mRNA and protein expressions of HO-1. These events trigger the antioxidant pathway and inhibits ionizing radiation induced oxidative damage.

### Inflammatory Signaling Pathway

Ionizing radiation-induced DNA damage results in phosphorylation and activation of multiple transcription factors (such as NF- $\kappa$ B, p53, and MAPK) by stimulated ATM kinases. ROS is also involved in these processes (Purbey et al., 2017). After exposure to ionizing radiation, the secretion of various inflammatory cytokines (IL-1, IL-6, TNF- $\alpha$ , IFN- $\gamma$ , COX-2) is elevated. Inflammatory cytokines recruit immune cells that regulate cell microenvironment with a crucial impact on local or systemic tissues (Harding et al., 2017). Chinese Herbal Medicines exhibit a two-way regulation effect on inflammatory factors. The first one is by inhibiting the secretion of inflammatory factors, preventing fibrosis and inflammatory lesions after irradiation. The second strategy is that it plays an immunomodulatory role by regulating signaling pathways such as TLRs and NF- $\kappa$ B to reduce apoptosis (Scholch et al., 2015; Liu et al., 2018).

Traditional Chinese Medicine exhibits its curative effects on multiple body systems (such as hematopoiesis, immunity, reproduction, respiration, and circulation) by inhibiting oxidative stress, reducing DNA damage, and regulating abnormally activated signaling pathways. The Mechanism is as shown in **Figure 2**. It is worth noting that Chinese Herbal Medicines are particularly useful in anti-lipid peroxidation. Recently, a new regulatory cell death method (ferroptosis) has attracted considerable attention. Excessive ROS results in membrane lipid peroxidation. The accumulation of iron-dependent lipid peroxides leads to ferroptosis. Radiation induced damage to the hematological system and the lungs can be relieved by intervening in ferroptosis-related pathways (Li et al., 2019c; Zhang et al., 2020). This is an avenue for Traditional Chinese Medicine research in future.

**FIGURE 2 |** Mechanism of Chinese herbal medicines in preventing radiation injury. 1) Chinese herbal medicines reduce DNA damage; 2) Chinese herbal medicine promote DNA repair; 3) Chinese herbal medicines regulate cell cycle arrest; 4) Chinese herbal medicines prevent excessive accumulation of ROS and inhibits oxidative damage; 5) Chinese herbal medicine suppress extrinsic and intrinsic apoptotic pathways via reduction of P53, caspase, BAX/Bcl2 activation; 6) Chinese herbal medicines are involved in the regulation of inflammatory response; 7) Chinese herbal medicines participate in the regulation of multiple abnormally activated signaling pathways.

## CONCLUSION

Ionizing radiation injuries are systemic damages that affect multiple organs and tissues. The Traditional Chinese Medicine characteristic theory lies in its holistic view: man and nature as a harmonious and unified whole, emphasizing the interactions between man and the environment, achieving a balance between the two. Simultaneously, various systems of the human body as a whole are connected physiologically and pathologically influence each other. Based on this holistic view, Chinese medicines and Chinese Herbal Prescriptions are suitable for use as therapeutic options for multi-system damages caused by ionizing radiation.

Compared to a single herb, the composition of Chinese Herbal Prescription is more complex and exhibits its therapeutic effects by having multiple targets (Yang et al., 2017; Wang et al., 2019b). The synergy between the Chinese medicines in the Chinese Herbal Prescriptions improves its efficacy while inhibiting toxic and side effects. A rationally designed Chinese Herbal Prescription will exhibit a better protective effect.

Chinese medicine has favorable economic benefits and is an economical option for the development of safe and effective radioprotectors. With positive effects, many Chinese Herbal Prescriptions have been used in clinical settings to reduce

radiation induced damage. Studies on the anti-radiation activities and mechanisms of single Chinese medicines and their active compounds are limited. However, due to their sophisticated active compounds, it is difficult to elucidate on their potential radio-protective mechanisms. More studies are needed to evaluate the efficacy of these medicines. Systemic biology and network pharmacology applications may provide alternative methods and strategies for the applications of Chinese Herbal Prescriptions (Boezio et al., 2017; Tavassoly et al., 2018), and may, therefore, help in the development of innovative drugs for radiation protection.

## AUTHOR CONTRIBUTIONS

XZ conceived the topic and wrote the manuscript. SH revised and modified the manuscript. XC, LW, CH, and ZS helped to revise the manuscript and draw the figures. QF, WX and SZ consulted the references.

## FUNDING

This work was supported by the National Natural Science Foundation of China (No. 11675027, 12075035).

Pharmacol.* 11:590457. doi: 10.3389/fphar.2020.590457

**Objectives:** To evaluate the pharmacodynamical effects and pharmacological mechanism of Ginsenoside H dripping pills (GH) in chronic unpredictable mild stress (CUMS) model rats.

**Methods:** First, the CUMS-induced rat model was established to assess the anti-depressant effects of GH (28, 56, and 112 mg/kg) by the changes of the behavioral indexes (sucrose preference, crossing score, rearing score) and biochemical indexes (serotonin, dopamine, norepinephrine) in Hippocampus. Then, the components of GH were identified by ultra-performance liquid chromatography-iron trap-time of flight-mass spectrometry (UPLC/IT-TOF MS). After network pharmacology analysis, the active ingredients of GH were further screened out based on OB and DL, and the PPI network of putative targets of active ingredients of GH and depression candidate targets was established based on STRING database. The PPI network was analyzed topologically to obtain key targets, so as to predict the potential pharmacological mechanism of GH acting on depression. Finally, some major target proteins involved in the predictive signaling pathway were validated experimentally.

**Results:** The establishment of CUMS depression model was successful and GH has antidepressant effects, and the middle dose of GH (56 mg/kg) showed the best inhibitory effects on rats with depressant-like behavior induced by CUMS. Twenty-eight chemical components of GH were identified by UPLC/IT-TOF MS. Subsequently, 20(S)-ginsenoside Rh2 was selected as active ingredient and the PPI network of the 43 putative targets of 20(S)-ginsenoside Rh2 containing in GH and the 230 depression candidate targets, was established based on STRING database, and 47 major targets were extracted. Further network pharmacological analysis indicated that the cAMP signaling pathway may be potential pharmacological mechanism regulated by GH acting on depression. Among the

cAMP signaling pathway, the major target proteins, namely, cAMP, PKA, CREB, *p*-CREB, BDNF, were used to verify in the CUMS model rats. The results showed that GH could activate the cAMP-PKA-CREB-BDNF signaling pathway to exert antidepressant effects.

**Conclusions:** An integrative pharmacology-based pattern was used to uncover that GH could increase the contents of DA, NE and 5-HT, activate cAMP-PKA-CREB-BDNF signaling pathway exert antidepressant effects.

**Keywords:** ginsenoside H dripping pills, depression, network pharmacology, chronic unpredictable mild stress, cAMP signaling pathway

## INTRODUCTION

Depression is a mental disorder illness with a high disability, morbidity and recurrence rate (Chen et al., 2008). The main clinical features are decreased food-intake, low mood, anhedonia, activity decrease, irritability and other symptoms (Yang et al., 2018). In severe cases, they may have suicidal tendency (Zhu et al., 2020). An epidemiological multicenter study showed the odds of being depressed among cancer patients were more than five times higher than in the general population (Götze et al., 2020). Remarkably, comorbid depression in patients with cancer was compellingly established as a risk factor for suicide as well as rapid cancer progression (Shoval et al., 2019). There is no specific drug for the treatment of depression in cancer patients, and antidepressants are generally used. At present, the commonly used chemical antidepressants are mainly divided into four classes according to the chemical formula and the mechanism, including selective serotonin-re-uptake inhibitors (SSRI) such as sertraline and fluoxetine, serotonin and norepinephrine reuptake inhibitors (SNRI) like duloxetine and milnacipran, tricyclic antidepressants (TCA) such as amitriptyline and imipramine, monoamine oxidase inhibitors (MAOI) like moclobemide and phenelzine (Zhao et al., 2015; Ostuzzi et al., 2018). There are several Chinese herbal formulae for the treatment of depression including Chaihu Shugan powder, Xiaoyao Pill and Shugan Jieyu capsule (Du et al., 2014; Fu et al., 2014; Wang et al., 2014). Clinically, although chemical antidepressants are widely used, their side effects are common, such as hepatotoxicity, drowsiness, sexual dysfunction, nausea, irritability and psychomotor impairment (Dai et al., 2010; Gorzalka and Hill, 2011; Zhu et al., 2020). Compared with chemical drugs, traditional Chinese medicine (TCM) are attracting more and more attention due to its advantages such as low toxicity and side effects, high safety, and high efficacy and toxicity reduction (Xie et al., 2018). Therefore, the research on the treatment of depression with TCM has certain clinical value.

Ginsenoside H dripping pills (GH), originated from Tasly Group, is the class 5 new traditional Chinese medicine which obtained from leaves of *Panax quinquefolium* Linn by extracting, chemical degrading and chromatography separating (Chen et al., 2018). It is designed to be used for replenishing qi and blood, and is used as an adjuvant drug for treating cancer. The main ingredient of the drug is ginsenoside Rh2 and the content of ginsenoside Rh2 is about 30% (Ma et al., 2018). Early studies have indicated that ginsenoside Rh2 could significantly inhibit the

growth of U14 cervical cancer bearing mouse (Zhang et al., 2013). Besides, ginsenoside Rh2 can significantly improve the depressive behavior of depressing mice (Wang et al., 2016). It can be said that GH not only has significant anti-tumor effects, but also has antidepressant effects, which provides exclusive drugs for the treatment of depression in cancer patients and has research value. However, it is still unclear that antidepressant effects and mechanism of GH. Therefore, the study adopted the integrated pattern of “pharmacodynamics - network pharmacological analysis - mechanism verification” to deeply study the antidepressant effects and potential mechanism of GH.

Chronic unpredictable mild stress (CUMS) model in rats was the closest animal model to clinical depression (Su et al., 2017). During the modeling process, rats which were subjected to different kinds of chronic unpredictable mild stress, fully simulated the social living environment of depressive patients and induced rats to produce many behavioral abnormal symptoms similar to those of depressive patients (Antoniuk et al., 2019; Li et al., 2019). For example, the reducing the sucrose preference in rats simulated the symptoms of anhedonia in depressive patients; the reducing the score of Open field exercise simulated the symptoms of low ability of autonomic movement in depressive patients (Tan et al., 2015; Liu et al., 2018). Therefore, the decrease of behavioral indexes (sucrose preference and open field exercise score) showed that CUMS depression model in rats were successfully established. In addition, the pathogenesis of depression is complex. Although several hypotheses about depression have been proposed, the monoamine hypothesis is still the most common hypothesis for depression, because most of the current antidepressants act on monoamine transporters or receptors (Auclair et al., 2013; Liu et al., 2020). The hypothesis believes that the occurrence of depression is mainly due to the lack of major monoamine neurotransmitters such as 5-hydroxytryptamine (5-HT), dopamine (DA) and norepinephrine (NE) in the central nervous system of the brain (Jesulola et al., 2018). Hence, the contents of 5-HT, DA and NE in hippocampus were decreased, which indicated that CUMS depression model in rats was successfully established. In conclusion, the antidepressant effects of GH were evaluated from the behavioral and biochemical indexes of depression model rats.

Network pharmacology was first proposed by Hopkins in 2007, which is based on disease-gene-target-drug interaction network to predict the material basis and mechanism of drug intervention in diseases (Li and Zhang, 2013). With the

establishment of TCM database systems such as Encyclopedia of Traditional Chinese Medicine and Traditional Chinese Medicine Systems Pharmacology Database (Ru et al., 2014; Xu et al., 2019), network pharmacology has been widely used in TCM (Xu et al., 2014; Yu et al., 2017; Zhang et al., 2017; Li et al., 2018). Interestingly, the holistic philosophy of TCM is consistent with the key idea of emerging network pharmacology (Li et al., 2014). Our group had previously predicted the underlying pharmacological mechanism of Xuesuan-Xinmai-Ning (XXNT) acting on coronary heart disease (CHD) through network pharmacology method, and found that the XXNT in the treatment of CHD might be involved into the signal transduction in nervous-endocrine-immune-cardiovascular-metabolic system, and it is verified by experiments that XXNT plays a role in treating CHD via VEGF signal pathway (Mao et al., 2019). In addition, through network pharmacology analysis, it is found that Zhile alleviated depression-like behaviors by upregulating the cAMP-CREB-BDNF signaling pathway (Wu et al., 2019). Therefore, the pharmacological mechanism of the anti-depressant effects of GH could be evaluated by network pharmacology analysis.

In this study, the integrated pharmacology-based pattern, which adopted pharmacodynamics-network pharmacology-mechanism verification, was used to elucidate the pharmacological mechanism of GH in treatment of depression. The antidepressant effects of GH were first confirmed by using chronic unpredictable mild stress model rats. The chemical components containing in GH were then identified by UPLC/IT-TOF MS, and the active ingredients of GH were further screened out based on OB and DL. Network pharmacology analysis was conducted to predict the potential pharmacological mechanism of GH in treatment of depression. At last, the results predicted by network pharmacology were further validated by western blotting and enzyme-linked immunosorbent assay. A flowchart of this study is illustrated in **Figure 1**.

## MATERIALS AND METHODS

### Reagents and Materials

Bulk substance of Ginsenoside H dripping pills (GH) and GH (specification: 30 mg/pill, the total saponin content: 3.12 mg) were obtained from Tianjin Tasly Pharmaceutical Co., Ltd. (Batch NO. 20120606-16, 20160309, respectively, Tianjin, China). Fluoxetine hydrochloride (Flu) was provided by Suzhou Eli Lilly and Company (Suzhou, China). Chromatographic grade methanol and acetonitrile were obtained from Fisher Scientific Co. (Loughborough, United Kingdom). Pseudoginsenoside RT5, 20(S)-ginsenoside Rh1, 20(R)-ginsenoside Rh1, 20(S)-ginsenoside F1, ginsenoside Rh4, ginsenoside CK, 20(S)-ginsenoside Rh2, 20(R)-ginsenoside Rh2, isoginsenoside Rh3 standards were obtained from China National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). ginsenosides Rk2 standard was purchased from Chengdu Mansite Pharmaceutical Co., Ltd. (Chengdu, China). All standards were of at least 98% purity

and were suitable for UPLC/IT-TOF analysis. The enzyme-linked immunosorbent assay (ELISA) kits, including serotonin (5-HT), dopamine (DA), norepinephrine (NE) and cyclic Adenosine monophosphate (cAMP) were supplied by Shanghai Lianshuo Biological Technology Co., Ltd. (Shanghai, China). The radioactive cyclic-AMP dependent protein kinase A (PKA) assay kit was purchased from Promega Corporation (Madison, Wisconsin, United States). The primary antibodies against brain derived neurotrophic factor (BDNF), cAMP-response element binding protein (CREB), phosphorylated cAMP-response element binding protein (*p*-CREB) and the secondary antibodies goat anti-rabbit IgG-HRP were purchased from Affinity Biosciences (Cincinnati, OH, United States). Bicinchoninic acid assay (BCA) kits was produced by Beyotime Institute of Biotechnology Co., Ltd. (Nanjing, China).

### Animals

A total of 80 Specific-pathogen free (SPF) male Sprague Dawley rats (180–220 g) were obtained from the China National Institutes for Food and Drug Control (SCXK (jing) 2017-0005). The rats were kept in an environmentally controlled room (temperature  $22 \pm 2^{\circ}\text{C}$ , humidity  $50 \pm 10\%$ , 12 h/12 h light/dark cycle) and were allowed to eat and drink freely. The laboratory animals were used according to requirements of the Ethics Committee of Tianjin University of Traditional Chinese Medicine (Tianjin, China), and the experimental methods were in line with the principles for protection of laboratory animals.

### Animal Grouping

After 7 days habituation, the rats were randomly divided into six groups ( $n = 10$ ) according to the similar sucrose preference, crossing score and rearing score: the control group, CUMS group, low dose group of GH (28 mg/kg), middle dose group of GH (56 mg/kg), high dose group of GH (112 mg/kg), and Flu group (10 mg/kg).

### Establishment of Chronic Unpredictable Mild Stress (CUMS) Model and Drug Treatment

The CUMS procedure was carried out as described in the existing literatures (Zhong et al., 2018; Lu et al., 2019). The animals, except the control group, were separately placed and repeatedly exposed to a set of CUMS as follows: restraint stress (4 h), noise environment (110 dB, 1 h), electric shock to the foot (3 mA, one shock/5 s), tail clamp (tail nipped at 1 cm from the tip of the tail for 3 min), damp bedding (24 h), reversed light/dark cycle (24 h), high temperature stress ( $40^{\circ}\text{C}$ , 20 min), ice-cold swimming ( $4^{\circ}\text{C}$ , 5 min),  $45^{\circ}$  tilted cage (12 h), cage shaking (15 min), fasting food (24 h), water deprivation (24 h). Two stressors were applied every day and the whole stress procedure lasted for 5 weeks in a completely random order. During the modeling period, rats in the GH group and the Flu group were administrated with corresponding drugs; rats in the control group and the CUMS group were administrated with

saline. Rats in all group were injected via gastric gavage at 10 ml/kg once daily.

## Behavioral Tests

### Sucrose Preference Test

Sucrose preference test (SPT) was conducted at the day 0 and day 35 in accordance with previously described methods (Zhu et al., 2017). Briefly, 72 h before the test, the rats were bred individually two bottles 1% sucrose solution for 24 h, which were aimed to adapt to sucrose solution. Then, rats were exposed to one bottle of 1% sucrose solution and one bottle of water for 24 h. Finally, water and food were deprived for another 24 h. Sucrose preference test was conducted, in which rats were placed in separate cages and were freely access to two bottles containing

sucrose solution (1%, w/v) and water, respectively. After 24 h, the weight of solution in every bottle was measured, and the rate of sucrose preference was calculated by the following formula:

$$\text{Sucrose preference} = \frac{\text{sucrose consumption}}{\text{water consumption} + \text{sucrose consumption}} \times 100\%$$

### Open Field Test

The open field test (OFT) was carried out at day 0 and day 35 according to previously described methods (Dai et al., 2010). The activity of rats in each group were measured in a 100 cm × 100 cm × 50 cm box without ceiling, the inner wall and floor of which were

coated with black paint. A video camera was used to record the rat behavior. The rats were released from the center of the arena, and were observed for 3 min. The following behavioral parameters were taken into the account: the crossing score (grid lines it crossed with at least three paws) and the rearing score (defined as standing upright with hind legs). To avoid the possible disturbance, the 75% alcohol was used to clean the floor box before each test.

## Hippocampus Sampling

The rats were sacrificed, 24 h after the behavioral tests. The whole brain was quickly dissected from the rats in ice-cold saline. The hippocampi were isolated on ice bath and immediately stored in liquid nitrogen for enzyme-linked immunosorbent assay and western blot analysis. All samples were stored at  $-80^{\circ}\text{C}$  until assays.

## Preparation of Samples and Standard Solution

Bulk substance of GH was weighed 100 mg precisely. The powder was soaked in 20 ml methanol, extracted by ultrasonic at room temperature for 30 min, and precipitated to 25 ml volume. A stock solution containing ten standards (pseudoginsenoside RT5, 20(S)-ginsenoside Rh1, 20(R)-ginsenoside Rh1, 20(S)-ginsenoside F1, ginsenoside Rh4, ginsenoside CK, 20(S)-ginsenoside Rh2, 20(R)-ginsenoside Rh2, isoginsenoside Rh3 and ginsenoside Rk2) was prepared in methanol. All samples were filtered through 0.22  $\mu\text{m}$  nylon membrane filters and the filtrate was analyzed directly by UPLC/IT-TOF.

## UPLC/IT-TOF Conditions

The UPLC analysis was performed on a Shimadzu LC-20A (Shimadzu, Kyoto, Japan) with a Waters Acquity UPLC HSS T3 column ( $2.1 \times 100 \text{ mm}$ ,  $1.8 \mu\text{m}$ ). The column temperature was set at  $35^{\circ}\text{C}$ . The flow rate was set at 0.44 ml/min. The target sample temperature is set at  $10^{\circ}\text{C}$  and 5  $\mu\text{L}$  of each sample was injected onto the column. The solvent system composed of mobile phase A (water) and mobile phase B (acetonitrile) in the following gradient: 0–9 min, 28–47%B; 9–17 min, 47–55%B; 17–22 min, 55–90%B; 22–24 min, 90–28%B; 24–25 min, 28–28% B. The experiment was performed on both ESI (+) ionization mode. The desolvation temperature was set at  $200^{\circ}\text{C}$  with desolvation gas flow set at 1.5 L/min. The capillary voltage was set at 4.5 kV for ESI (+). The full scan data acquisition range was 100–1,300 Da. The LabSolutions-LCMS software (Shimadzu, Kyoto, Japan) were employed for data analysis and the chemical components of GH was identified.

## Targets Fishing

The chemical components containing in GH identified by UPLC/IT-TOF were filtered by integrating oral bioavailability (OB), drug similarity (DL) from Traditional Chinese Medicine Systems Pharmacology Database (TCMSP).<sup>1</sup> The chemical components that meet both of the requirements  $\text{OB} \geq 30\%$ ,  $\text{DL} \geq 0.18$ , were retained as candidate active ingredients (Tao et al., 2013). The

targets of candidate active ingredients were obtained from Swiss Target Prediction<sup>2</sup> (Daina and Zoete, 2019). Species were selected as “Homo sapiens” and the targets with probability greater than 0 were predicted as the putative targets.

Known therapeutic targets acting on depression were collected from the DrugBank<sup>3</sup> (Knox et al., 2011). Therapeutic Target Database (TTD)<sup>4</sup> (Li et al., 2018) and Online Mendelian Inheritance in Man (OMIM) database<sup>5</sup> (Hamosh et al., 2005) with the keyword “depression”. All targets enrolled in this research were human genes/proteins.

## Network Construction and Topological Analysis

Protein-protein interaction (PPI) data were obtained from STRING database<sup>6</sup> (Szklarczyk et al., 2017) with setting species as “Homo sapiens” and the results were imported into the Cytoscape software (version 3.7.1, Boston, MA, United States) where the interaction network was constructed and analyzed. The topological features were calculated using Network Analyzer and the nodes with degree greater than twice the median degree of all nodes will be defined as major targets (Guo et al., 2020).

## Pathway Enrichment Analysis

To explore potential mechanism of predicted major targets, the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis (Kanehisa et al., 2017) was performed using the Database Visualization and Integrated Discovery (DAVID)<sup>7</sup> (Huang et al., 2007). KEGG pathways with enrichment  $p$  value less than 0.05 were employed for further study.

## Enzyme-Linked Immunoassay

Tissues from the rat hippocampus were homogenized by adding phosphate buffered saline (PBS) at pH 7.4 (Solarbio Science & Technology Co., Ltd., Beijing, China). Homogenate was centrifuged at  $4^{\circ}\text{C}$  for 10 min at 12,000 rpm to obtain the supernatant. The supernatant was separated and stored at  $-20^{\circ}\text{C}$  until analysis. The concentration of 5-HT, DA, NE and cAMP were measured using commercially available ELISA kits in accordance with the manufacturer's instructions. The absorbance at 450 nm was measured with a GloMax microplate reader (Promega, Madison, WI, United States), and the measured OD values were used to quantify the expression of the 5-HT, DA, NE and cAMP. All samples were determined three times repeatedly in the same assay to minimize inter-assay differences.

## Assay of PKA Activity

PKA activity was assayed using a radioactive PKA assay kit in accordance with the manufacturer's instructions.

## Western Blot

Hippocampus tissue (approximately 50 mg) was solubilized by radio immunoprecipitation assay lysis buffer (Beijing, China) for 30 min on ice. The buffer contained 1% phenylmethylsulphonyl fluoride (Beyotime, China) and/or 1% phosphatase inhibitor. The pyrolysis products were clarified by centrifuging at 4°C for 15 min at 12,000 rpm. The supernatant was collected and the protein concentration was measured with the bicinchoninic acid protein assay kit. Proteins were separated by 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and then were transferred to polyvinylidene difluoride (PVDF) membranes, which were blocked in 5% nonfat milk or 5% BSA for 2 h and then washed three times with Tris Buffer Saline supplemented with 0.1% Tween-20 (TBST) buffer for 10 min each time. The membranes were incubated overnight at 4°C with primary antibodies BDNF (1:1,000 dilution), CREB (1:1,000 dilution), *p*-CREB (1:1,000 dilution), and rat polyclonal antibody GAPDH (1:1,000 dilution). Subsequently, the membranes were washed three times with TBST and were incubated for 2 h at room temperature with suitable goat anti-rabbit immunoglobulin G-horseradish peroxidase (IgG-HRP) secondary antibody (1:5,000 dilution). After rewashing with TBST, the immunoreactivity was observed using ECL reagent. The membranes were scanned by using an imaging system (Bio-Rad, Hercules, CA, United States) and the band strength was analyzed by using ImageJ software (National Institutes of Health, Bethesda, MD, United States).

## Statistical Analysis

Data were expressed using the mean  $\pm$  the standard deviation (SD). SPSS version 21.0 software (IBM, Chicago, IL, United States) was used for statistical analysis. One-way analysis of variance (ANOVA) was used, and *p* value <0.05 was considered to be statistically significant.

## RESULTS

### Establishment of CUMS Model and Antidepressant Effects of GH

In the study, CUMS rat model was established according to materials and methods. At the same time, the rats were intragastric administration. The antidepressant effects of GH were evaluated by the behavioral and biochemical indexes.

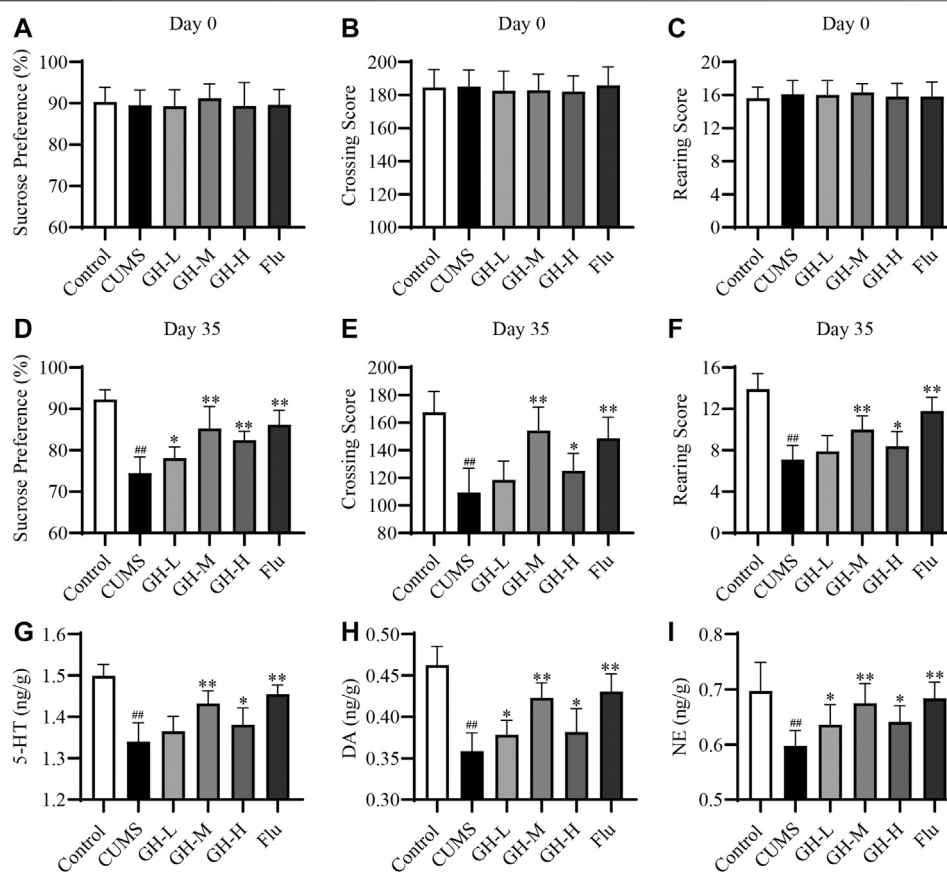

The results of behavioral indexes of rats in each group were shown in **Figures 2A–F**, the sucrose preference, the crossing score and the rearing score of rats in all groups were basically same at day 0 ( $p > 0.05$ ,  $p > 0.05$ ,  $p > 0.05$ , respectively). However, the sucrose preference, the crossing score and the rearing score of the CUMS group had a significant decrease compared with the control group at day 35 ( $p < 0.01$ ,  $p < 0.01$ ,  $p < 0.01$ , respectively). The changes of the sucrose preference, the crossing score and the rearing score of rats are typical characteristics of depression, which indicated that the establishment of depression model was successful. The sucrose preference of rats in low dose group of GH, middle dose group of GH, high dose group of GH, and Flu

group were obviously higher than the CUMS group ( $p < 0.05$ ,  $p < 0.01$ ,  $p < 0.01$ , respectively), showing the significant remission of depression symptoms. In the open field test, the crossing score and the rearing score of CUMS rat treated with middle dose of GH, high dose of GH, and Flu were markedly increased compared with the CUMS group ( $p < 0.01$ ,  $p < 0.05$ ,  $p < 0.01$ , respectively). However, there was no significant difference in crossing score and rearing score between low dose group of GH and the CUMS group ( $p > 0.05$ ). Taken these results together, GH has antidepressant effects, and the middle dose of GH showed powerfully inhibitory effects on rats with depressant-like behavior induced by CUMS.

The results of biochemical indexes of rats in each group were demonstrated in **Figures 2G–I**. CUMS exposure significantly reduced the concentration of 5-HT, DA and NE ( $p < 0.01$ ,  $p < 0.01$ , respectively) compared with the control group, which indicated that the establishment of depression model was successful. The treatments with middle dose of GH, high dose of GH, and Flu significantly increased the concentration of 5-HT ( $p < 0.01$ ,  $p < 0.05$ ,  $p < 0.01$ , respectively), DA ( $p < 0.01$ ,  $p < 0.05$ ,  $p < 0.01$ , respectively) and NE ( $p < 0.01$ ,  $p < 0.05$ ,  $p < 0.01$ , respectively) compared with the CUMS group. Meanwhile, the treatments with low dose of GH significantly increased the DA ( $p < 0.05$ ) and NE ( $p < 0.05$ ) concentration compared to the CUMS group. However, low dose of GH had no significant effects on the 5-HT concentration in the CUMS-exposed rats ( $p > 0.05$ ). Overall, the results indicated that middle dose of GH had better antidepressant effects. In the following mechanism verification experiment, the study mainly focused on the treatment group of GH at the middle dose (56 mg/kg).

### Identification of Chemical Components in GH by UPLC/IT-TOF MS

The UPLC/IT-TOF conditions was systemically optimized to receive good chromatographic separation and appropriate ionization. The total ion chromatogram (TIC) of the GH sample and mixed standard sample in the positive ion modes are, respectively, presented in **Figures 3A,B**. The 10 chemical components (component 3, 5, 6, 9, 15, 21, 23, 24, 27, 28) were identified as pseudoginsenoside RT5, 20(S)-ginsenoside Rh1, 20(R)-ginsenoside Rh1, 20(S)-ginsenoside F1, ginsenoside Rh4, ginsenoside CK, 20(S)-ginsenoside, 20(R)-ginsenoside Rh2, ginsenoside Rk2, isoginsenoside Rh3 by comparing the retention time, accurate and high-resolution mass and tandem mass spectra with chemical standards respectively. For the components without chemical standards, the molecular formula was established based on high precision quasi molecular ion such as  $[M+H]^+$ ,  $[2M+H]^+$  or  $[M+Na]^+$  within a mass error of 5.0 ppm. Moreover, the MS<sup>2</sup> information was used for confirming the structures of components by comparing the fragmentation regularity with ten standards or the related literatures (Patel et al., 2012; Zhu et al., 2018). Overall, a total of 28 chemical components were identified in GH and the related information of retention times and MS data was summarized in **Table 1**. The structures of 16 compounds related to 28 chemical components are displayed in **Figure 4**.

**FIGURE 2 |** Effect of GH on CUMS rats in SPT, OET and neurotransmitters levels in hippocampus. **(A)** Sucrose preference of rats in each group at day 0. **(B)** Crossing score of rats in each group at day 0. **(C)** Rearing score of rats in each group at day 0. **(D)** Sucrose preference of rats in each group at day 35. **(E)** Crossing score of rats in each group at day 35. **(F)** Rearing score of rats in each group at day 35. **(G)** The concentration of 5-HT in each group. **(H)** The concentration of DA in each group. **(I)** The concentration of NE in each group. All data were expressed as mean  $\pm$  standard error of mean ( $n = 10$ ). <sup>##</sup> $p < 0.01$  versus control group; <sup>\*</sup> $p < 0.05$ , <sup>\*\*</sup> $p < 0.01$  versus CUMS group. GH-L (low dose group of GH), GH-M (middle dose group of GH), GH-H (high dose group of GH).

## PPI Network Construction

Among the 16 compounds, only 20(S)-ginsenoside Rh2 satisfied the screening rules, OB  $\geq 30\%$  and DL  $\geq 0.18$ . So, 20(S)-ginsenoside Rh2 was selected as active ingredient. Detailed information about OB and DL of 16 compounds was shown in **Supplementary Table S1**. The structure of 20(S)-ginsenoside Rh2 was used for predicting the putative targets in Swiss Target Prediction database. Totally, 43 putative targets of 20(S)-ginsenoside Rh2 containing in GH were predicted. Detailed target information about putative targets was shown in **Supplementary Table S2**. A total of 5 and 43 known therapeutic targets for depression were collected from DrugBank and Therapeutic Target Database (TTD) database, respectively, and 184 known targets of depression were obtained from OMIM database. In total, 230 depression candidate targets were enrolled after removing redundant entries. The detailed information is supplemented in **Supplementary Table S3**. The PPI network of the 43 putative targets of 20(S)-ginsenoside Rh2 containing in GH and the 230 depression candidate targets, was established based on STRING database, consisting of 184 nodes

and 1,392 edges. Detailed information about this network was reflected in **Supplementary Table S4**.

## Network and Pathway Analysis

Network analyzer was employed to calculate the topological feature degree of the nodes in the PPI network. Nodes with degrees higher than two-fold median value of all nodes in the network (degree  $>23$ ) were identified as the major targets. Consequently, 47 major targets were extracted. Among them, 29 targets were putative targets of 20(S)-ginsenoside Rh2 containing in GH, 32 targets were depression candidate targets, 15 targets were common targets, which were between putative targets of GH and depression candidate targets. The details were shown in **Supplementary Table S5**.

In order to analyze the representative pathways related to the major targets, KEGG pathway analysis was performed to explore the potential pathways effected by GH and totally 45 significant pathways ( $p$  value  $<0.05$ ) were obtained. The top 10 signal pathways were selected by  $p$  value for further study and were as shown in **Figure 5A**. The top 10 significant pathways could be

**FIGURE 3 |** Total ion chromatogram (TIC) of GH sample (A) and mixed standard sample (B) in positive ion mode using UPLC/IT-TOF MS.

divided into three functional modules, which were related to dopamine, hypothalamic-pituitary-adrenal (HPA) axis and neural plasticity respectively. Detailed information about results of pathways analysis was provided in **Supplementary Table S6**. Afterward a network consisted of the interactions between the active ingredient of GH, major targets, and top 10 significant pathways was constructed to illustrate the potential mechanism (**Figure 5B**). This network illustrated that GH may indirectly influence or directly interact with major targets which are involved in pathways related to HPA axis (such as pathways in cancer, proteoglycans in cancer), dopamine (such as neuroactive ligand-receptor interaction, cocaine addiction, dopaminergic synapse) and neural plasticity (such as cAMP signaling pathway, glutamatergic synapse, gap junction, PI3K-Akt signaling pathway and estrogen signaling pathway) to achieve the antidepressant effects.

## Experimental Validation of Major Targets and Pathway

To explore the effects of GH on the cAMP pathway, we examined the concentration of cAMP via ELISA, PKA activity using a radioactive PKA assay kit, and protein expression levels of BDNF, CREB, *p*-CREB in the hippocampus of each group rats by Western blot (**Figure 6**). Compared with the control group, a significant decrease in cAMP concentration and PKA activity was observed in the hippocampus of the CUMS group ( $p < 0.01$ ,  $p < 0.01$ , respectively), but daily administration of GH (56 mg/kg) or fluoxetine (10 mg/kg) obviously increased cAMP concentration and PKA activity in the hippocampus ( $p < 0.01$ ,  $p < 0.01$ , respectively) compared with the CUMS rats. Meanwhile, BDNF expression levels and the *p*-CREB/CREB ratio in the

hippocampus of the CUMS group were decreased ( $p < 0.01$ ,  $p < 0.01$ , respectively). Following treatment with GH (56 mg/kg) or fluoxetine (10 mg/kg), BDNF expression levels and the *p*-CREB/CREB ratio in the GH and Flu groups were significantly higher than the CUMS group ( $p < 0.01$ ,  $p < 0.01$ , respectively), suggesting that GH may regulate the cAMP-PKA-CREB-BDNF signal pathway to play an antidepressant role.

## DISCUSSION

Depression is a mental disease characterized by constant low mood, loss of interest, anhedonia, unresponsiveness and sleeplessness (Wang et al., 2017). The causes of depression are complex, among which the increasing competitive pressure, unreasonable living habits and weak adaptability to the social environment are more crucial inducing factors (Wang et al., 2020). The CUMS is a mature animal model of depression that can simulate the chronic stress encountered by depressed patients in clinical observation (Yang et al., 2018). Currently, the widely used assays for depressive-like behaviors include the Sucrose preference test (SPT) and the Open field test (OFT). The SPT could mimic anhedonia-like behavior, a core symptom of depression in human (Sideromenos et al., 2020), and the OFT was used to determine general activity and exploratory behavior, signs of depression (Adelöf et al., 2018). Thus, the study established CUMS rat model and conducted a series of behavioral tests, including SPT and OFT, to study the effects of GH on antidepressant-like behaviors. The results of behavioral indexes of rats in each group indicated that GH has antidepressant effects, and the middle dose of GH showed powerfully inhibitory effects on rats with depressant-like behavior induced by CUMS.

**FIGURE 4 |** Structures of compounds in GH.

Based on the characteristics of multi-channel and multi-target effects of Chinese herbal compound, the monoamine neurotransmitters such as DA, NE and 5-HT were regarded as the biochemical indexes to further study the antidepressant

effects of GH (Gu et al., 2018). The monoamine hypothesis believes that the deficiency of major monoamine neurotransmitters (5-HT, DA, and NE) will lead to decrease of neurotransmission in the brain and the impairment of cognitive

performance which may lead to depression (Kofler et al., 2019). Therefore, this study established a CUMS rat model for five weeks to observe the effects of GH intervention on the depressive-like behaviors and the changes of the monoamine neurotransmitters levels in the hypothalamus. The results of biochemical indexes of rats in each group indicated that GH has antidepressant effects, and middle dose of GH had stronger antidepressant effect. In the following mechanism verification experiment, the study mainly

focused on the treatment group of GH at the middle dose (56 mg/kg).

Chromatographic techniques coupled with mass spectrometry has been an available method for rapid identification of components in Chinese medicine (Guo et al., 2018). UPLC/IT-TOF MS analysis was performed to identify the chemical components in GH. In this study, the 28 chemical components of GH were identified. Among the chemical

**FIGURE 6 |** Experimental validation of target proteins involved in cAMP signaling pathway in the hippocampus of CUMS-induced rats. **(A)** Effect of GH treatment on cAMP concentrations ( $n = 10$ ). **(B)** Effect of GH treatment on PKA activity ( $n = 10$ ). **(C)** Effect of GH treatment on BDNF expression. **(D)** Effect of GH treatment on p-CREB/CREB ratio. All data were expressed as mean  $\pm$  standard error of mean. <sup>##</sup> $p < 0.01$  versus control group; <sup>\*</sup> $p < 0.05$ , <sup>\*\*</sup> $p < 0.01$  versus CUMS group.

components, only 20(S)-ginsenoside Rh2 was selected as active ingredient which satisfied the screening rules, OB  $\geq 30\%$  and DL  $\geq 0.18$ . It is consistent with previous studies that ginsenoside Rh2, a main component in GH (Zhou et al., 2014), was a detectable compound in human plasma (Yue et al., 2019), and it can be filtered out by cell membrane chromatography (Ma et al., 2018).

To investigate the pharmacological mechanism of antidepressant effects of GH, 20(S)-ginsenoside Rh2, the active ingredient of GH, was used for network pharmacological analysis, and the top 10 significant signaling pathways were enriched by KEGG according to the  $p$  value. Based on literature search, the top 10 significant signaling pathways could involve in the occurrence of depression in varying degrees. For example, pathways in cancer and proteoglycans in cancer indirectly change the probability of depression by influencing HPA axis function (Young and Singh, 2018); Neuroactive ligand-receptor interaction, cocaine addiction and dopaminergic synapse could affect the occurrence of depression through regulating dopamine levels, emotion, learning and memory

functions (Haile et al., 2007; Yang et al., 2017; Sun et al., 2018); cAMP signaling pathway, PI3K-Akt signaling pathway, estrogen signaling pathway, glutamatergic synapse and gap junction could intervene the occurrence of depression by mediating neural plasticity (Hennebelle et al., 2014; Crider and Pillai, 2017; Peng et al., 2018; Ren et al., 2018; Wu et al., 2018).

At present, the antidepressant mechanism of GH is unknown. Among the top 10 signaling pathways predicted by network pharmacological, the signaling pathway ranking at the top had strong correlation with the antidepressant effects of GH, which is the main signaling pathway of the antidepressant mechanism of GH. Therefore, the signaling pathway ranking at the top has more research value (Xiong et al., 2020). The first signaling pathway is neuroactive ligand-receptor interaction, which was related to all receptors and ligands associated with intracellular and extracellular signaling pathways in the plasma membrane (Pan et al., 2011). However, the neuroactive ligand-receptor interaction signaling pathway was related to the occurrence of various diseases, the mechanism of action on depression is not

**FIGURE 7 |** The cAMP-PKA-CREB-BDNF signaling pathway.

specific, and there are only two targets of receptor and ligand. Consequently, the first signaling pathway was not selected to further research. The second signaling pathway is cAMP signaling pathway, which was the most widely studied signaling pathway in the mechanism of antidepressant effects. In the cAMP signaling pathway, BDNF, the terminal downstream protein neurotrophic factor, could resist the damage of neurons, promote the repair and regeneration of neurons, and increased the secretion of monoamine neurotransmitters. Hence, Stress events compromise neuroplasticity via reduction of BDNF and lead to the occurrence of depression (Schmitt et al., 2016). According to the literature, neuroimaging and post-mortem studies have revealed impaired cAMP signaling in depressive patients, indicating cAMP signaling pathway was significantly associated with depression (Plattner et al., 2015). Thus, cAMP signaling pathway is selected to study the antidepressant mechanism of GH.

It is extremely clear that the mechanism of the cAMP signal pathway on depression. Under normal physiological conditions, monoamine neurotransmitters (such as 5-HT, DA, NE) interacts with specific G protein-coupled receptors (including 5-HT receptors, DA receptors, NE receptors) on the cell membrane to activate G protein (Cabrera-Vera et al., 2003; Fredriksson et al., 2003). The G-protein binds to Guanosine triphosphate (GTP) and subsequently GTP-G protein binds to the C2 domain and activates the adenylate cyclase (AC) enzyme. Activated AC catalyzes the biosynthesis of cAMP from adenosine triphosphate (ATP) (Frezza et al., 2018). The cAMP binds to the regulatory subunits of PKA (a tetramer consists of two regulatory subunits and two catalytic subunits), which resulted in the dissociation of catalytic subunit of PKA and enter to the cell

nucleus (Wang et al., 2018). In the nucleus, the catalytic subunit of PKA binds to the Ser-133 site of CREB and phosphorylates CREB (Tu et al., 2019). Phosphorylated CREB (p-CREB) combines with the cAMP responsive elements (CRE) in the promoter region of BDNF, which can regulate BDNF transcription (Björkholm and Monteggia, 2016). Under the pathological conditions, continuous mental stress and stimulation would lead to the decrease in the content of monoamine neurotransmitters in the patient's body and weaken the transduction of cAMP signaling pathway, which cause the decrease of BDNF expression (Zhang et al., 2012). Lower expression of BDNF is difficult to resist the injury of neurons under stress, which could lead to depression (van den Buuse et al., 2020).

In cAMP signaling pathway, 11 target proteins, such as BDNF, GRIA1, CREB1, ADORA1 and so on, were enriched. The high-degree target proteins in the network may account for the essential therapeutic effects of GH on depression (Guo et al., 2019). The degree value of BDNF is the largest, indicating that BDNF is the most important in cAMP signaling pathway. BDNF is related to the survival, growth, and differentiation of neurons, and plays an important role in the signal transduction of depression (Wang et al., 2017). As the upstream protein of BDNF, p-CREB could regulate the expression of BDNF. At the same time, CREB has been confirmed to be related to the pathogenesis of depression and is one of the transcription factors with the most research on antidepressant effects (Wang et al., 2018). Therefore, Western blot was used to determine the expression level of BDNF and the ratio of p-CREB/CREB to study the antidepressant mechanism of GH. The results showed that GH significantly increased the expression level of BDNF and the

ratio of *p*-CREB/CREB in the hippocampus of CUMS model rats. In order to further study the antidepressant mechanism of GH, the radioactive PKA assay kit was used to assay the activity of PKA which is the upstream protein of CREB. ELISA was used to detect the contents of cAMP which is the activator of PKA. As shown in our results, GH significantly upregulated the activity of PKA and the content of cAMP in hippocampus of CUMS model rats. Therefore, GH may play an antidepressant effects by regulating cAMP-PKA-CREB-BDNF signaling transduction. The cAMP-PKA-CREB-BDNF signaling pathway was presented in **Figure 7**.

Fluoxetine, a serotonin reuptake inhibitor (SSRI), is mainly used in the treatment of depression in clinic, which can improve the content of 5-HT. The 5-HT combined with its receptors, which resulted in that the cAMP signal pathway is activated and the levels of cAMP, PKA and the ratio of *p*-CREB/CREB were increased (Mato et al., 2010; Zhang et al., 2018). Then the expression level of BDNF is increased, which resisted the injury of neurons under stress, and exert antidepressant effects (Xie et al., 2019). During this process, BDNF increased the content of monoamine neurotransmitters by improving the activity of dopaminergic neurons and noradrenergic neurons, which is more conducive to play an antidepressant effects (Siuciak et al., 1996; Zhang et al., 2007). Therefore, fluoxetine was selected as a positive drug to explore whether GH exerts antidepressant effects by activating the cAMP signal pathway. The results indicated that GH could activate cAMP signaling pathway to play an antidepressant role, but whether it has the same antidepressant mechanism as fluoxetine through increasing 5-HT content and activating cAMP signaling pathway remains to be further studied.

## CONCLUSION

In the present study, an integrative pharmacology-based pattern, which adopted pharmacodynamics-network pharmacology-mechanism verification, was used to uncover the pharmacological mechanism of GH against depression. Firstly, it was found that GH at the middle dose (56 mg/kg) obviously alleviated depression-like behaviors induced by CUMS and showed powerful antidepressant effects. Then, we identified 28 main chemical components of GH by UPLC/IT-TOF MS. Furthermore, network pharmacology analysis predicted that cAMP signaling pathway may be the potential pharmacological mechanism regulated by GH acting on depression. Finally, the cAMP signaling pathway was verified as the mechanism of GH against depression through experimental validation of the target proteins (cAMP, PKA, *p*-CREB, and BDNF). Taken together, the current study suggested that GH could exert antidepressant effects by

activating the cAMP-PKA-CREB-BDNF signaling pathway in hippocampus, which provided an effective method to uncover the pharmacological mechanism of traditional Chinese medicine.

Guizhi-Fuling capsule (GZFLC), originated from a classical traditional Chinese herbal formula Guizhi-Fuling Wan, has been clinically used for primary dysmenorrhea in China. Nonetheless, the underlying pharmacological mechanisms of GZFLC remain unclear. The integration of computational and experimental methods of network pharmacology might be a promising way to decipher the mechanisms. In this study, the target profiles of 51 representative compounds of GZFLC were first predicted by a high-accuracy algorithm, drugCIPHER-CS, and the network target of GZFLC was identified. Then, potential functional modules of GZFLC on primary dysmenorrhea were investigated using functional enrichment analysis. Potential bioactive compounds were recognized by hierarchical clustering analysis of GZFLC compounds and first-line anti-dysmenorrhea drugs. Furthermore, the potential anti-dysmenorrhea mechanisms of GZFLC were verified through enzyme activity assays and immunofluorescence tests. Moreover, effects of GZFLC on primary dysmenorrhea were evaluated in oxytocin-induced dysmenorrhea murine model. In the network target analysis, GZFLC may act on five functional modules of pain, inflammation, endocrine, blood circulation and energy metabolism. Integrating computational and experimental approaches, we found that GZFLC significantly inhibited the writhing response and reduced the degree of uterine lesions in oxytocin-induced dysmenorrhea murine model. Furthermore, GZFLC may partially alleviate primary dysmenorrhea by inhibiting cyclooxygenase 2 (COX2) and downregulating MAPK signaling pathway. Consequently, GZFLC presented pain relief and sustained benefits for primary dysmenorrhea. This study could provide a scientific approach for deciphering pharmacological mechanisms of herbal formulae through network pharmacology.

**Keywords:** primary dysmenorrhea, network target, network pharmacology, pharmacological mechanisms, Guizhi-Fuling capsule

## INTRODUCTION

Primary dysmenorrhea (PD) is defined as abnormally painful menstruation in the absence of any evident underlying pelvic pathology (Kho and Shields, 2020). Characterized by recurrent, painful, spasmodic cramping in the lower abdomen during menstruation, primary dysmenorrhea is the most common menstrual symptom among adolescent girls and young women, with the prevalence rate ranging from 41.7% to 90% (ACOG, 2018; Hu et al., 2020). As one of the most common gynecologic disorders, primary dysmenorrhea has significant effects on patients' normal school or work, as well as quality of life (Burnett et al., 2005; Wong 2018). The pathogenesis of primary dysmenorrhea is most widely accepted and considered to be the overproduction of uterine prostaglandins (PGs) (Iacovides et al., 2015). Owing to the PGs-based etiology of primary dysmenorrhea, the current first-line pharmacological agents for primary dysmenorrhea include non-steroidal anti-inflammatory drugs (NSAIDs) and hormonal contraceptives (Kho and Shields 2020).

Despite the sufficient evidence supporting the efficacy of NSAIDs in pain relief for patients with primary dysmenorrhea, there are approximately 15% of patients not responding to, or being intolerant to NSAIDs due to many side effects (Campbell and McGrath 1999; Marjoribanks et al., 2010). Oral hormonal contraceptives are also effective for primary dysmenorrhea, however, a meta-analysis has demonstrated the long-suspected association between oral contraceptive use and the risk of venous thromboembolism (Manzoli et al., 2012). Given these disadvantages of NSAIDs and hormonal contraceptives, effective and safe alternative treatments, such as Traditional Chinese Medicine (TCM), are receiving increasing attention worldwide. TCM characterized as holistic thinking emphasizes on regulating the integrity of the human body (Li et al., 2007) and intervenes multiple aspects related to etiological factors and pathogenesis simultaneously, which has accumulated numerous valuable clinical experiences and herbal formulae through long history of development.

Guizhi-Fuling capsule (GZFLC), a Chinese patent medicine approved by China Food and Drug Administration (CFDA), is clinically used for blood stasis syndromes in gynecological diseases including primary dysmenorrhea. It originated from a classical traditional Chinese herbal formula Guizhi-Fuling Wan which was first described in a classics named the Essential Prescriptions from the Golden Cabinet (Jin Kui Yao Lue) documented in 150–219 A.D. Guizhi-Fuling capsule is the modern dosage form of Guizhi-Fuling Wan, and the dosage and ratio of each Chinese herbal medicine in Guizhi-Fuling capsule is the same as Guizhi-Fuling Wan, consisting of five herbs: *Cinnamomum cassia* (L.) J. Presl (Guizhi), *Poria cocos* (Fuling), *Paeonia lactiflora* Pall (Baishao), *Paeonia × suffruticosa* Andrews (Mudanpi) and *Prunus persica* (L.) Batsch (Taoren). Pharmacokinetic-pharmacodynamic modeling study has demonstrated that GZFLC exhibited significant therapeutic effect on primary dysmenorrhea in rat model (Cheng et al., 2018). Moreover, a randomized controlled trial showed that GZFLC significantly relieved pain and reduced the duration of

pain compared with placebo during the 3-months treatment period, as well as in the 3-months follow up period, demonstrating a sustained benefit for patients with primary dysmenorrhea (Liu et al., 2013). However, the underlying comprehensive pharmacological mechanisms of GZFLC on primary dysmenorrhea remain unclear.

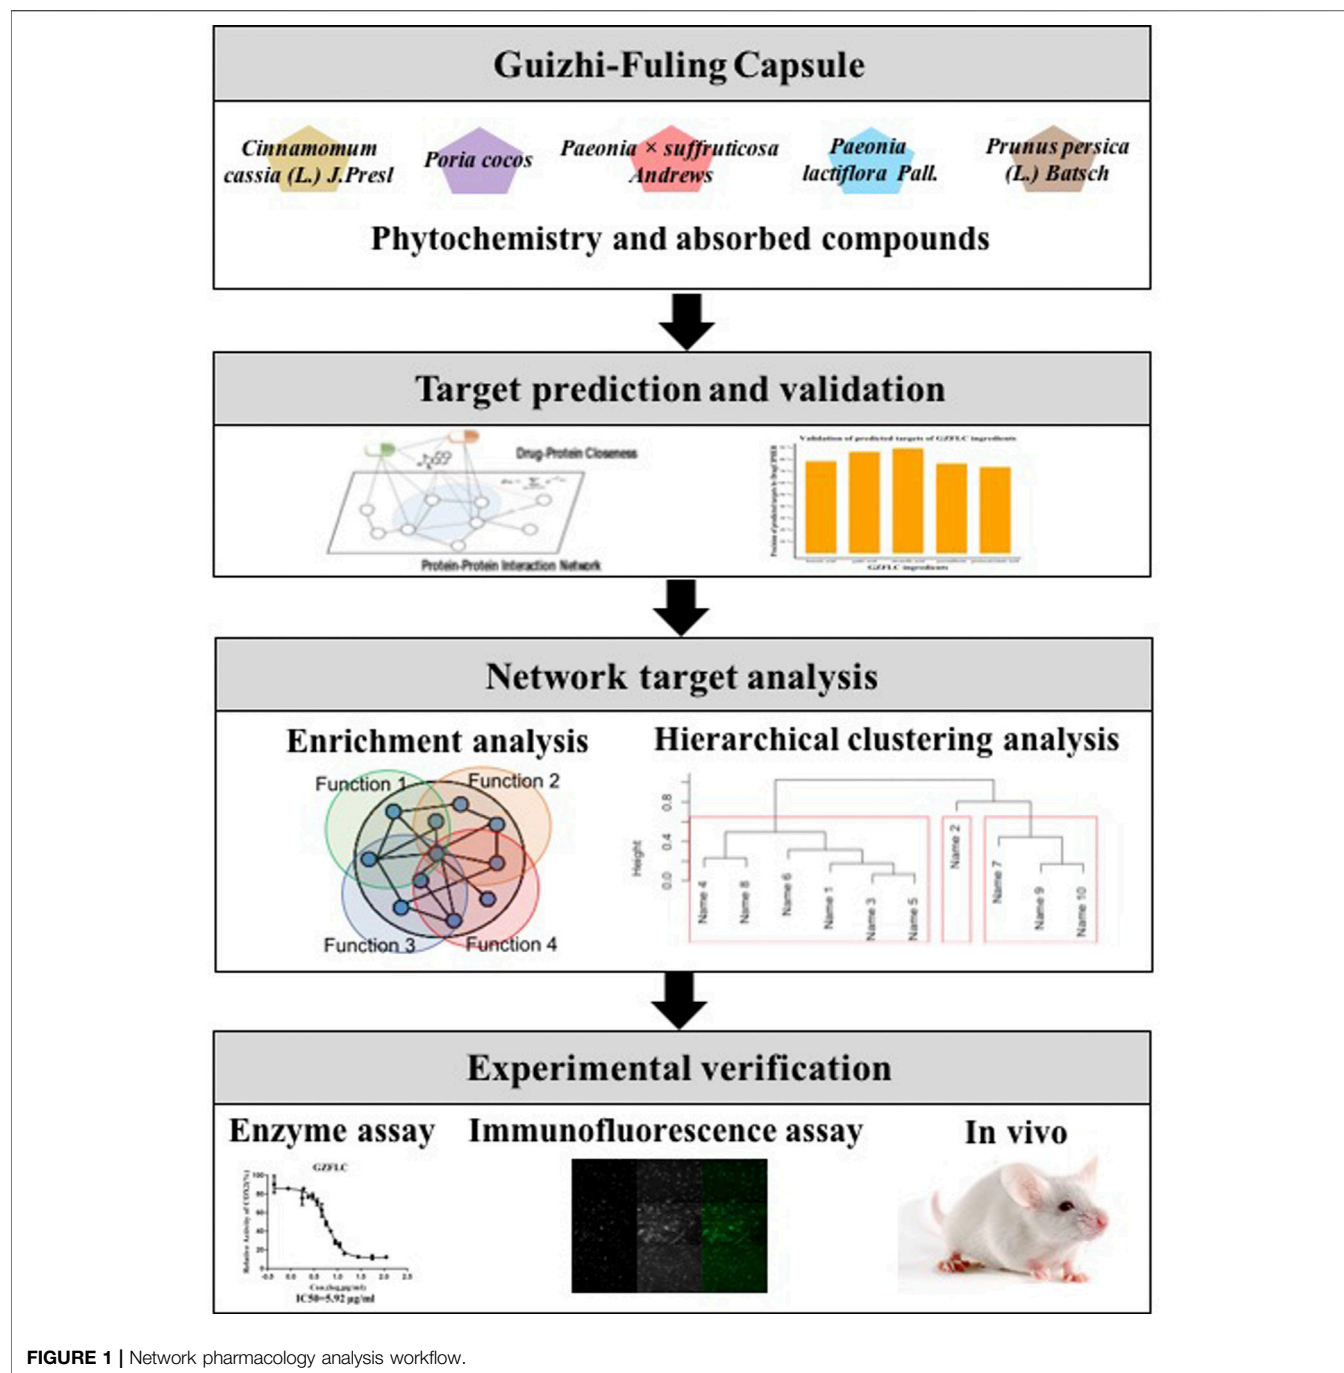

There are several substantial challenges in terms of deciphering pharmacological mechanisms of herbal formulae. Firstly, herbal formulae are complex chemical systems usually composed of numerous chemical compounds. Secondly, a great majority of bioactive compounds in herbs may have weak or moderate effects on multiple biological molecules, different from most western drugs designed to act on a single target selectively (Ji et al., 2009). Thus, routine pharmacologic analysis methods are difficult to systematically elucidate the mechanisms of herbal formulae. Network pharmacology, a newly developed cross-discipline, is preferable in investigation and elucidation of comprehensive mechanisms of TCM (Li et al., 2007; Hopkins 2008). The key ideas of Network pharmacology share much with the holistic philosophy of TCM (Li and Zhang 2013). TCM network pharmacology highlights a “network target, multicomponent therapeutics” approach (Li et al., 2011; Li 2015) to help elucidate the complex molecular mechanisms of traditional herbal formulae. The core theory of network pharmacology is “network target” distinct from “one target, one drug” paradigm (Li 2011; Li et al., 2011). More specifically, the core principle of network target is constructing a disease-specific biological network as the therapeutic target that herbal formulae are applied to (Li 2015). TCM network pharmacology has been successfully applied in many researches such as molecular mechanism elucidation of herbal formulae (Liang et al., 2014; Zuo et al., 2018), new bioactive compounds discovery (Qi et al., 2016), comprehensive pharmacological function of natural products identification (Zhang et al., 2018) and mechanism of action of toxic components in traditional Chinese medicines (Li et al., 2019).

In this study, we proposed an approach to investigate the underlying pharmacological mechanisms of GZFLC on primary dysmenorrhea based on network pharmacology as shown in **Figure 1**. First, we collected important phytochemistry and absorbed compounds of GZFLC. Second, we predicted the potential targets of GZFLC compounds utilizing a high-accuracy target prediction algorithm, and then validated the potential targets in literatures to ensure the reliability of predictions. Third, we made the network target analysis of GZFLC to investigate the pharmacological mechanisms and bioactive compounds of GZFLC on primary dysmenorrhea, including functional enrichment analysis and hierarchical clustering analysis. These network target analysis results were verified *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Representative Compounds in GZFLC Collection

The dosages and ratios of GZFLC compounds could influence their intervention intensity on targets. Considering the influence of GZFLC compounds' dosages and ratios, we selected major

**FIGURE 1 |** Network pharmacology analysis workflow.

phytochemistry compounds and absorbed compounds of GZFLC as representative compounds to analyze GZFLC's pharmacological mechanisms through network pharmacology. We have investigated phytochemistry compounds of GZFLC and absorbed compounds of GZFLC in plasma previously (Zhong et al., 2016a; Yin et al., 2016; Zhang et al., 2017; Yang et al., 2020). In total, 51 compounds were selected from our previous investigations of phytochemistry and absorbed compounds of GZFLC based on the following criteria: 1) the characteristic compounds were accounted for the major proportion and

verified with reference substances; 2) the compounds were quantitatively recorded in each herb from Chinese Pharmacopoeia (2015) (Committee 2015); 3) each compound had specified chemical structure and Pubchem CID.

### Preparation and Analysis of GZFLC

GZFLC was provided by the company Jiangsu Kanion Pharmaceutical Co., Ltd., composed of *Cinnamomum cassia* (L.) J. Presl (20%), *Poria cocos* (20%), *Paeonia × suffruticosa* Andrews (20%), *Paeonia lactiflora* Pall. (20%), *Prunus persica* (L.).

*Batsch* (20%). The full taxonomic names of all herbs included have been fully validated using the Kew Medicinal Plant Names Service. Guizhi-Fuling capsules have established fingerprints (Wang et al., 2009; Li et al., 2012) from herb to preparation to make sure that the quality of the preparation is uniform and stable (Li et al., 2015). Guizhi-Fuling capsule is a Chinese patent medicine approved and supervised by CFDA under the same strict quality control standards. Meanwhile, Guizhi-Fuling capsules in our study have come from the same preparation. The chemical constituents analysis of GZFLC has been reported in the literature (Yang et al., 2020). The UPLC analysis of GZFLC (Jiangsu Kanion Pharmaceutical Co., Ltd. Jiangsu, China, No. 20160319) was performed on Agilent SB-RRHD C18 (100 mm × 2.1 mm, 1.8 μm) column at 30°C with a mobile phase consisting of acetonitrile and 0.02% trifluoroacetic acid for gradient elution and the flow rate of 0.2 ml/min. The detection wavelength was set at 230 nm. The representative UPLC fingerprints of GZFLC were shown in **Supplementary Figure S1** in the Supplementary Materials.

## Target Predication and Validation for Compounds in GZFLC

To explore the relativity of representative GZFLC compounds and targets, the potential target profiles of compounds in GZFLC were predicted by drugCIPHER-CS (Zhao and Li, 2010), a high-accuracy algorithm developed for global prediction of compound targets. In principle, drugCIPHER-CS used a linear regression model which related chemical similarity vector between compounds in GZFLC and drugs in DrugBank (Wishart et al., 2008) to the drug-protein closeness vector based on a protein-protein interaction network to calculate the concordance score of each compound-protein pair. The concordance score was treated as the likelihood of the compound targeting the protein. Thus, the candidate proteins with high concordance scores were prioritized to be potential targets of the compound. Top 100 ranking predicted proteins of each compound were kept as potential target profiles.

To validate the target prediction of compounds, literature mining method was used to obtain the co-occurrence results of biomolecules and each compound. The biomolecules related to each compound from literature mining were manually examined to delete the false positive results and then considered as the reported targets. Comparing the reported targets with the predicted targets via direct mapping and indirect link, the reliability of target prediction was measured by  $\frac{|\text{The predicted targets related to the reported targets}|}{|\text{The predicted targets}|} \times 100\%$ .

## Holistic Target Prediction for GZFLC and Each Herb

To identify potential targets regulated by GZFLC or herbs, predicted proteins ranking top or appearing in the target profiles of many compounds in GZFLC or herbs were hypothesized to be important in the pharmacological effects of GZFLC or herbs. Based on this hypothesis, the potential targets of GZFLC or herbs were considered as significantly frequently occurring targets ( $p < 0.05$ ) by comparing the number of occurrences of a target protein in the target profiles of all compounds in GZFLC or herbs to that in random background

(Liang et al., 2014). A Poisson binomial statistical model was used to obtain the random background distribution and represented as:

$$P(K = k) = \sum_{A \in F_k} \prod_{j \in A} p_j \prod_{j \in A^c} (1 - p_j).$$

$P(K = k)$  is the probability of a certain target in  $k$  compounds' target profiles,  $F_k$  is the set including all sets containing  $k$  compounds,  $A$  is an element of  $F_k$ , and  $A^c$  is the complement of  $A$ .  $p_i$  and  $p_j$  are the probabilities of a certain target in  $i$  and  $j$  compound's target profiles respectively.

## Functional Enrichment Analysis and Biological Network Construction

To investigate the potential signaling pathways or biological processes regulated by GZFLC and each herb, functional enrichment analysis was carried out in Comparative Toxicogenomics database (Davis et al., 2019) to obtain the over represented Gene Ontology (GO) biological processes (BP)/KEGG signaling pathways based on the potential targets of GZFLC and each herb. The significantly enriched GO BP/KEGG signaling pathways with  $p < 0.05$  after Benjamin's correction were selected for further study. All significantly enriched GO BP/KEGG signaling pathways were categorized by means of key words mapping.

The herbs-compounds-biological functional modules-biological molecules network of GZFLC was constructed to elucidate its putative anti-primary dysmenorrhea mechanisms by considering protein-protein interactions and crosstalk among pathways. First, herbs were connected to their representative compounds. Second, the potential targets of GZFLC were mapped into protein-protein interaction network and the targets were annotated by its biological functions. Third, an edge was added between herbs and biological functional modules if potential targets of a certain herb were significantly enriched in biological functional modules related GO BP or KEGG signaling pathways ( $p < 0.05$ ). The herbs-compounds-biological functional modules-biological molecules network was visualized using Cytoscape v3.7.2 (Shannon et al., 2003).

## Hierarchical Clustering Analysis of Anti-Primary Dysmenorrhea Drugs and Compounds in GZFLC

We hypothesized that the drugs with similar target profiles predicted by drugCIPHER-CS may have similar biological activities. The resemblance of compounds' and drugs' biological activities could be further defined on the basis of the similarity between concordance scores of their target profiles. Hierarchical clustering analysis of target profiles was applied to measure the biological activity resemblance of compounds and drugs. Thus, to identify anti-primary dysmenorrhea candidate compounds, hierarchical clustering analysis was conducted using R statistic software (R version 3.6.3) based on target profiles of FDA-approved anti-primary dysmenorrhea drugs and 51 compounds of GZFLC.

## COX2 Activity Assay

As GZFLC had multiple compounds and targets, we first qualitatively explored the relativity of representative GZFLC compounds and targets. And then we selected predicted compounds and a specific target for preliminary analysis of their dosages and ratios as a starting point. *In vitro* enzyme activity assays were used to analyze the relationship between predicted GZFLC compounds' different dosages and their intervention intensity on a specific target COX2, and to investigate GZFLC's intervention intensity on COX2 under the specific ratio of GZFLC compounds which is relatively fixed in GZFLC. The content in the GZFLC (Jiangsu Kanion Pharmaceutical Co., Ltd. Jiangsu, China, No. 170601) was weighed and extracted with dimethyl sulfoxide (DMSO, 32.308:1, W/V, mg/ml) at 37°C for 30 min. The liquid was collected by centrifugation, and the supernatant was filtered through a 0.22 µ filter. The effect of GZFLC or pure chemicals including 1,2,3,4,6-penta-O-galloyl-beta-D-glucopyranose (purity (%) ≥98%, CAS: 14,937-32-7, Pubchem CID: 65238, Nanjing SenBeiJia Biological Technology Co., Ltd.), galloylpaconiflorin (purity (%) ≥98%, CAS: 122,965-41-7, Pubchem CID: 46882879, Nanjing SenBeiJia Biological Technology Co., Ltd.), ethyl gallate (purity (%) ≥98%, CAS: 831-61-8, Pubchem CID: 13250, Nanjing SenBeiJia Biological Technology Co., Ltd.) and gallic acid (purity (%) ≥98%, CAS: 149-91-7, Pubchem CID: 370, Nanjing SenBeiJia Biological Technology Co., Ltd.) on COX2 activity was measured using cyclooxygenase-2 inhibitor screening kit (Beyotime, Cat. No. #S0168). Briefly, the recombinant human COX2 assay mixture (total volume = 90 µL/well) consisting of assay buffer, cofactor, COX2 enzyme, and test compound (diluted in DMSO, 5.56% DMSO finally in assay) was incubated at 25°C for 5 min. Detection of the product was performed by adding probe (5 µL/well). Arachidonic acid was added and the reaction was allowed to proceed for 15 min at 37°C. The fluorescence of the resulting solution was measured using SpectraMax M2e multilabel plate reader (Molecular Devices, United Kingdom). COX2 specific inhibitor ibuprofen (98.82% purity, AbMole, Cat. No. M3359) was included as a positive control. Data was represented as  $\bar{X} \pm SD$  of duplicated samples. The effect of the samples on COX2 was calculated using the following equation:

$$\text{Relative activity of COX2 (\%)} = \left( \frac{RFU_{\text{sample}} - RFU_{BW}}{RFU_A - RFU_{BW}} \right) \times 100\%.$$

## Animals

Female ICR mice (18–22 g of weight, SPF, license number: SCXK (SU) 2012-0004) were provided by the comparative medicine center of Yangzhou University. All animal experimental procedures were performed in accordance with the Guide for the Care and Use of Laboratory Animals and were approved by the animal ethics committee of the Institutional Animal Care and Use Committee (IACUC) of Kanion Pharmaceutical Co., Ltd.

## Uterine Myometrial Cells Culture

Isolation and culture of primary myometrial cells were prepared as previously reported (Mosher et al., 2013; Sun et al., 2017). Briefly, Uterine were removed from adult female ICR mice (7–8 weeks old, purchased from Nanjing Branch of Beijing Weitong Lihua Laboratory Animal Technology Co., Ltd., license number: SCXK (SU) 2016-0003). Uterine were cut longitudinally, and endometria were scraped gently. The myometrial cells were digested in 2 ml collagenase II (GIBCO, Cat. No. 1797319) (0.025 g L<sup>-1</sup>), then cells were plated onto 25 cm<sup>2</sup> culture bottle (Costar, US) and were cultured in complete DMEM (GIBCO, Cat. No. 11330032) at 37°C with 5%CO<sub>2</sub>.

## Immunofluorescence Assay

Myometrial cells were seeded in 96 well black-walled clear-bottom plates (Costar, US) (4 × 10<sup>4</sup>/ml density), and incubated overnight at 37°C in air containing 5%CO<sub>2</sub>. The blank group and model group were added with 100 µL serum-free medium, and the GZFLC group was added with GZFLC (Jiangsu Kanion Pharmaceutical Co., Ltd. Jiangsu, China, No. 20160319) solution prepared with serum-free medium (25 g L<sup>-1</sup>) for 1 h. The supernatant was discarded, 100 µL serum-free medium was added to the control group, and 100 µL oxytocin (Cayman, 11,799) (final concentration of 28 µM) was added to the model group and GZFLC group for 15 min respectively. The supernatant was discarded, fixed with paraformaldehyde (Amresco, Cat. No. J531) (0.4 g L<sup>-1</sup>) for 15 min, washed with PBS for 5 min 3 times, and blocked with 5% goat serum (Boster, Cat. No. 10E12B09)/0.3% tritonx-100 for 1 h. Then cells were incubated with primary antibody against p-SAPK/JNK(CST), p-p44/42 MAPK(Erk1/2) (CST), p-p38(CST) (1:150, 1:150, 1:2000) at 4°C overnight. The next day, it was equilibrated to room temperature, followed by 1 h incubation with Alexa Fluor® 488 Conjugate (1:1000, Invitrogen, United States) at room temperature, washed 3 times with PBS, counterstained with DRAQ5® for 5 min, washed once with PBS, and imaged with a high-content instrument (Thermo, ArrayScanVII).

## Oxytocin-Induced Dysmenorrhea in Mice

Oxytocin-induced dysmenorrhea in mice was performed according to the method previously reported (Sun et al., 2002). Fifty female ICR mice (license number: SCXK (SU) 2012-0004) were evenly divided into five groups as follows: normal group, model group, ibuprofen group and the GZFLC groups of different doses (0.54 g/kg and 1.08 g/kg). Except for the normal group (subcutaneous injection of saline), the other groups were administrated by subcutaneous estradiol benzoate injection (0.05 ml/mouse on the first and 10th day, and 0.025 ml/mouse on the remaining days) for ten consecutive days. The model group, GZFLC groups, and Ibuprofen group were orally administrated on the fourth day with 0.5% CMC-Na of the same volume (20 ml/kg), GZFLC (0.54 g/kg and 1.08 g/kg) and ibuprofen (0.1 g/kg) for seven days (once a day) in the period, respectively. On the 10th day, oxytocin (0.2 ml/2 IU/mouse) was administered by peritoneal injection 1 h after the last administration. The number of animal writhing times was

observed and recorded within 30 min after injection of oxytocin. The number of writhing inhibition rate (IR %) was calculated according to the formula (inhibition rate% = (number of writhing times in the model group - number of writhing times in the medication group) / number of writhing times in the model group)  $\times$  100%). The mice were sacrificed immediately. The uterus tissues were fixed with 10% formalin for further study.

## Pathological Examination

The uterus tissues were fixed in 10% formalin and stained with hematoxylin and eosin (H&E). Histopathological changes were observed by optical microscope (OLYMPUS DX45, Japan) including degeneration and necrosis in the endometrial epithelial cells, congestion, edema, inflammatory cell infiltration in the lamina propria, the number of glands (increased or decreased), secretion in the gland cavity, and lesions in the muscle layer and serosal layer. According to the severity of the lesion, it was recorded as one point (mild), two points (moderate), three points (severe), four points (extremely severe), no lesion was recorded as 0 point. All scores were accumulated and the average score ( $\bar{X} \pm SD$ ) of each animal in each group was calculated.

## Statistical Analysis

The Fisher's exact test was used to identify significantly enriched KEGG signaling pathways and GO biological processes. The immunofluorescence assay results were analyzed by SPSS 13.0 software. One-way and two-way analysis of variance (ANOVA) were used to calculate statistical levels between groups. The enzyme activity assay results were analyzed using Graphpad Prism software (Graph Pad, United States) presented as  $\bar{X} \pm SD$  of duplicated samples. The animal assay results were analyzed using Graphpad Prism software (Graph Pad, United States) presented as  $\bar{X} \pm SEM$  or  $\bar{X} \pm SD$  of duplicated samples. *p*-value less than 0.05 was considered to be statistically significant.

## RESULTS

### Targets Prediction and Validation of GZFLC Compounds

We selected 51 representative compounds of GZFLC according to our previous investigations to further study. It has been known that bioactive natural compounds may have multiple targets to exert certain therapeutic effects. To reveal the pharmacological mechanisms of GZFLC for treating primary dysmenorrhea, potential targets of 51 representative compounds were predicted by our state-of-art network-based algorithm drugCIPHER-CS due to the lack of these compounds' known target records. The top 100 predicted targets of each compound were selected as its potential targets for high precision in this algorithm, called target profiles of each compound. Moreover, the reliability of the predicted targets was verified making use of literature mining method based on text searching. The predicted targets were validated by the reported targets with literature evidence via direct mapping or indirect link as shown in **Figure 2A**. The precision of predicted targets was used to measure the reliability, which stands for the percentage of the

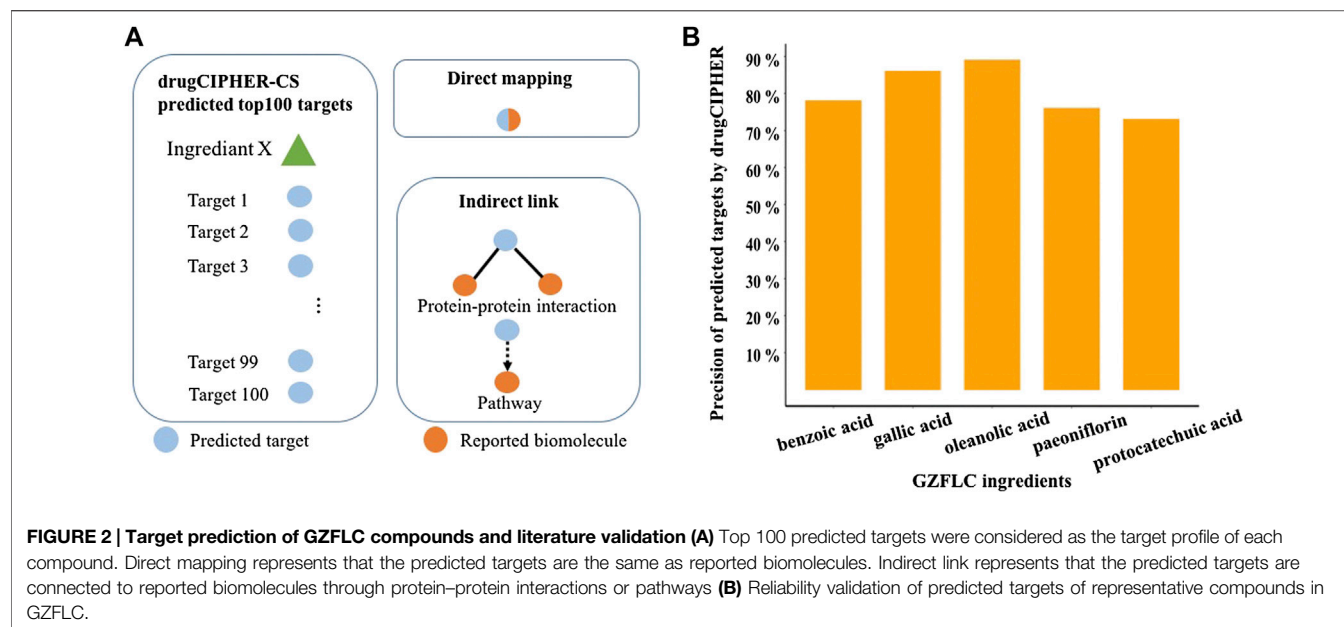

predicted targets supported by literatures. Greater than 73% of the predicted targets of compounds could be supported with literature evidence in **Figure 2B**, while the others could be novel targets which would be investigated in the future study. These results indicated the reliability of our predicted targets of GZFLC compounds used for further investigation of pharmacological mechanisms.

### Network Target Analysis of Anti-Primary Dysmenorrhea Mechanisms of GZFLC

At first, there was a hypothesis that if a biological molecule was an important target in the pharmacological effects of GZFLC, it may rank top or appear in the target profiles of many compounds in GZFLC. Then, based on this hypothesis, we selected the most representative targets of GZFLC compared to the null model with Poisson binomial statistics as potential targets regulated by GZFLC to uncover its therapeutic mechanisms for primary dysmenorrhea. Finally, we got 240 potential targets as GZFLC network target and made functional enrichment analysis on these targets. The significantly enriched biological processes and signaling pathways were achieved as listed in **Table 1**. According to key words mapping, the network target of GZFLC significantly enriched in some pain, inflammation, endocrine, blood circulation and energy metabolism related biological processes and signaling pathways (*p* < 0.05). Hence, potential functional modules regulated by GZFLC on primary dysmenorrhea could be related to pain, inflammation, endocrine, blood circulation and energy metabolism.

We also got the potential targets of each herb in GZFLC respectively and conducted the functional enrichment analysis for these targets of each herb with the significantly enriched biological processes and signaling pathways of GZFLC as shown in **Figure 3A**. Those results could help us to better elucidate effects of GZFLC for treating primary dysmenorrhea. *Cinnamomum cassia* (L.) J. Presl, *Prunus persica* (L.) Batsch mainly regulated pain, inflammation, endocrine, blood circulation modules. *Paeonia lactiflora* Pall. and *Paeonia*  $\times$  *suffruticosa* Andrews mainly regulated pain, inflammation, endocrine, blood circulation and energy metabolism modules. *Poria cocos* mainly regulated inflammation, endocrine and energy metabolism modules. To further elucidate the underlying molecular mechanisms of GZFLC, the biological molecular network targeted by GZFLC was constructed to uncover the relationships among herbs, compounds, biological functional modules and targets in **Figure 3B**. These results suggested that GZFLC could reduce pain and inflammation, and improve endocrine, blood circulation and energy metabolism, which was supported by evidences from the following *in vitro* and *in vivo* experiments.

Moreover, the hierarchical clustering analysis of GZFLC compounds and first-line drugs for primary dysmenorrhea was performed to further investigate the anti-primary dysmenorrhea activities of GZFLC compounds. The therapeutic effects of first-line drugs might suggest hypothetical effects for several compounds in GZFLC within the same cluster. The target profiles of GZFLC compounds and nine FDA-approved anti-primary dysmenorrhea drugs including non-steroidal anti-inflammatory drugs (NSAIDs: Ibuprofen, Naproxen sodium,

Mefenamic acid and celecoxib) and oral contraceptives (OCs: Norgestimate, Ethynodiol diacetate, Drospirenone, Mestranol and Norethisterone) were predicted by drugCIPHER-CS firstly. Then, hierarchical clustering analysis was performed based on target profiles of GZFLC compounds, NSAIDs and OCs. These two kinds of first-line drugs have different mechanisms on primary dysmenorrhea. First, NSAIDs are often taken to exert analgesic effects via inhibition of cyclooxygenase (Brune and Patrignani, 2015). The compounds of GZFLC in the same cluster with the NSAIDs might be potential active compounds to exert analgesic effects. As shown in **Figure 3C**, the four NSAIDs were clustered into two major groups including 36 compounds of GZFLC, indicating that these compounds might have a similar mechanism of analgesic effects to relieve primary dysmenorrhea with NSAIDs. Second, the OCs were used to regulate hormone levels to suppress ovulation, thereby reducing dysmenorrhea (Proctor et al., 2001). The compounds in GZFLC in the same cluster with OCs were considered to have a similar therapeutic mechanism on primary dysmenorrhea with OCs. As shown in **Figure 3C**, the five oral contraceptives were clustered with 23 compounds from GZFLC, which mainly derived from *Paeonia lactiflora* Pall. and *Paeonia × suffruticosa* Andrews, suggesting that these compounds might have the bioactivity of regulating hormone levels to improve endocrine, thereby relieving primary dysmenorrhea.

## The Underlying Mechanisms of GZFLC on Primary Dysmenorrhea

Recent studies have demonstrated that hyper-secretion of prostaglandins and an increased uterine contractility are two causes of pain associated with dysmenorrhea (Bernardi et al., 2017). NSAIDs exert analgesia effects to effectively alleviate primary dysmenorrhea through decreasing prostaglandin levels via

inhibition of cyclooxygenase-mediated production (Marjoribanks et al., 2010). COX2 is an important cyclooxygenase that catalyzes arachidonic acid conversion to prostaglandins, which is a major target of NSAIDs. Meanwhile, COX2 was predicted as an important biomolecule regulated by GZFLC from our network target analysis. We therefore examined whether GZFLC and its potential bioactive compounds above could affect COX2 activity. We found that GZFLC and four predicted main compounds, including 1,2,3,4,6-penta-O-galloyl-beta-D-glucopyranose, galloylpaeoniflorin, ethyl gallate and gallic acid, could inhibit the activity of COX2 *in vitro*. As shown in **Figure 4A**, GZFLC inhibited the activity of COX2 *in vitro* with an IC<sub>50</sub> value of 5.92 µg/ml. 1,2,3,4,6-penta-O-galloyl-beta-D-glucopyranose, galloylpaeoniflorin, ethyl gallate and gallic acid inhibited the activity of COX2 *in vitro* with IC<sub>50</sub> values of 0.38 µM (0.36 µg/ml), 0.74 µM (0.47 µg/ml), 1.11 µM (0.22 µg/ml) and 1.95 µM (0.33 µg/ml) respectively. Ibuprofen was selected as the positive control in our study and the results showed that ibuprofen potently inhibited the activity of COX2 with an IC<sub>50</sub> value of 50.09 µM (10.33 µg/ml).

As a result, the network target of GZFLC was significantly enriched in MAPK signaling pathway. MAPKs could increase cPLA2 activity and hence result in prostaglandin production and myometrial contraction (Lin et al., 1993). Therefore, we used the immunofluorescence assay to determine whether GZFLC could affect MAPK signaling pathway to reduce myometrial contraction. We found that uterine smooth muscle cells in oxytocin-induced dysmenorrhea murine model displayed the increase of p-SAPK/JNK, p-p44/42 MAPK (Erk1/2) and p-p38 protein levels, and this effect was attenuated in cells pre-treated with GZFLC (25 g·L<sup>-1</sup>) as shown in **Figure 4B**, which suggested that GZFLC could downregulate the MAPK signaling pathway.

Integrating network target analysis and *in vitro* experiments, as shown in **Figure 4C**, GZFLC could inhibit the activity of COX2 and

**TABLE 1 |** Several enriched biological processes and signaling pathways predicted to be regulated by GZFLC using functional enrichment analysis.

Class	Biological processes and signaling pathways	p-value
Pain	cAMP signaling pathway	8.80E-14

	ATP metabolic process	8.81E-09
	AMPK signaling pathway	4.53E-09

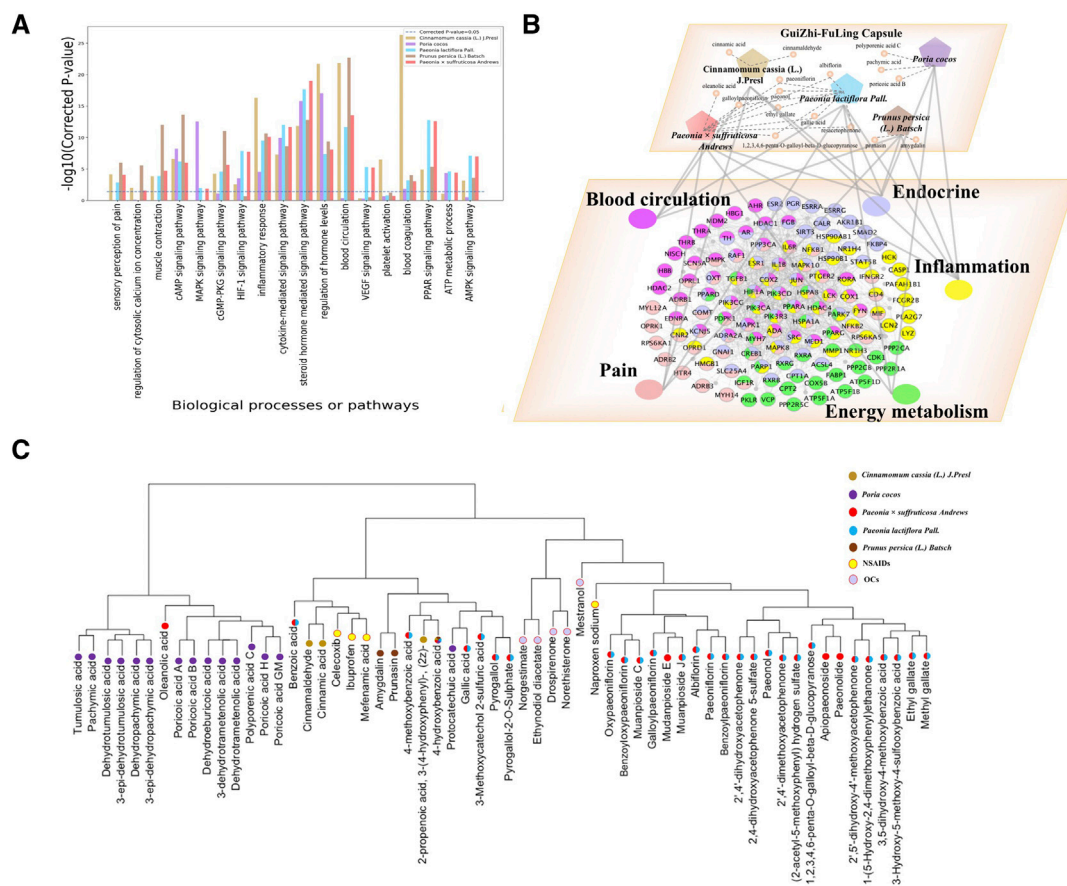

downregulate MAPK signaling pathway to reduce the production of PGs and myometrial contraction to exert analgesia effects for treating primary dysmenorrhea. In addition, GZFLC could regulate cytosolic calcium ion concentration, intervene oxytocin

receptor (OTR) to reduce myometrial contraction and decrease inflammation, which was validated in literatures (Sun et al., 2016a; Zhong et al., 2016b) and subsequent *in vivo* experiments.

Primary dysmenorrhea is also related to imbalances in women's endocrine system during the menstrual cycle (Britannica, The Editors of Encyclopedia, 2016). And a color Doppler study (Altunyurt et al., 2005) has found that there was increased impedance to blood flow within the uterus of patients with primary dysmenorrhea on the first day of the menstrual cycle, suggesting the disturbance of blood circulation in primary dysmenorrhea patients. Meanwhile, a previous study (Xiong et al., 2019) has found that there were disorders of energy metabolism in primary dysmenorrhea rats. Thus, Blood circulation, endocrine and energy metabolism may be three important functional modules to be regulated to gain sustained beneficial effects. According to the network target analysis, GZFLC was predicted to regulate blood circulation, endocrine and energy metabolism-related biological processes and signaling pathways, which may contribute to the sustained beneficial effects of GZFLC on primary dysmenorrhea. The effect of GZFLC on blood circulation, endocrine and energy metabolism have been verified in literatures (Su et al., 2015; Sun et al., 2016a; Xiong et al., 2019).

## Effects of GZFLC on Primary Dysmenorrhea in Oxytocin-Induced Murine Model

We have investigated the effect of GZFLC on the writhing response in oxytocin-induced dysmenorrhea murine model to study its analgesic activity. Analgesic activity was determined by observed decreases of writhing times in oxytocin-induced murine model, which was a method for quantitative evaluation of pain. As shown in **Figure 5**, GZFLC significantly inhibited the oxytocin-induced writhing response. The inhibition percentages of writhing times were 43.3% and 52.8% after oral administration of GZFLC (0.54 g/kg and 1.08 g/kg) respectively while 85.5% after oral administration of ibuprofen. The numbers of writhing times at GZFLC groups (0.54 g/kg and 1.08 g/kg) and ibuprofen group (0.1 g/kg) were  $18.5 \pm 4.5$ ,  $15.4 \pm 4.6$  and  $5.9 \pm 2.1$  respectively, significantly lower than that of the model group ( $32.6 \pm 8.5$ ). Each herbal medicine in GZFLC was of the same amount and their dosages and ratios were the same as the traditional dosages and ratios in Guizhi Fuling Wan (Committee 2015). Next, we have investigated effect of GZFLC on uterine histopathology in oxytocin-induced dysmenorrhea murine model. As shown in **Figures 6A,B**, the histopathological results showed that compared with the normal group, the model group mainly showed degeneration and necrosis of endometrial epithelial cells, lamina propria edema, a small amount of inflammatory cell infiltration, reduced number of glands in the lamina propria, secretions in the gland cavity, and the disordered arrangement of smooth muscle cells in the muscle layer. There was a significant difference between the model group and the normal group, indicating that the oxytocin-induced dysmenorrhea murine model was successfully constructed. Meanwhile, ibuprofen and GZFLC had the effect on reducing the degree of uterine lesions as shown in **Figures 6C–E**. Moreover, there was a significant difference in 1.08 g/kg of GZFLC group compared with the model group ( $p < 0.05$ ) as shown in **Figure 6F**.

**FIGURE 3 | (A)Functional enrichment analysis of each herb's potential targets (B)Herbs-compounds-biological functional modules-biological molecules network to depict the underlying biological mechanisms of GZFLC (Different color nodes represent different function module and its related biomolecules, namely, fuchsia nodes: Blood circulation function module and its related biomolecules; lavender nodes: Endocrine function module and its related biomolecules; yellow nodes: Inflammation function module and its related biomolecules; green nodes: Energy metabolism function module and its related biomolecules; pink nodes: Pain function module and its related biomolecules.) (C)Hierarchical clustering tree of GZFLC compounds and current anti-primary dysmenorrhea drugs.**

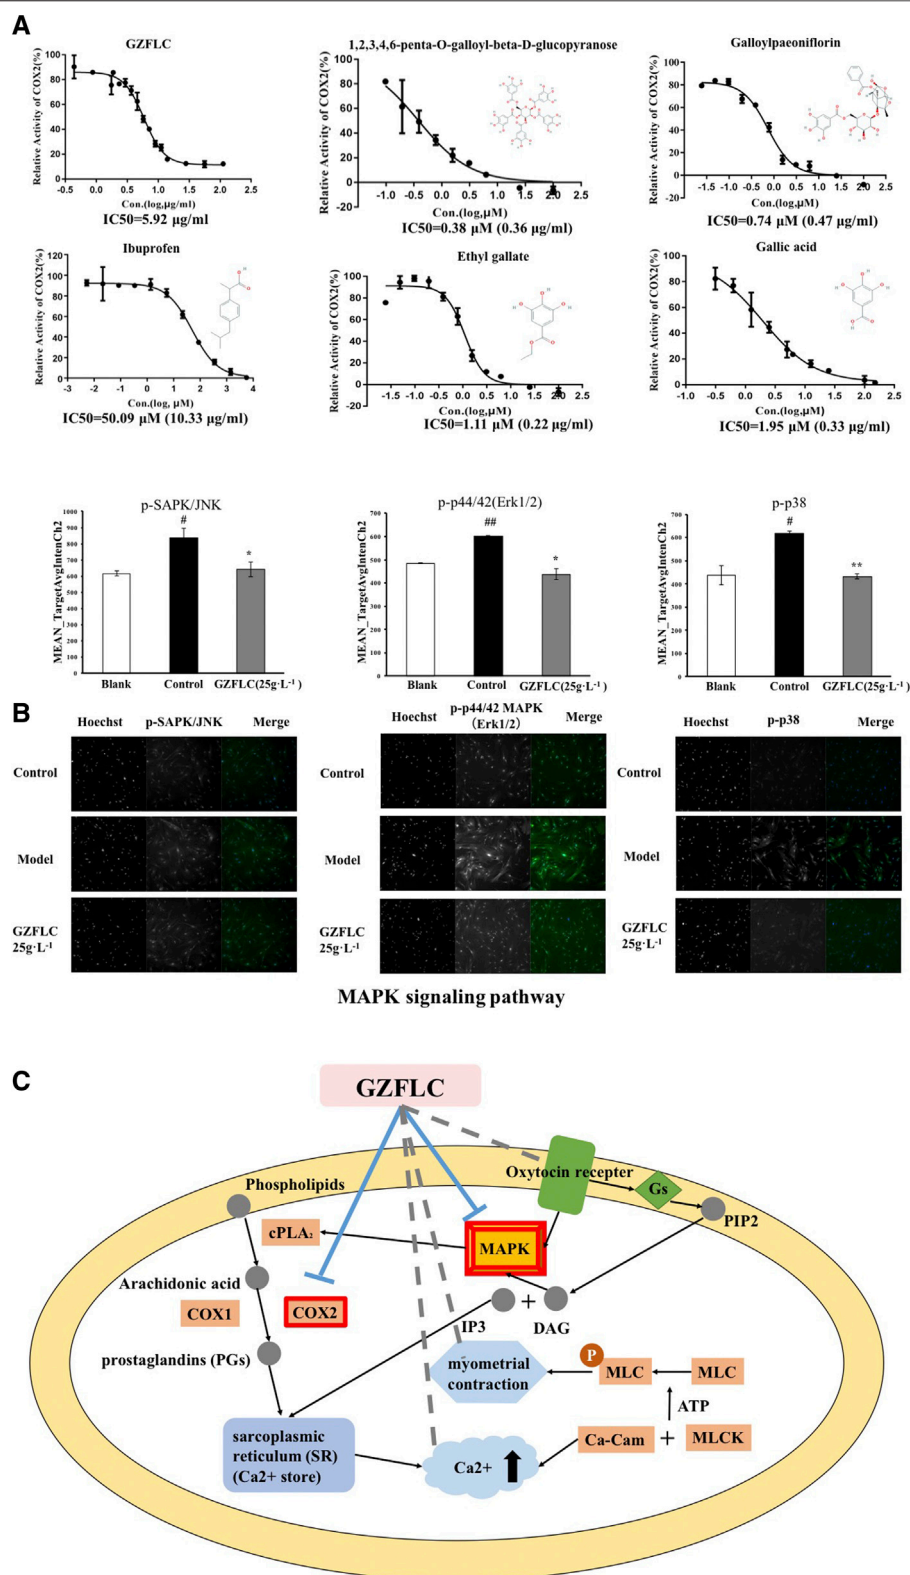

## DISCUSSION AND CONCLUSION

Guizhi-Fuling capsule, derived from a classic herbal formula, has been used for the therapy of primary dysmenorrhea for a long time in China. The clinical data has shown the analgesic and sustained beneficial effects of GZFLC on menstruating women with primary dysmenorrhea. However, the pharmacological mechanisms of GZFLC on primary dysmenorrhea are less characterized from a holistic perspective. In this study, we analyzed underlying pharmacological mechanisms of GZFLC in terms of two major clinical effects of GZFLC on primary dysmenorrhea. Generally, the network target analysis of GZFLC indicated that GZFLC may exert analgesic and sustained beneficial effects on primary dysmenorrhea through these five biological functional modules including pain, inflammation, endocrine, blood circulation, and energy metabolism.

GZFLC exerted therapeutic effects on basis of its compounds and their intervention on targets. For analgesic effect, GZFLC and four predicted compounds, including 1,2,3,4,6-penta-O-galloyl-beta-

D-glucopyranose, galloylpaeoniflorin, ethyl gallate and gallic acid, were verified to inhibit COX2 activity *in vitro* through COX2 activity assays, which gave hints that 1,2,3,4,6-penta-O-galloyl-beta-D-glucopyranose, galloylpaeoniflorin, ethyl gallate and gallic acid could be used as quality control markers of GZFLC in the treatment of primary dysmenorrhea. In the meanwhile, COX2 and its production PGF2 $\alpha$  could be used as optimizing objective and quantitative surrogate outcomes of GZFLC for primary dysmenorrhea. In addition, GZFLC was verified to downregulate MAPK signaling pathway in uterine smooth muscle cells to reduce uterine smooth muscle contraction via an immunofluorescence assay.

From perspectives of TCM, GZFLC is mainly used to treat blood stasis syndromes, and a meta-analysis of randomized clinical trials for GZFLC in the treatment of primary dysmenorrhea (Xing et al., 2019) suggested that GZFLC may be more effective on primary dysmenorrhea in a subgroup of patients with cold blood stasis syndrome, which is one of the common cold syndromes. According to our previous research (Ma et al., 2010), cold syndromes related genes acted as a pivotal part in

**FIGURE 4 | The potential molecular mechanisms of analgesia effects of GZFLC on primary dysmenorrhea (A)** GZFLC and four of its compounds were verified to inhibit COX2 *in vitro*, ibuprofen was selected as a positive control **(B)** GZFLC was verified to downregulate predicted MAPK signaling pathway in uterine smooth muscle cells. \**p* < 0.05, \*\**p* < 0.01, GZFLC group compared with Model group. #*p* < 0.05, ##*p* < 0.01, Model group compared with blank group. energy metabolism, which were tightly connected with the genes of neurotransmitters, hormones and cytokines in the neuro-endocrine-immune interaction network. Interestingly, the network target analysis has found that GZFLC could reduce pain and inflammation, improve endocrine, blood circulation and energy metabolism, which were consistent with the cold syndrome related biological modules. Hence, our study about the pharmacological mechanisms of GZFLC on primary dysmenorrhea could give a potential explanation to the underlying biological basis of the subgroup results in clinical trials.

Oxytocin-induced murine model is a commonly used animal model for primary dysmenorrhea. Our study has investigated the effect of GZFLC on the writhing response, uterine histopathology in oxytocin-induced dysmenorrhea murine model. The results showed that GZFLC could significantly inhibit the writhing response in oxytocin-induced dysmenorrhea murine model. Our network target analysis results about mechanisms of anti-primary dysmenorrhea of GZFLC were partially validated by *in vivo* experiments. The pathological assay showed that high dose of GZFLC had a significant effect on reducing the degree of uterine lesions, indicating that GZFLC could decrease inflammation. These results gave support to efficacy of GZFLC on primary dysmenorrhea. Moreover, The experiment in the early study showed GZFLC markedly reduced the expression of COX2 in uterus tissue of the experimental murine models induced by oxytocin (Sun et al., 2016a). Meanwhile, the previous study showed GZFLC suppressed P42/44 MAPK phosphorylation level in the uterus tissue in PGF2 $\alpha$ -induced model animals (Sun et al., 2016b).

In total, GZFLC could treat primary dysmenorrhea through “multi-compound, multi-target, multi-pathway” mode, which distinguished it from two kinds of first-line drugs with few targets to selectively act on. Network target derived from the multi-target nature of TCM could be preferable to analyze and reflect complicated interactions between biological molecules of the human body and chemical compounds in TCM formulae from the perspective of network (Li and Zhang 2013). There are also some limitations in this study. Firstly, some compounds in GZFLC have been ignored which may lead to bias in our study. However, we have selected important phytochemistry and absorbed compounds of GZFLC as representatives. Secondly, the exploration about relationship between the predicted compounds, targets and functional interpretation and dosages and ratios of GZFLC compounds was limited. The analysis about dosages and ratios of compounds in TCM formulae is of great significance, which has addressed lots of researchers’ attention. There also have been several research methods developed for this issue (Zhou and Su 2019), and it is urgent to develop more appropriate methods in network pharmacology to investigate this issue. We would explore this issue in more depth in the further study. Briefly, we would first clarify the dosages and ratios of GZFLC’s representative compounds using component analysis technology such as liquid chromatography-mass spectrometry (LC-MS), then we would predict those compounds’ intervention intensity on targets and integrate their comprehensive effects on interacting targets of different biological functions within the primary dysmenorrhea related biological molecular network based on quantitative network pharmacology analysis *in silico*.

In summary, this work adopted combination of computational and experimental methods to reveal the underlying pharmacological mechanisms of GZFLC on primary dysmenorrhea. In the network target analysis, GZFLC may act on five functional modules of pain, inflammation, endocrine, blood circulation and energy metabolism. Next, we found that GZFLC significantly inhibited the writhing response and reduced the degree of uterine lesions in oxytocin-induced murine dysmenorrhea model. Furthermore, GZFLC may partially alleviate primary dysmenorrhea by inhibiting COX2 and downregulating MAPK signaling pathway *in vitro*. Thus, GZFLC presented pain relief and sustained benefits for primary dysmenorrhea. The results of this study showed that integrating TCM Network pharmacology and several different experimental methods could effectively elucidate underlying biological molecular mechanisms of GZFLC and identify part of the bioactive compounds. This study could provide a scientific approach for deciphering the pharmacological mechanisms of TCM herbal formulae and developing potential optimizing objective and quantitative surrogate outcomes of GZFLC for primary dysmenorrhea through network pharmacology.

**Background and Purpose:** Ultrafine particulate matter (UFPM) induces oxidative stress (OS) and is considered to be a risk factor of myocardial ischemia (MI). Shengmai formula (SMF) is a traditional Chinese medicine with antioxidant properties and has been used to treat cardiovascular diseases for a long time. The aim of this study was to explore the protective role of SMF and the mechanism by which it prevents myocardial injury in UFPM-exposed rats with MI.

**Methods:** An MI rat model was established. Animals were randomly divided into five groups: sham, UFPM + MI, SMF (1.08 mg/kg-d) + UFPM + MI, SMF (2.16 mg/kg-d) + UFPM + MI, and SMF (4.32 mg/kg-d) + UFPM + MI. SMF or saline was administrated 7 days before UFPM instillation (100 µg/kg), followed by 24 h of ischemia. Physiological and biochemical parameters were measured, and histopathological examinations were conducted to evaluate myocardial damage. We also explored the potential mechanism of the protective role of SMF using a system pharmacology approach and an *in vitro* myoblast cell model with small molecule inhibitors.

**Results:** UFPM produced myocardial injuries on myocardial infarct size; serum levels of LDH, CK-MB, and cardiac troponin; and OS responses in the rats with MI. Pretreatment with SMF significantly attenuated these damages *via* reversing the biomarkers. SMF also improved histopathology induced by UFPM and significantly altered the PI3K/AKT/MAPK and OS signaling pathways. The expression patterns of *Cat*, *Gstk1*, and *Cyba* in the UFPM model group were reversed in the SMF-treated group. In *in vitro* studies, SMF attenuated UFPM-induced reactive oxygen species production, mitochondrial damage, and OS responses. The PI3K/AKT/p38 MAPK/Nrf2 pathway was significantly changed in the SMF group compared with that in the UFPM group, whereas opposite results were obtained for pathway inhibition.

**Conclusion:** These findings indicate that SMF prevents OS responses and exerts beneficial effects against myocardial injury induced by UFPM + MI in rats. Furthermore, the PI3K/AKT/p38 MAPK/Nrf2 signaling pathway might be involved in the protective effects of SMF.

## INTRODUCTION

Particulate matter (PM) is a complex mixture composed of coarse particles (diameter, 2.5–10  $\mu\text{m}$ ;  $\text{PM}_{2.5-10}$ ), fine particles (diameter,  $\leq 2.5 \mu\text{m}$ ;  $\text{PM}_{2.5}$ ), and ultrafine particles (diameter,  $\leq 0.1 \mu\text{m}$ ;  $\text{PM}_{0.1}$  or UFPM). PM is considered an environmental risk factor and a life-threatening public health challenge for humans; PM pollution accounts for approximately 12% of the global burden of disease (Zhou et al., 2019). A growing number of epidemiological studies have demonstrated that UFPM is closely associated with morbidity and mortality due to both acute and chronic cardiovascular diseases (Ruckerl et al., 2007). Chen et al. reported that UFPM could trigger the onset of nonfatal myocardial infarction at a sub-daily timescale (Chen et al., 2020). Short-term acute exposure or long-term exposure to fine PM can cause acute cardiovascular events such as myocardial ischemia (MI), ischemic stroke, and congestive heart failure (Wei et al., 2019), which are favored by the smaller particles (Araujo and Nel, 2009). Consequently, UFPM can exert significant adverse effects on patients with cardiovascular disease, resulting in a large number of deaths.

Several mechanistic pathways are responsible for the cardiovascular effects of acute and chronic exposures to UFPM (Chin, 2015; Hadei and Naddafi, 2020). The translocation of pollutants may increase blood pressure, cause endothelial injury/dysfunction, and induce systemic oxidative stress (OS) (Lee et al., 2014) and inflammation (Tsai et al., 2012), which can cause thrombosis, coagulation (Chiarella et al., 2014), and arterial vasoconstriction (Rao et al., 2014) and decrease the heart rate variability, leading to MI events. Divergence in the toxicological mechanisms of PM could be attributed to the different origins of air particles with distinct chemical components that can trigger various pathways (Ronkko et al., 2018). Although different signaling pathways may be involved, systemic OS plays a major role in the cardiovascular effects of PM pollutants (Li R. et al., 2015; Miller, 2020).

Numerous treatment measures to alleviate the risk of PM exposure have been adapted and evaluated, including the use of masks or air purifiers and antioxidants (Zhong et al., 2017; Bolcas et al., 2019). In addition, extracts of traditional medicinal plants and natural products have been used to attenuate or prevent PM-induced injury in laboratory animals (Lee et al., 2019; Sanjeewa et al., 2020). Zhang reported that walnut protein isolates exerted protective effects in a PM-induced acute lung injury mouse model. The walnut protein isolates inhibited myeloperoxidase (MPO), nitric oxide (NO), interleukin-1 $\beta$  (IL-1 $\beta$ ), and interleukin-6 (IL-6) in bronchoalveolar lavage fluid. In addition, pro-inflammatory cytokine production and acyl

carrier protein levels were decreased by the walnut extract (Zhang et al., 2019). Tanshinone IIA effectively reduced  $\text{PM}_{2.5}$  damage to EA.hy926 cells by inhibiting the p38/MAPK pathway (Jia et al., 2012). However, the therapeutic or preventive effects of these agents on MI events following exposure to UFPM have not been reported.

Shengmai formula (SMF) is composed of Ginseng radix et Rhizoma Rubra (*Panax ginseng* C. A. Mey.), Ophiopogonis Radix [*Ophiopogon japonicus* (Thunb.) Ker Gawl.], and Schisandrae Chinensis Fructus [*Schisandra chinensis* (Turcz.) Barll.]. SMF has long been used clinically for the treatment of heart failure and has outstanding curative effects on cardiovascular diseases owing to its free radical scavenging activity (Li F. et al., 2015). In addition, SMF increases superoxide dismutase (SOD) activity and reduces inflammatory and OS activities to protect the myocardium and strengthen the heart (Zhu et al., 2019). SMF is a strong natural antioxidant used in traditional Chinese medicine and has a 2000-year history of use. SMF has cardioprotective properties and strong antioxidant, anti-atherogenic, and immune-modulating effects (Ichikawa et al., 2003).

In the present study, the protective effects of SMF on myocardial injury after exposure to UFPM were tested in rat and H9C2 cell models. The aims of this study were to determine whether SMF could inhibit UFPM-induced OS responses in rats with MI and improve the recovery of myocardial tissue damaged following exposure to UFPM + MI. In addition, the potential mechanism involved in the process was examined. Network pharmacology, RT-qPCR, western blot analysis, and inhibitors were used to investigate the pharmacological effects of SMF on myocardial injury and identify potential therapeutic targets and pathways.

## MATERIALS AND METHODS

### Animals and Reagents

Healthy adult male Sprague Dawley rats weighing  $200 \pm 20 \text{ g}$  were purchased from the China Institute of Food and Drug Testing. All rats were raised in light-controlled and air-conditioned ( $23 \pm 2^\circ\text{C}$ ) rooms and had free access to food and water. This study was approved by the Animal Ethics Committee of the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences. All reagents were purchased from Sigma-Aldrich (Missouri, United States) unless otherwise stated. UFPM (NIST® SRM® 1650b) was obtained from MilliporeSigma Corporate Offices (CAS Number 1333-86-4), and chemical characterization of UFPM can be found at <https://www-s.nist.gov/srmors/certificates/1650b.pdf>.

## Quality Control and Preparation of Shengmai Formula

SMF was purchased from Beijing Tongrentang Co., Ltd. (batch number, 16262159). Beijing Tongrentang Co. is a Chinese pharmaceutical company founded in 1669 and is the largest producer of traditional Chinese medicine. The drug is a multi-herbal preparation prepared according to the Pharmacopoeia of the People's Republic of China (Chinese Pharmacopoeia Commission, 2010). High-performance liquid chromatography-mass spectrometry (HPLC-MS) was used to identify the main chemical components of SMF. The active ingredients are shown in **Supplementary Figure S1; Supplementary Table S1**. The concentration of two major compounds in SMF, schisandrin ( $C_{24}H_{32}O_7$ ) and ruscogenin ( $C_{27}H_{42}O_4$ ), were 0.022 mg/mg and 0.132 mg/mg, respectively, as determined using HPLC and ultraviolet-visible (UV-Vis) spectrometry. The chromatogram for schisandrin is shown in **Supplementary Figure S1**.

For the preparation of SMF, Ginseng radix et Rhizoma Rubra, Ophiopogonis Radix, and Schisandrae Chinensis Fructus were mixed at a ratio of 1:2:1 (w/w). These three ingredients were pulverized to a coarse powder and macerated in 65% ethanol for 24 h. Approximately 4,500 ml of percolate was collected and concentrated to approximately 250 ml under vacuum. After cooling, the solution was diluted with 400 ml of water and filtered. Next, 300 ml of 60% syrup and a quantity of preservative was added, the pH was adjusted to the specified range, and the volume was adjusted to 1000 ml. After stirring thoroughly, the solution was allowed to stand, filtered, packed, and sterilized. For detailed information on the three herbal ingredients in SMF, see **Supplementary Table S2**. The structures of active compounds in SMF are shown in **Supplementary Figure S2**.

## SMF Administration, UFPM Exposure, and Myocardial Infarction Model

The rats were anesthetized with chloral hydrate (60 mg/kg, i.p.), and the specified dose of SMF or saline was given by oral administration daily for 7 days. Twenty-four hours after the final SMF administration, the animals were intubated with a tracheal tube through which 2.0 mg of UFPM suspended in 0.3 ml of saline was instilled (purchased from National Institute of Standards and Technology, Maryland, United States). MI was induced by ligating the left anterior descending coronary artery, as previously described (Wu et al., 2011; Li et al., 2012). The coronary artery was not ligated in the sham group. Specifically, the MI model with UFPM exposure was constructed by ligating the left anterior descending coronary artery, followed by 24 h UFPM exposure. Subsequently, the rats were killed after 24 h of ischemia.

## Animal Experimental Design

The rats were randomly divided into five groups ( $n = 10$  each) as follows: sham group; UFPM + MI group, treated with saline for 7 days before administration of UFPM followed by 24 h of

ischemia; SMF (1.08 mg/kg-d, orally, 7 days) + UFPM + MI group, treated with SMF for 7 days before UFPM instillation, followed by 24 h of ischemia; SMF (2.16 mg/kg-d, orally, 7 days) + UFPM + MI group, treated with SMF for 7 days before UFPM instillation, followed by 24 h of ischemia; and SMF (4.32 mg/kg-d, orally, 7 days) + UFPM + MI group, treated with SMF for 7 days before UFPM instillation, followed by 24 h of ischemia (**Figure 1A**). To measure the effect of SMF on cardiac function from the pathological and blood indexes of heart tissue, lactate dehydrogenase (LDH), creatine kinase myocardial band (CK-MB), cTnT levels, triphenyl tetrazolium chloride (TTC) staining and hematoxylin and eosin (H&E) assays were performed. To further clarify which biological processes are affected by SMF, we tested the oxidative stress response based on previous reports. Generally, mitochondrial damage can lead to oxidative stress reaction. Therefore, we evaluated mitochondrial function-related indicators [mitochondrial membrane potential (MMP), Seahorse and mitochondrial ultrastructure], levels of myocardial malondialdehyde (MDA), NADPH oxidase (NOX), heme oxygenase-1 (HO-1), catalase (CAT), total SOD (T-SOD), and phospholipid hydroperoxide glutathione peroxidase (GSH-Px) and mRNA levels of *SOD1*, *CAT*, *GSH-Px*, and *NOX* in myocardial tissues. Furthermore, we sought to determine which pathway or molecule mediates the changes in oxidative stress.

## Quantification of Infarct Size (Rats)

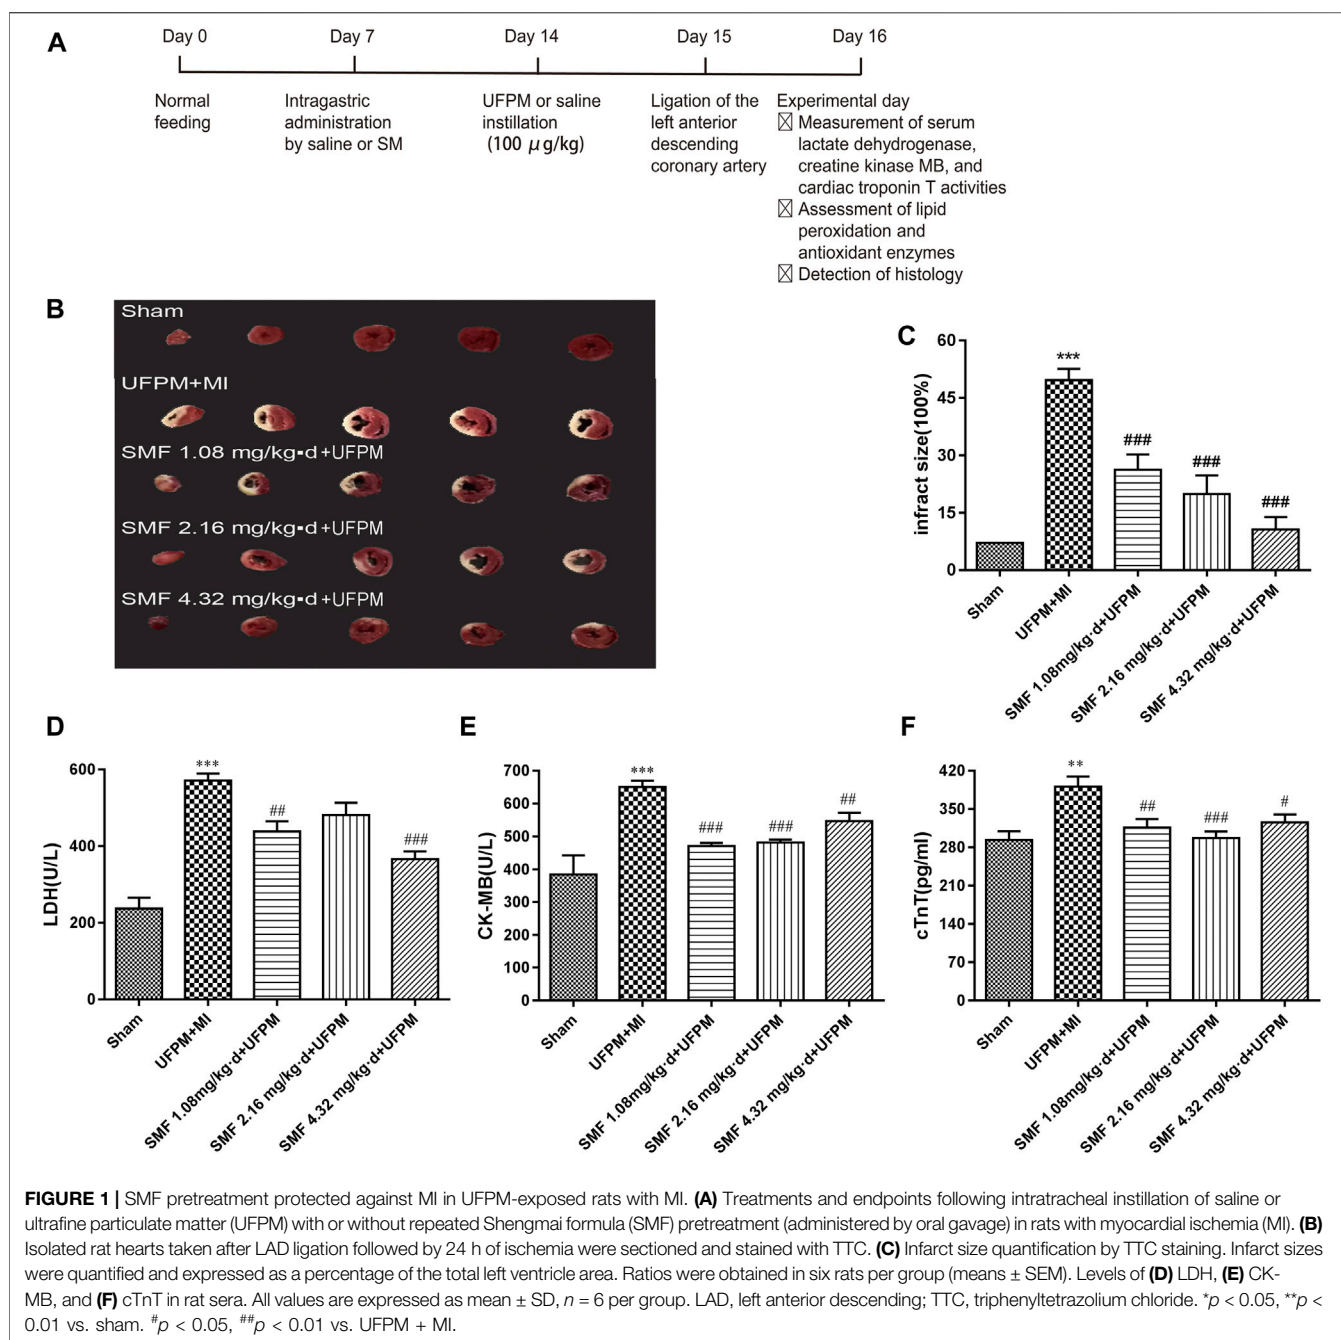

The infarct size was determined as described previously (Gao et al., 2011). Briefly, the heart was promptly removed after euthanasia and stored for 8 min at  $-80^{\circ}\text{C}$ . Then, 2-mm-thick sections were cut, stained with 1% 2,3,5-triphenyl tetrazolium chloride (TTC) in phosphate buffer (pH 7.4) for 20 min at  $37^{\circ}\text{C}$ , and fixed overnight in 10% formalin. Normal myocardium was stained red by TTC, whereas infarcted myocardium was pale in color due to cell membrane damage. Images of the slices were acquired, and the myocardial infarct area was calculated as a percentage of the total area using Image-Pro Plus 6.0.

## Measurement of Serum Lactate Dehydrogenase, Creatine Kinase MB, and Cardiac Troponin T Activities

LDH and CK-MB activities in serum were assessed using commercial kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer's protocols, as described previously (Kim et al., 2017). LDH and CK-MB activities were expressed in U/L. Blood samples were obtained 24 h after MI, and serum cTnT levels were measured (pg/ml) using a commercial assay kit (ab246529, Cambridge MA, United States) according to the manufacturer's instructions, as described previously (Hortmann et al., 2017).

## Assessment of Lipid Peroxidation and Antioxidant Enzymes

MD, NOX, HO-1, CAT, T-SOD, and GSH-Px levels in the heart and serum were measured using commercial kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China).

## Histology

Twenty-four hours after MI induction, the hearts were removed, fixed in 4% paraformaldehyde, and embedded in paraffin. The paraffin-embedded tissues were sliced into 5-mm sections and stained with hematoxylin and eosin (H&E). An optical microscope (Olympus, Japan) was used to observe pathological changes in the tissues. To determine the myocardial ultrastructure, the myocardium was fixed in 3% glutaraldehyde, followed by fixation in 1% osmium tetroxide and dehydration in ethanol. Epoxy resin was used to embed the tissues, followed by the use of a hardener, accelerator, and

growth agent. Subsequently, 70-nm-thick sections were cut using an ultra-microtome and stained with a solution containing uranyl acetate and lead citrate. Changes in the myocardial ultrastructure were observed using a JEM-1200EX transmission electron microscope (TEM, JEM 1200EX II, Jeol, Japan).

## Network Pharmacology-Based Analysis

An integrated pharmacology network-computing platform for traditional Chinese medicine (TCMIP V2.0, <http://www.Tcmip.cn>, updated on September, 2019) (Xu et al., 2019) and the SymMap databases (<https://www.symmap.org/>) (Wu et al.,

2019) were used to collect the SMF compounds. TCMIP V2.0, SymMap, and Swiss Target Prediction (<http://www.swisstargetprediction.ch/index.php>) databases were used to predict the targets of active ingredients. Disease-associated target prediction was performed using DisGeNET (<http://www.disgenet.org/web/DisGeNET/>), Therapeutic Target Database (TTD), and Human Phenotype Ontology (HPO) databases and published literature. The potential targets of SMF were predicted using the DrugBank database (<http://www.drugbank.ca/>, version: 3.0). The relevant protein–protein interaction network was extracted from the Human Protein Reference Database and String databases. This information along with information about the herbs, ingredient-related proteins, and disease-related proteins were entered into a bioinformatics software, Cytoscape (version 3.7.1), to construct a complete network for SMF. The Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway database was used to analyze the disease-related targets of SMF and toxicity-related pathways of UFPM.

## Experimental Validation

### Oxidative Stress-Related Gene Expression Analysis

Mitochondria of the heart tissue were homogenized and lysed with Trizol reagent (Life Technologies) to extract total RNA after 24 h of MI. The extracted RNA samples were purified using the spin column-based RNeasy Mini Kit (Qiagen, Hilden, Germany). The quality and concentration of RNA were measured using a NanoDrop® ND-1000 spectrophotometer (Thermo Fisher Scientific, Massachusetts, United States). The A260/280 values of all the RNA samples were 1.8–2.1. cDNA was transcribed using the RT<sup>2</sup> First Strand Kit (Qiagen, Hilden, Germany). The RT<sup>2</sup> Profiler PCR array (Qiagen, 48-well format, catalog no. PARN-065ZA) was used to analyze gene expression using a Stratagene Mx3005P real-time (RT) quantitative polymerase chain reaction (qPCR) system (Agilent Technologies).

### RT-qPCR Analysis

RT-qPCR assays for *Nrf2*, *HO-1*, *CAT*, *T-SOD*, *Gpx1*, *NQO1*, *Nox4*, and *GAPDH* (housekeeping gene) were performed for further validation (see **Supplementary Table S3** for primers). RNA was isolated and cDNA was synthesized using the High Capacity cDNA Reverse Transcription Kit (Invitrogen Life Technologies). Gene expression levels were determined by RT-qPCR using the SYBR Green PCR Master Mix (Qiagen, Hilden, Germany) and normalized to the level of the housekeeping gene *GAPDH*. Gene expression levels in the SMF-treated group were expressed as fold-changes when compared with gene expression levels in the UFPM-exposed MI rats using the  $2^{-\Delta\Delta CT}$  method. Similarly, the gene expression levels in the UFPM-exposed MI rats were determined by calculating the fold-change when compared with the sham control rats.

### Cell Culture and Treatment

Rat myoblast cells (H9C2) were purchased from American Type Culture Collection and cultured in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum, 100 U/mL penicillin, and 100 µg/ml streptomycin (Gibco, Madison,

United States) under sterile conditions. The cells were incubated with 5% CO<sub>2</sub> at 37°C. For the cell viability assay, H9C2 cells were exposed to UFPM (25, 50, 100, and 200 mg/ml) for 24 h or SMF (0.28, 0.56, 1.12, and 2.24 mg/ml) for 24 h. Cell Counting Kit 8 (WST-8/CCK8) (ab228554, Abcam) was used for analysis. To analyze the mechanism of SMF, H9C2 cells pre-incubated with either medium or LY294002 (50 µM)/SB 203580 (10 mM) for 4 h were then cultured with medium or SMF for 24 h followed by culture with or without UFPM (50 mg/ml) for 6 h. The lysates from H9C2 were resolved on 10% SDS-PAGE, transferred onto membranes, and blotted with specific antibodies. The supernatants were collected for analysis of OS biomarkers (T-SOD, CAT, GSH-PX, and NOX) using ELISA assays.

### Seahorse Assay

The XF96 Extracellular Flux Analyzer (Seahorse Bioscience) was used to measure oxygen consumption rates (OCRs) and extracellular acidification rates. The cells were diluted to 2× the final optical density, and 90 µl of cell culture was added to XF Cell Culture Microplates pre-coated with poly-D-lysine. The cells were centrifuged for 10 min at 1,400 × g in a Heraeus Multifuge ×1R (M-20 rotor) to attach them to the pre-coated plates. After centrifugation, 90 µl of fresh media was added to each well. To achieve uniform cell seeding, the initial OCR was measured for two cycles (7 min) before UFPM exposure. The maximal OCR that can be read on the analyzer is approximately 700–800 pmol/min; above this rate, the consumption rate exceeds the replenishment of the system and the curves show a false declination in OCR, which was excluded from the graphical presentation.

### Western Blotting

Proteins were extracted from frozen heart tissues. The bicinchoninic acid protein assay was used to determine the protein concentration using bovine serum albumin as a standard (Pierce Rockford, IL). Equal amounts of proteins were loaded on SDS-PAGE gels; after separation, the proteins were transferred to a polyvinylidene difluoride membrane. The membranes were incubated with anti-MAPK p38 (CST, #8690S), p-MAPK p38 (CST, #4511S), rat anti-AKT (ab8805, Abcam), p-AKT (ab81283, Abcam), rabbit anti-Nrf2 (1:1000, 16396-1-AP, Proteintech), rabbit anti-PCNA (1:1000, 10205-2-AP, Proteintech), rabbit anti-HO-1 (1:1000, #82206S, CST), and rabbit antibody to β-Actin (1:2500, #8457, CST) antibodies. The bands were visualized by enhanced chemiluminescence and scanned using FLUORCHEM™ E (ProteinSimple, United States). The densitometric results were quantified using ImageJ software. The results from western blotting were normalized to the control group.

MAPK inhibitor (SB203580) was purchased from Merck-Millipore (Billerica, MA, United States), and PI3K inhibitor (LY294002, ab120243) was purchased from Abcam.

### Statistical Analysis

Data were expressed as mean ± standard error of the mean. One-way analysis of variance was used to analyze the differences

**TABLE 1 |** Survival rates (%) after SMF pretreatment in UFPM-exposed rats with MI.

Groups <sup>a</sup>	SMF dose (mg/kg·d)	Survival rate (%)
Sham	—	66.7
UFPM + MI	—	45.0
UFPM + MI + SMF	1.08	66.7
	2.16	86.7
	4.32	73.3

<sup>a</sup>n = 15 animals per group. SMF, Shengmai formula; UFPM, ultrafine particulate matter; MI, myocardial ischemia.

among the experimental groups. Dunnett's multiple comparison test was used for inter-group comparisons. A *p*-value of less than 0.05 was considered statistically significant.

## RESULTS

### Effects of UFPM Exposure, MI, and SMF on Survival Rates

Survival rates after UFPM exposure and 24 h of MI are shown in Table 1. The survival rate was 45% after UFPM exposure + MI and decreased compared with that in the sham group. Pretreatment with SMF (UFMI + MI + SMF groups) improved survival compared with that in the UFPM + MI group. Survival rates after 1.86, 2.16, and 4.32 mg/kg·d SMF pretreatment were 66.7, 86.7, and 73.3%, respectively.

### MI Size Quantification

As shown in Figures 1B,C, a significant difference in myocardial infarct size was observed between the experimental and control groups. The myocardial infarct size in the UFPM-exposed MI group ( $49.69 \pm 7.167$ ) was significantly larger than that in the sham group ( $10.22 \pm 2.739$ ). Moreover, the infarct sizes were smaller in the SMF-treated groups than in the UFPM-exposed MI group ( $26.29 \pm 9.684$ ,  $19.91 \pm 11.92$ , and  $10.56 \pm 8.197$  in the 1.86, 2.16, and 4.32 mg/kg·d SMF pretreatment groups, respectively). A typical example of a myocardial infarct is shown in Figure 1B.

### Serum Markers of Myocardial Damage

Serum markers of myocardial damage are shown in. LDH levels significantly increased in the UFPM-exposed MI group compared with that in the sham group. However, SMF pretreatment significantly restored the LDH values to close to sham levels (Figure 1D). Furthermore, the CK-MB (212.3 U/L) and cTnT (97.7 pg/ml) levels in the UFPM-exposed MI group were significantly higher than those in the sham group (Figures 1E,F). These values were significantly improved by pretreatment with SMF in the UFPM-exposed MI group. These results indicate that SMF attenuated cardiac injury induced by UFPM exposure and MI.

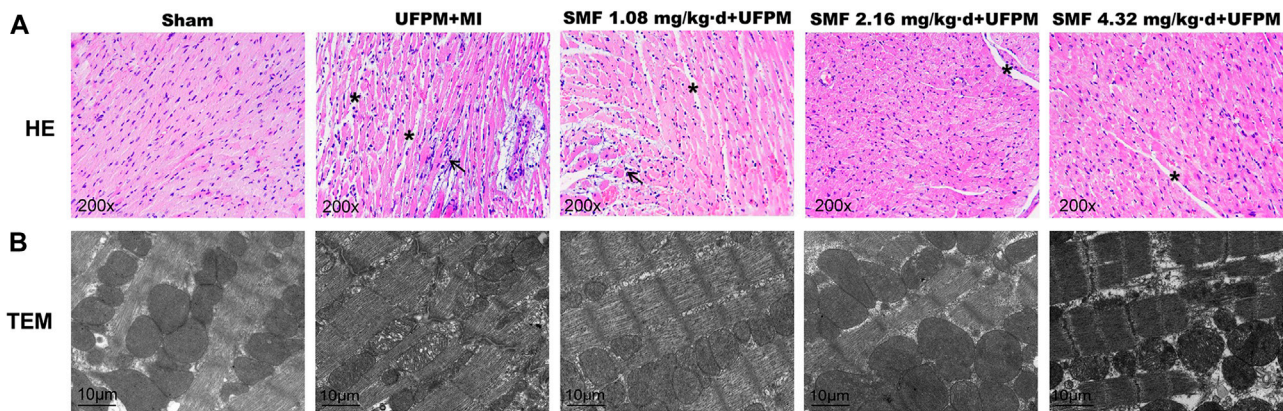

## Histopathological Assessment of Heart Tissues

To evaluate the effects of SMF on cardiac morphology, myocardial sections were stained with H&E (Figure 2A). The myocardial muscle fibers in the sham group were regularly arranged, and no edema was observed between the cells. In contrast, the tissues in the UFPM-exposed MI group exhibited moderate vascular edema, myocardial fiber edema, connective tissue hyperplasia, and enlarged myocardial fibers with inflammatory cell infiltration. These morphological signs of myocardial injury were attenuated in the SMF pretreated groups. Specifically, heart tissues in the low-dose SMF pretreatment group showed local hemorrhage, myocardial fiber edema, red blood cells between the myocardial fibers, and enlarged myocardial fibers with inflammatory cell infiltration. Myocardial tissues in the middle- and high-dose SMF pretreatment groups showed decreased numbers of red blood cells, reduced intracellular gaps between myocardial fibers, and reduced infiltration of inflammatory cells compared with myocardial tissues in the UFPM-exposed MI group.

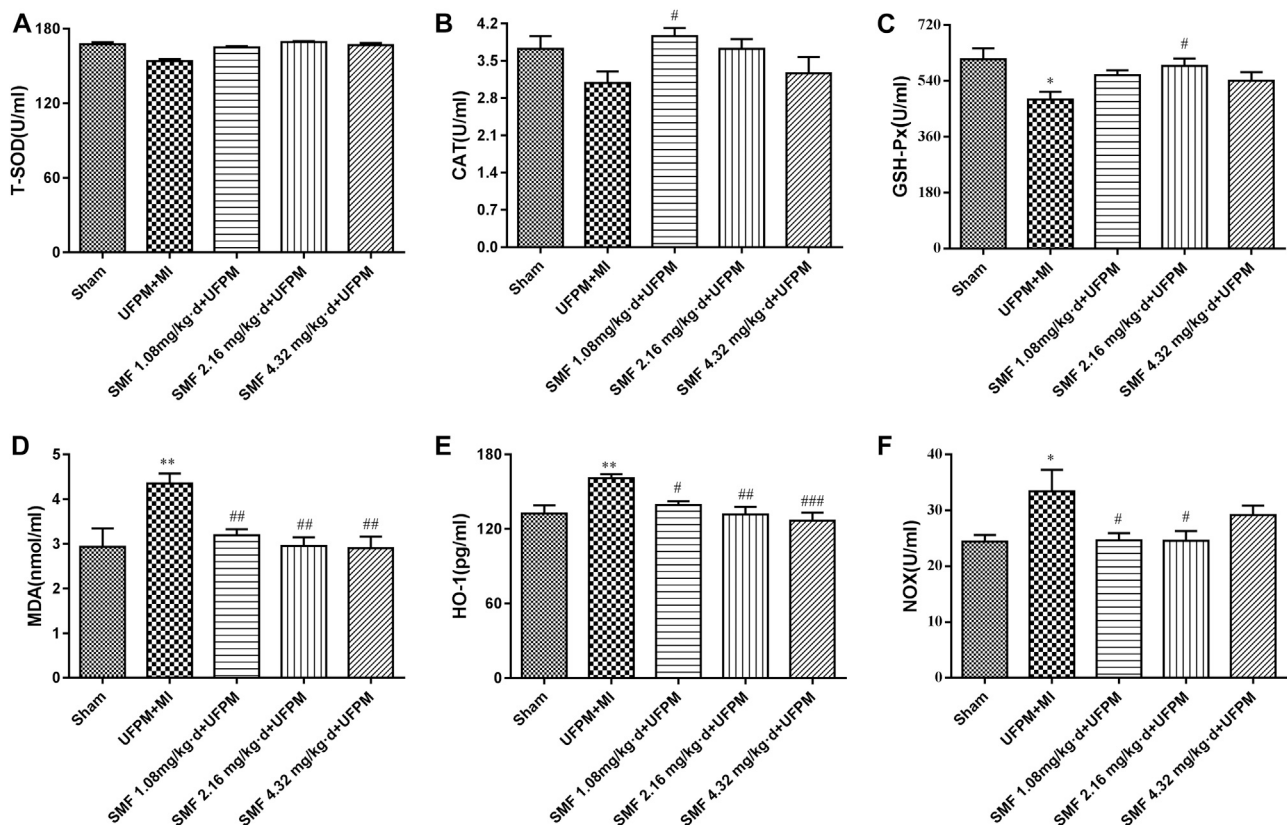

The myocardial ultrastructure in rats in the sham group was generally normal (Figure 2B). The myocardial cells and nuclear membranes were intact, no edema was detected, the myofibril structure was neatly arranged, the mitochondrial structure was intact, the ridges were dense, and no swelling or vacuole-like changes were observed. The myocardial ultrastructure in rats in the UFPM + MI group demonstrated abnormal changes, including edema in some myocardial cells, blurred light and dark bands of muscle segments, broken myofilaments, swollen mitochondria, dissolved ridges, and vacuole-like changes. In the low-dose SMF pretreatment group, the size and number of lesions were reduced. Specifically, myofibrils were neatly arranged, the sarcomere structure was clear, the mitochondria were slightly swollen, and vacuole-like changes were observed in the low-dose SMF group. In the middle-dose SMF group, the size and number of myocardial lesions were also reduced compared with that in the UFPM + MI group, with fewer mitochondrial lesions, neatly arranged myofibrils, and clearly-structured sarcomeres. Moreover, the mitochondrial structure was found to be swollen occasionally and the palate was regular and dense.

### Biomarkers of OS in Heart Tissue

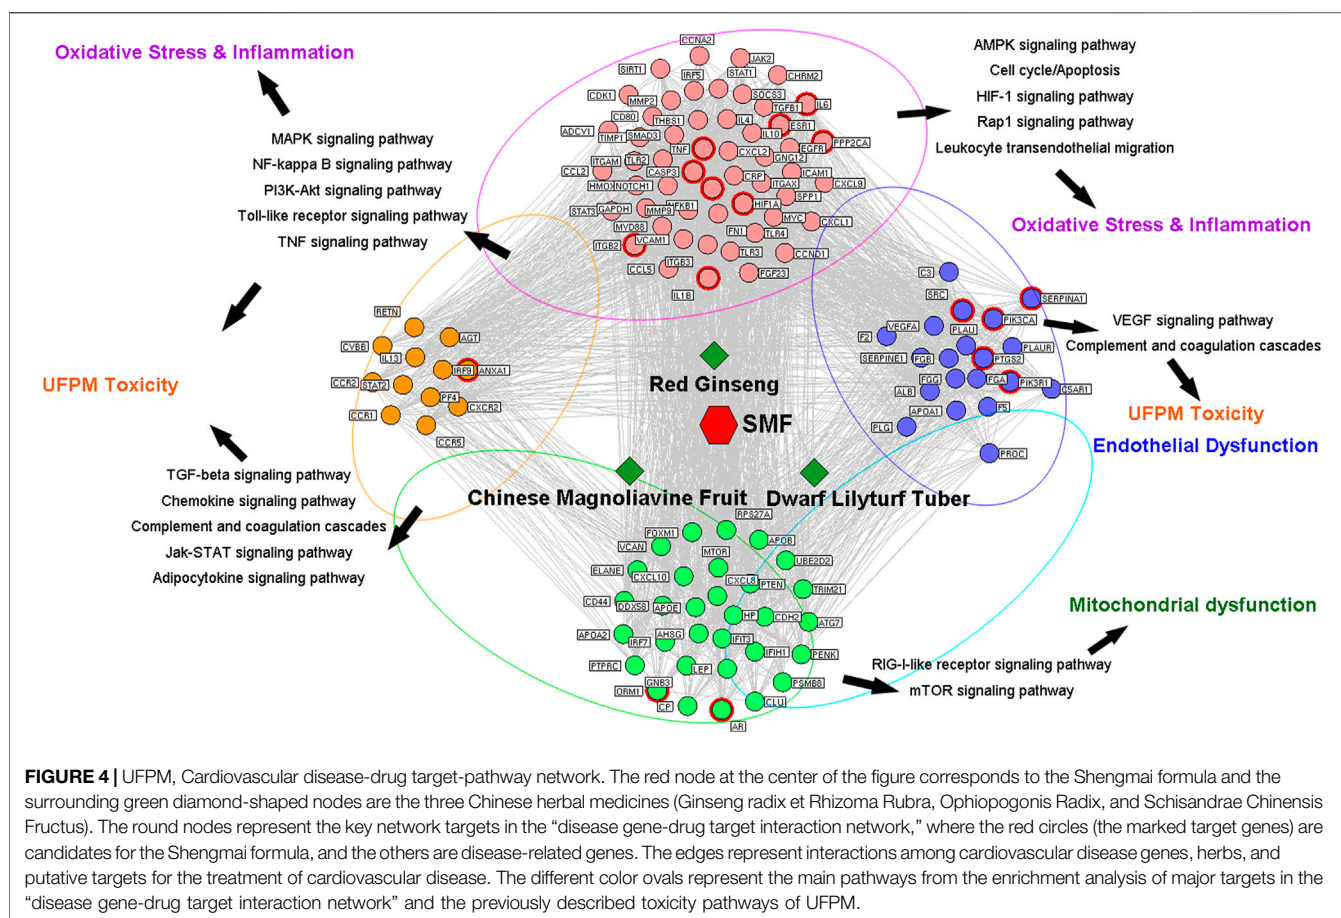

Significant reductions in the levels of T-SOD, CAT, and GSH-Px (lowest levels reaching 13.5, 0.649, and 130 U/mL, respectively) were observed in the UFPM + MI rats compared with that in the sham group (Figures 3A–C). However, SMF pretreatment significantly restored the levels of antioxidant enzymes to those in the sham group. The HO-1, NOX, and MDA levels were increased significantly in the UFPM + MI rats compared with those in the sham group ( $p < 0.05$ ), and these changes were attenuated in the SMF pretreatment groups ( $p < 0.05$ ;  $26.08 \pm 5.0$  vs.  $33.4 \pm 10.8$  for NOX,  $3.01 \pm 0.6$  vs.  $4.36 \pm 0.62$  for MDA), as shown in Figures 3D–F. These results indicate that pretreatment with SMF improves the OS response to UFPM + MI.

**FIGURE 2 |** Protective effects of SMF on toxic changes in myocardial tissues in acute UFPM-exposed rats with MI, as shown by hematoxylin and eosin (H&E) staining and transmission electron microscopy (TEM). Representative images of H&E staining (**A**,  $\times 200$ ) and TEM (**B**, bar = 10  $\mu\text{m}$ ) in myocardial tissues from the sham or MI groups pretreated with different SMF concentrations before UFPM exposure. MI, myocardial ischemia; SMF, Shengmai formula; UFPM, ultrafine particulate matter.

**FIGURE 3 |** Effects of SMF on UFPM-induced oxidative stress in rats with MI. **(A)** T-SOD (total superoxide dismutase), **(B)** CAT (catalase), and **(C)** glutathione peroxidase (GSH-Px) activity were measured in serum from the five experimental groups. **(D)** Malondialdehyde (MDA), **(E)** Heme oxygenase-1 (HO-1), and **(F)** NADPH oxidase (NOX) were analyzed. Data are represented as mean  $\pm$  SEM. \* and \*\*, significant difference from sham group at  $p < 0.05$  and  $p < 0.01$ ; #, ## and ###, significant differences from the UFPM group at  $p < 0.05$ ,  $p < 0.01$ , and  $p < 0.001$ , respectively. MI, myocardial ischemia; SMF, Shengmai formula; UFPM, ultrafine particulate matter.

**FIGURE 4 |** UFPM, Cardiovascular disease-drug target-pathway network. The red node at the center of the figure corresponds to the Shengmai formula and the surrounding green diamond-shaped nodes are the three Chinese herbal medicines (Ginseng radix et Rhizoma Rubra, Ophiopogonis Radix, and Schisandrae Chinensis Fructus). The round nodes represent the key network targets in the “disease gene-drug target interaction network,” where the red circles (the marked target genes) are candidates for the Shengmai formula, and the others are disease-related genes. The edges represent interactions among cardiovascular disease genes, herbs, and putative targets for the treatment of cardiovascular disease. The different color ovals represent the main pathways from the enrichment analysis of major targets in the “disease gene-drug target interaction network” and the previously described toxicity pathways of UFPM.

## Network Pharmacology Analysis

To identify the molecular mechanism by which SMF attenuates myocardial damage in response to UFPM and MI, a UFPM-cardiovascular-drug target-pathway network analysis was performed based on the related proteins and their signaling pathways. Putative targets of SMF, composed of Ginseng radix et Rhizoma Rubra, Ophiopogonis Radix, and Schisandrae Chinensis Fructus, were predicted using the DrugBank database. A total of 475 putative targets for SMF were identified; 376 genes were predicted as putative targets after removing the duplicates (**Supplementary Table S4**). The cardiovascular-related genes were carefully collected from DisGeNET (3,240 genes), HPO (1,018 genes), and TTD (2,398 genes), and previously published research articles (1,347 genes) are listed in **Supplementary Table S5**. Subsequently, 1,343 genes were collected after removing the duplicates. A network was constructed, including the 376 predicted genes and 1,343 cardiovascular-related genes. The cutoff value was set at 0.626, and a total of 1,214 nodes and 6,370 pairs of interactions were included in the network.

The hubs in a network have excessively high levels of node degree and are likely to be major genes. Based on previous studies, we defined a node as a hub if the node degree was more than twice the median degree of all the nodes in the network (Li S. et al., 2007). Consequently, 354 nodes were identified as hubs, and an

interaction network comprising these nodes was constructed (**Supplementary Table S6**). By calculating the topological characteristic values of these nodes based on the hub interaction network (“Degree,” “Node betweenness,” and “Closeness”), the major nodes and key network targets of SMF action were successfully screened, and 116 key network targets were obtained (**Supplementary Table S7**). A pathway enrichment analysis of the above network targets was performed based on the KEGG pathway by combining the UFPM toxicological pathways in cardiovascular diseases (CVDs) and the literature (**Figure 4; Supplementary Table S8**). Among the enriched pathways, the two largest functional modules were OS (PI3K/AKT, MAPK, and AMPK signaling pathways) and inflammation pathways (p53, chemokine, and NOD-like receptor signaling pathways and cytokine-cytokine receptor interactions). The other modules were involved in mitochondrial dysfunction and endothelial dysfunction. For SMF, IL-6, ESRI, PPP2CA, TNF, CASP3, NFKB1, ITGB2, IL-1 $\beta$ , HIF1A, SERPINE1, PIK3CA, PLAUI, PTGS2, PIK3R1, and GNB3 were identified as major targets (red circle in **Figure 4**) that play essential roles in OS and inflammation and were regarded as the key markers of SMF treatment in CVD. Notably, the putative targets of TNF, CASP3, NFKB1, and IL-1 $\beta$  were involved in the p38 MAPK signaling pathway and were strongly associated with the pathological, toxicological, and pharmacological mechanisms

of CVD, UFPM, and SMF, respectively. The p38 MAPK signaling pathway can be stimulated by numerous stress signals, including OS, leading to the production of antioxidants. Based on the integrated UFPM-cardiovascular-drug target-pathway network, we propose that the antioxidant effects of SMF in rats subjected to UFPM exposure and MI are associated with key targets (TNF, CASP3, NFKB1, and IL-1 $\beta$ ) regulating the OS response.

Furthermore, to gain the main chemical composition, we screened candidate compounds and predicted the gene targets of SMF (**Supplementary Table S9**), and an ingredient-target network of SMF was established. After eliminating all duplicate compounds and overlapping targets, SMF yielded 56 candidate compounds and a total of 290 targets were identified (**Supplementary Figure S3**). Specifically, the network included 155 nodes and 268 ingredient-target interactions. In the network, we found that IL-1 $\beta$ , TNF, CASP3, IL-4, FN1 and CCND1, which were involved in p38 MAPK/PI3K/AKT pathway, were targets of Kaempferol, Ginsenoside Rd, Ginsenoside Rf, Ginsenoside Rg1, Ginsenoside Rh2, 20-Glucosylginsenoside Rf, D-Limonene, Geraniol and Citral-B, as highlighted in **Supplementary Figure S3**. Additionally, by HPLC-MS assay, we identify the main chemical components of SMF, including Ginsenoside Rf, Ginsenoside Rg1, Ginsenoside Rh2, which were described above. Thus, we speculate that Ginsenoside Rf, Ginsenoside Rg1, Ginsenoside Rh2 could be the main chemical composition by which SMF play its protection roles *via* PI3K/AKT/p38 MAPK/Nrf2 pathway.

## Experimental Validation

### Evaluation of H9C2 Cell Viability After UFPM Exposure and SMF Treatment

H9C2 cells were exposed to various concentrations of UFPM, and alterations in cell viability were observed using the CCK8 assay. A dose-dependent decrease in cell survival was observed following UFPM exposure (**Supplementary Figure S4A**). Cells exposed to high doses of UFPM (50, 100, and 200 mg/ml) demonstrated significant reductions in cell viability ( $p < 0.05$ ). The cell survival rate after 100  $\mu$ g/ml UFPM exposure was approximately 57%. This group was selected for subsequent *in vitro* studies.

To examine the functional role of SMF, H9C2 cells were pretreated with 0.28, 0.56, 1.12, and 2.24 mg/ml SMF before UFPM exposure and cell viability was measured (**Supplementary Figure S4B**). Pretreatment with SMF resulted in significantly improved viability in UFPM-treated cells (concentrations 0.28, 0.56, and 1.12 mg/ml) compared with the vehicle ( $p < 0.05$ ).

### SMF Suppresses UFPM-Induced ROS Production in H9C2 Cells

UFPM induces ROS generation to promote OS. Therefore, we examined whether SMF could decrease ROS generation and the expression levels of ROS-dependent genes. First, we detected ROS by H2DCF-DA staining. **Supplementary Figure S4C** shows that the ROS levels in the H9C2 cells after UFPM exposure were significantly higher than those in the control cells. This effect was attenuated by SMF.

### SMF Attenuated UFPM-Induced Mitochondrial Damage in H9C2 Cells

Previous studies showed that UFPM-induced OS promoted changes in the MMP. As shown in **Figures 5A,B**, JC-1 exhibited a monomeric form in UFPM-exposed cells and  $\Delta\psi_m$  significantly decreased ( $p < 0.05$ ). Compared with that in the UFPM group, the red fluorescence intensity in the SMF group increased and the green fluorescence intensity decreased. The red/green fluorescent signal ratios in the control and UFPM cells were  $1.109 \pm 0.39$  and  $0.50 \pm 0.09$ , respectively, whereas the signal in the SMF (1.12 mg/ml) + UFPM group was  $0.6935 \pm 0.22$  (**Figure 5B**).

To determine whether the SMF-induced attenuation of mitochondrial dysfunction in UFPM-treated cells was followed by functional changes in energetics, the Seahorse assay was used. We found that SMF increased OCR levels markedly under basal conditions (UFPM control,  $33.63 \pm 2.11$  pmol/min; 0.56 mg/ml SMF,  $40.11 \pm 3.09$ ; **Figure 5C**) and increased proton leak (UFPM control,  $6.073 \pm 0.79$ ; 0.28 mg/ml SMF,  $9.87 \pm 0.58$ ; **Figure 5D**), ATP production (UFPM control,  $25.18 \pm 1.07$ ; 0.28 mg/ml SMF,  $30.68 \pm 2.16$ ; **Figure 5E**), and non-mitochondrial respiration (UFPM control,  $31.34 \pm 2.01$ ; 0.56 mg/ml SMF,  $39.61 \pm 4.69$ ; **Figure 5F**) compared with that in UFPM-exposed cells.

### PCR Array

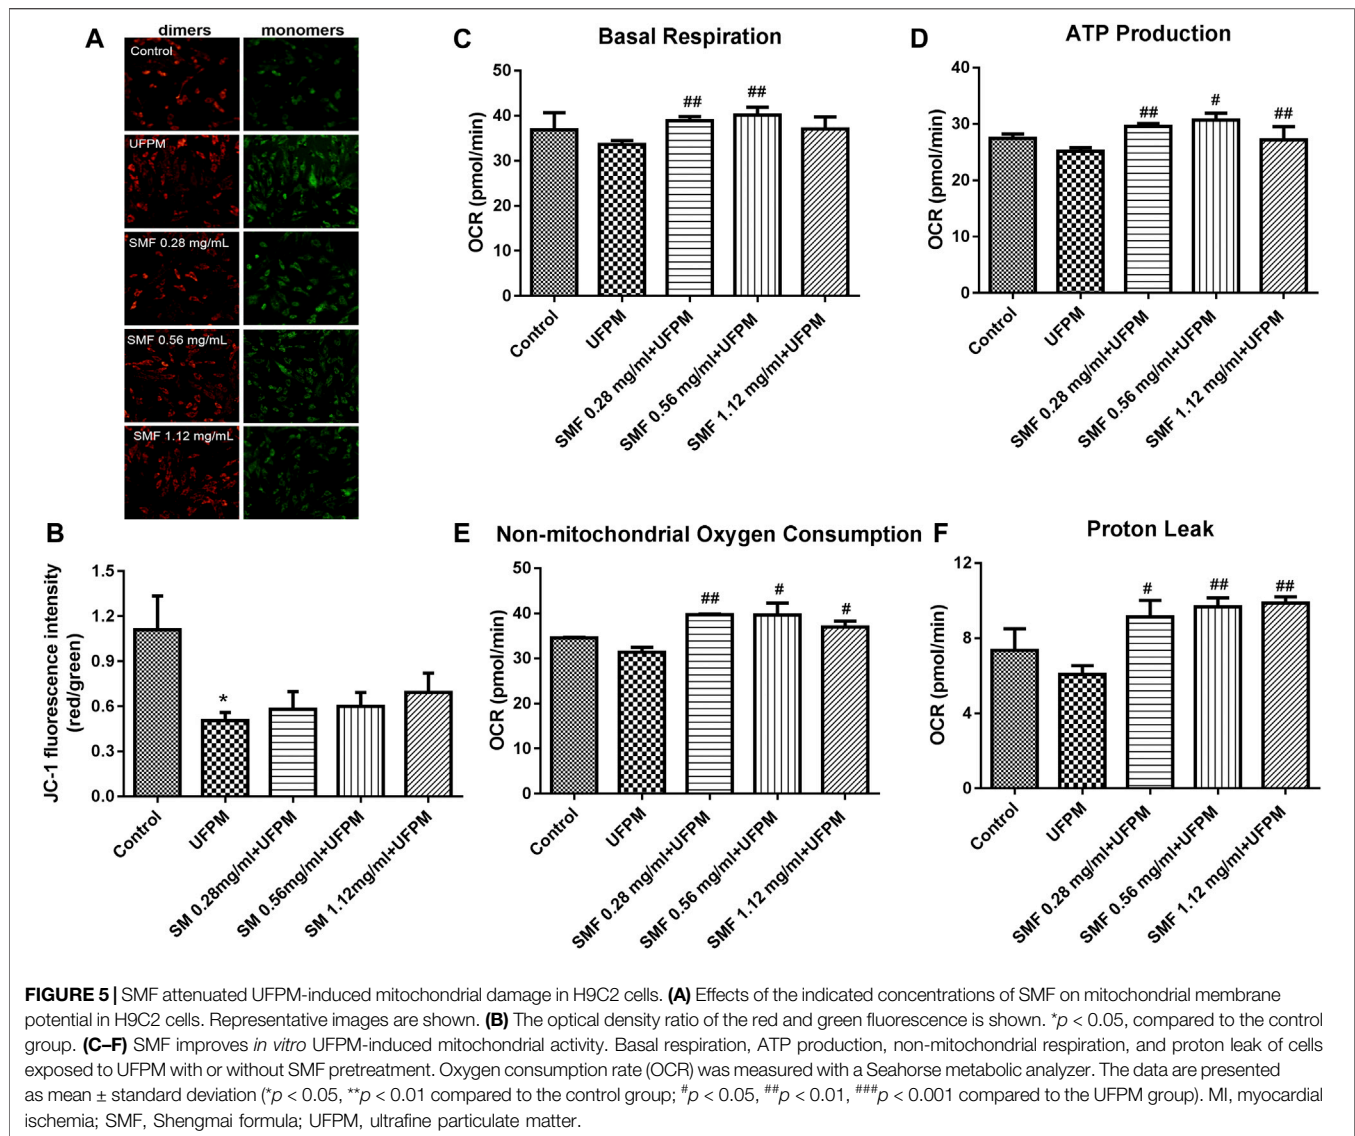

Changes in the expression levels of several OS-associated genes were evaluated (**Figures 6A,B**). Of the 84 genes assayed in the array, the expression levels of two changed at least 2-fold (*Cyba* and *Ucp3*) and those of five changed 0.5-fold (*Cat*, *Gstk1*, *Cygb*, *Idh1*, and *Sqstm1*) in the UFPM-exposed MI rats compared with those in the sham control rats (**Table 2**). The expression levels of *Cat*, *Mb*, *Ucp3*, and *Txnrd2* were upregulated and the expression levels of *Txn1* and *Cyba* were downregulated in the SMF treatment group compared with those in the UFPM-exposed MI rats ( $p < 0.05$ ; **Table 3**). The genes that exhibited opposite expression patterns in the drug and UFPM model groups were termed contrary genes (*Cat*, *Gstk1*, and *Cyba*). RT-qPCR was performed using these contrary genes to validate the results obtained by the PCR array analysis (**Figures 6C,D**). Trends in the expression levels of these genes confirmed that SMF treatment can maintain oxidative homeostasis.

### Involvement of the p38 MAPK, PI3K/AKT, and Nrf2/HO-1 Pathways

We examined the effect of UFPM and SMF on p38 MAPK and PI3K/AKT signaling by measuring the expression levels of phosphorylated (p)-p38 MAPK and AKT in H9c2 cells (**Figures 7A,C**). The expression levels of p-p38 MAPK and p-AKT were significantly higher in the UFPM-treated group than in the untreated cells (**Figures 7B,D**;  $p < 0.001$  and  $p < 0.01$ , respectively). Conversely, treatment with SMF significantly reduced p-p38 MAPK and p-AKT levels compared with those in the UFPM group ( $p < 0.05$ ).

Nrf2/HO-1 is a positive downstream pathway of MAPK and PI3K. We investigated the potential effects of SMF on Nrf2/HO-1 in H9c2 cells by western blot analysis. UFPM exposure resulted in

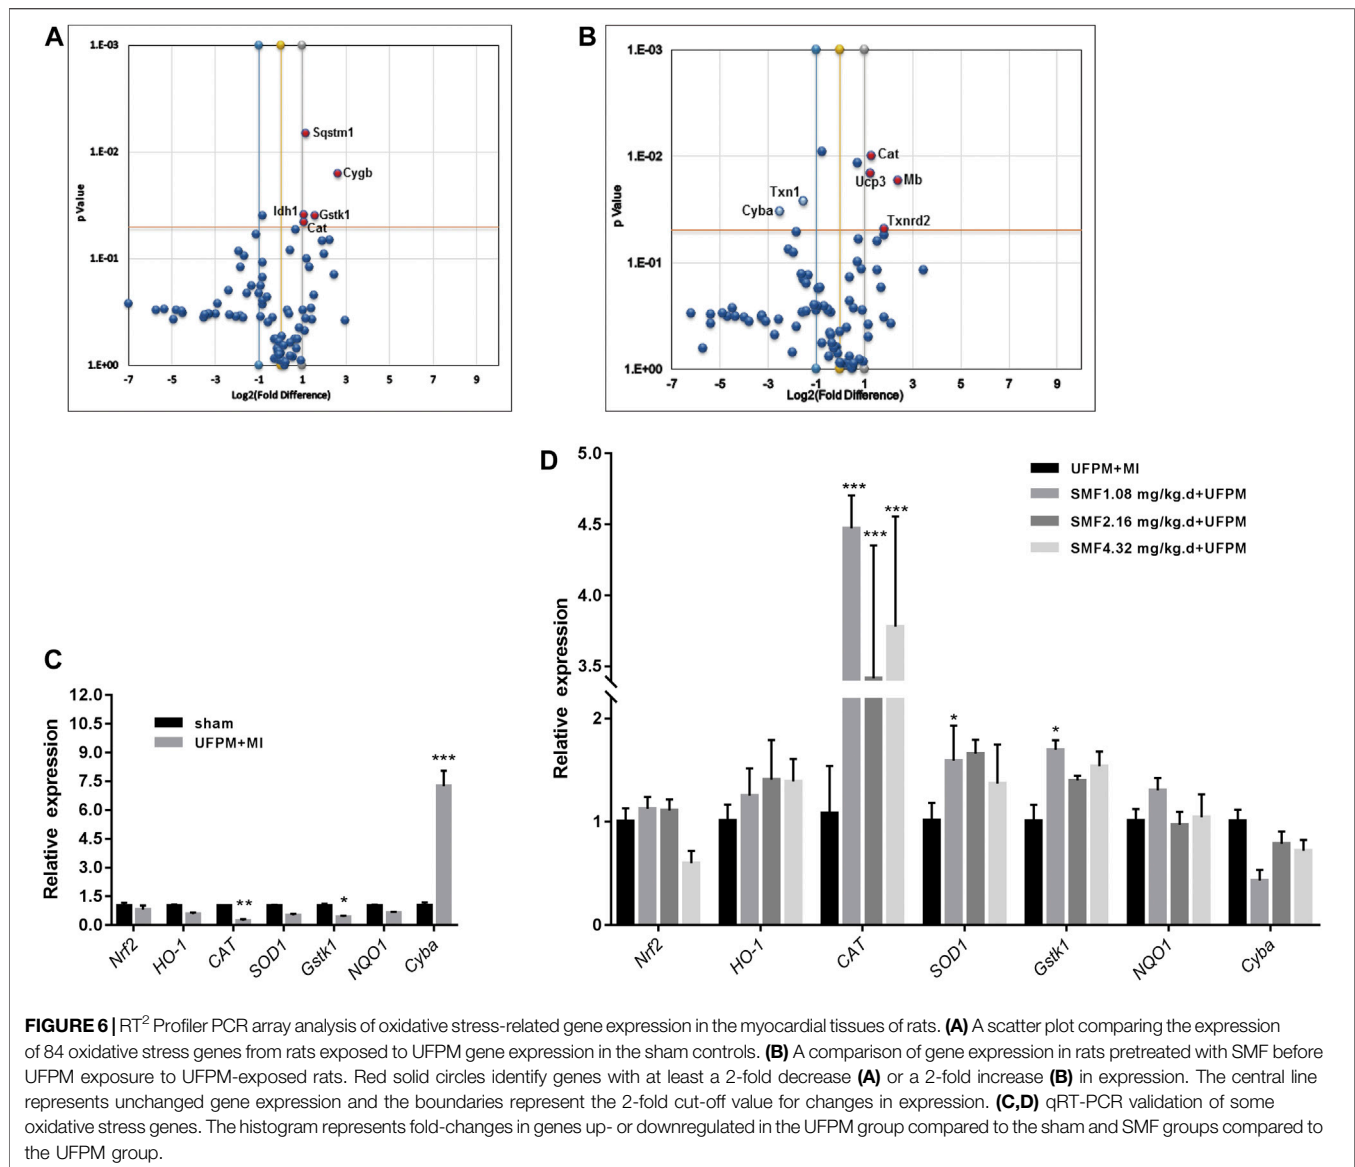

a considerable increase in the protein expression of HO-1 and nuclear Nrf2 ( $p < 0.01$ ; **Figures 8A,B**). SMF treatment further increased HO-1 and Nrf2. The effects of p38 MAPK (SB 203580) and PI3K (LY294002) inhibitors on Nrf2/HO-1 expression were evaluated in H9c2 cells. As shown in **Figures 8A,B**, UFPM + SB203580/LY294002 treatment significantly decreased HO-1 and nuclear Nrf2 expression levels compared with those in the UFPM-exposed group ( $p < 0.001$ ). However, SMF treatment significantly reversed this decrease ( $p < 0.01$  and  $p < 0.05$ , respectively). These results suggest that UFPM can act as a stimulating factor for the translocation of free Nrf2 into the nucleus to increase the expression of antioxidant-stress proteins, while SMF can promote this activation. However, inhibitors of p38 MAPK and PI3K prevented these effects.

The combination of UFPM and SB203580/LY294002 significantly increased the levels of T-SOD, CAT, GSH-Px and reduced the level of NOX in the medium compared to UFPM exposure without inhibitors (**Figures 8C–I**). In contrast, when

SMF was added to UFPM and SB203580/LY294002 treatment, the level of GSH-Px in the medium decreased (**Figures 8E,H**), compared with that in the SMF and UFPM treatment (without the inhibitors) ( $p < 0.01$ ). Furthermore, SMF + SB203580/LY294002 administration increased the levels of the NOX factors in UFPM-exposed H9c2 cells compared with SMF treatment alone (**Figures 8F,I**), suggesting a slight reversal in the effect of SMF on the expression of NOX factors. These findings indicate that SMF exerts antioxidative effects on UFPM-induced H9c2 cells *via* the PI3K/AKT and p38 MAPK pathways.

## DISCUSSION

In this study, we showed that SMF treatment can protect cells against UFPM-induced myocardial injury and OS events both *in vitro* and *in vivo*. In addition, UFPM exposure induced ROS

production, which activated the p38 MAPK/PI3K pathway, increased the expression levels of Nrf2/HO-1, and decreased the expression of antioxidative proteins. In contrast, SMF attenuated the UFPM-induced activation of MAPK/PI3K and

increased the expression level of Nrf2, resulting in increased expression of HO-1 and antioxidative proteins.

In the present study, we analyzed the effect of acute exposure to UFPM on cardiovascular endpoints. The toxicity of PM can

influence remote organs, including the heart (Du et al., 2016). The intratracheal instillation method used in the present study is regarded as an efficient method for the delivery of foreign substances (Driscoll et al., 2000). The dosage of UFPM used in the current study was similar to the dosage in previous studies involving rat models exposed to PM (Adams et al., 2019).

Our data show that acute exposure to UFPM causes significant myocardial damage characterized by increased myocardial infarct size, increased serum CK-MB and cTnT, and histopathological

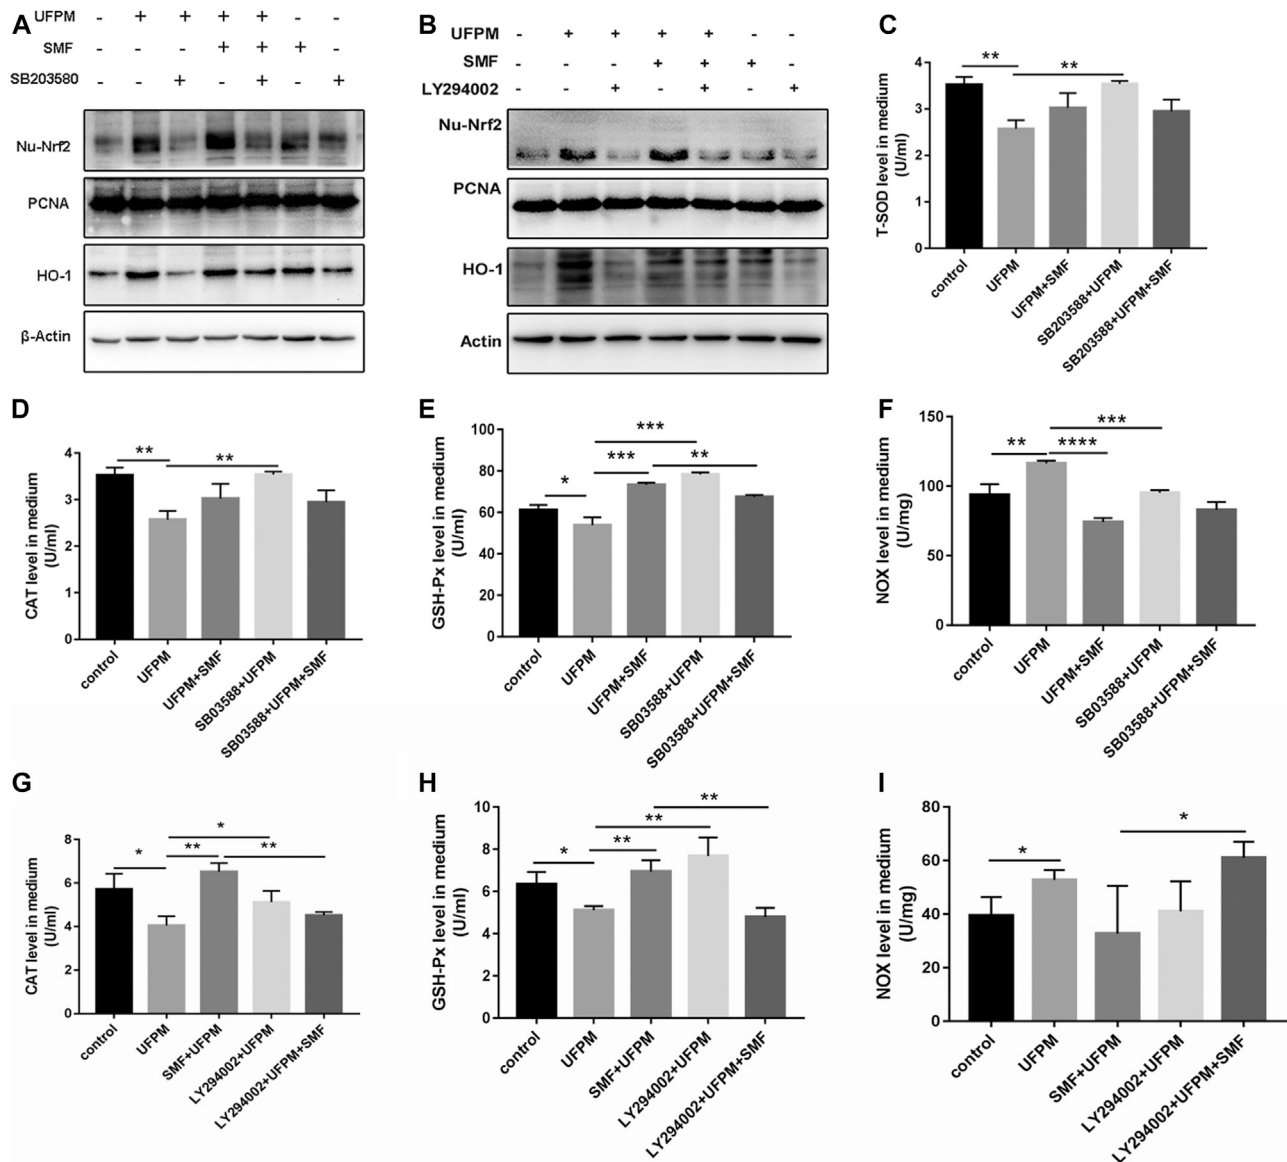

injury to the heart. In the present study, exposure to UFPM resulted in cardiomyocytedamage and mitochondrial dysfunction. In addition, the appearance of hyperplastic connective tissue and increased inflammatory cells suggested that UFPM exacerbates myocardial tissue injury leading to myocardial fiber edema. This may explain the low survival rate after MI in rats and the increased cardiovascular events accompanying urban air pollution. In addition, we examined cTnI, LDH, and CK-MB levels in serum, as specific markers of myocardial damage. The levels of these myocardial damage markers were higher in rats after UFPM exposure and MI compared with sham rats, supporting the involvement of UFPM in myocardial dysfunction. Published studies also demonstrate that PM<sub>2.5</sub> exposure aggravates myocardial damage in hyperlipidemia rats (Wang et al., 2019).

The mechanisms by which UFPM induces cardiac damage remain unclear. UFPM may affect extra-pulmonary sites via inflammatory factors produced in the lung and secreted into the circulation (Thomson, 2019). Alternatively, UFPM may avoid the normal defenses of the lungs and gain access to the heart or brain (Du et al., 2016). However, one study showed that OS plays a critical role in the toxic mechanism of UFPM; UFPM may induce the formation or aggregation of free radicals (Yang et al., 2014).

In our study, UFPM exposure and MI significantly modified the OS status in rats, as indicated by increased MDA and NOX. Meanwhile, in our *in vitro* study, elevated levels of ROS were

**FIGURE 7 |** SMF inhibits UFPM-induced p38 MAP kinase and PI3K/AKT activation. H9C2 cells pre-incubated with either medium or SMF (1.12 mg/ml) for 24 h were stimulated with UFPM (50 mg/ml) for 6 h. The lysates from H9C2 were analyzed by western blotting using specific antibodies to (A) phospho-p38 MAP kinase (p-p38 MAPK) and (B) p-AKT. The cells were cultured with medium (lane 1), SMF (lane 2), UFPM (lane 3), and UFPM and SMF (lane 4). Fold increases in amounts of phosphorylated p38 MAP kinase proteins are indicated. The amounts of p-p38 MAPK and p-AKT were quantified using NIH Image Analyzer and are shown as the amounts relative to control cells. Three identical experiments were independently performed providing similar results.

**FIGURE 8 |** SB 203580, LY294002 and SMF inhibit UFPM-induced HO-1 and Nrf2 expression and T-SOD, CAT, NOX, and GSH-Px production. H9C2 pre-incubated with medium or SB 203580 (10 mM) for 60 min and LY294002 (50  $\mu$ M) for 4 h were cultured with medium or SMF for 24 h, and then treated with or without UFPM (50 mg/ml) for 6 h (**A,B**) Western blot analysis of HO-1 and Nrf2 expression in cells. T-SOD (**C**), CAT (**D,G**), GSH-Px (**E,H**), and NOX (**F,I**) concentrations in the culture supernatants were determined 6 h after UFPM exposure. The results are expressed as the mean  $\pm$  SD of three different experiments. Asterisks indicate significant differences by *t*-test, \**p* < 0.05, \*\**p* < 0.01, \*\*\**p* < 0.001.

observed in the H9C2 cells exposed to UFPM, consistent with an imbalance in the oxidation/reduction observed in our *in vivo* study. A previous study demonstrated a significant difference in the expression levels of MDA, CAT, and GSH-Px in lung tissues of PM<sub>2.5</sub>-treated mice compared with saline-treated control mice (Huang et al., 2019). Similar increases in the levels of HO-1 and NOX in the lung and heart have been reported after particle exposure in rats; the differences were dependent on particulate size (Aztatzi-Aguilar et al., 2015). However, contrary to our findings, a recent study by OG Aztatzi-Aguilar reported a significant increase in SOD2 mRNA expression in the aorta of

rats exposed to PM when compared to those in the filtered air group (Aztatzi-Aguilar et al., 2018). One explanation for this discrepancy is that the mRNA expression of SOD2 might have been elevated at the beginning of PM exposure in the previous study to increase the anti-oxidation ability of the myocardial cells and resist free radical damage.

The poor outcomes in response to MI in the current study may be due to the development of pulmonary artery hypertension (PAH) after UFPM exposure. PAH disturbs cardiac function. This is consistent with the findings of a previous study, which showed the general cytotoxicity of PM arising from different

areas, possibly due to the similarities in the species used in the studies (Bein and Wexler, 2015). Several mechanisms may explain PAH-induced toxicity, including antioxidant defense impairment and OS (Holme et al., 2019). The antioxidant system attenuates oxidative injuries. Natural antioxidants have received increased attention over the past ten years. The effective biological activities of natural antioxidants are crucial during conditions that cause OS, such as air pollution (Zhang and Gao, 2014).

SMF is a known potent antioxidant agent; however, the protective effects of SMF on UFPM-induced cardiac damage/OS have not been reported. In the current study, SMF increased the survival rate in rats subjected to UFPM exposure and MI, suggesting that UFPM exposure-induced cardiotoxicity can be reversed by SMF. Cardiac dysfunction after UFPM exposure and MI impacted the survival rate and administration of SMF, which is beneficial in improving the heart function, improved the survival rate (Zhao et al., 2016).

Myocardial infarct size is a key prognostic factor in a wide range of adverse cardiovascular outcomes. Although there is little direct evidence for the induction of cardiac ischemia following exposure to UFPM in humans, experimental animal models have demonstrated an association between PM exposure and infarct size and/or MI. The results of the present study showed that SMF, administered 24 h after an acute single intranasal instillation of UFPM, significantly decreased the myocardium infarct size, indicating a significant recovery of myocardial function in rats with MI. This effect was further demonstrated by measuring LDH, CK-MB, and cTnT levels in the serum and the histopathological evaluation of the myocardial tissue. A previous study reported that three representative components in SMF showed significant protective effects on cardiac function after MI injury (Mo et al., 2015; Li et al., 2018). Thus, our results can be ascribed to specific components of SMF that interact in a complex way to regulate LDH, CK-MB, and cTnT activities. Further assessment is needed to connect the specific chemical components and biological activities.

As described above, UFPM disrupted OS status both in the MI rat model and in H9C2 cells. The disrupted OS status was signified by an imbalance of oxidative markers, mitochondrial membrane potential, and energy metabolism, while SMF prevented these outcomes. These results corroborate the findings of Zhu et al. (2019) (Zhu et al., 2019) demonstrating that the decreased levels of SOD, GSR, and CAT induced by H<sub>2</sub>O<sub>2</sub> were upregulated following SMF treatment. The current study provides evidence that co-treatment with SMF in UFPM-exposed MI rats protected the heart from OS injury. Notably, the protective effects of SMF against UFPM-induced cardiotoxicity were not dose-dependent in the present study. This may be because differences in the selected doses in the current study were not large enough; hence, differences in the protective effects of SMF could not be detected.

Because SMF significantly attenuated UFPM effects in the serum and myocardial tissue, we hypothesized that multiple signaling pathways play a key role in the protective effects of SMF in rats exposed to UFPM and MI. To confirm this hypothesis, a herb-major hub-CVD disease-UFPM toxicity-

pathway network was constructed to visualize the relationships among SMF herbs, major targets, CVD disease, and PM toxicity. Based on the integrated network-pathway analysis, SMF exerts antioxidant effects by regulating OS, which was identified as an important mechanism involved in UFPM toxicity and MI progression (Li et al., 2005; Kurian et al., 2016). OS was regulated *via* the PI3K/AKT signaling pathway, which was an important functional module with a high enrichment score in our study. In addition, the p38 MAPK pathway had a higher number of genes that were significantly affected but had low enrichment scores. We choose the p38 MAPK pathway based on the findings of previous studies. Austin Nguyen (2019) showed that inter-gene correlation could affect the enrichment score resulting in a pathway with lower expression values but more significantly affected genes (Austin Nguyen, 2019). Furthermore, PM causes a time- and dose-dependent increase in the phosphorylation of p38 MAPK in human pulmonary artery endothelial cells (Li et al., 2005). Marchini et al. (2016) showed that acute exposure to PM increased the levels of TNF- $\alpha$ , IL-6, and IL-1 $\beta$ , increased the ratio of active Caspase 3/pro-Caspase 3, and activated the NF $\kappa$ B pathway (Marchini et al., 2016; Li X. et al., 2017). TNF, CASP3, and NF $\kappa$ B1, which are among the key targets of SMF, are involved in p38 MAPK signaling. In addition, TNF, CASP3, and NF $\kappa$ B1 are targets of Ginseng radix et Rhizoma Rubra, Ophiopogonis Radix, and Schisandrae Chinensis Fructus, suggesting that these three targets play important roles in SMF action.

Because the OS response was also observed in the network analysis, the RT<sup>2</sup> Profiler PCR array of myocardial tissue was designed to analyze a panel of genes related to the OS pathway. Our findings were in agreement with the detection of CAT in the serum of MI rats. A similar study also reported that SMF injection restored the mRNA expression of CAT after suppression by H<sub>2</sub>O<sub>2</sub> (Zhu et al., 2019). Furthermore, the present study showed that SMF downregulated the gene expression of Cyba, which was consistent with a dramatic decrease in NOX levels in the serum of PM-treated MI rats. Cyba encodes a subunit of NOX. Thus, downregulation of Cyba reflected the decrease in myocardial OS after SMF treatment. NOX4 is highly expressed in cardiomyocytes and NOX4 activation causes cardiac dysfunction (Lassegue et al., 2012). Therefore, decreased myocardial NOX in the serum and myocardial tissue might help maintain myocardial function, supporting the protective effects of SMF in UFPM-induced oxidative injury. Additionally, the mRNA level of the antioxidant enzyme T-SOD was upregulated after SMF treatment in myocardial tissues of rats subjected to UFPM exposure and MI, in agreement with elevated serum T-SOD.

To further investigate the effects of SMF on the regulation of the OS pathways, we evaluated the p38 MAPK and PI3K/AKT pathways based on the net pharmacological data. UFPM induced the phosphorylation of p38 MAPK and AKT, decreased the levels of antioxidative factors such as GSH-Px, T-SOD, and CAT, and increased NOX production in H9C2 cells. These effects were prevented by SMF treatment. Nrf2 is activated under OS conditions and promotes the expression of numerous antioxidative enzymes such as T-SOD, CAT, and GSH-Px.

Subsequently, protein expression levels of Nrf2/HO-1 were increased in response to SMF in H9C2 cells exposed to UFPM. However, Nrf2/HO-1 levels were also increased in the UFPM-exposed cells, which may be due to the specific components of UFPM and the stress response to acute UFPM exposure. Both SB 203580 and LY294002, specific inhibitors of p38 MAPK and PI3K, respectively, restored the inhibition of UFPM-induced NOX formation and the promotion of GSH-Px and CAT levels in SMF + UFPM-treated H9C2 cells. Meanwhile, SB 203580 and LY294002 decreased the expression levels of Nrf2/HO-1 in SMF + UFPM-treated H9C2 cells. Therefore, we speculated that p38 MAPK and PI3K/AKT might be involved in UFPM-induced OS. Our findings are in line with a previous report, which showed that the PI3K/AKT and p38 MAPK signaling pathways regulate HO-1 expression in RAW264.7 macrophages during anti-inflammatory responses (Li T. et al., 2017). Additionally, our data are consistent with previous studies, which showed the beneficial antioxidant effects of SMF on H<sub>2</sub>O<sub>2</sub>-induced oxidative injury (Zhu et al., 2019) and cerebral oxidative damage in rats (Ichikawa et al., 2003). Based on the findings that UFPM activated both p38 MAPK and PI3K/AKT, while their inhibitors and SMF inhibited these effects, we assume that the regulation of HO-1 expression and antioxidant proteins is controlled by the PI3K/AKT/p38 MAPK/Nrf2 pathways.

This study presents limitations. We have used the TTC staining method to measure the infarct size of MI rats. However, the normalized of area under ligation should be quality controlled by expressing infarct vs area at risk (AAR) by evan blue dye staining. We make sure that infarct size measurement will be normalized to AAR by evan blue dye staining in our following study. For cardiac injury analysis, flipped LDH combined with cTNT, CK-MB will be used in subsequent study rather than total LDH used in this study. In addition, an *in vitro* cell culture model related to MI and UFPM could be advantageous and the best way to present the signaling activation in animal model is to perform western blot analysis using heart tissue homogenate from animal treated with LY294002 or SB203580. Actually, we have tried to establish cell model about MI by hypoxia stimulation, however, most cells with hypoxia were dead after UFPM exposure due to the extremely harsh conditions. Considering that UFPM and MI can both produce the same toxicological effects, i.e., oxidative stress, therefore, we established the *in vitro* model which can reflect the oxidative stress injury by UFPM exposure to be maximally approximation to the true state of *in vivo* study. Meantime, we will perform western blot analysis using heart tissue homogenate from animal treated with LY294002 or SB203580 in our following study. Again, we will analysis mitochondrial respiration in isolated mitochondria from heart tissue of rat exposed to UFPM prior to LAD ligation for demonstrating mitochondrial respiration dysfunction directly.

In conclusion, the present study demonstrated that exposure to UFPM induced myocardial damage and mitochondria dysfunction, increased MDA, and decreased the levels of antioxidant factors in rats with MI. Pretreatment with SMF significantly relieved the cardiac-linked pathologies, inhibited the release of MDA and NOX, elevated the levels of antioxidant factors, and prevented the cardiovascular effects mediated, in part, by the PI3K/AKT/p38 MAPK/Nrf2 signaling pathway. Our results indicate that SMF is a potent antioxidant that protects against the deleterious effects of UFPM in the heart. SMF may be used to prevent and treat the cardiovascular events caused by UFPM exposure.

The occurrence of lipotoxicity during obesity-associated cardiomyopathy is detrimental to health. Salvianolic acid A (SAA), a natural polyphenol extract of *Salvia miltiorrhiza* Bunge (Danshen in China), is known to be cardioprotective. However, its clinical benefits against obesity-associated cardiomyocyte injuries are unclear. This study aimed at evaluating the protective effects of SAA against lipotoxicity-induced myocardial injury and its underlying mechanisms in high fat diet (HFD)-fed mice and in palmitate-treated cardiomyocyte cells (H9c2). Our analysis of aspartate aminotransferase and creatine kinase isoenzyme-MB (CM-KB) levels revealed that SAA significantly reversed HFD-induced myocardium morphological changes and improved myocardial damage. Salvianolic acid A pretreatment ameliorated palmitic acid-induced myocardial cell death and was accompanied by mitochondrial membrane potential and intracellular reactive oxygen species improvement. Analysis of the underlying mechanisms showed that SAA reversed myocardial TLR4 induction in HFD-fed mice and H9c2 cells. Palmitic acid-induced cell death was significantly reversed by CLI-95, a specific TLR4 inhibitor. TLR4 activation by LPS significantly suppressed SAA-mediated lipotoxicity protection. Additionally, SAA inhibited lipotoxicity-mediated expression of TLR4 target genes, including MyD88 and *p*-JNK/MAPK in HFD-fed mice and H9c2 cells. However, SAA did not exert any effect on palmitic acid-induced SIRT1 suppression and *p*-AMPK induction. In conclusion, our data shows that SAA protects against lipotoxicity-induced myocardial damage through a TLR4/MAPKs mediated mechanism.

**Keywords:** salvianolic acid A, lipotoxicity, myocardial injury, TLR4, MAPKs

## INTRODUCTION

Obesity is a global epidemic that is characterized by excessive amounts of circulating free fatty acids (FFAs), resulting in a variety of metabolic disorders, including lipotoxic cardiomyopathy (Schrammel et al., 2013). Lipotoxicity occurs when FFAs form heterotopic deposits in non-adipose tissues, including the kidney, skeletal muscles, and liver (Sletten et al., 2018). Lipotoxicity-induced myocardial damage accelerates advanced heart disease development. Palmitic acid (PA), the most abundant saturated fatty acid in human diet, has been found to be significantly elevated in blood samples of both obese individuals and high-fat diet (HFD) -fed animals (van Rooijen and Mensink, 2020). Therefore, PA is widely used to induce lipotoxicity *in vitro*.

Although the mechanisms underlying obesity-associated cardiac dysfunction are not fully understood, several factors, including toll-like-receptor 4 (TLR4) have been implicated. TLR4 is a well-known activator of innate immune responses against pathogens and has recently been shown to mediate obesity-induced cardiac inflammation, glucose metabolic derangement and injury (Jackson et al., 2015; Chen et al., 2020; Liu et al., 2020). Palmitate is an endogenous TLR4 ligand that significantly upregulates TLR4 levels in hepatocytes (Dou et al., 2020). Palmitate also enhances TLR4 expression in cardiomyocytes (Wang et al., 2017). Studies on HFD-induced obesity have shown that myocardial damage is significantly alleviated by TLR4 depletion (Wang et al., 2017). MyD88 is an adapter protein that mediates TLR4 signal transduction and activation of mitogen-activated protein kinase (MAPK) signaling pathway. MyD88 or MAPKs (including JNK and ERK1/2) inhibition has been shown to improve lipotoxicity-induced cardiac injury in both obese mice and cultured cardiomyocytes (Liu et al., 2014; Wang et al., 2016). Additionally, adenosine monophosphate activated protein kinase (AMPK), a key cellular energy sensor, has been implicated in HFD-induced cardiac hypertrophy, palmitate-induced apoptosis, and cardiomyocytes lipid deposit (Gélinas et al., 2018; Yang et al., 2018; Zhang et al., 2019). AMPK activation inhibits myocardial hypertrophy by regulating energy metabolism through sirtuin 1 (SIRT1) (Ma et al., 2018).

*Salvia miltiorrhiza* Bunge (Danshen in China) is a Chinese medicinal herb that has traditionally been used for the treatment of cardiovascular diseases. Salvianolic acid A (SAA) is the main water-soluble component of Danshen. It has been established that SAA has a range of pharmacological effects, including anti-oxidant, anti-inflammatory, anti-fibrotic, and anti-carcinogenic activities (Yang et al., 2012; Zheng et al., 2015; Wang et al., 2019a). Animal models have shown that SAA is cardioprotective, including during ischemic-reperfusion, cardiomyocyte infarction, and arsenic trioxide-induced injury (Ho and Hong, 2011; Feng et al., 2017; Wang et al., 2019b). However, its clinical benefits against lipotoxicity-induced myocardial damage have not been established.

In this study, we investigated the clinical benefits of SAA against lipotoxicity-induced cardiac injuries in both HFD-induced obese mice and palmitate-exposed cardiomyocytes.

Our findings highlight the potential therapeutic values of SAA in the prevention and treatment of obesity-associated myocardial damage.

## MATERIALS AND METHODS

### Animals Studies

Animal care and experiments complied with National Institute of Animal Health guidelines on animal research. Ethical approval was granted by the Animal Ethics Committee at Zhejiang Chinese Medical University. Eight-week old male C57BL/6J mice were housed at  $22 \pm 2^\circ\text{C}$  and 12-h light/dark cycle. Animals were divided into the following groups (6 mice each); normal diet group (Control), HFD group (HFD), normal diet with 40 mg/kg BW SAA group (SAA), and HFD with 40 mg/kg BW SAA (SAA + HFD) group. The Control group was fed AIN-93G diet. HFD mice were fed 60% fat diet to induce obesity (60% fat, D12492, Research Diets, New Brunswick, NJ), and water enriched with high fructose and sucrose. 42 g/L of carbohydrates was added to drinking water at a ratio of 45% sucrose and 55% fructose (St. Louis, MO) by weight. SAA was dissolved in sterilized physiologic saline to a stock concentration of 20 mg/ml. 100  $\mu\text{L}$  aliquots of the SAA solution or sterilized physiologic saline were intraperitoneally administered to mice every other day for 12 weeks. Body weight was recorded weekly. At the end of the experiment, mice were fasted overnight, anesthetized using sodium pentobarbital (50 mg/kg BW), and sacrificed to obtain plasma and hearts for analysis. The obese mice model was successfully established by the evaluating of body weight and plasma lipids (Supplementary Figure S1).

### Measurement of Plasma Lipids, AST, CK-MB Level

Mice were sacrificed under anesthesia, blood was obtained and plasma was harvested by centrifugation for 5 min at 3,000 rpm. Plasma AST, CK-MB, triglyceride (TG), free fatty acids (FFA), total cholesterol, high-density lipoprotein-cholesterol (HDL-C), low-density lipoprotein-cholesterol (LDL-C) levels were then measured using commercial kits (Nanjing Jiancheng BioTech. Co. Ltd., Nanjing, China) according to the manufacturers' instructions.

### Immunohistochemistry

Hearts were fixed in 4% PFA and embedded in paraffin. Sectioned tissues were then stained using H&E and their myofibers analyzed histologically. H&E sections were examined and imaged under brightfield illumination on a Leica microscope (Carl Zeiss, Gottingen, Germany).

### Reagents

Lipopolysaccharides (LPS) was purchased from Selleck Chemicals (Huston, TX). PA, stearic acid (SA), oleic acid (OA), and SAA were purchased from Sigma-Aldrich

**FIGURE 1 |** SAA reverses PA-induced lipotoxicity in H9c2 cardiomyocytes **(A)** Cardiomyocytes were seeded onto 24-well plates and grown to 80–90% confluence before treatment with the indicated SAA concentrations for 24 h. Cell viability was determined using MTT. **(B), (C)** Cardiomyocytes were pretreated with indicated SAA concentrations for 1 h and incubated with 0.4 mM palmitic acid (PA) for 12 h and cell viability and LDH release measured. **(D)** Western blot analysis of cleaved Caspase-3, Bcl-2, and Bax. Values are presented as mean  $\pm$  SD for three or more independent tests. **(E)** Hoechst staining for nuclei. Cell death was detected by morphologic examination after Hoechst staining by fluorescence microscopy (mag = 200X). **(F)** ROS levels were measured using DCFH-DA. **(G)** MFI analysis of mitochondrial membrane potential using Rh123. Values with different superscripts are significantly different at  $p < 0.05$ . \* shows comparison with normal control group while # shows comparison with PA-only treatment group.

(St. Louis, MO). CLI-95 was purchased from Invitrogen (Carlsbad, CA). SA-BSA and PA-BSA were processed as previously described (Dou et al., 2020). Briefly, SA or PA were solubilized in 100% ethanol and saponified with sodium hydroxide. The sodium salt was desiccated and resuspended in PBS. It was then heated at 80°C to achieve complete dissolution. We then added an isovolumetric 20% (w/v) BSA and stirred the mixture at 50°C for 4 h to allow SA or PA to bind BSA. The SA-BSA or PA-BSA complex (3 mmol/L fatty acid:1.5 mmol/L BSA, molar ratio, 2:1) was sterilized by filtration, and aliquoted for use. Oleate was complexed with 10% BSA to produce a stock solution, which was diluted in culture medium prior to use. The control and vehicle groups were treated with equal amounts of solvents (BSA or DMSO).

## Cell Culture

H9c2 cells were obtained from Shanghai Institute Cell Bank (Shanghai, China). Cells were cultured in DMEM medium (Gibco, Eggenstein, Germany) containing 5.5 mmol/L D-glucose and supplemented with 10% FBS (Biological Industries, ISR) as well as 100 U/mL/100 mg/ml pen/strep, at 37°C, in a humidified incubator, O<sub>2</sub>/CO<sub>2</sub> (19:1) atmosphere.

## Cell Death Assay

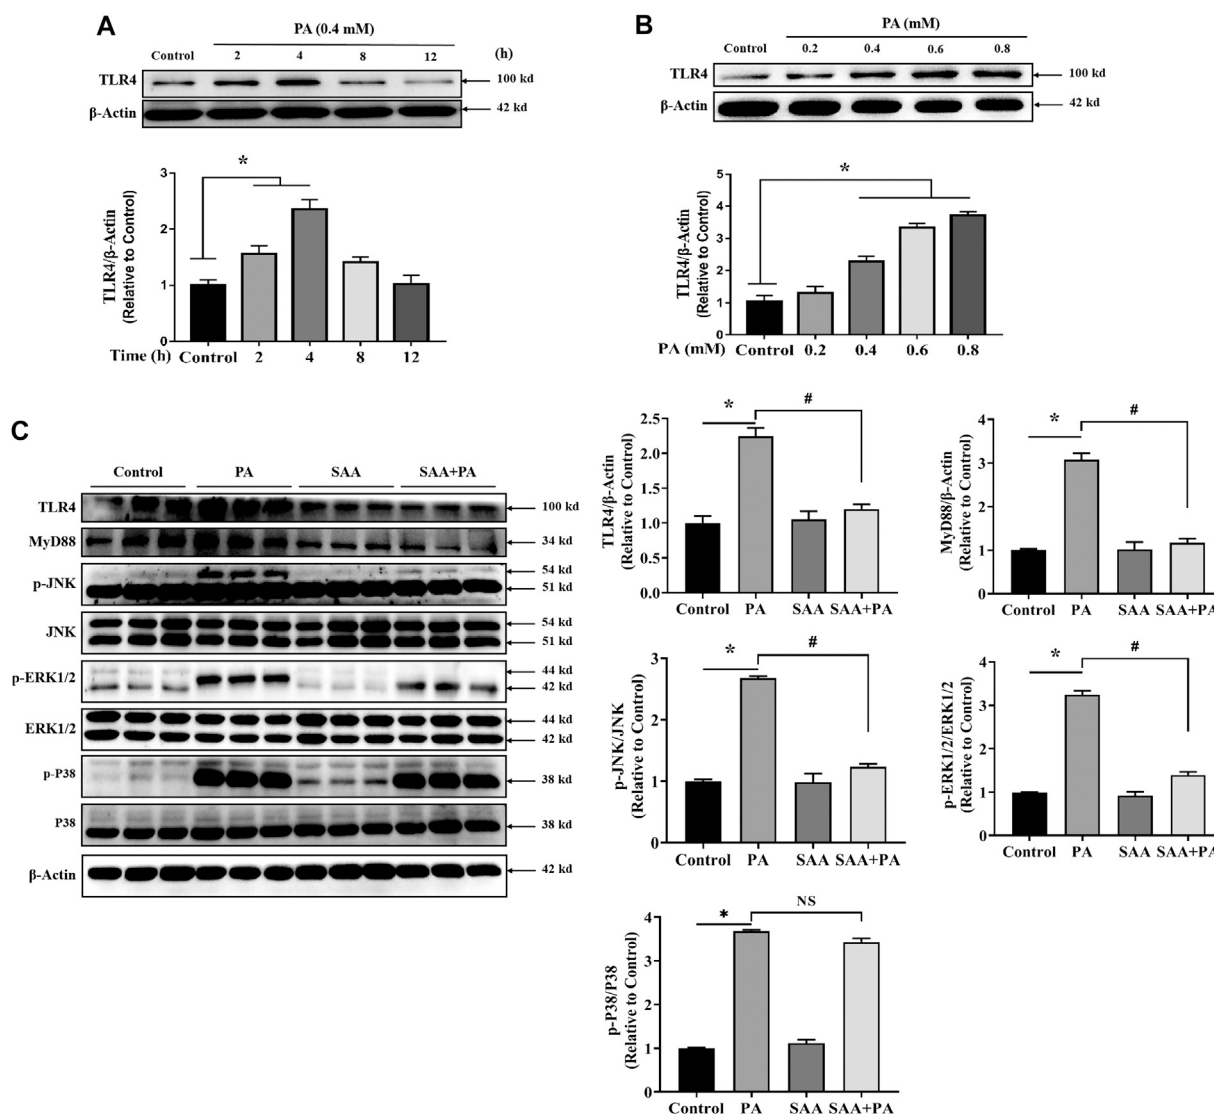

$2 \times 10^5$  cells/well were seeded onto a 24-well plate and cultured in normal media or media containing indicated concentrations of palmitate in the presence or absence of SAA (5, 10, 20, 40 μM). After 12 h, 450 μM MTT solution was added into each well and incubated for 4 h. The supernatant was removed and 600 μL DMSO added to dissolve the resulting formazan. Absorbance was then read at 470 nm using FLUOstar Omega (BMG Labtech). For the LDH test, the culture medium was collected and LDH assayed using an LDH assay kit (Thermo Scientific Inc., VA) according to the manufacturers' instructions. Nuclear morphological changes were examined by staining with 5 mg/L Hoechst 33342 for 10 min at 37°C before being imaged under a fluorescent microscope (Leica).

## Reactive Oxygen Species (ROS)

ROS levels were evaluated as described before (Li et al., 2014). After treatments, cells were washed and placed in serum free medium. 2, 7-dichlorodi-hydrofluorescein diacetate (DCFH-DA) was added to each well at a final concentration of 10 μM and cells cultured at 37°C for 20 min. They were then washed thrice using ice-cold PBS. Fluorescence intensity was determined using an inverted fluorescent microscope (Leica, Wetzlar, Germany). The

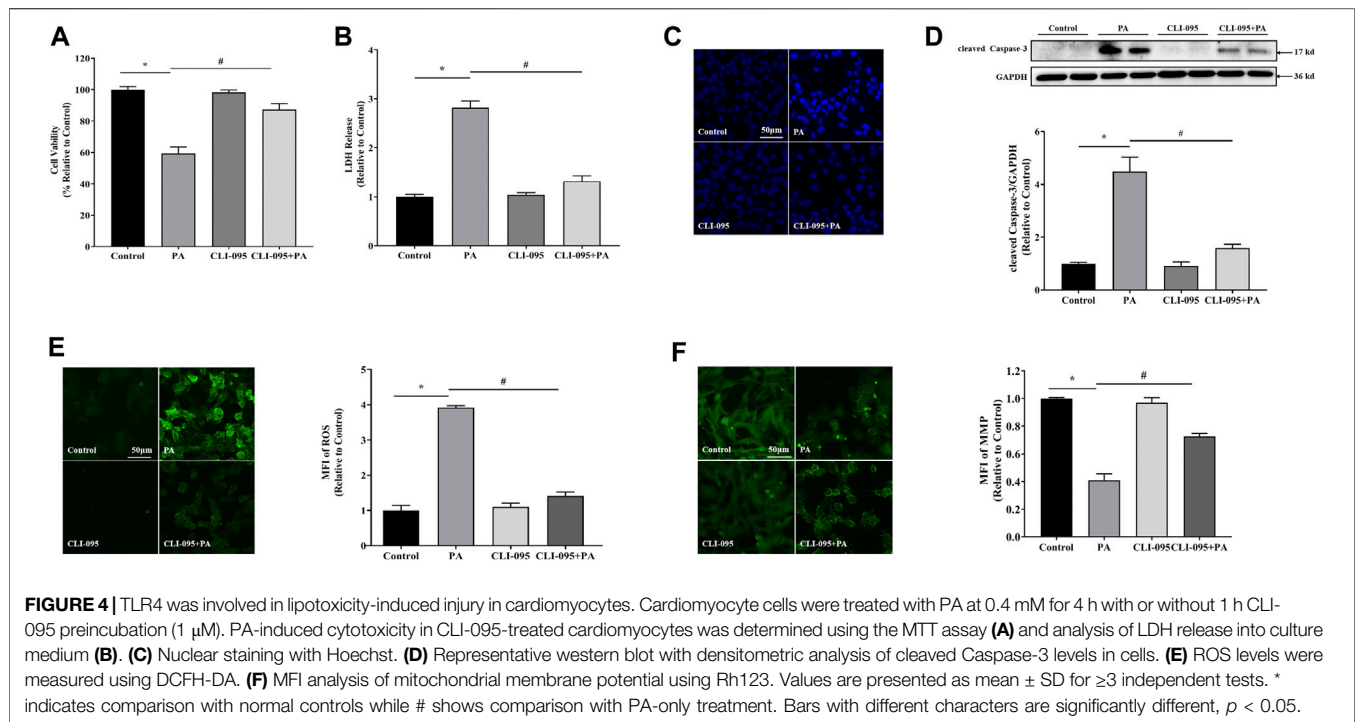

**FIGURE 2 |** SIRT1/AMPK pathway is not involved in SAA protection from lipotoxicity. Cardiomyocytes were incubated with 0.4 mM palmitic acid (PA) for 12 h. 10  $\mu$ M SAA was added 1 h before PA treatment. SIRT1, AMPK, and p-AMPK, protein levels were determined by western blot. Data were quantified by densitometric analysis as fold changes. Values are presented as mean  $\pm$  SD for  $\geq 3$  independent tests. Bars with different characters are significantly different,  $p < 0.05$ .

**FIGURE 3 |** SAA attenuates palmitate-induced TLR4 activation. Cardiomyocytes were seeded onto 24-well plates and grown to 80% confluence before treatment with 0.4 mM PA for 2, 4, 8 and 12 h (A) or 0.2, 0.4, 0.6, or 0.8 mM PA for 4 h (B). For the detection of anti-lipotoxicity role of SAA, H9c2 cells were incubated with 0.4 mM palmitic acid (PA) for 4 h. 10  $\mu$ M SAA was added 1 h before free fatty acids treatment. Representative western blot data on TLR4 levels. Data are shown as mean  $\pm$  SD. Total protein was extracted from myocardial cells. TLR4, MyD88, p-JNK, and p-ERK1/2 levels were determined by western blot. Values with different superscripts are significantly different at  $p < 0.05$ . \* indicates comparison with normal control group while # indicates comparison with PA-only treatment group.

mean fluorescence intensity (MFI) of five random fields was determined using ImageJ.

### Mitochondrial Membrane Potential (MMP) Assay

MMP was evaluated using Rhodamine123 (Rh123) at a final concentration of 100  $\mu$ g/ml for 45 min. Fluorescence was measured using a fluorescent microscope (Leica, Wetzlar, Germany). The mean fluorescence intensity (MFI) of five random fields was determined using ImageJ.

### Western Blotting

Western blotting was done as previously described (Li et al., 2014) using the following antibodies: anti- $\beta$ -actin, anti-cleaved-caspase3, anti-Bcl-2, anti-Bax, anti-MyD88, anti-JNK, anti-phospho-JNK, anti-ERK1/2, anti-phospho-ERK1/2, and anti-GAPDH from Cell Signaling Technology; Anti-TLR4, anti-SIRT1, anti-AMPK, anti-phospho-AMPK, from Santa Cruz Biotechnology.  $\beta$ -actin and GAPDH were used as loading controls. Protein levels were detected using HRP-conjugated secondary antibodies, and signal developed using ECL.

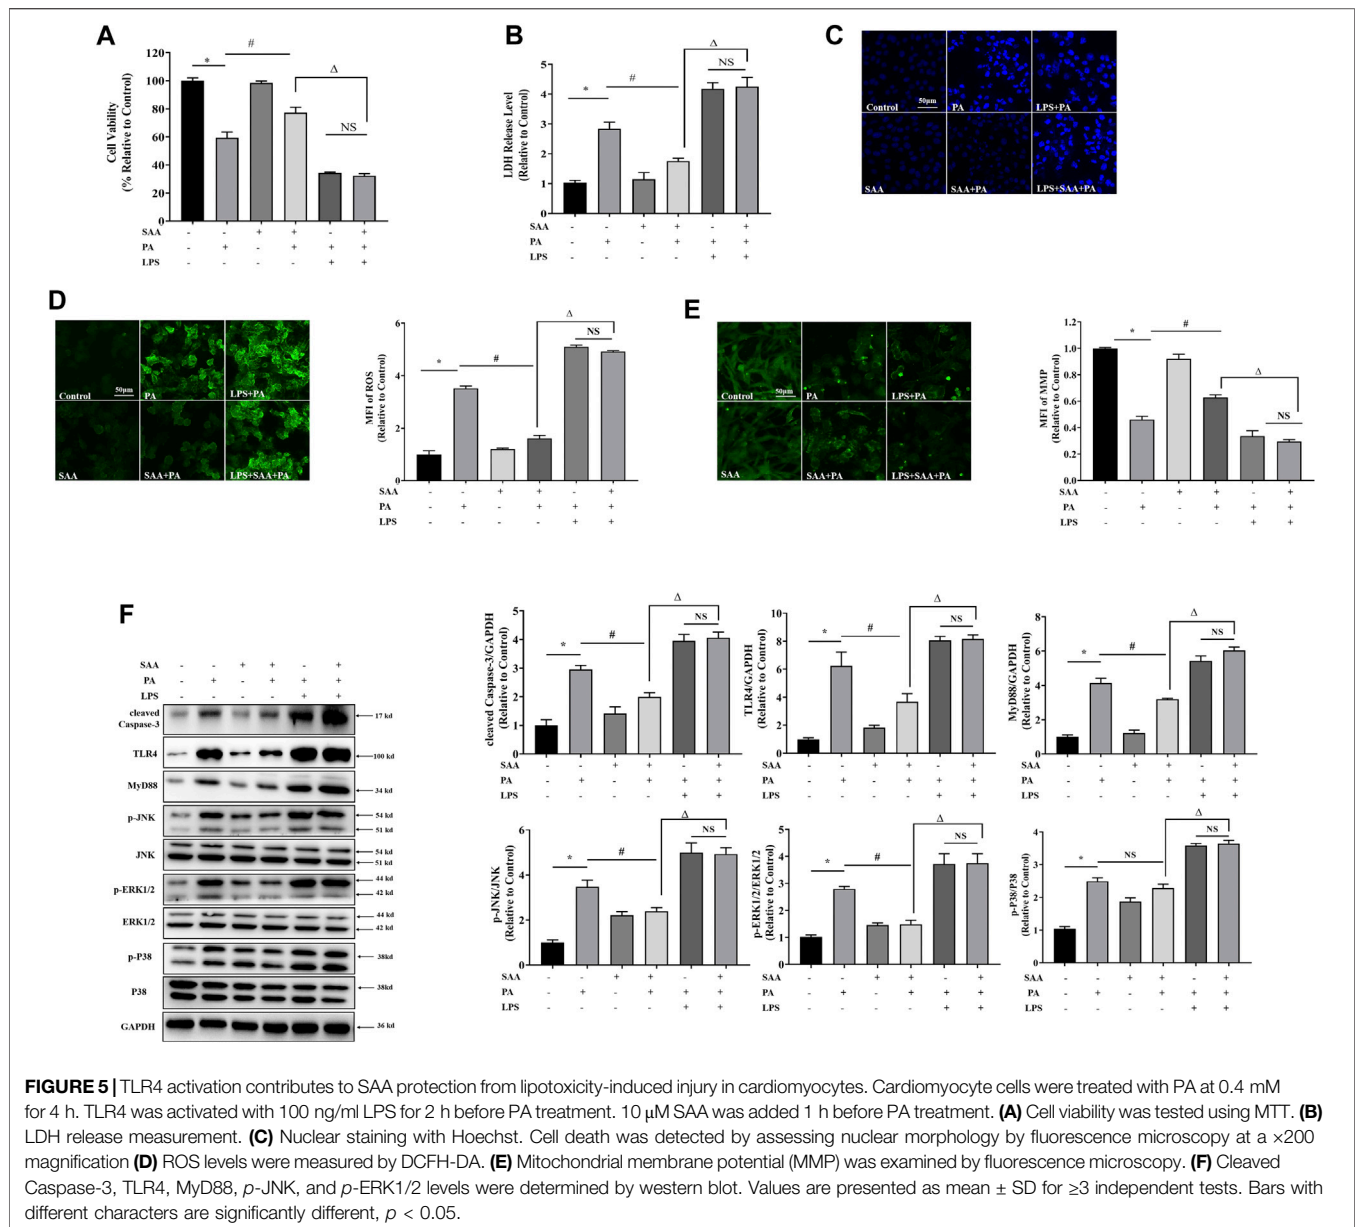

### Statistical Analysis

Data are presented as mean  $\pm$  SD for  $\geq 3$  independent biological experiments with three replicates per experiment. Statistical analysis was done using SPSS. Student's t-test or one-way ANOVA followed by Tukey test were used for pairwise comparisons between groups.  $p < 0.05$  was set as the threshold for statistical significance.

## RESULTS

### SAA Protects Against Lipotoxicity-Induced Myocardial Cell Injury

First, we tested the cytotoxic effects of various FFAs on myocardial cells with or without SAA. Analysis of LDH levels in the culture media revealed that long-chain saturated fatty acids (LSFAs), including PA and SA, exhibited significant dose-dependent lipotoxicity (Supplementary Figures S2A–D). OA, an important representative of long-chain monounsaturated fatty acids, did not exert lipotoxic effects in myocardial cells (Supplementary Figures S2E,F). Based on these results, we chose 0.4 mM PA to stimulate myocardial cells. To establish appropriate SAA concentrations for the experiments, we evaluated SAA cytotoxicity in cells without fatty acid treatment, and found that tolerance was up to 800  $\mu$ M SAA (Figure 1A). Cell viability and LDH assays indicated that SAA significantly suppressed PA-induced cell death (Figures 1B,C). *In vitro* assays were done using SAA at a maximum concentration of 40  $\mu$ M. Pretreating cells with SAA significantly reversed PA-induced cytotoxicity in a dose-dependent manner (Figures 1B,C). Then, 10  $\mu$ M of SAA were chosen for the subsequent experiments. It was found that 10  $\mu$ M SAA inhibited PA-mediated upregulation of cleaved Caspase-3, Bcl-2, Bax, and Bcl2/Bax ratio, indicating suppressed apoptosis (Figure 1D). Additionally, PA-stimulated chromatin damage was reversed by SAA pre-treatment (Figure 1E). Reduced circulating FFA levels enhanced oxidative stress during cardiomyopathy. This prompted us to assess SAA's capacity to scavenge PA-induced ROS in cardiac cells. The DCFH-DA assay showed that 0.4 mM PA significantly

increased ROS levels relative to control cells (Figure 1F). However, SAA was shown to significantly suppress ROS production. MFI values showed that SAA significantly reduced PA-induced ROS production. Pretreatment with SAA was also shown to significantly reverse PA-induced reduction of mitochondrial membrane potential (MMP) (Figure 1G). Together, these data demonstrate the protective effects of SAA against mitochondrial damage, apoptosis, and oxidative stress-mediated injury.

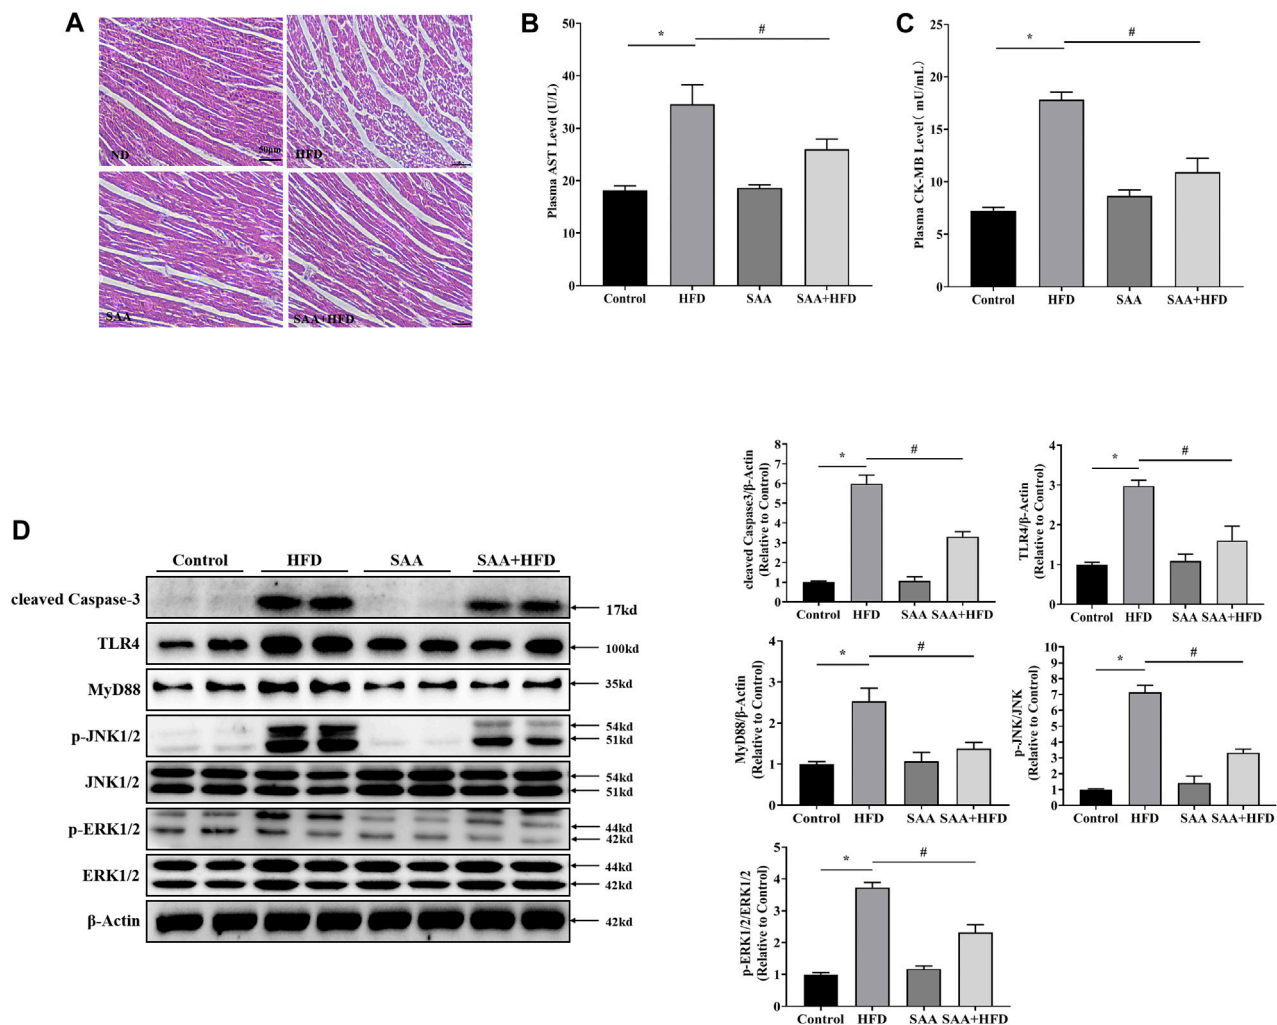

## The Protective Role of SAA Is Independent of SIRT1 and AMPK Pathways

Next, we determined whether SIRT1 mediates the beneficial effects of SAA against PA-induced cardiac lipotoxicity and

found that SIRT1 levels were significantly reduced in PA-treated cells, while SAA treatment did not reverse SIRT1 suppression by PA (Figure 2). Analysis of potential AMPK involvement showed that pretreatment with SAA did not effectively improve PA-induced alteration of AMPK (Figure 2), implying that SIRT1 and AMPK did not mediate SAA effects in myocardial cells.

## Activation of TLR4/AMPK Signaling Pathway Contributes to SAA Lipo-Protective Effects in Cardiac Cells

TLR4 inhibition is thought to be an SAA target during liver injury. Therefore, we determined if TLR4 signaling modulated

**FIGURE 6 |** TLR4/MAPKs pathway is involved in SAA protection of cardiomyocytes from lipotoxicity-induced injury in high-fat diet (HFD)-fed mice. Animals were divided into the following groups (6 mice each); normal diet group (Control), HFD group (HFD), normal diet with 40 mg/kg BW SAA group (SAA), and HFD with 40 mg/kg BW SAA (SAA + HFD) group. The Control group was fed AIN-93G diet. HFD mice were fed 60% fat diet to induce obesity (60% fat, D12492, Research Diets, New Brunswick, NJ) and water enriched with high fructose and sucrose. SAA was dissolved in sterilized physiologic saline with a stock concentration of 20 mg/mL. A total volume of 100  $\mu$ L SAA diluted solution or sterilized physiologic saline was intraperitoneally administered every other day for 12 weeks. **(A)** H/E staining of cardiomyocytes - scale bars = 50  $\mu$ m. **(B)** Plasma aspartate aminotransferase (AST) level **(C)** plasma creatine kinase, MB (CK-MB) level. **(D)** Cleaved Caspase-3, TLR4, MyD88, JNK, *p*-JNK, ERK1/2 and *p*-ERK1/2 levels in mouse heart tissues were determined by western blot. Values with different superscripts are significantly different at  $p < 0.05$ . \* indicates comparison with normal controls while # shows comparison with HFD-fed group.

the protective effects of SAA against lipotoxicity. Analysis of TLR4 expression levels in PA-treated cardiac cells showed that treatment with PA at 0.4 mM for 2–4 h significantly increased TLR4 levels. At 8–12 h, the expression levels of TLR4 were not found to be significantly different from the untreated cardiac cells (Figure 3A). Then, we determined the expression level of TLR4 after the treatment with indicated concentrations (0.2, 0.4, 0.6, 0.8 mM) of *p*A. It was found that TLR4 were significantly up-regulated by PA treatment in a dose-dependent manner (Figure 3B). We then tested 0.4 mM concentration of PA on H9c2 cells for 4 h with or without SAA. MAPKs mediate SAA protection of liver injury. Analysis of whether MAPKs signaling mediate SAA protection against PA-induced lipotoxicity showed

that SAA pretreatment significantly reversed PA-induced upregulation of MyD88, *p*-JNK and *p*-ERK1/2 levels. This implies that SAA lipo-protective effects are, partly, mediated by TLR4/MyD88/MAPKs signaling (Figure 3C).

### TLR4 Upregulation Mediates PA-Induced Lipotoxicity in Cardiac Cells

To confirm whether TLR4 regulates lipotoxicity in cardiomyocytes, we inhibited TLR4 using CLI-095 in H9c2 cells. TLR4 inhibition significantly suppressed cytotoxicity and LDH release relative to palmitate-treated cells (Figures 4A,B), supporting the observation that TLR4 facilitates PA-induced

lipotoxicity in cardiomyocytes. Moreover, inhibiting TLR4 also suppressed PA-induced elevation of cleaved Caspase-3 and ROS, mitochondrial membrane potential repression, and apoptosis in cardiac cells (**Figures 4C–F**), implying that TLR4 is involved in PA-induced lipotoxicity in cardiac cells.

## TLR4/MAPKs Is Involved in SAA Lipo-Protective Effects in Cardiomyocytes

To determine the role of TLR4/MAPKs in SAA's lipo-protective effects in cardiomyocytes, we activated TLR4 using LPS and found that it significantly suppressed the protective properties of SAA against lipotoxicity, including cell viability, LDH release, MMP, ROS formation, apoptosis, and cleaved Caspase-3 levels (**Figures 5A–F**). Moreover, TLR4 upregulation mitigated the lipo-protective effects of SAA through PA-induced targets of MyD88 and MAPKs, including *p*-JNK and *p*-ERK1/2 (**Figure 5F**). These findings confirmed that TLR4 signaling is involved in the exertion of the lipo-protective effects of SAA in cardiomyocytes.

## TLR4/MAPKs Mediate SAA Lipo-Protective Effects in Cardiomyocytes of HFD-Fed Mice

To determine the protective effects of SAA in cardiomyocytes of HFD-fed mice, we examined the pathological alterations of cardiomyocytes in various groups using H&E staining. There were structural abnormalities in the cardiomyocytes of HFD-fed mice, including altered cellular structures and broken fibers, which were significantly alleviated by SAA treatment (**Figure 6A**). The plasma levels of AST and CK-MB are indicators of cardiomyocyte injury. We found that SAA significantly reduced HFD-driven increase in plasma AST and plasma CK-MB levels (**Figures 6B,C**). Furthermore, SAA significantly suppressed HFD-induced increase in cleaved Caspase-3 in mouse myocardial tissues (**Figure 6D**), implying that SAA prevented against cardiomyocyte lipotoxicity in HFD fed mice.

We then examined the role of TLR4/MAPKs in SAA anti-lipotoxic effects *in vivo* and found that SAA significantly suppressed HFD-induced elevation of TLR4, MyD88, *p*-JNK and *p*-ERK1/2, consistent with our *in vitro* data (**Figure 6D**). These findings suggest that TLR4/MAPKs inhibition contributes to SAA's protection of cardiomyocytes from lipotoxicity.

## DISCUSSION

We have shown that SAA, a phytochemical found in Danshen, protects against lipotoxicity in HFD-fed mice and cultured cardiomyocytes. Its benefits are associated with its effects on TLR4/MAPKs signaling. SAA is a bioactive component of *Salvia miltiorrhiza* Bunge. In traditional Chinese medicine, Danshen is used to enhance blood flow, resolve blood stasis and for the prevention and treatment of cardiovascular diseases. However, the cardioprotective benefits of SAA are not well understood.

Lipotoxicity refers to cellular damage and death caused by free fatty acids elevation and aberrant lipid metabolism. Lipotoxicity by saturated fatty acids (SFAs) promotes myocardial lipotoxic injury. Sustained SFA elevation leads to myocardial lipotoxic injury, resulting in cardiac dysfunction (Wende and Abel, 2010). As documented in literature, PA and SA, but not OA, cause significant myocardial cell injury by suppressing cell viability and enhancing LDH activity in a dose-dependent manner. Moreover, PA elevated Bcl2: Bax ratio, as well as Caspase-3 levels, implying that it mediates cardiomyocyte apoptosis. These data established that SFAs induce myocardial lipotoxic injury *in vitro*. LSFA induction of myocardial injury, mitochondrial dysfunction, and subsequent mitochondrial apoptosis mediate cardiomyopathic pathogenesis (Murphy et al., 2016). We found that cardiomyocytes are susceptible to PA stimulation, causing mitochondrial damage, increased ROS, decreased MMP, and reduced Bcl2/Bax ratio. To our knowledge, a limited number of studies have evaluated the protective effects of SAA against SFA-induced myocardial lipotoxicity. Analysis of the effect of SAA on PA-induced myocardial lipotoxicity revealed that SAA exposure inhibited the PA-induced LDH release and cell viability in a dose-dependent manner by reversing the effect of lipotoxicity on MMP, ROS, and Bcl2/Bax ratio. These findings are in tandem with the role of SAA on PA-induced hepatic lipotoxic injury in NAFLD (Li et al., 2020).

Activation of SIRT1/AMPK signaling may prevent oxidative stress and inflammation during lipotoxicity-related hepatocyte injury (Xu et al., 2020). SAA alleviates insulin resistance and HFD-induced NAFLD through AMPK activation (Li et al., 2020). Moreover, SIRT1/AMPK attenuates palmitate-induced oxidative stress in cardiomyocytes. Multiple bioactive compounds, including curcumin (Zhang et al., 2019) and resveratrol (Feng et al., 2019) protect cardiomyocytes from apoptosis through the AMPK pathway. However, in this study, SAA did not reverse PA-induced activation of SIRT1 and AMPK phosphorylation in cardiomyocytes.

Another potential mechanism for SAA is through the TLR4 axis (Yang et al., 2019). In myocardial cells, TLR4 acts as a cellular injury sentinel and mediates inflammatory responses (Zhou et al., 2020). PA has been reported to be a TLR4 ligand during the induction of myocardial inflammatory responses where it activates TLR4 after HFD-induced injury (Wang et al., 2017). In line with the reports, we found TLR4 expression levels were upregulated in PA-stimulated cardiomyocytes injury, *in vitro*. In addition, TLR4 inhibition using CLI-095 significantly suppressed PA-induced cardiomyocytes mitochondrial dysfunction and apoptosis. This implies that TLR4 inhibition is a potential therapeutic target for lipotoxic heart disease. Interestingly, the cytoprotective effects of SAA in various cellular contexts are attributed to TLR4 inhibition (Zeng et al., 2020). Through modulating TLR4 signaling, SAA reduces oxidative stress, inflammation, and apoptosis in liver tissue during insulin resistance (Yang et al., 2019). Thus, we determined whether TLR4 signaling involved in the protection of SAA against lipotoxicity-induced myocardial damage. Accordingly, SAA significantly alleviated PA-activated TLR4 protein levels,

concurrent with reduction of its downstream factor MyD88 to activate the MAPK family members.

In cardiomyopathy, MAPK signaling activation induces cardiomyocytes apoptosis and promotes inflammation injury (Liang et al., 2019). *In vitro*, MAPKs overactivation has been reported to be involved in LSFAs-induced apoptosis in various cell types, including cardiomyocytes, pharmacologically inhibiting MAPKs or silencing them significantly elevates H<sub>2</sub>O<sub>2</sub> levels and LSFAs-induced cell death (Oh et al., 2014). Previously, we have shown that TLR4/MAPK activation contributes to PA-induced cell death in hepatocytes. Analysis of if TLR4/MAPK signaling is mechanistically involved in PA-induced cell death in cardiomyocytes and SAA's cardioprotective effects found that PA upregulated TLR4/MAPKs expression in H9c2 cells *in vitro*, SAA reversed the expression of TLR4, MAPK and its downstream signals *p*-JNK, ERK1/2.

To further delineate the role of TLR4 in SAA and PA-induced lipotoxicity in cardiomyocytes lipotoxicity, we further dissected potential underlying mechanisms. In our previous study (Dou et al., 2020), activating TLR4 using LPS markedly blocked the lipid-reducing effects of Salidroside. Consistent with the results, the TLR4 activation by LPS prominently abolished the beneficial role of SAA on TLR4-regulated MAPKs inhibition and myocardial apoptosis, which indicated that TLR4-regulated MAPKs pathway was mechanistically involved in SAA protection against cardiomyocytes lipotoxicity. However, we still do not know how SAA regulates TLR4/MAPKs expression in cardiomyocytes. In addition, LPS is a very strong activator of TLR4 pathway, which induction markedly aggravated PA-induced adverse effects, which might mask the potential protective effect of SAA through other pathways. Therefore, the participation of other potential signaling pathways in SAA-prevented lipotoxicity could also not be excluded, although it seems like that LPS completely abolished the beneficial effects of SAA.

In summary, we show that SAA has anti-inflammatory and anti-mitochondrial dysfunction effects *in vitro* and *in vivo*. Thus, the clinical benefits of SAA are closely associated with its ability to reduce TLR4 and inhibit MAPKs. We provide important insights into the mechanisms by which SAA mediates myocardial protection against lipotoxic injury, thereby highlighting SAA

as a potential dietary supplement or therapeutic agent for preventing and treating lipotoxicity-induced heart diseases.

Osteoporosis is a common skeletal disease in post-menopausal women. *Palmul-tang*, an herbal medicine, has been treated for gynecological disease such as anemia, anorexia, anti-fatigue, unspecified menstruation and female infertility in East Asia. In this study, ameliorative effects of *Palmul-tang* soft extracts (PMT), a Korean Medicine, on osteoporosis were investigated. Ovariectomized (OVX) osteoporotic ICR mice were intragastrically administrated PMT for 4 weeks. The level of bone mineral density (BMD) was analyzed in bone tissues by dual X-ray absorptiometry. The bone medullary cavity and deposition of collagen were investigated by histological analysis. In addition, the BMP-2 signaling-related molecules, osteoblastic differentiation and formation markers, were determined in femoral tissues. The levels of BMD and bone mineral content were significantly increased in tibia, femurs and LV by treatment of PMT. PMT replenished bone marrow cavity and increased collagen deposition in bone marrow cells of femur. In addition, administration of PMT recovered serum ALP, bALP, osteocalcin and calcium levels in osteoporotic mice. Moreover, PMT treatment up-regulated the expressions of BMP-2, RUNX2 and OSX with its downstream factors, ALP, OPN and BSP-1, in the femoral tissues. Taken together, PMT restored the bone minerals and improvement of bone integrity by bone-forming BMP-2 signaling pathway. These results demonstrate that PMT could be an ameliorative agent for osteoporosis.

**Keywords:** osteoporosis, traditional herbal medicine, palmul-tang, bone integrity, BMP-2

## INTRODUCTION

Osteoporosis is a skeletal disease by occurring the impairment of osteoblast and osteoclast balances (Chen et al., 2018). During the procession of osteoporosis, the reduction of bone mass and deterioration of bone tissue leads to augmentation of bone fragility, thereby lowering bone mineral density (BMD) and increasing the risk of bone fractures such as wrist, hip and vertebrae (Kanis, 2002; Cheng et al., 2011). More than 30% of women over the age of 50 estrogen deficient which also causes environmental changes such as increased treatment costs and poor quality of life (Dickenson et al., 1981). Accordingly, management and prevention of osteoporosis is the most representative public health issue for the assignment of global strategies (Lewis et al., 2019).

A common prescription for treatment of osteoporosis is hormone therapy, bisphosphonates and supplements such as calcium and vitamin D (Bowring and Francis, 2011). The mode of action by

anti-osteoporosis drugs is associated with improvement of balances for abnormal function of osteoblast and osteoclast that increase the bone mass and offset the bone loss (Tanaka et al., 2005; Nanjundaiah et al., 2013). However, the possibility of experiencing side effects including hot flush, breast cancer, blood clots, heart failure and osteonecrosis of jaw still remains an obstacle to be overcome and drives us to find new prospective drugs for improving osteoporosis (Nam et al., 2012; Tella and Gallagher, 2014).

Traditional herbal medicine in Korea is used to treat various diseases because of its low side effects and high efficacy in prevention and treatment (Yuan et al., 2016). *Palmul*-tang, also known as *Paljin*-tang in Korean, *Hachimotsu-to* in Japanese and *Bawu*-tang in Chinese, is a herbal formula which consists of eight herbs, *Panax ginseng* C. A. Meyer, *Atractylodes macrocephala* Koidz, *Poria cocos* F. A. Wolf, *Glycyrrhiza uralensis* Fischer, *Rehmannia glutinosa* (Gaertner) Liboschitz, *Paeonia lactiflora* Pallas, *Ligusticum officinale* (Makino) Kitag and *Angelica gigas* Nakai (Eom et al., 2017; Jin et al., 2017). *Palmul*-tang has traditionally been prescribed for anemia, anorexia, anti-fatigue, and neuralgia (Heo et al., 2003; Park et al., 2004a; Park et al., 2004b; Ma et al., 2007b; Shin and Shin, 2012; Kim and Bak, 2015). Especially, *Palmul*-tang has been used for women diseases such as unspecified menstruation, reproductive activities and female infertility (Ma et al., 2007a). Also, *Palmul*-tang was used for women diseases such as unspecified menstruation, reproductive activities and female infertility (Ma et al., 2007a). Recent study showed inhibitory effects of *Palmul*-tang on inflammatory mediator production related to NF- $\kappa$ B, MAPK and HO-1 pathway in macrophages (Oh et al., 2014). According to the traditional theory including Korean medicine, traditional Chinese medicine and Kampo medicine, *Palmul*-tang has been known for improving the basis of metabolism and enhancing the organ activity by nourishing “qi” and enriching “blood.” Tonifying “qi” induces bone marrow to nourish the bone, resulting in growth of skeleton (Wang et al., 2016b). Interruption of “blood” circulation is highly involved in increasing osteoclastic activities leading to induction of cumulative bone loss as a crucial factor for bone growth (Fricke and Krokowski, 1975; Alagiakrishnan et al., 2003). In addition, *Palmul*-tang is a combination of *Sagunja*-tang and *Samul*-tang, which is reported to be effective for osteoporosis (Lee et al., 1995; Shim et al., 2011; Yim et al., 2018). Based on the recent studies, we anticipated that *Palmul*-tang soft extracts (PMT) has ameliorative effects on post-menopausal osteoporosis. In the present study, the effects of PMT on bone loss was investigated by assessing BMC and BMD levels and bone-forming BMP-2 signaling pathway-related molecules were determined in bone tissues.

## MATERIALS AND METHODS

### Samples

PMT (Lot. #8001), which is a standardized Korean medicine for health insurance, was obtained from Kyoungbang pharmacy Inc. (Incheon, Korea). The total volume of PMT is 10 g per pack and composed of *Panax ginseng* C. A. Meyer, *Atractylodes*

**TABLE 1 |** Components of *Palmul*-tang soft extract one pack.

Y	Family	Source	Weight (mg)
<i>Panax ginseng</i> C. A. Meyer	Araliaceae	Korea	420
<i>Atractylodes macrocephala</i> Koidz	Asteraceae	Korea	495
<i>Poria cocos</i> F. A. Wolf	Polyporaceae	Korea	225
<i>Glycyrrhiza uralensis</i> Fischer	Fabaceae	Korea	660
<i>Rehmannia glutinosa</i> (Gaertner) Liboschitz	Orobanchaceae	Korea	720
<i>Paeonia lactiflora</i> Pallas	Paeoniaceae	Korea	495
<i>Ligusticum officinale</i> (Makino) Kitag	Apiaceae	Korea	645
<i>Angelica gigas</i> Nakai	Apiaceae	Korea	495

*macrocephala* Koidz, *Poria cocos* F. A. Wolf, *Glycyrrhiza uralensis* Fischer, *Rehmannia glutinosa* (Gaertner) Liboschitz, *Paeonia lactiflora* Pallas, *Ligusticum officinale* (Makino) Kitag and *Angelica gigas* Nakai (Table 1). Voucher specimen PMT (Lot. #8001) is deposited in our laboratory.

### High-Performance Liquid Chromatography

Three packets (45 g) of PMT was thoroughly mixed, extracted and filtered to make a test liquid for injecting into the Alliance HPLC e2695 system with 2489 UV/Vis detector. A full scan spectrum in positive ESI mode was obtained for the main ingredient identification of PMT. Then the reference standards of atractylenolide I and atractylenolide III were accurately weighed and dissolved in methanol. The chromatographic separations of the analytes were conducted on Kromasil C18 column (4.6  $\times$  159 mm, 3.5  $\mu$ m). The mobile phase consisted of (A) water and (B) acetonitrile (30:70, v/v) flowed at a rate of 1.0 ml/min. Then 10  $\mu$ L of the sample was injected for the analysis. Contents of atractylenolide I and atractylenolide III were  $0.033 \pm 0.0010$  mg and  $0.039 \pm 0.0002$  mg, respectively ( $n = 3$ ). (Supplementary Figure S1).

### Animals

All experiments were conducted with the approval of the Committee on Care and Use of Laboratory Animals of Kyung Hee University, Seoul, Korea (KHSASP-19-097). Female ICR mice aging of 5 weeks old were obtained from RaonBio Inc. (Yongin, Korea). All mice were acclimated at least 1 week under standard housing conditions (22–24°C, 12 h/12 h light/dark cycle) and had freely access food and water. The experimental groups divided into 6 groups ( $n = 7$ ); 1) sham (blank control), 2) OVX (negative control), E2 (OVX + 17 $\beta$ -estradiol, 10  $\mu$ g/kg, positive control), PMT 61.7 (OVX + PMT 61.7 mg/kg), PMT 617 (OVX + PMT 617 mg/kg), PMT 6170 (OVX + PMT 6170 mg/kg).

### Experimental Protocol

All mice were intraperitoneally injected with avertin (Sigma-Aldrich, St. Louis, United States) and shaved dorsal midline skin. The shaved skins were longitudinally incised and operated sham or removed bilateral ovaries. Exposed skin and muscle were closed with silk 4-0 suture (AILEE co., Busan, Korea) and applied povidone iodine on surgical area to disinfect the skin.

Following induce osteoporosis for 10 weeks, Day 70, OVX-operated groups were assigned to 5 groups in accordance with body weights. The PMT samples were administrated 5 days per week for 4 weeks; sham and OVX groups were orally treated with vehicle, E2 group was intraperitoneally injected with 10 µg/kg of 17β-estradiol, PMT groups were orally treated with dose of 61.7, 617, 6,170 mg/kg of PMT diluted in distilled water. The doses of PMT were selected from formula for dose translation by human equivalent dose (Nair and Jacob, 2016). The dosage of samples in use for human is 30 g/60 kg/day (3 packs). Dosage for human (30 g/60 kg/day) is converted into mice (6,170 mg/kg/day) by using human equivalent dose equation as high dosage of this study. During animal experiments, body weight was monitored by weekly. The body weights of osteoporotic mice showed almost same values in whole experimental periods without any adverse events. At the end of experiments, Day 96, the mice were sacrificed by cervical dislocation. The sacrifice mice dissected blood, tibiae, femora and L4~L6 vertebrae (LV) to analyzed efficacy of PMT on osteoporosis.

### Dual Energy X-Ray Absorptiometry Test

To measure bone mineral content (BMC; g) and bone mineral density (BMD; g/cm<sup>2</sup>), excised tibiae, femora and LV were detected by using dual energy X-ray absorptiometry (DXA, Medikors, Seongnam, Korea).

### Histopathological Examination

Excised left femurs were fixed in 10% neutralized formalin for 24 h and demineralized using 0.1 M ethylene diamine tetra acetic acid (EDTA) for 2 weeks. After decalcification, femurs were dehydrated with a graded series of alcohol, xylene and paraffin. The femurs were embedded for sagittal sections in paraffin and harden in the freezer for 24 h. Paraffin blocks were sliced using microtome into 10 µm-thick and placed on gelatin-coated glass slides. To evaluate the recovery of bone marrow cavity and interstitial collagen, hematoxylin and eosin (H&E) staining and picosirius red staining were performed. Stained sections were photographed with magnification ×400 under microscope.

### ELISA Analysis of Osteoblastic Factors

Collected blood sample were isolated by centrifuge at 17,000 rpm for 20 min and supernatants were kept at -20°C until use. The serum samples were moved at 4°C 1 day before usage. Serum alkaline phosphatase (ALP), bone-specific ALP (bALP) (AnaSpec, United States), osteocalcin (TaKaRa Bio Inc., Japan) and Ca (Nikken SEIL Co., Japan) levels were analyzed using enzyme-linked immunosorbent assay (ELISA) kit. The procedures were conducted according to manufacturer's instructions.

### RT-PCR Analysis

To analyze osteoblastic markers, right femurs were pulverized using liquid nitrogen with mortar and pestle into fine powder. Powdered femurs were incubated with trizol (Invitrogen, United States) at 4°C for overnight and homogenized. Total RNA was extracted according to the manufacturer's protocols. Total RNA

was measured and synthesized cDNA using 1 µg RNA and Maxime RT premix (Invitrogen). Reverse transcription polymerase chain reaction (RT-PCR) was performed using Maxim PCR premix (Invitrogen). Osteoblastic markers specific primers were as follows: 5'-GCGGTGGACTGCACAGGGAC-3' and 5'-CTACCCTTCCCCGTGGGGGA-3' for *bone morphogenetic protein 2* (BMP-2), 5'-CCGCACGACAACCGC ACCAT-3' and 5'-CGCTCCGGCCCAAAATCTC-3' for *runt-related transcription factor 2* (RUNX2), 5'-TAATGGGCTCCT TTCACCTG-3' and 5'-CACTGGGCAGACAGTCAGAA-3' for *osterix* (OSX), 5'-TGGAGCTTCAGAAGCTCAACACCA-3' and 5'-ATCTCGTTGTCTGAGTACCAGTCC-3' for *alkaline phosphatase* (ALP), 5'-CATTGCCTCCTCCCTCCCGGTG-3' and 5'-GTCATCACCTCGGCCGTGGGG-3' for *osteopontin* (OPN), 5'-GAGCCAGGACTGCCGAAAGGAA-3' and 5'-CCGTTGTCTCCTCCGCTGCTGC-3' for *bone sialoprotein* (BSP-1), 5'-GGCATGGACTGTGGTCATGA-3' and 5'-TTC ACCACCATGGAGAAGGC-3' for *glyceraldehyde 3-phosphate dehydrogenase* (GAPDH). The gene expressions were detected by 1% agarose gel and normalized to housekeeping gene, GAPDH. All bands were analyzed by image J software.

### Statistical Analysis

All data are analyzed by using GraphPad Prism 5 software (GraphPad Software Inc., La Jolla, CA, United States). Significance was determined by one-way analysis of variance (ANOVA) and Tukey multiple comparison tests. Data were presented as the mean ± standard error. In all analyses, *p* < 0.05 was taken to indicate statistical significance. All data underlying the study was deposited in our laboratory.

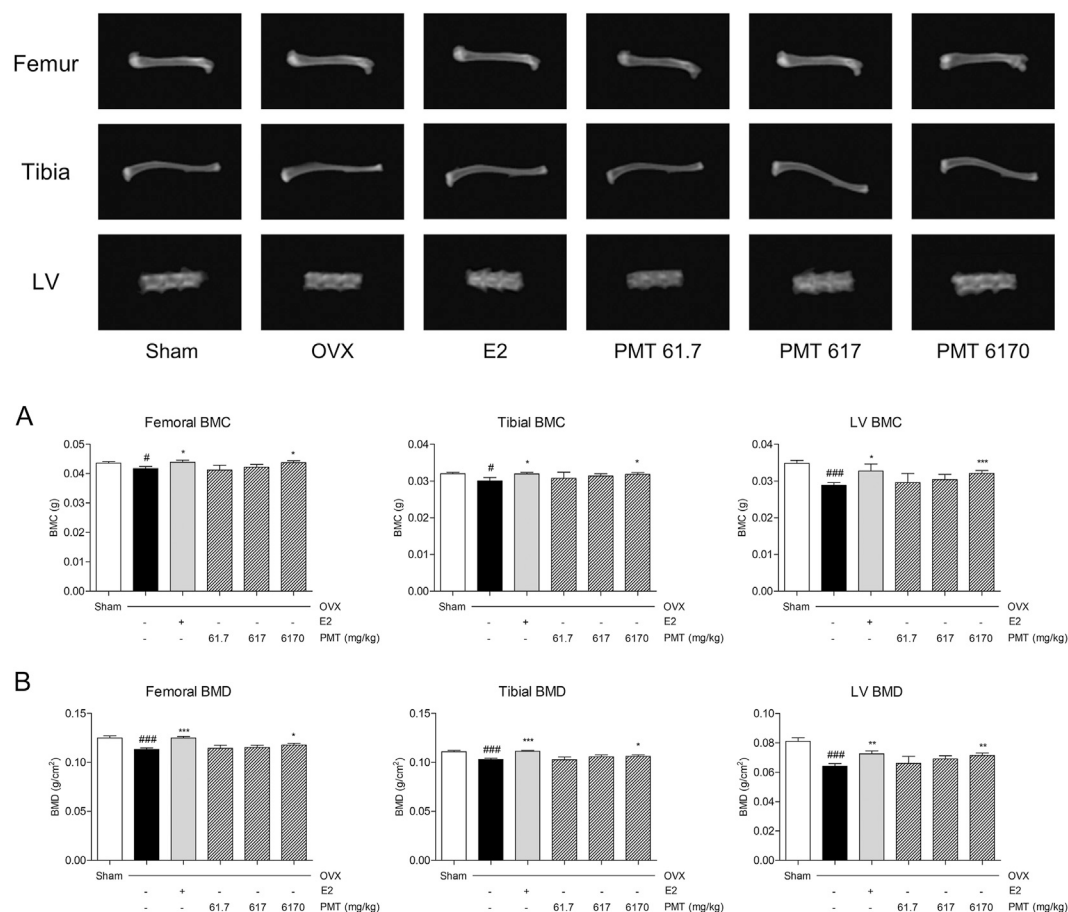

## RESULTS

### Effects of PMT on BMC and BMD

Femoral, tibial and LV were used to evaluate the levels of BMC and BMD. As shown in **Figure 1A**, levels of femoral, tibial and LV BMC was declined 4.33, 6.01 and 17.31% in OVX group compared to sham group and recovered 5.20, 6.33 and 13.65% in E2 group compared to OVX group. Treatment of PMT up-regulated BMC in femur, tibia and LV compared to OVX group, especially increased 4.69, 5.86 and 11.32% in 6,170 mg/kg of PMT. As similar as result from **Figure 1B**, levels of BMD on femora, tibial and LV were decreased 9.29, 7.12 and 20.87% in OVX group by PMT. Also, treatment of E2 increased levels of BMD by 10.24% in femora, 8.06% in tibiae and 13.10% in LV. In addition, 6,170 mg/kg of PMT improved levels of BMD, 3.97, 3.10 and 11.34%, respectively.

### Effects of PMT on Histological Changes

The bone marrow cavity in femoral shaft was used to determine by H&E staining. In **Figure 2A**, OVX group appeared high adiposity of bone marrow compared to sham group, whereas treatment of E2 and PMT ameliorated bone marrow adiposity, particularly treated with 6,170 mg/kg of PMT. Picosirius red staining showed quantitatively improvement of collagen fibers in femur. As demonstrated

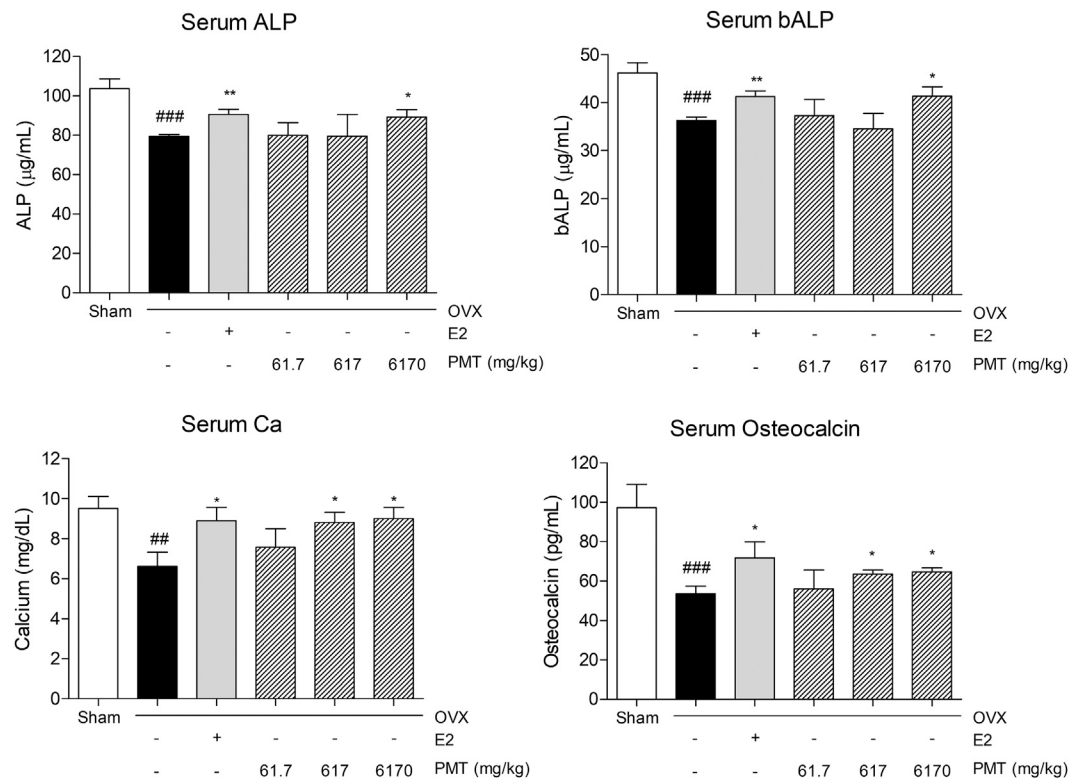

**FIGURE 1 |** Effects of PMT on BMC and BMD in osteoporotic mice. Bone mineral content and bone mineral density of tibiae, femora and lumbar vertebrae were analyzed by DXA. **(A)** Levels of bone mineral content in tibia, femur and LV. **(B)** Levels of bone mineral density in tibia, femur and LV. Results are presented as mean  $\pm$  standard error of the mean. <sup>#</sup> $p < 0.05$ , <sup>###</sup> $p < 0.01$  and <sup>\*\*\*</sup> $p < 0.001$  vs. Sham group; <sup>\*</sup> $p < 0.05$ , <sup>\*\*</sup> $p < 0.01$  and <sup>\*\*\*</sup> $p < 0.001$  vs. OVX group. OVX, ovariectomized group; E2, 17 $\beta$ -estradiol group; PMT, *Palmul*-tang soft extracts; LV, lumbar vertebrae; BMC, bone mineral content; BMD, bone mineral density.

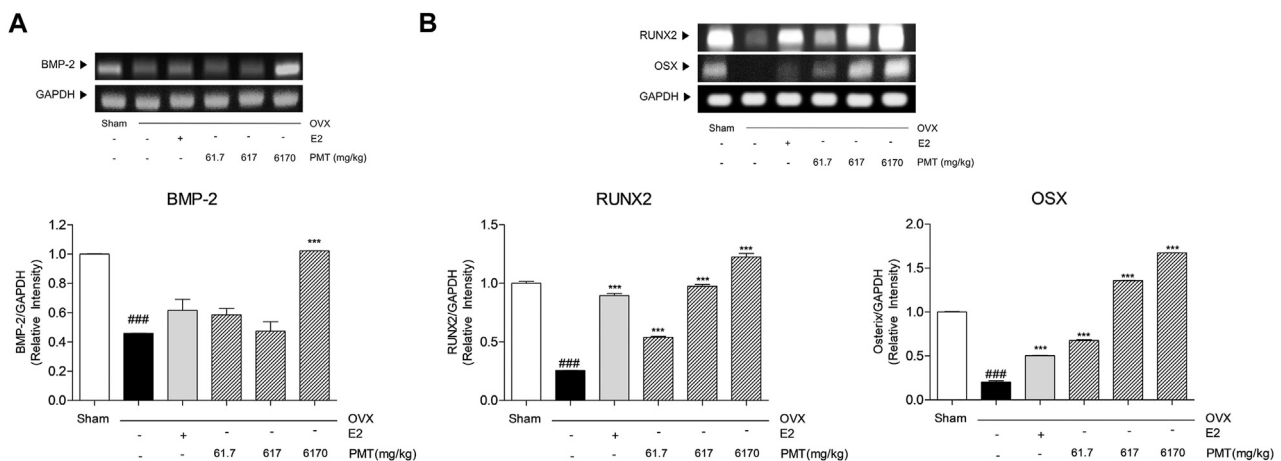

**FIGURE 2 |** Effects of PMT on histological changes in femur. Evaluation of histological changes using hematoxylin and eosin staining for bone marrow cavity and picrosirius red staining for detecting deposition of collagen. Magnification of images were  $\times 400$ . OVX, ovariectomized group; E2, 17 $\beta$ -estradiol group; PMT, *Palmul*-tang soft extracts.

in **Figure 2B**, the collagen fibers were markedly aggravated in OVX group compared to sham group. However, treatment of

E2 and PMT recovered expression of collagen fibers, especially 6,170 mg/kg of PMT treatment.

**FIGURE 3 |** Effects of PMT on bone specific markers in serum. Secretion of bone specific markers in serum was analyzed by ELISA. Results are presented as the mean  $\pm$  standard error. ### $p < 0.01$  and ### $p < 0.001$  vs. Sham group; \* $p < 0.05$  and \*\* $p < 0.01$  vs. OVX group. OVX, ovariectomized group; E2, 17 $\beta$ -estradiol group; PMT, *Palmul*-tang soft extracts; ALP, alkaline phosphatase; bALP, bone-specific alkaline phosphatase.

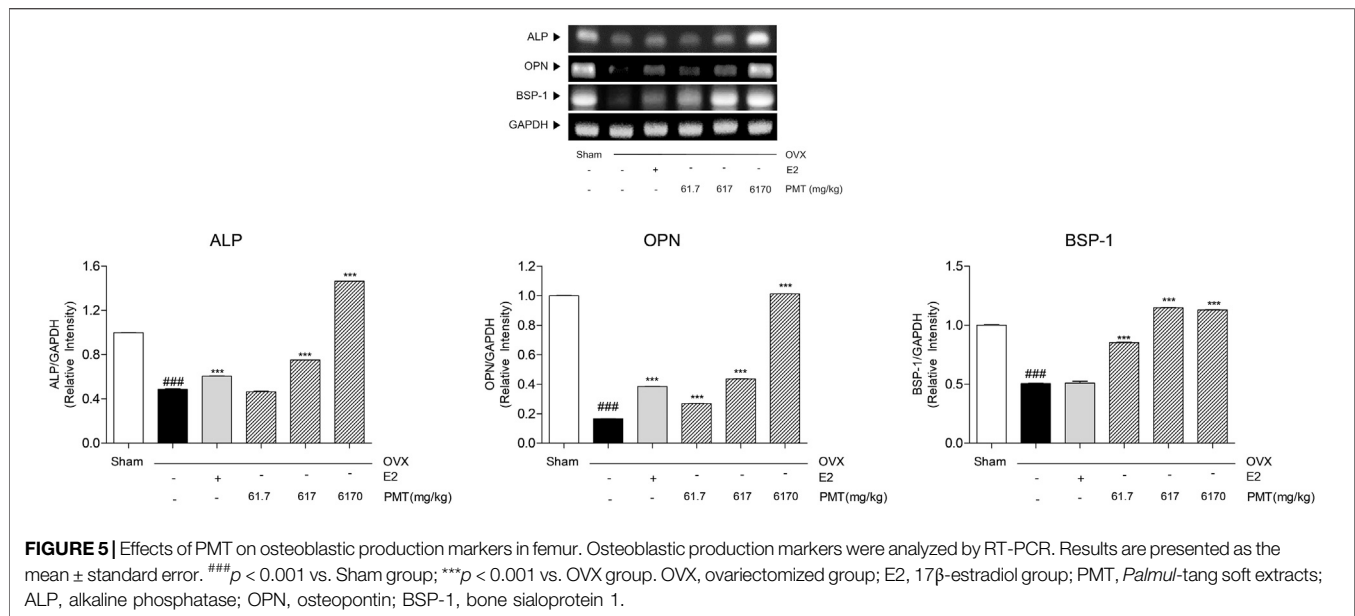

**FIGURE 4 |** Effects of PMT on osteoblastic differentiation initiation markers in femur. Osteoblastic differentiation initiation markers were analyzed by RT-PCR. Results are presented as the mean  $\pm$  standard error. ### $p < 0.001$  vs. Sham group; \*\*\* $p < 0.001$  vs. OVX group. OVX, ovariectomized group; E2, 17 $\beta$ -estradiol group; PMT, *Palmul*-tang soft extracts; BMP-2, bone morphogenetic protein 2; RUNX2, Runt-related transcription factor 2; OSX, osterix.

## Effects of PMT on Bone Specific Markers in Serum

The ALP and bALP levels were decreased in OVX group, 23.29 and 21.43%, respectively, whereas E2 treatment increased levels of

ALP and bALP compared to OVX group, 13.89 and 13.59%, respectively. In addition, the levels of ALP and bALP were recovered by administrating PMT compared to OVX group. Particularly 6,170 mg/kg of PMT treatment significantly

increased expression levels by 12.31% in ALP and 13.86% in bALP. In addition, serum Ca levels were diminished 30.39% in OVX group, and rise 34.31% in E2 group. Treating PMT remarkably improved levels of Ca 32.96% in PMT 617 group and 36.04% in PMT 6170 group. Serum levels of osteocalcin, similar to Ca, was decreased 44.93% in OVX group and increased 34.07% in E2 group. Treatment with 617 and 6,170 mg/kg of PMT significantly advanced 18.7 and 20.85% Ca levels, respectively, in OVX-induced osteoporotic mice (Figure 3).

## Effects of PMT on Osteoblastic Markers in Femur

As shown in Figure 4A, BMP-2 was expressed in OVX group 54.14% lower than sham group, however, there was no significance in E2 group. While 6,170 mg/kg of PMT treatment recovered 122.63% higher than OVX group. Expression levels of BMP-2 in PMT 6170 group seems to be approximated with sham group. In addition, transcription factors in osteoblast, RUNX2 and OSX, were decreased 74.45 and 79.73%, respectively, in OVX group. Expression of RUNX2 and OSX were significantly increased 250.37 and 148.25%, respectively, treated with E2. The treatment three doses of PMT remarkably up-regulated expressions of RUNX2 and OSX dose-dependent manner, 1.1, 2.81 and 3.79 folds of RUNX2 and 2.34, 5.7 and 7.25 folds of OSX, respectively (Figure 4B). By regulating osteoblast differentiation, ALP, OPN and BSP-1 were lowly expressed in OVX group, 51.21, 83.33 and 49.41%, respectively. On the contrary, treatment of E2 highly expressed mRNA levels of ALP and OPN, 24.27 and 130.7%, respectively. However, there was no significance expression of BSP-1 in E2 group. Administration of PMT increased levels of ALP, OPN and BSP-1 dose-dependent manner. These markers were significantly expressed 60.95, 161.13 and 507.68% of OPN and 68.49, 127.12 and 123.36%

of BSP-1, respectively. Additionally, expression levels of ALP were increased 54.27 and 200.06% by treating 617 and 6,170 mg/kg of PMT (Figure 5).

## DISCUSSION

Postmenopausal osteoporosis is a metabolic and skeletal disease that has a high prevalence of age-related bone loss with porous and low levels of bone density (Garnero, 2014). BMD is commonly used in the clinics for the standards of osteoporosis, which is diagnosed with -2.5 or lower levels BMD T-score in the region of the femoral neck and lumbar spine (Kanis, 2002). In addition, the collapse of bone microstructure results in increases of the risk of fractures by reducing bone strength (Chesnut et al., 2001). Moreover, to form of mature osteoblast, collagen is essential extracellular matrix protein for increasing bone strength and remodeling (Elango et al., 2018). In this study, OVX-induced osteoporotic mice group, levels of BMC and BMD in femur, tibia and LV were lowered compared to sham-operated mice group. On the contrary, the levels of BMC and BMD were significantly improved in PMT-treated mice. In addition, PMT reduced bone marrow adiposity, which was promoted the deposition of collagen tissue in the bone marrow. Accordingly, PMT enhanced the levels of BMC, BMD and refilled a cavity with bone mineral which leads to improvement of bone integration.

Impaired osteoporotic bone is the imbalance of osteoblast and osteoclast (Aggarwal et al., 2012). Especially, postmenopausal osteoporosis reveals the inactivation of osteoblasts due to the insufficiency of estrogen, which disrupted the equilibrium of osteoblast and osteoclast (Paschalis et al., 2003). Promotion of osteoblastic activities, which lead to bone proliferation, maturation and formation, is recommended to prioritize for treating post-menopausal osteoporosis (Wang et al., 2016a).

Bone turnover markers including ALP, bALP, Ca and osteocalcin, as specific and sensitive markers of bone formation, have been investigated in clinical and experimental studies in the early and late stages of osteoporosis (Risteli and Risteli, 1993). Several reports related to bone metabolism that the expression of ALP is maximized during bone matrix maturation (Alcantara et al., 2011). In addition, osteocalcin is a calcium-dependent biomarker that has a high affinity for the bone matrix to complete bone formation (Singh et al., 2015). In our study, levels of serum ALP and bone-specific ALP were lowly expressed in osteoporotic mice, while significantly recovered by administering PMT 6170 mg/kg. Additionally, OVX-induced mice treated with PMT augmented that diminished levels of serum Ca and osteocalcin. Thus, osteoblast differentiation is attributed to PMT by increasing levels of serum ALP, bALP, Ca and osteocalcin.

To clarify the underlying mechanism of PMT on the recovery of bone loss, osteoblastogenetic factors were investigated in femoral specimens. BMP-2 activates the expression of RUNX2 and OSX, which are mediated for osteoblast differentiation and new bone formation (Lee et al., 2003; Fan et al., 2013). In addition, bone-specific matrix proteins such as ALP, OPN and BSP-1 are also associated with osteoblast maturation for bone formation (Cowles et al., 1998). Hence, those genes are considered as the key markers of osteoporosis that newly construct a bone matrix. The present study determined that expression of osteoblastic markers BMP-2, RUNX2, OSX, ALP, OPN and BSP-1 were significantly decreased in OVX-induced osteoporosis while treating PMT increased those of osteoblastic markers in a dose-dependent manner. Therefore, PMT influences on osteoblasts to repair the balances of bone homeostasis and the formation of new bone matrix.

## CONCLUSION

Taken together, PMT has ameliorative effects on postmenopausal osteoporosis. In the previous study, *P. ginseng*, *P. lactiflora* and *L. officinale*, consists of *Palmul-tang*, is recently reported to enhance the osteoblast activities, leading to generation of new bone matrix (Yen et al., 2007; Kim et al., 2013; Dong et al., 2020). In addition, *A. macrocephala* and *P. cocos*, and decursin derived from *A. gigas* are known to ameliorate the development progress of osteoporosis by inhibiting osteoclast differentiation (Ha et al., 2013; Wang et al., 2016c; Hwang et al., 2020). Moreover, *G. uralensis* and *R. glutinosa* showed protective effects on osteoporosis by maintaining bone mineral density (Lim and Kim, 2013; Galanis et al., 2019). *Palmul-tang*, which is a combination of those eight herbs as a traditional herbal formula, was assumed to exhibit a synergic effect on bone formation in osteoporosis. In this study, PMT ameliorated bone loss in osteoporosis by activating osteoblastic markers

such as BMP-2 signaling pathway, leading to improving bone integrity. The bone marrow adiposity cavity filled with collagen fibers to restore the bone marrow tightly. Moreover, the expressions of the BMP-2 signaling pathway were upregulated by PMT treatment, resulting in an increase of bone differentiation and formation. These results might provide evidence of expanding the medical category and the basis of medical insurance in Korea for postmenopausal osteoporosis.

doi: 10.3389/fphar.2021.590602

**Objectives:** This study aimed to explore the mechanism of Xiong-Pi-Fang (XPF) in the treatment of coronary heart disease (CHD) with depression by an integrative strategy combining serum pharmacochimistry, network pharmacology analysis, and experimental validation.

**Methods:** An ultrahigh performance liquid chromatography-quadrupole-time-of-flight tandem mass spectrometry (UPLC-Q-TOF/MS) method was constructed to identify compounds in rat serum after oral administration of XPF, and a component-target network was established using Cytoscape, between the targets of XPF ingredients and CHD with depression. Furthermore, Gene Ontology and Kyoto Encyclopedia of Genes and Genomes pathway enrichment analyses were performed to deduce the mechanism of XPF in treating CHD with depression. Finally, in a chronic unpredictable mild stress (CUMS)-and isoproterenol (ISO)-induced rat model, TUNEL was used to detect the apoptosis index of the myocardium and hippocampus, ELISA and western blot were used to detect the predicted hub targets, namely AngII, 5-HT, cAMP, PKA, CREB, BDNF, Bcl-2, Bax, Cyt-c, and caspase-3.

**Results:** We identified 51 compounds in rat serum after oral administration of XPF, which mainly included phenolic acids, saponins, and flavonoids. Network pharmacology analysis revealed that XPF may regulate targets, such as *ACE2*, *HTR1A*, *HTR2A*, *AKT1*, *PKIA*, *CREB1*, *BDNF*, *BCL2*, *BAX*, *CASP3*, cAMP signaling pathway, and cell apoptosis process in the treatment of CHD with depression. ELISA analysis showed that XPF decreased Ang-II content in the circulation and central nervous system, inhibited 5-HT levels in peripheral circulation, and increased 5-HT content in the central nervous system and cAMP content in the myocardia and hippocampus. Meanwhile, western blot analysis indicated that XPF could upregulate the expression levels of PKA, CREB, and BDNF both in the myocardia and hippocampus. TUNEL staining indicated that the apoptosis index of myocardial and hippocampal cells increased in CUMS-and ISO-induced CHD in rats under depression, and XPF could increase the expression of Bcl-2, inhibit the expression of Bax, Cyt-c, and caspase-3, and rectify the injury of the hippocampus and myocardium, which exerted antidepressant and antimyocardial ischemia effects.

**Conclusion:** Our study proposed an integrated strategy, combining serum pharmacochimistry and network pharmacology to investigate the mechanisms of XPF in treating CHD with depression. The mechanism of XPF in treating CHD with depression may be related to the activation of the cAMP signaling pathway and the inhibition of the apoptosis.

**Keywords:** integrative pharmacology, serum pharmacochimistry, network pharmacology analysis, Xiong-Pi-Fang, coronary heart disease with depression

## INTRODUCTION

Coronary heart disease (CHD) is a chronic and complex disease that poses a serious threat to human health (Mozaffarian et al., 2016; Blais et al., 2020). Traditional risk factors are mainly related to hypertension, hyperlipidemia, diabetes, etc (Li C et al., 2020). Moreover, depression is another independent risk factor for CHD, as it has been shown to diminish the quality of life of patients with CHD and also increase the incidence and mortality of major adverse cardiac events (Su et al., 2018; de Heer et al., 2020). Increasing evidence suggests that the incidence of CHD with depression is increasing, ranging from approximately 15–18%, moreover, approximately 31% of these patients develop major depressive disorder (MDD) (Carney and Freedland, 2017). However, there are no effective chemicals to improve the quality of life and survival rate of patients with comorbid CHD and depression (Lee et al., 2018; Magaard et al., 2018).

The ideal medication for CHD with depression would be integrated, improving myocardial blood supply and regulating nervous system function at the same time (Yeung et al., 2014; Chen M et al., 2018; Xue et al., 2019). Xiong-Pi-Fang (XPF), a classical traditional Chinese medicine (TCM) formula, consists of Radix Bupleuri (*Bupleurum chinense* DC. and *Bupleurum scorzoniferifolium* Willd.) 15 g; Ligusticum wallichii (*Conioselinum anthriscoides* 'Chuanxiong' and *Ligusticum striatum* DC.) 12 g; Rhizoma Cyperi (*Cyperus rotundus* L.) 12 g; Sanders (*Santalum album* L.) 9 g; Fructus aurantii (*Citrus × aurantium* L. and *Citrus trifoliata* L.) 9 g; Dried tangerine peel (*Citrus × aurantium* L.) 15 g; Pinellia ternata (*Pinellia ternata* (Thunb.) Makino) 15 g; Herba Menthae (*Mentha haplocalyx* Briq.) 10 g; Perilla Stem (*Perilla frutescens* (L.) Britton) 15 g; Poria Cocos (*Wolfiporia extensa* (Peck) Ginns) 15 g; Rhizoma Atractylodis Macrocephalae (*Atractylodes Macrocephala* Koidz) 15 g; Radix Glycyrrhizae (*Glycyrrhiza uralensis* Fisch.) 9 g. It is widely used in clinical practices, showing satisfactory therapeutic effects in relieving angina pectoris, chest pain, and depression symptoms (Hou et al., 2017). However, it is difficult to fully understand the therapeutic mechanism of XPF for treating CHD with depression solely using traditional pharmacological methods. Hence, an integrated pharmacology-based strategy including computer high-throughput analytical techniques and biological experimental tools was established in this study, which provides a helpful method to reveal the potential bioactive ingredients and modern pharmacological mechanism of TCM (Park et al., 2018; Fang et al., 2019).

Integrative pharmacology, combined with conventional pharmacology, network pharmacology, bioinformatics, and

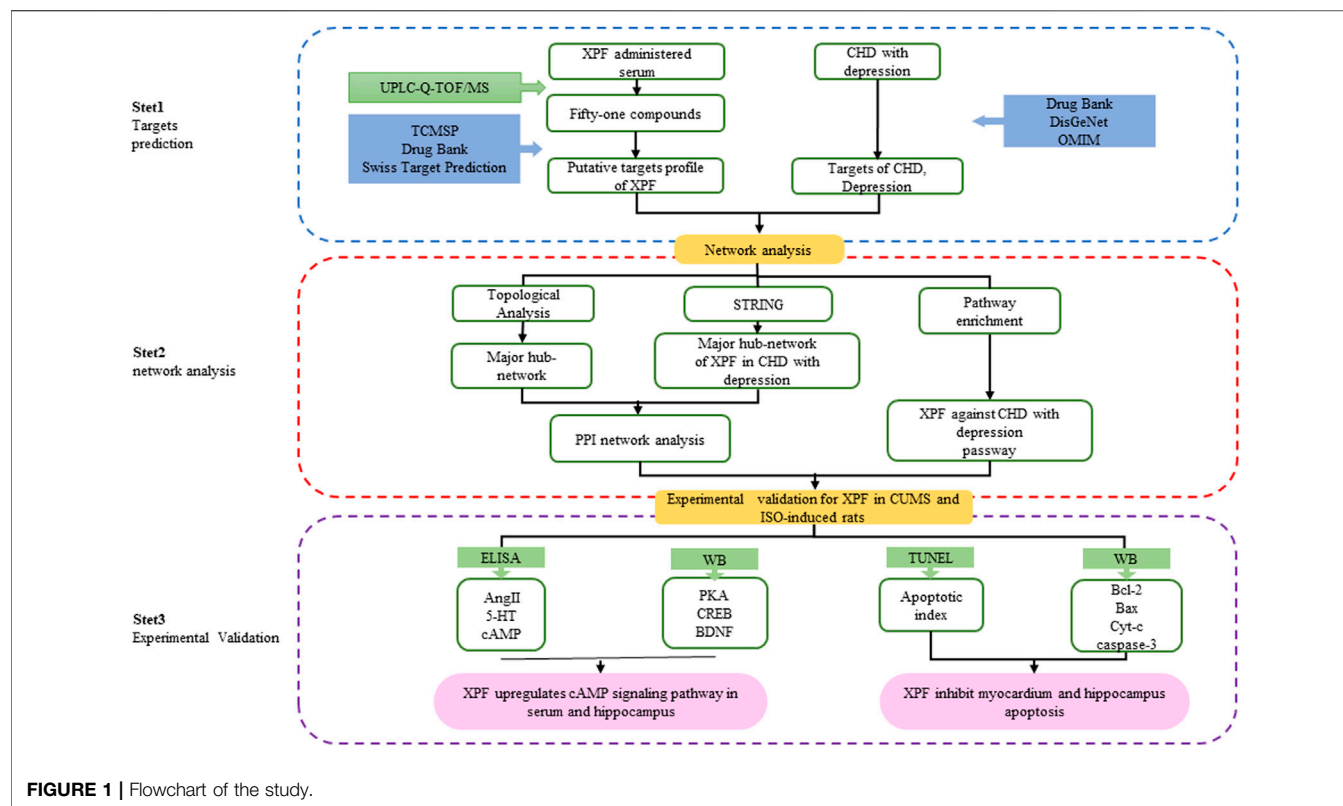

other disciplines, is the systematic study of the overall interactions between drugs and humans at the molecular, cell, organ, and network levels (Hart and Xie, 2016; Zhang R. et al., 2018; Zhang R. et al., 2019). Network pharmacology, characterized by integration, systematization, and emphasis on drug interaction (Yuan et al., 2017), predicts the biological molecular mechanism of drug treatment of diseases from a holistic perspective by constructing an interaction network between active ingredients and disease targets. However, most TCM-related databases provide information on chemical ingredients extracted *in vitro* (Zhang W et al., 2019). Previous studies have shown that the drug ingredients absorbed into the blood circulation may be the main active constituents (Chen et al., 2014; Li et al., 2016). Therefore, it is critical to combine serum pharmacochimistry with a network pharmacology strategy to accurately establish the network.

In this study, an integrated pharmacology strategy employing serum pharmacochimistry, network pharmacological analysis, and experimental validation was conducted to illustrate the therapeutic mechanism of XPF in treating CHD with depression (Figure 1). Briefly, An ultrahigh performance liquid chromatography-quadrupole-time-of-flight tandem mass spectrometry (UPLC-Q-TOF/MS) method was established to determine the main active components of XPF in rat serum. Furthermore, a serum pharmacochimistry-based network was constructed and the component–target network between CHD comorbid depression-relevant genes and the targets of active components in XPF was established. Finally, we validated the predicted molecular mechanisms obtained from the network analysis of XPF in treating CHD with depression in a chronic unpredictable mild stress (CUMS)-and isoproterenol (ISO)-induced CHD in a rat model of depression.

## MATERIALS AND METHODS

### Reagents and Materials

Sertraline hydrochloride (Pfizer Inc., United States), metoprolol (Asilkan, United Kingdom), Isoproterenol (Sigma Aldrich Co., United States) were purchased from the Shanghai Yuanye Biotechnology Co. Ltd (Shanghai, China). UPLC-Q-TOF/MS grade acetonitrile and HPLC grade acetonitrile, methanol, formic acid, were provided by Fisher Scientific International Inc (Fair Lawn, NJ). The ELISA assay kits for Ang-II (142191202), 5-HT (106191202), cAMP (202004) were purchased from Tianjin Zihan Biotechnology Co., Ltd. (Tianjin, China). TUNEL assay kit (7E310H9) was purchased from Vazyme Biotech Co., Ltd. (Nanjing, China), Rabbit

**FIGURE 1 |** Flowchart of the study.

antihuman monoclonal antibodies PKA (5842), CREB (6188), BDNF (3189), Bcl2 (26,593-1-12p), Bax (50,599-2-1 g), Cytochrome c (10993-1-Ap), and mouse antihuman monoclonal antibodies caspase-3 (66,470-E1g) and  $\beta$ -actin were provided by Proteintech Group, Inc. (Wuhan, China).

## Animals

Male Sprague-Dawley rats (weighing  $200 \pm 20$  g) were purchased from the Experimental Animal Center of the Academy of Military Medical Sciences (Beijing, China), and kept in an environmentally controlled room (temperature  $22 \pm 2^\circ\text{C}$ , humidity  $50 \pm 10\%$ ) with food and water available. This study was carried out in accordance with the principles of the Basel Declaration and the guidelines of the National Institutes of Health. All animal experiments were approved by the Ethics Committee of Tianjin University of Traditional Chinese Medicine (Tianjin, China).

## UPLC-Q-TOF/MS Method for Serum Pharmacochimistry Analysis

XPF was prepared by the pharmacy of the Second Affiliated Hospital of Tianjin University of Traditional Chinese Medicine (Tianjin, China). Twelve rats were randomly divided into a control group ( $n = 6$ , 0.9% saline IG), and According to the calculation method of equivalent dose coefficient of experimental animals in *Methodology of Pharmacological Experiment* (Xu et al., 2018), the XPF group ( $n = 6$ , 32.7 g/kg XPF IG), equivalent to twice the clinical effective dose, for three days (Xu et al., 1997). All

rats fasted for 12 h before the experiment and then the serum samples were collected at 120 min after oral administration, via the postorbital venous plexus. The serum samples were centrifuged at 12,000 rpm for 10 min at  $4^\circ\text{C}$ . Then, 300  $\mu\text{L}$  of serum was added to three times the amount of acetonitrile, vortexed for 2 min, followed by ultrasonic extraction for 10 min, and centrifugation (12,000 rpm, 10 min). and The supernatant was collected and placed in a  $\text{N}_2$  blower to blow dry at  $40^\circ\text{C}$ , 50% acetonitrile (50  $\mu\text{L}$ ) was added to the residue, vortexed for 3 min, ultrasound for 10 min, centrifugation (12,000 rpm, 10 min), and the supernatant was collected for UPLC-Q-TOF/MS analysis.

UPLC-Q-TOF/MS analysis was analyzed on a Waters ACQUITY<sup>TM</sup> UPLC BEH C18 (100 mm  $\times$  2.1 mm, 1.7  $\mu\text{m}$ ) system, maintained at  $30^\circ\text{C}$ . The flow rate was set at 0.45 ml/min, and the injection volume was 5  $\mu\text{L}$ . The mobile phase was consisted of water (A) and methanol (B) both containing 0.1% (v/v) formic acid for astragaloside (0–5 min, 2% B; 5–8 min, 2%–20% B, 8–11 min, 20% B, 11–14 min, 20%–48% B, 14–20 min, 48%–70% B, 20–23 min, 70%–90% B, 23–26 min, 90%–100% B, 26–30 min, 100% B). The mass spectrometer analysis was performed with reaction monitoring both in positive and negative ion modes.

## Construction of the Compound-Target and Disease-Target Networks

All targets of active components of XPF determined by serum pharmacochimistry analysis were collected from TCM-related databases, including TCMSP (<http://tcmspw.com/tcmsp.php>)

(Ru et al., 2014), DrugBank (<https://www.drugbank.ca/>) (Wishart et al., 2018), Swiss Target Prediction (<http://www.swisstargetprediction.ch/>) (Gfeller et al., 2014), and Similarity Ensemble Approach (<http://sea.bkslab.org/>) (Wang et al., 2016).

Known therapeutic targets related to CHD and depression were obtained from the DrugBank database (Wishart et al., 2018), Online Mendelian Inheritance in Man (OMIM) (<http://www.omim.org/>) (Amberger and Hamosh, 2017), DisGeNet database

(<http://www.disgenet.org/web/DisGeNET/menu/home>) (Li Y et al., 2020), and Therapeutic Target database (TTD) (<https://db.idrblab.org/ttd/>) (Li et al., 2018). The common potential target of XPF in the treatment of CHD with depression was obtained by comparing the component target with the disease target analysis. Then, the component–target network between the targets of active components in XPF and CHD with depression was established using Cytoscape (Version 3.8.0) (Otasek et al., 2019).

## Topological Analysis and Pathway Enrichment Analysis

A network analyzer was used to calculate the topological analysis of the nodes of the component–target network. Nodes with degrees higher than the average number 4) were identified as the core targets, and were brought into the STRING database (<https://string-db.org/>) (Szklarczyk et al., 2017) to obtain the interacting proteins. Then, the PPI network was constructed using Cytoscape for visual analysis and, according to topological features (degree centrality), the major hub target was extracted. Further, the core targets were brought into the DAVID database (<https://david.ncifcrf.gov>) (Dennis et al., 2003), and Kyoto Encyclopedia of Genes and Genomes (KEGG) signaling pathway enrichment analysis and Gene ontology (GO) were performed to obtain the representative biological processes and pathways (cutoff at  $p < 0.05$ ) of XPF in treating CHD with depression.

## Animal Model Preparation and Drug Treatments

Sixty-four male Sprague-Dawley rats (weighing  $200 \pm 20$  g) were randomly divided into a normal control group ( $n = 8$ ) and a depressive-like behavioral group ( $n = 56$ ). Experimental rats ( $n = 56$ ) were exposed to chronic unpredictable mild stress (CUMS) to induce depression. The regimen consisted of immobilization for 4 h; cage tilting at  $45^\circ$  for 12 h; continuous illumination for 24 h; clip the distal 1 cm rat tails with tongs for 3 min; deprivation of water for 24 h; noise stimulation for 30 min; damp animal bedding for 24 h; foot shock for 3 min; removal of animal bedding for 24 h; high-speed agitation for 10 min; deprivation of food 24 h; and forced cold swim stress for 6 min at  $4^\circ\text{C}$ . Each animal received two stressors randomly per day for a total of 28 days. The normal control group ( $n = 8$ ) remained undisturbed. Subsequently, the CUMS-induced rats were injected with ISO (8 mg/kg) for five days to form the CHD model (Aa et al., 2019; Hu et al., 2020). The rat model for CHD with depression induced by CUMS and ISO was evaluated by measuring rat body weight change, open field test, sucrose preference test, and ST-segment of the electrocardiogram. Then, all CHD with depression rats were randomly divided into a model group ( $n = 15$ , 0.9% saline, IG), Ser + Met group ( $n = 8$ , sertraline 10 mg/kg + metoprolol 5 mg/kg, IG), Ser group ( $n = 8$ , sertraline 10 mg/kg, IG), Met group ( $n = 8$ , metoprolol 10 mg/kg, IG), high-dose XPF (XPF-H) group ( $n = 8$ , 32.7 g/kg, IG), equivalent to CH 3.13 g/kg, CX 2.5 g/kg, XF 2.5 g/kg, TX 1.88 g/kg, ZQ 3.13 g/kg, CP 3.13 g/kg,

BX 3.13 g/kg, BH 2.08 g/kg, FL 3.13 g/kg, BZ 3.13 g/kg, ZS 3.13 g/kg, GC 3.13 g/kg, medium-dose XPF (XPF-M) group ( $n = 8$ , 16.35 g/kg, IG), equivalent to CH 1.65 g/kg, CX 1.25 g/kg, XF 1.25 g/kg, TX 0.94 g/kg, ZQ 1.65 g/kg, CP 1.65 g/kg, BX 1.65 g/kg, BH 1.04 g/kg, FL 1.65 g/kg, BZ 1.65 g/kg, ZS 1.65 g/kg, GC 0.94 g/kg, and low-dose XPF (XPF-L) group ( $n = 8$ , 8.175 g/kg, IG), equivalent to CH 0.78 g/kg, CX 0.62 g/kg, XF 0.63 g/kg, TX 0.47 g/kg, ZQ 0.78 g/kg, CP 0.78 g/kg, BX 0.78 g/kg, BH 0.52 g/kg, FL 0.78 g/kg, BZ 0.78 g/kg, ZS 0.78 g/kg, GC 0.47 g/kg. The control group received 0.9% saline via oral administration. The drugs were administered daily for three weeks, while the animals were exposed to CUMS, except for the control group. At 24 h after the last treatment, all rats were sacrificed, and the brain, hippocampus, and heart tissues were rapidly extracted from each rat, stored at  $-80^\circ\text{C}$  until analysis. One part of the brain and heart tissues were placed into a flask containing 4% paraformaldehyde.

## TUNEL Staining

TUNEL staining was performed according to the manufacturer's instructions, to determine hippocampus and myocardial apoptosis. The apoptotic cells showed red fluorescence and the nucleus showed blue fluorescence, six high-power fields were selected from each sample. All cells and positive stained cells were counted, the percentage of positively stained cells was apoptotic index (AI) (AI = number of apoptotic cells/total number of nucleated cells).

## ELISA Analysis

The level of 5-HT, Ang-II, cAMP in hippocampus and myocardial were quantified by ELISA assay kit, according to the manufacturer's instruction. After color development, the absorbance was measured at 450 nm with fluorescence reader (THERMO USA).

## Western Blot Analysis

Hippocampus, hearts tissue proteins were mechanically homogenized in lysis buffer, centrifuged at 12,000 rpm for 10 min at  $4^\circ\text{C}$ , collected the supernatant. BCA protein assay was used to determine protein concentrations. Equal concentrations of protein were resolved on 10% SDS-PAGE gels, and were transferred onto PVDF membranes. These membranes PVDF were soaked in TBST buffer with 5% non-fat skim milk for 2 h, and then These membranes PVDF were incubated in the primary antibodies (PKA, CREB, BDNF, Bcl-2, Bax, Cyt-c, caspase-3, and  $\beta$ -actin) overnight at  $4^\circ\text{C}$ . Subsequently, the membrane was washed for 5 times with TBST, followed by secondary antibodies incubated with horseradish peroxidase for 2 h at room temperature. After rewashing with TBST, the membranes were scanned on X-ray film by chemiluminescence reaction, used ImageJ software to analysis the band intensity.

## Statistical Analysis

Data were expressed as mean  $\pm$  SD. Differences between groups were analyzed using a one-way analysis of variance (ANOVA), followed by Dunnett's  $t$  test. All data were analyzed statistically

**FIGURE 2 |** BPI chromatograms of XPF in serum sample in positive **(A)** and negative **(B)** ion modes determined by UPLC-Q-TOF/MS.

using GraphPad Prism 8.0 (GraphPad Software, Inc., La Jolla, CA, USA),  $p$ -value < 0.05 was considered significant.

## RESULTS

### Serum Pharmacochemistry Analysis of XPF by UPLC-Q-TOF/MS

Based on the established UPLC-Q-TOF/MS method, 51 serum prototypes of the drugs were analyzed and identified (**Table 1**). These compounds can be roughly divided into three categories: phenolic acids, saponins, and flavonoids. **Figure 2** shows the base peak chromatogram (BPC) of each typical sample in the mode of positive and negative ions, and peaks 1–51 are the original components entering the blood. These 51 compounds of XPF detected in the serum were determined to be the main active components and further selected to predict the targets and pathways using network analysis.

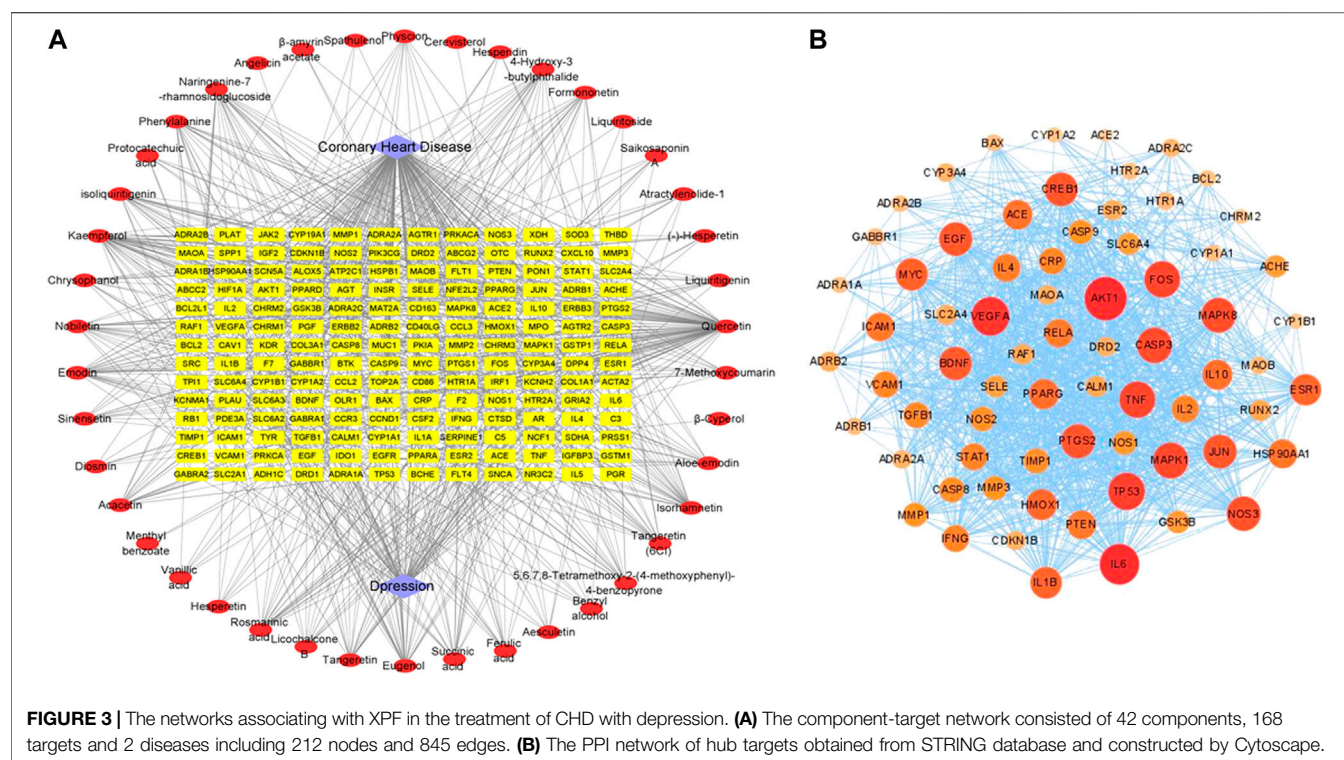

### Component-Target Network Construction

In this work, 820 targets for the 51 (Nine of them had no therapeutic targets) components were explored by using TCMSP, Swiss Target Prediction, Drugbank, and Swiss Target Prediction as shown in **Supplementary Table S1**, and 1817 candidate targets of CHD and depression were obtained from Drugbank, OMIM, and DisGeNet databases as shown in **Supplementary Table S2**. Taking the intersection of component targets and candidate targets associated with CHD and depression, 168 consensus targets were generated as potential targets for XPF in treating CHD and depression, which were used

to construct a component–target network using Cytoscape. As shown in **Figure 3A**, the network comprised 42 components, 168 targets, and two diseases, and included 212 nodes and 845 edges.

### Topological Analysis and Pathway Enrichment Analysis

Among the 168 consensus targets, 75 major targets with degrees higher than the average number 4) were considered as the major targets (**Table 2**). Ten components with degrees higher than 20 were identified as the main active components (Kaempferol and quercetin were not included because they are widely distributed and have many targets, but their pharmacological effects are weak) (**Table 3**). The 75 major targets were brought into the STRING database to obtain protein-protein interaction (PPI) predictions. The PPI network was constructed using Cytoscape, and hide disconnected nodes in the network (5 nodes). A network analyzer was used to calculate topological features (degree) of the 70 major targets (**Figure 3B**). Among these, 10 target genes (*ACE2*, *HTR1A*, *HTR2A*, *AKT1*, *PKIA*, *CREB1*, *BDNF*, *BCL2*, *BAX*, and *CASP3*), with higher degree were recognized as the major hub targets of XPF in treating CHD with depression. KEGG pathway enrichment and GO analyses of the 75 major targets were performed using the DAVID database. GO analysis showed 184 enriched processes (**Supplementary Table S3**), including 126 biological processes, 39 molecular functions, and 19 cellular components. The top 30 according to  $p$ -values are shown in **Figure 4A**. KEGG pathway enrichment showed 117 signaling pathways, as shown in **Supplementary Table S4**, and the top 20 pathways according to  $p$ -values are shown in **Figure 4B**.

## Experimental Validation

### Evaluation of Depressive-like Behaviors of Chronic Stress-Depressed Rats

The open field test can reflect the spatial exploration behavior of rats (Chen et al., 2019), and sucrose preference test could be the objective indicator of hedonic behavior (Gross and Pinhasov, 2016b). All rats were evaluated by open field test, sucrose preference test before and after the CUMS and ISO-induced process, then all CHD with depression rats were randomly divided into 7 groups. After three weeks of administration, open field test and sucrose preference test were performed again of all rats. As shown in **Table 4**, after CUMS and ISO-induced, compared with the control group the open-field test and sucrose preference scores were significantly reduced in the model group and each administration groups ( $p < 0.005$ ). It was shown that the depression model was successfully established. After treatment for 21 days, compared with the model group, XPF administration significantly improve the open-field test and sucrose preference scores ( $p < 0.005$ ).

## Effects of XPF on Myocardial and Hippocampal Apoptosis

Apoptosis can cause myocardial and hippocampal injury and dysfunction, which are the major mechanisms of CHD and depression. As shown in **Figure 5**, the myocardial and hippocampus of the CUMS and ISO-induced rats were injured. The effects of XPF on myocardial apoptosis are shown in **Figure 5A**. And the effects of XPF on hippocampal apoptosis are shown in **Figure 5B**. Compared with the control

group, the myocardial and TUNEL-positive cells were significantly increased in the model group, as shown in **Figure 5C** ( $p < 0.005$ ). The myocardial apoptotic index of the XPF-H and XPF-M groups was significantly lower than that of the model group ( $p < 0.01$ ). Sertraline 10 mg/kg + metoprolol 5 mg/kg and metoprolol 10 mg/kg also significantly inhibited the apoptosis in the myocardia (**Figure 5C**) ( $p < 0.005$ ). Sertraline (10 mg/kg) and low-dose XPF treatment did not alter myocardial apoptosis.

There were significant differences in the total apoptotic index in the hippocampus after XPF treatment for 21 days. In the model group, the apoptotic index significantly increased compared with the control group, as shown in **Figure 5D**. Furthermore, XPF administration significantly decreased the apoptotic index in the hippocampus. Additionally, sertraline and metoprolol also significantly inhibited apoptosis in the hippocampus ( $p < 0.005$ ).

The results indicated that the brain and myocardial tissues of the rats were injured after CUMS and ISO-induced damage. It was shown that the CHD with depression model was successfully established, while the treatment of XPF can inhibit apoptosis of myocardial and brain tissue simultaneously.

According to key proteins with a higher degree in the PPI network and KEGG pathway enrichment analysis, it is suggested that the mechanism of XPF in the treatment of CHD with depression may be through the regulation of *ACE2*, *HTR1A*, *HTR2A*, *AKT1*, *PKIA*, *CREB1*, *BDNF*, *BCL2*, *BAX*, *CASP3*, cAMP signaling pathway, and the cell apoptosis process. As the second intracellular messenger, cAMP regulates the expression of downstream proteins and plays an important role in cell growth and apoptosis (Zhou et al., 2012). Bcl-2 and Bax, as

targets downstream of CREB and BDNF, regulate apoptosis through the mitochondrial pathway (Mi et al., 2015; Tang et al., 2016). Recent studies have shown that the cAMP-PKA-CREB-BDNF signaling pathway is closely related to depression (Wang et al., 2017; Ye et al., 2017). Meanwhile, the related proteins in the cAMP-PKA-CREB-BDNF signaling pathway can also improve myocardial microcirculation, improve the ability of myocardial cells to resist ischemia and hypoxia, and effectively prevent the development and deterioration of CHD (Huang et al., 2016). To verify whether XPF works in treating CHD with depression by intervening in the cAMP-PKA-CREB-BDNF signaling pathway and cell apoptosis process, the expression of 5-HT, Ang-II, cAMP, PKA, CREB, BDNF, Bcl-2,

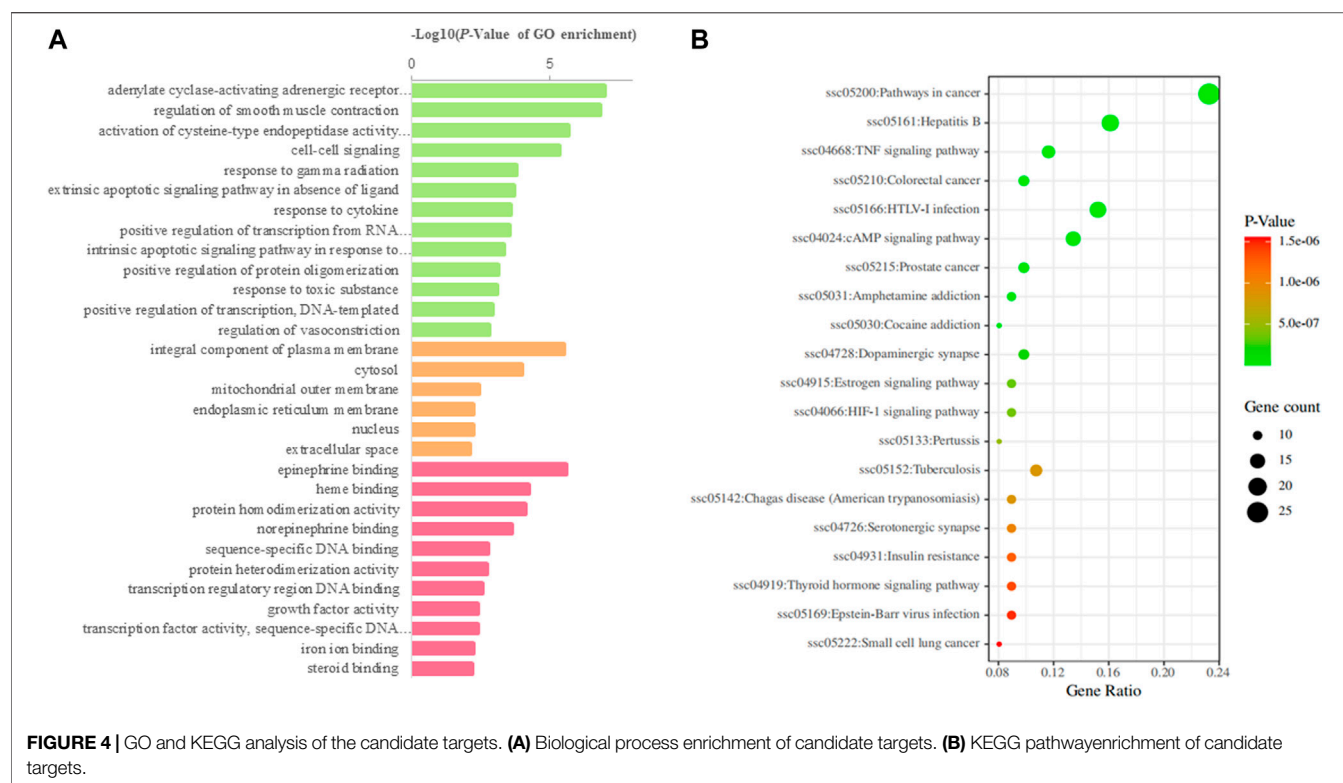

Bax, Cyt-c, and caspase-3 in the myocardial and hippocampal tissues were detected.

### 3.4.3 Effects of XPF on the Expression of Ang-II, 5-HT, and cAMP in Myocardial Tissues

As shown in **Figures 6A–C**, it was noted that compared with the control group, the levels of Ang-II and 5-HT were significantly increased in the myocardial tissues in the model group. Compared with the control group, the expression of cAMP in the myocardial tissues was markedly lower in the model group ( $p < 0.005$ ). After treatment for 21 days, high-dose XPF decreased the levels of Ang-II and 5-HT in the myocardium ( $p < 0.01$ ). The treatments with middle-dose XPF solely decreased the levels of Ang-II ( $p < 0.05$ ), whereas low-dose XPF had no effect on the levels of Ang-II and 5-HT in the myocardium. The levels of cAMP were significantly increased, in a dose-dependent manner, in the myocardium of the rats in the XPF-H, XPF-M, and XPF-L groups ( $p < 0.005$ ).

### 3.4.4 Effects of XPF on the Expression of Ang-II and 5-HT cAMP in the Hippocampus

As shown in **Figures 6D–F**, it was noted that, compared with the control group, the levels of Ang-II were significantly increased in the hippocampus of the model group. Conversely, the expression of 5-HT and cAMP in the hippocampus was markedly lower in the model group. After treatment for 21 days, the treatment with

Values are expressed as the mean ± SD; n = 6–8 in each group. Compared with control group after CUMS and ISO-induced.

\*\*\*P < 0.005. Compared with model group after CUMS and ISO-induced, <sup>Δ</sup>P > 0.05. Compared with model group after treatment, \*\*\*P < 0.005.

high-dose XPF and middle-dose XPF significantly decreased the levels of Ang-II ( $p < 0.005$ ) and increased the levels of 5-HT and cAMP in the hippocampus ( $p < 0.05$ ). Similarly, treatment with metoprolol markedly decreased the levels of Ang-II, and treatment with sertraline increased the levels of 5-HT and cAMP in the hippocampus ( $p < 0.05$ ). However, low-dose XPF had no effect on the levels of Ang-II, 5-HT, and cAMP in the hippocampus.

### Effects of XPF on the Expression of PKA, CREB, and BDNF on Myocardial Tissue

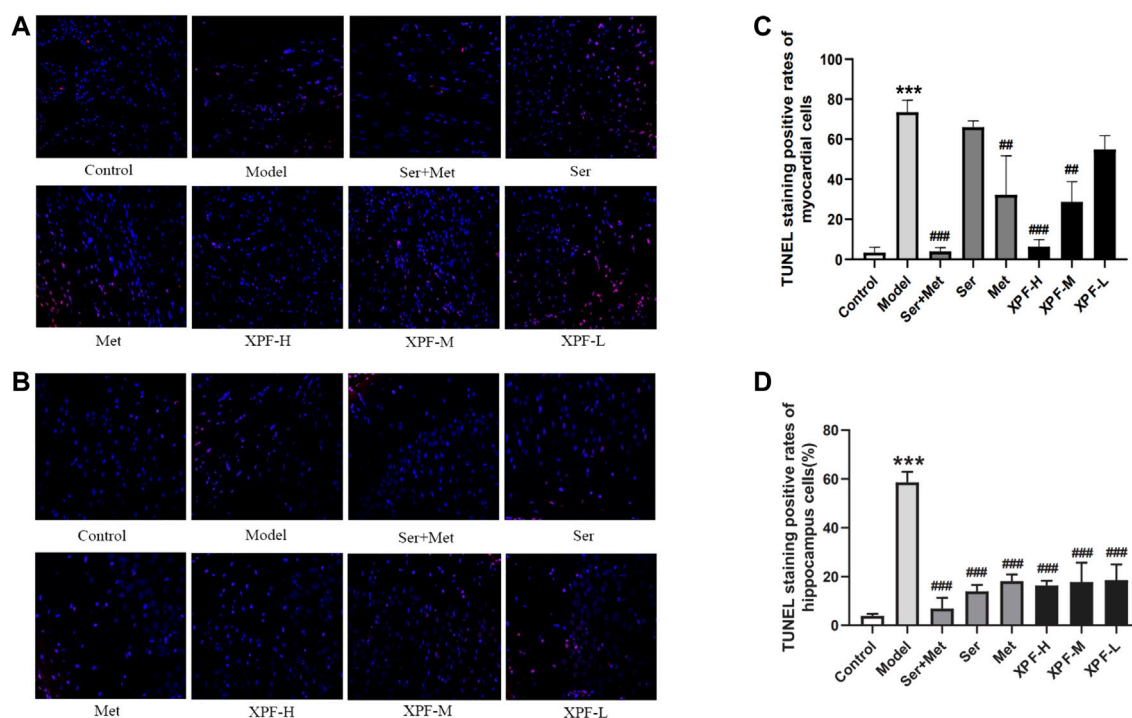

As presented in **Figures 7A–C**, the results of the WB analysis indicated that the expression of PKA, CREB, and BDNF in the

myocardium in the model group was significantly lower than that of the control group ( $p < 0.005$ ). XPF could upregulate the expression of PKA, CREB, and BDNF compared with the model group ( $p < 0.05$ ).

### Effects of XPF on the Expression of PKA, CREB, and BDNF in the Hippocampus

As shown in **Figures 7D–F**, the PKA, CREB, and BDNF protein levels of the model group were significantly lower than those of the control group. High-dose XPF and middle-dose XPF was able to upregulate the expression of PKA, CREB, and BDNF compared with the model group ( $p < 0.005$ ). However, low-dose XPF had no effect on the levels of CREB and BDNF in the hippocampus.

**FIGURE 5 |** Anti-apoptosis effect of XPF on CUMS and ISO-induced rats ( $\times 400$ ). **(A)** Representative images of myocardial apoptosis stained by TUNEL. **(B)** Representative images of hippocampal apoptosis stained by TUNEL. **(C)** Rate of myocardial apoptosis in each group. **(D)** Rate of hippocampal apoptosis in each group. Data were presented as means  $\pm$  SD ( $n = 3$ ). \*\*\* $p < 0.05$  compared with the control group, ## $p < 0.01$ , # $p < 0.005$  compared with the model group.

### Effects of XPF on the Expression of Bcl-2, Bax, Cyt-C, and Caspase-3 in the Myocardium

As shown in **Figure 8** and **Table 5**, compared with the control group, the levels of Bax, Cyt-c, and caspase-3 were significantly increased in the model group, although Bcl-2 levels significantly decreased. Treatment with XPF significantly increased the levels of Bcl-2 and decreased the levels of Bax, Cyt-c, and caspase-3 ( $p < 0.005$ ), in a dose dependent manner.

### Effects of XPF on the Expression of Bcl-2, Bax, Cyt-C, and Caspase-3 in the Hippocampus

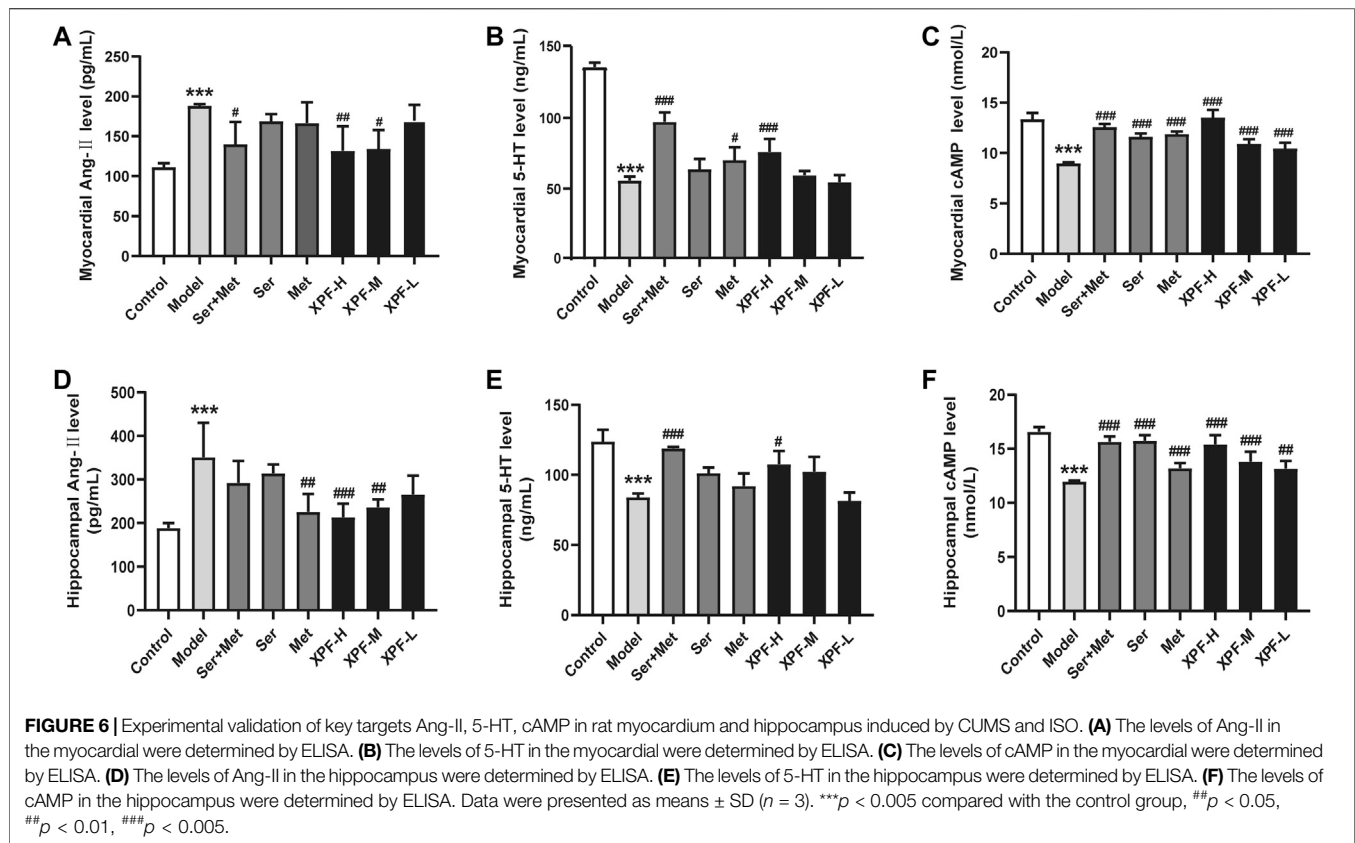

As shown in **Figure 9** and **Table 6**, the results of the WB analysis indicated that the expression of Bax, Cyt-c, and caspase-3 was significantly increased in the model group, while Bcl-2 levels were significantly decreased. After treatment for 21 days, high-dose XPF and middle-dose XPF significantly decreased the levels of Bax, Cyt-c, and caspase-3 ( $p < 0.005$ ). High-dose, and middle-dose XPF also increased the levels of Bcl-2 ( $p < 0.05$ ), in a dose-dependent manner. In contrast, low-dose XPF only inhibited the expression of Bax and Cyt-c ( $p < 0.005$ ), but had no effect on the expression of Bcl-2 and caspase-3.

## DISCUSSION

XPF, characterized by multiple components and targets, has been shown to have a relatively satisfactory therapeutic effect in treating CHD with depression. XPF can improve myocardial

blood supply and mental state of patients at the same time, which reflects the overall concept of traditional Chinese medicine (Hou et al., 2017). Through this study, we found that XPF could protect the myocardium and hippocampus in CUMS and ISO-induced CHD in depression rats, it shows that XPF has the advantages and characteristics of treating the heart and brain at the same time. However, it is difficult to accurately identify and understand the active compounds and mechanisms of XPF in treating CHD with depression solely by using conventional pharmacological methods. Therefore, new research approaches to reveal the interaction between components of TCM and biological system networks are urgently required. Here, an integrated strategy was established by combining serum pharmacology and network pharmacology to comprehensively and systematically investigate the components and mechanisms of XPF in treating CHD with depression, and validated in experiments.

In this study, 51 compounds were detected in rat serum after oral administration of XPF using UPLC-Q-TOF/MS technology. The identified constituents, mainly phenolic acids, saponins, and flavonoids, were determined to be the main active components of XPF. Among them, phenolic acids, such as rosmarinic acid and eugenol, can inhibit vascular smooth muscle cell proliferation and have a cardioprotective effect (Liu Y et al., 2018). Rosmarinic acid can treat neurodegenerative diseases via anti-neuroinflammatory activity (Wei et al., 2018). Furthermore, saponins, such as saikosaponin A, are the major bioactive component extracted from *Radix Bupleuri* (Chen et al., 2018; Liu R et al., 2018) and

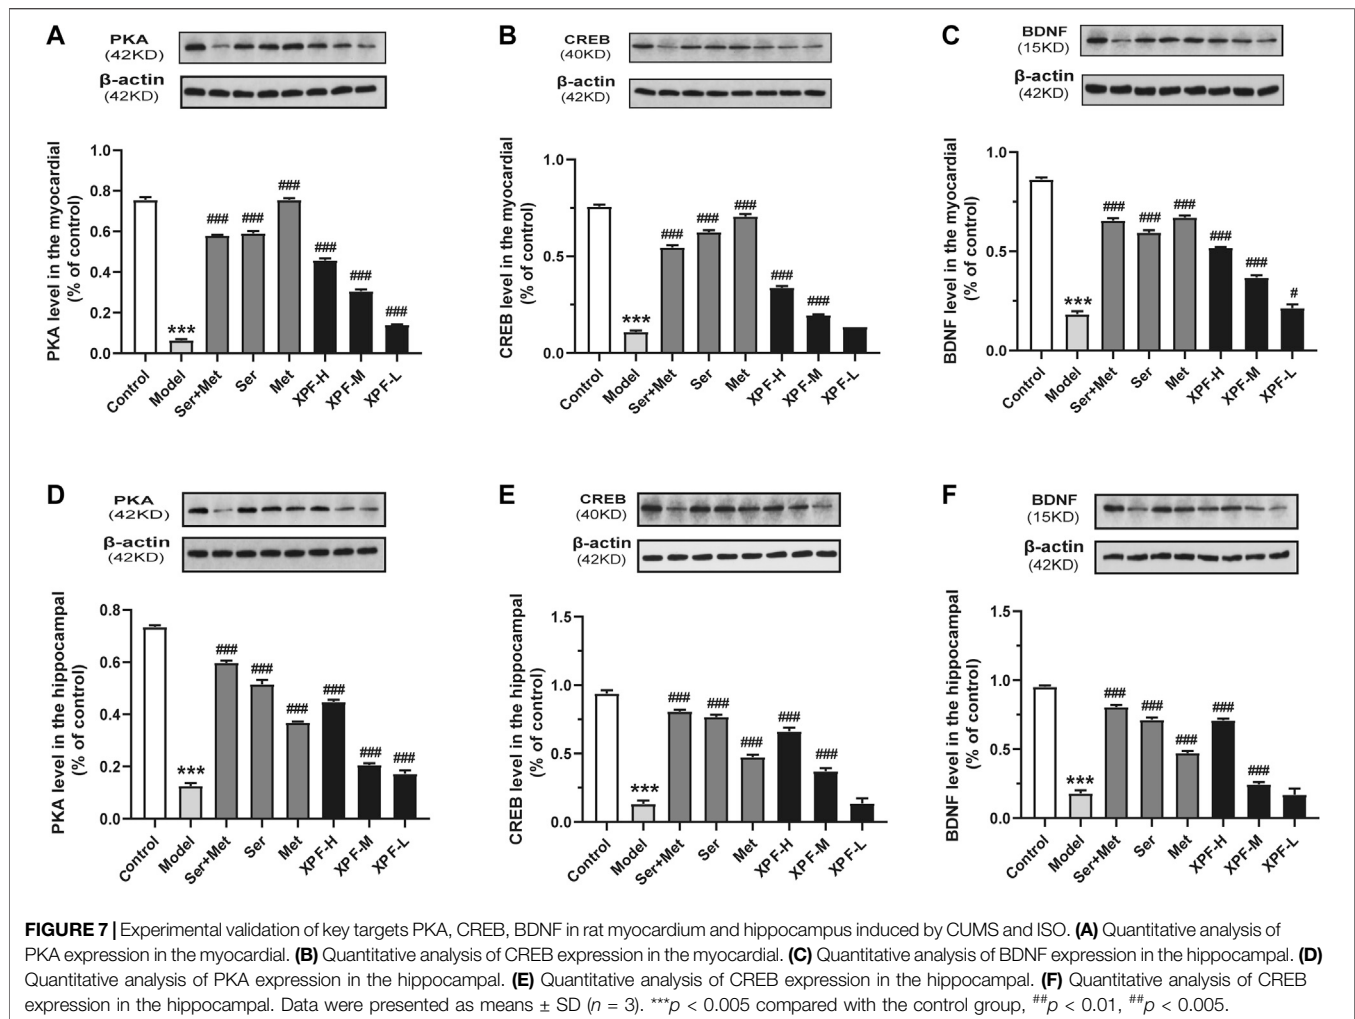

have anti-inflammatory and antioxidant pharmacological activities, as well as a good therapeutic effect on many diseases of the central nervous system and cardiovascular system (Guo et al., 2020). Flavonoids, such as hesperidin and hesperetin, can inhibit inflammatory reactions and oxidative stress, and protect nerve cells and vascular endothelium (Hwang et al., 2012; Van Ryment et al., 2017).

Moreover, the component-target network between the targets of absorbed components in the serum of XPF and CHD with depression was built using Cytoscape, followed by topological parameters and PPI analysis. As a result, 8 components (eugenol, emodin, isorhamnetin, nobiletin, isoliquiritigenin, rosmarinic acid, 4-Hydroxy-3-butylphthalide, and acacetin), with higher degree centrality were determined to be the active ingredients of XPF, and 10 hub targets, including (ACE2, HTR1A, HTR2A, AKT1, PKIA, CREB1, BDNF, BCL2, BAX, CASP3, cAMP) were determined as hub targets of XPF in treating CHD with depression. GO analysis and KEGG pathway enrichment analysis showed that XPF may regulate the cAMP signaling and apoptosis pathways by interfering with the expression of Ang-II, 5-HT, cAMP, PKA, CREB, BDNF, Bcl-2, Bax, Cyt-c, and caspase-3.

In this study, CUMS and ISO-induced CHD in a rat model of depression was used to explore the mechanism of XPF in treating CHD with depression. These rats showed a large number of apoptotic cells in myocardial and hippocampal tissues compared with the control group, which indicated

that the CHD with depression model was successfully established. Sertraline and metoprolol were used as positive control drugs to treat CHD in rats with depression. Sertraline can increase the content of 5-hydroxytryptamine (5-HT) in the brain and exert antidepressant-like effects (Sun et al., 2020). Metoprolol is a beta-blocker commonly used in the clinic (Podlesnikar et al., 2019; Qin et al., 2020). Studies have shown that metoprolol could reduce the oxygen consumption of the myocardium and reduce the risk of cardiovascular events (Assimon et al., 2018). However, co-administration of sertraline and metoprolol increases the blood concentration of metoprolol. Therefore, we adjusted the dose of metoprolol in the sertraline and metoprolol groups in this study (Bahar et al., 2018).

Under these experimental conditions, XPF could decrease Ang-II content in the circulation and central system, inhibit 5-HT level in peripheral circulation, and increase 5-HT content in the central nervous system. Meanwhile, XPF could upregulate the expression levels of cAMP, PKA, CREB, and BDNF both in the myocardium and hippocampus, which matched the predicted results of the network pharmacological analysis. Interestingly, sertraline regulated the cAMP, PKA, CREB, and BDNF levels in the hippocampus, but had a limited effect on the myocardium. Metoprolol can regulate the cAMP, PKA, CREB, and BDNF expression in myocardial, but it has a limited effect on the central nervous system. XPF treatment not only activated the cAMP signal pathway, but also further inhibited apoptosis and protected

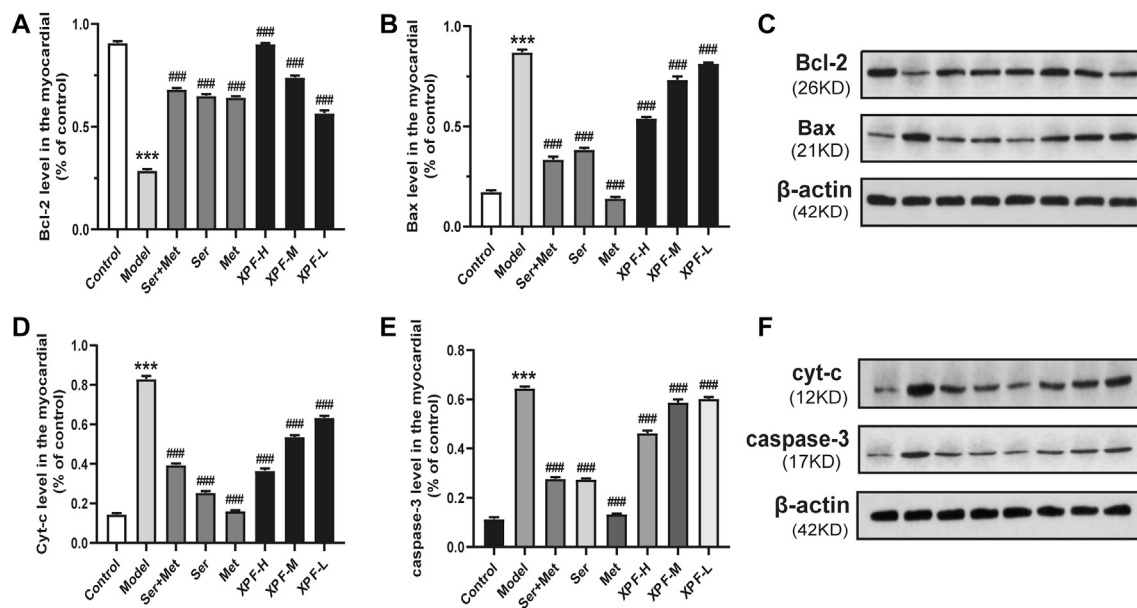

the myocardium and hippocampus. The cAMP signaling pathway can increase the expression of Bcl-2 and inhibit the activation of caspase-3 by regulating the expression of CREB and BDNF proteins (Mo et al., 2020; Yang et al., 2020). In this study, XPF rectified the injury of the hippocampus and myocardium caused by CHD in depressed rats, significantly decreasing the hippocampal and myocardial levels of Bax, Cyt-c, caspase-3, and increased Bcl-2 expression, which suggests that XPF may inhibit hippocampal and myocardial apoptosis, improve heart function and nerve function, and exert antidepressant and anti-myocardial ischemia effects.

Chronic stressful life events can stimulate the renin-angiotensin-aldosterone system (RAAS). Evidence has shown that Ang-II levels are significantly higher in patients with CHD and depression. Ang-II is metabolized into Ang-(1-7), which directly interferes with the intestinal uptake of tryptophan and affects the metabolism of 5-HT (Klempin et al., 2018; W et al., 2020). The decrease of 5-HT levels in the central nervous system leads to depression or other mental disorders (Jiao et al., 2019; Wenxiu et al., 2020). 5-HT metabolic disorder inhibits the cAMP signaling pathway (Louiset et al., 2017). The cAMP signaling

pathway was observed in both CHD and depression patients (Amare et al., 2017; Wang and Mao, 2019; Sandrini et al., 2020).

Activated cAMP and PKA can phosphorylate the  $Ca^{2+}$  channel on the cell membrane, promote calcium flow in cardiomyocytes, promote excitation contraction coupling, enhance myocardial contractility, improve the anti-ischemic effects of cardiomyocytes, and produce protective effects on cardiomyocytes (Inserre et al., 2004; Zhang et al., 2010). At the same time, cAMP and PKA are also widely distributed in the nervous system, which can guide the regeneration of neurons, improve the plasticity of synapses, and play a role in protecting the nervous system (Zhang M et al., 2018). CREB is involved in a wide range of neural plasticity processes, including neuronal survival, neuroprotection, neurogenesis, synaptic plasticity, and regulation of emotional expression (Liu et al., 2016; Tang et al., 2020). BDNF is a classical downstream target gene of CREB, which can nourish nerves and promote the differentiation, increment, and regeneration of neurons (Wang et al., 2019). BDNF also has a modulatory role in cardiovascular function, is involved in angiogenesis maintenance of endothelial integrity (Kaess et al., 2015; Jin et al., 2018), repairing myocardial

microcirculation, and maintaining myocardial cell function after myocardial injury (Lee et al., 2017). Low expression of CREB and BDNF causes Bax overexpression, Bcl-2 expression is inhibited, and the promotion of the release of apoptosis factors such as cytochrome c (Cyt-c) into the cytoplasm and increased caspase-3. Caspase-3, the final executive factor of apoptosis, leads to apoptosis (Xu et al., 2018). Bcl-2 can form a heterodimer with Bax to inhibit its function, Bcl-2 can also inhibit the activation of caspase-3, and inhibit apoptosis (Abu et al., 2018). Meng (Meng and Wang, 2013) have found that Baishile (BSL) capsule could significantly improve the CUMS rats with depression-like behavior; K252a could block the cAMP signaling pathway to antagonize the antidepressant effect of BSL capsule. Jiang (Jiang et al., 2017) have found that acupuncture could improve

depressive-like behaviors via PKA/CREB signaling pathway, H89 could block the PKA/CREB signaling pathway to antagonize the antidepressant effect of acupuncture. Mao (Mao and Zhang, 2014) have found H89 could block the PKA/CREB signaling pathway to antagonize the myocardial protective effect of Danlou tablets. Therefore, enhanced expression of related proteins in the cAMP signaling pathway and inhibition of the cell apoptosis process contributes to the alleviation of angina pectoris, chest pain, and depression symptoms. Essentially, it promotes protection of the cardiovascular and nervous system against coronary heart disease with depression.

The 8 active components (eugenol, emodin, isorhamnetin, nobletin, isoliquiritigenin, rosmarinic acid, 4-Hydroxy-3-butylphthalide,

and acacetin) in XPF have been reported to activate the cAMP signaling pathway of CHD and depression. Eugenol can reverse oxidative stress, inhibit of caspase-3 activity, and it has an anti-myocardial ischemia effect. Emodin opposes CUMS-induced depressive-like behavior in rats by upregulating the levels of hippocampal BDNF (Choudhary et al., 2006; Liu et al., 2017). Isorhamnetin has a positive effect on H/R-induced injury by reducing caspase-3 and attenuating oxidative stress in H9c2 cardiomyocytes (Zhao et al., 2018). Nobiletin and acacetin exerted antidepressant-like effects by increasing the level of 5-HT in the hippocampus (Yi et al., 2011). Isoliquiritigenin has been shown to have neuroprotective effects by increasing the level of cAMP in peripheral nerves (Shindo et al., 1992). Rosmarinic acid can regulate the expression of BDNF in the hippocampus (Makhathini et al., 2018), and inhibit angiotensin-converting enzyme activity (Ferreira et al., 2018).

Increasing evidence has shown a reciprocal causation relationship between CHD and depression. Regulating psychopathy can significantly improve the quality of life of patients with CHD and reduce the incidence of acute cardiovascular events (Kuhlmann et al., 2019). Recently, TCM has attracted increasing attention in treating cardiovascular and psychological diseases because of its holistic approach and satisfactory clinical efficacy. Through this study, we found that XPF could protect the myocardium and hippocampus in CUMS and ISO-induced CHD in depression rats by regulating the cAMP signal cascade. Furthermore, XPF can inhibit cell apoptosis, improve heart function, reduce neuropathy, improve nerve function, and exert an antidepressant and anti-myocardial ischemia effect. These results preliminarily show the material basis and mechanism of XPF in the treatment of CHD with depression.

## CONCLUSION

In this study, we proposed an integrative systems pharmacology strategy to illustrate the mechanism of XPF in treating CHD with depression by combining serum pharmacochemistry, network analysis, and experimental validation. First, we identified 51 ingredients in rat serum after oral administration of XPF, which was used for the construction and analysis of the component–target network between the targets of absorbed components in serum and CHD with depression. As a result, 10 components with higher degree centrality were determined to be the active ingredients of XPF, and 10 hub genes, including *ACE2*, *HTR1A*, *HTR2A*, *AKT1*, *PKIA*, *CREB1*, *BDNF*, *BCL2*, *BAX*, *CASP3*, and *cAMP* were determined as targets of XPF in treating CHD with depression. Furthermore, the hub targets (AngII, 5-HT, cAMP, PKA, CREB, BDNF, Bcl-2, Bax, Cyt-c, and caspase-3) predicted by network pharmacology analysis were validated. We confirmed the myocardial protective and neuroprotective effects of XPF in treating CHD with depression, which was associated with its activation of the cAMP signaling pathway and inhibition of myocardium and hippocampus apoptosis. In conclusion, these results indicate that the integrated pharmacology strategy provides an efficient approach for exploring the pharmacological mechanisms of TCM.

Muscle dysfunction is a complication of high-fat diet (HFD)-induced obesity that could be prevented by exercise, but patients did not get enough therapeutic efficacy from exercise due to multiple reasons. To explore alternative or supplementary approaches to prevent or treat muscle dysfunction in individuals with obesity, we investigated the effects of Rhodiola on muscle dysfunction as exercise pills. SIRT1 might suppress atrogenes expression and improve mitochondrial quality control, which could be a therapeutic target stimulated by exercise and Rhodiola, but further mechanisms remain unclear. We verified the lipid metabolism disorders and skeletal muscle dysfunction in HFD feeding mice. Moreover, exercise and Rhodiola were used to intervene mice with a HFD. Our results showed that exercise and Rhodiola prevented muscle atrophy and dysfunction in obese mice and activating the SIRT1 pathway, while atrogenes were suppressed and mitochondrial quality control was improved. EX-527, SIRT1 inhibitor, was used to validate the essential role of SIRT1 in salidroside benefit. Results of cell culture experiment showed that salidroside alleviated high palmitate-induced atrophy and mitochondrial quality control impairments, but these improvements of salidroside were inhibited by EX-527 in C2C12 myotubes. Overall, Rhodiola mimics exercise that activates SIRT1 signaling leading to improvement of HFD-induced muscle dysfunction.

**Keywords:** salidroside, SIRT1, atrogenes, mitochondrion, rhodiola

## INTRODUCTION

Skeletal muscle dysfunction (or muscle wasting) characterized with a reduction of myofibrillar, and mitochondrial dysfunction has been reported as an important complication of high-fat diet (HFD)-induced obesity (Perry et al., 2016). However, compared to its adverse impacts on type 2 diabetes, cardiovascular, or osteoarticular diseases, muscle dysfunction has received less attention. Thus, investigating the mechanisms and potential therapy against HFD-induced muscle dysfunction will have important clinical significance. Though the underlying mechanisms are not thoroughly understood, several factors are well known, for example, the oversupplied energy and impaired lipid metabolism damage the mitochondrial which is essential in maintain muscle quality (Jorgensen et al., 2015).

A major therapeutic strategy against muscle dysfunction is exercise that effectively increases muscle mass, strength, and physical performance (Pillard et al., 2011; Dun et al., 2019a; Dun et al., 2019b). Although the molecular mechanisms of exercise in regulating HFD-induced muscle dysfunction are largely unknown, previous evidence indicated that exercise could decrease transcription of atrogenes, such as muscle-specific RING finger protein 1 (MuRF1) and atrogin1, both of which inhibit protein degradation and facilitate myofibrillar synthesis. Exercise also promotes mitochondrial mass and functions (Sandri et al., 2006). Mitochondrial quality control (MQC), including mitochondrial biogenesis, mitophagy, and fusion/fission, has been used as an important evaluation for mitochondrial function. Our previous studies indicated that exercise activates MQC in skeletal and myocardial muscle (Xie et al., 2019; Jiang et al., 2021). However, exercise lacks a long-term therapeutic efficacy for muscle dysfunction due to poor compliance or disabilities resulted from skeleton-muscle system (Conraads et al., 2012). Therefore, alternative or supplementary approaches to prevent muscle dysfunction in individuals with overweight need to be explored.

Sirtuin 1 (SIRT1), a sirtuin family protein, displays a nicotinamide adenine dinucleotide (NAD) protein deacetylase activity (Milne and Denu, 2008). Thus, it can be activated by changes of NAD<sup>+</sup> levels during exercise. SIRT1 is associated with beneficial effects of exercise through resisting protein degradation and improving the quality of mitochondria (Tonkin et al., 2012). Overexpression of SIRT1 reduces muscle dysfunction by inhibiting key atrogenes and activating peroxisome proliferator-activated receptor gamma coactivator 1- $\alpha$  (PGC-1 $\alpha$ ) in skeletal muscle (Lee and Goldberg, 2013). SIRT1 also modulates transcription factors, such as FOXO3/PINK1/Parkin and MFN1/DRP1 that participate in the regulation of mitophagy and mitochondrial dynamics (Valero, 2014; Lei et al., 2020). Thus, SIRT1 might be a key therapeutic target for muscle atrophy or dysfunction stimulated by exercise.

*Rhodiola* is a natural plant which has been widely used to treat altitude sickness for hundreds of years (Kelly, 2001). Salidroside, an active ingredient from *Rhodiola* roots, activates the SIRT1 pathway to ameliorate diabetic nephropathy and hypoxia-induced neurodegeneration in mice via promoting mitochondrial biogenesis (Barhwal et al., 2015; Xue et al., 2019). More recently, salidroside was also found to improve denervation-induced muscle proteolysis and muscle atrophy (Wu et al., 2019). Our previous study also indicated that *Rhodiola chrysanthemifolia* subsp. *sacra* (Raym.-Hamet) H. Ohba (*R. sacra*) supplementary and exercise activated MQC of skeletal muscle, which contributes to the enhancement of exercise capacity and facilitates the muscle ability to resist fatigue in healthy mice (Dun et al., 2017). However, the effects of *R. sacra* on HFD-induced mitochondrial dysfunction and muscle atrophy remain unknown. Thus, in the present study, we explored the role of SIRT1 signaling pathway in mediating muscle dysfunction and compared the potential therapeutic effects of *R. sacra* and exercise.

## MATERIALS AND METHODS

### Animals

Male C57BL/6J mice (8 weeks old) were purchased from the Laboratory Animal Centre, Xiangya Medical School (Changsha, Hunan, China). The mice were housed in temperature-controlled (22°C  $\pm$  2°C) quarters with a 12:12 hour light-dark cycle and free access to water and food. All animal procedures were in accordance with the guidelines for the use of live animals of National Institute of Health and were approved by the Medicine Animal Welfare Committee of Xiangya Medical School, Central South University (Changsha, China) (approval ID: SYXK 2015-0017).

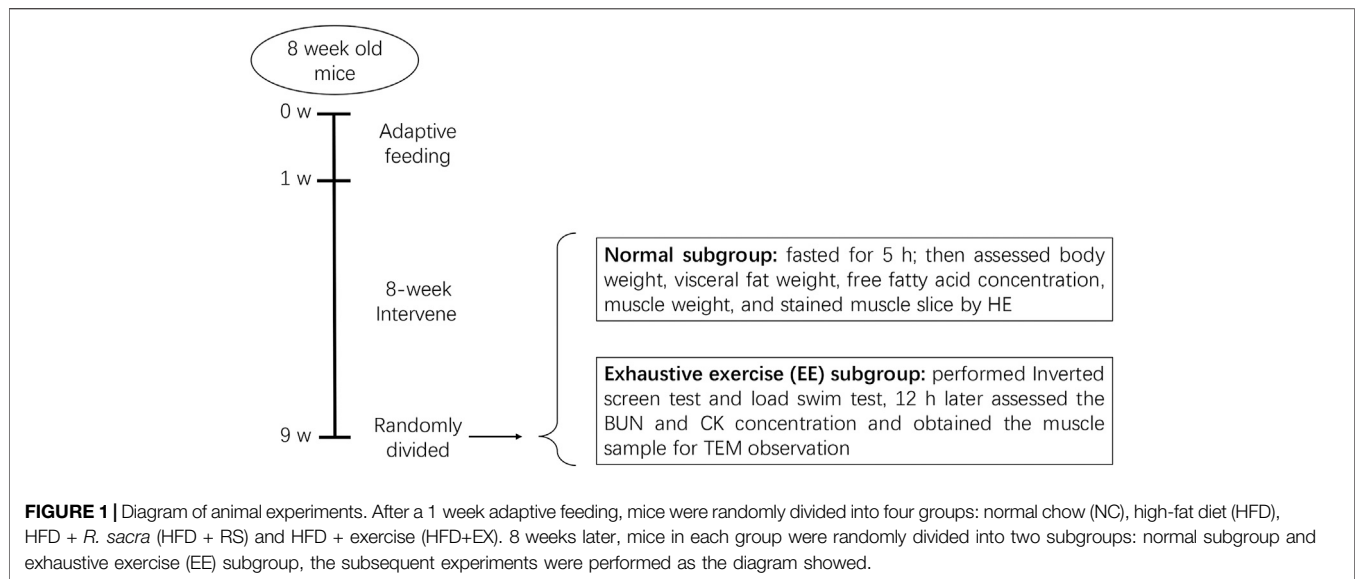

### Groups

After one-week feeding adaptation, mice were randomly divided into four groups ( $n = 16$  for each): normal chow (NC), high fat diet (HFD), HFD + *R. sacra* (HFD + RS) and HFD + exercise (HFD+EX). The HFD contains 45% of fat. The mice in the HFD + EX group were trained for exercise as described previously (Dun et al., 2017). In the HFD+RS group, mice were given 50 mg/ml of *R. sacra* per 500 mg/kg weight (Tibet Rhodiola Pharmaceutical Holding Company, Tibet, China) by gavage (0.1 ml/10 g weight) daily between 9 to 10 a.m. as previously described (Dun et al., 2017). The rest groups obtained normal saline by gavage at a dose of 0.1 ml per 10 g weight. Exercise, *R. sacra* and normal saline were administered together with HFD for 8 consecutive weeks. Body weights were weekly monitored during the whole experiment. An additional *R. sacra* treatment to the HFD mice didn't cause any observable change in food intake pattern or gastrointestinal reaction.

After 8 weeks, each group was further divided into two subgroups with or without exhaustive exercise ( $n = 8$ ). The mice in the EE subgroups further underwent an inverted screen test and load swimming (5% body weight) session as previously described (Dun et al., 2017). After the experiments, all mice were anesthetized via an intraperitoneal injection of 1% pentobarbital sodium (150 mg/kg) and then sacrificed via exsanguination. Blood samples were collected from the inferior vena cava. Gastrocnemius muscle and visceral fat including mesenteric, epididymal, and perirenal fat tissue were dissected and weighted eventually. The protocol has been described in Figure 1.

### R. Sacra

The highly pure extract from the root of *Rhodiola chrysanthemifolia* subsp. *sacra* (Raym.-Hamet) H. Ohba (*R. sacra*) was provided by the Tibet Rhodiola Pharmaceutical Holding Company. Root of *R. sacra* was decocted with double distilled water twice, first time for 1.5 hours and second time for 1 hour, then collect the decoction after filtration. The filtrated liquor was concentrated to the relative density 1.25–1.30 (detected in 40°C) and prepared to powder by spray-drying. HPLC-MS analysis revealed that the main effective components are salidroside (C<sub>14</sub>H<sub>20</sub>O<sub>7</sub>, 2.62%) and flavone (C<sub>27</sub>H<sub>30</sub>O<sub>16</sub>, 3.27%) (Supplementary Figure S1 and

Supplementary Table S1) and the exact preparation complied with The Chinese Pharmacopeia 2015 (inspection report number C1051612067). The extract powder was dissolved in distilled water (50 mg/ml) and it was administered to mice by gavage at a liquid/ body weight ratio of 0.1 ml/10 g for ten consecutive weeks (Every morning between 9 a.m. and 10 a. m.).

## Exercise Training

The mice in the HFD + EX group were subjected to a moderate intensity swim training as previously described (Dun et al., 2017). Briefly, the mice were placed in a Morris water maze pool (60 cm high and 120 cm in diameter) (XR-XM101-R, ZSdichuang, Beijing, China) for a swimming training from 10 to 60 min. Swimming exercise was performed between 9 a.m. to 2 p.m. and the mice exhibited minimal variations in aerobic capacity.

## Serum Free Fatty Acid

Mouse blood samples were collected and then assayed for serum free fatty acid according to the manufacturer's instructions (A042, Nanjing Jiancheng Bioengineering Institute, China). Free fatty acid and coenzyme A (CoA) reaction and produce acetyl-CoA. Then, acetyl-CoA produce H<sub>2</sub>O<sub>2</sub> with the acetyl CoA oxidase. We used peroxidase to make H<sub>2</sub>O<sub>2</sub> colorized and quantify free fatty acid indirectly.

## Cross-Sectional Area of Muscle Fibers

Sliced muscle was stained by hematoxylin and eosin. Then, use the image analysis software Image J to measure area of each muscle fiber. Eventually, we statistically analyze the difference among groups.

## Inverted Screen Test

Mice were placed on the center of an invertible 40 × 40 cm wire screen with a padded surface. After gently inverting the screen, the time for hanging on and the limb strength was recorded.

## Exhaustive Exercise (EE) Program

The mice in EE subgroup ( $n = 8$ ) performed a forced weight-loaded swimming session. The load composed of a lead sheath (0.8 mm thick, 0.5 cm wide) which is equal to 5% of each mouse body weight. The mice were enforced to swim till exhaustion, defined as the failure to rise the surface of water to breathe for 7 s. The swimming time was recorded and regarded as exercise capacity or muscular endurance.

## Transmission Electron Microscope (TEM)

The muscle tissues were resized to  $1 \times 1 \times 3 \text{ mm}^3$  and then fixed by 2.5% Glutaraldehyde and 1% osmic acid. After washed by 0.1 mol/L phosphate buffer, the tissue was dehydrated with acetone at a gradient concentration. Then embedding and solidify the tissue in 37°C for 12 hours and 60°C for 24 hours. After sliced to 50–100 nm and eventually they were examined by a transmission electron microscope (Tecnai G2 Spirit, FEI, United States) (Dun et al., 2017).

## Creatine Kinase (CK), and Blood Urea Nitrogen (BUN)

Blood samples were also collected from the EE subgroup 12 h after EE program. The CK concentration was determined via a colorimetric kit according to the manufacturer's instructions (A032-1, Nanjing Jiancheng Bioengineering Institute, Nanjing, China). And the BUN was determined by a urease methods kit (C013-2, Nanjing Jiancheng Bioengineering Institute, Nanjing, China). The urea produced ammonia when exposed to urease, and ammonia could be colorized in the alkaline environment.

## Western Blot

Muscle tissues or cells were lysed in radioimmunoprecipitation assay (RIPA) buffer (Beyotime) containing 1 mmol/L phenylmethanesulfonyl fluoride (PMSF; Beyotime) on ice to extract proteins. After SDS-PAGE, the proteins were detected

(Dun et al., 2017) and treated with primary antibodies against SIRT1, myosin heavy chain II (MyHC II), MuRF1, atrogin1, PGC1 $\alpha$ , Microtubule-associated proteins 1A/1B light chain 3B (LC3), PTEN-induced kinase 1(PINK1), mitofusin-1 (MFN1), dynamin-related protein 1 (DRP1), citrate synthase (CS), and Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (Proteintech, Rosemont, IL, USA), respectively. Following HRP-labeled goat anti-rabbit IgG or goat anti-mice IgG (Proteintech), the bands were analyzed using a gel documentation system (Bio-Rad, Hercules, CA, United States).

## Adenosine Triphosphate (ATP) Content

The ATP content in muscle tissues and lysed cells were determined via phosphomolybdic acid colorimetric method according to the manufacturer's instructions (A095-1-1, Nanjing Jiancheng Bioengineering Institute, Nanjing, China).

## Gene Expression Analysis

Total DNA was isolated from gastrocnemius using a DNeasy Kit (Qiagen). MtCO3 oligos and succinate dehydrogenase complex subunit A (SDHA) were analyzed to evaluate the quantification of mitochondrial and nuclear genomes. The primer sequences for the specific target genes are listed in the following Table 1.

## Cell Culture

C2C12 mouse myoblasts (Cobioer Biotechnology Ltd, Nanjing, China) were cultured in Dulbecco Modified Eagle Medium (DMEM) containing 10% fetal bovine serum and penicillin/streptomycin (5000U/5000  $\mu$ g/ml; Gibco, Grand Island, NY, USA). Cells with a 75% confluence were incubated with differentiation media (DMEM containing 2% horse serum, Gibco) for 5 days. Our preliminary data suggested that the

**TABLE 1** | Primer sequences for qPCR analyses on tissues

Gene	Primer	Product length
M-DNA-mt-Co3	F GCAGGATTCTTCTGAGCGTTCT R GTCAGCAGCCTCCTAGATCATGT	67 bp
M-DNA-Sdha	F TACTACAGCCCCAAGTCT R TGGACCCATCTTCTATGC	194 bp

concentrations of salidroside (UPLC  $\geq$ 98%, Sinopharm Chemical Reagent, Shanghai, China) above 50  $\mu$ g/ml will induce cell death. Thus, our current study only used a concentration of salidroside less than 50  $\mu$ g/ml to treat differentiated myotubes together with 0.75 mmol/L of palmitate for 24 hours, with or without pretreatment of 10  $\mu$ mol/L EX-527 (SIRT1 inhibitor, 6-Chloro-2,3,4,9-tetrahydro-1H-Carbazole-1-carboxamide).

## SIRT1 Activity

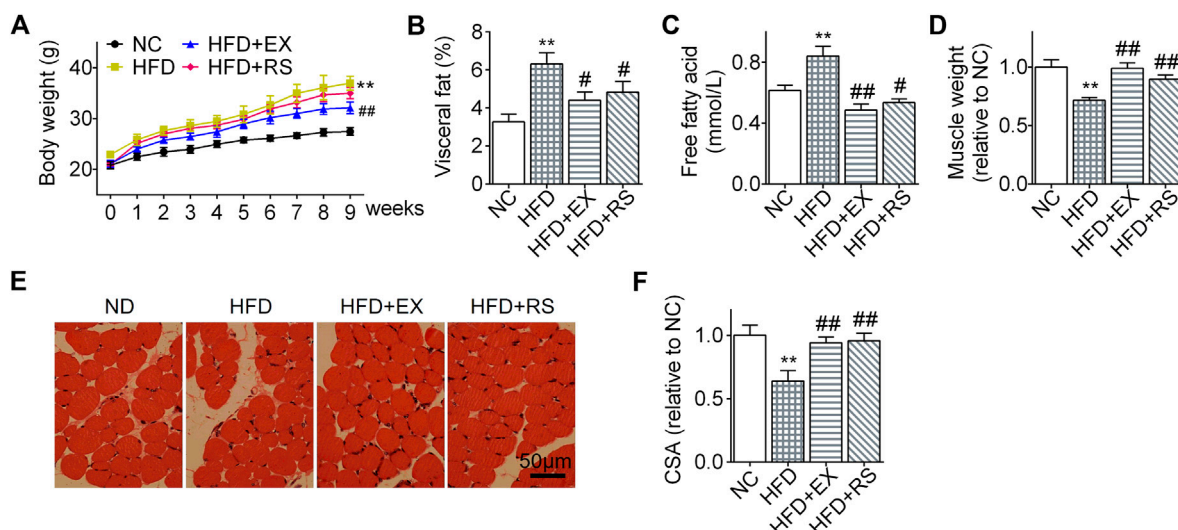

Cells' SIRT1 activity was measured by Colorimetric quantitative detection kit (Genmed Scientifics Inc. United States), each procedure follows the instruction.

## Immunofluorescence Staining

Cells were seeded on glass coverslips and incubated with anti-MyHC II (Proteintech). Following incubation with a fluorescent secondary antibody (Abcam, Cambridge, United Kingdom), images were acquired using a fluorescence microscope (Eclipse, Nikon, Japan).

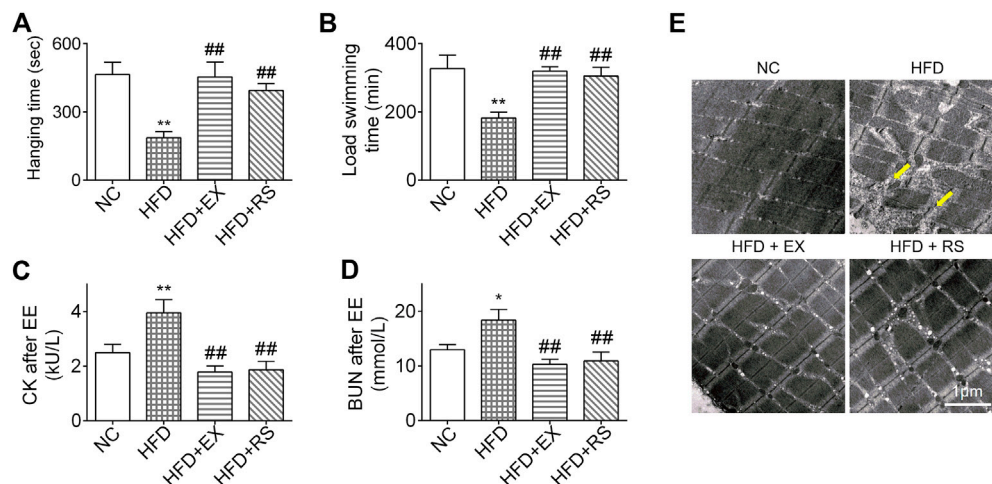

## Oxygen Consumption Rate (OCR)

C2C12 myoblasts were seeded in XF 24-well microplates (Seahorse Bioscience, Billerica, MA, United States) and

**FIGURE 2** | *R. sacra* alleviates HFD-induced muscle atrophy in mice as exercise. **(A)** 8 week-old mice were fed normal chow (NC) or high-fat diet (HFD) with either *R. sacra* treatment (RS) or exercise training (EX) for 8 weeks, body weight was monitored in the whole process; **(B)** after 8 weeks, visceral fat/body weight, **(C)** serum free fatty acid, and **(D)** muscle weight/body weight were calculated and assessed; **(E)** Representative gastrocnemius muscle sections were stained with hematoxylin-eosin, **(F)** the cross-sectional area (CSA) of muscle fiber were measured. **FIGURE 3 |** *R. sacra* or exercise improves muscle dysfunction in HFD mice **(A)** 8 week-old mice were fed normal chow (NC) or high-fat diet (HFD) with either *R. sacra* treatment (RS) or exercise training (EX) for 8 weeks, then the inverted screen test was performed and hanging time was analyzed; **(B)** and the forced weight-loaded swimming session were performed, and swimming time was analyzed; **(C)** 12 h after exhaustive exercise (EE), serum creatine kinase (CK), and **(D)** blood urea nitrogen (BUN) of mice were measured; **(E)** meanwhile, the morphology of muscle sample was observed by transmission electron microscope (TEM), and the damaged myofibrils (yellow arrows) were indicated in TEM images, scale bar = 1 μm. Data are expressed as Mean ± SEM,  $n = 3$ , \*, \*\* represent  $p < 0.05$ ,  $p < 0.01$  in comparison with NC; #, ## represent  $p < 0.05$ ,  $p < 0.01$  in comparison with HFD.

differentiated. Following treatments of mitochondrial inhibitors, including 1 μmol/L oligomycin, 1 μmol/L Carbonyl cyanide 4-(trifluoromethoxy) phenylhydrazone (FCCP) and 1 μmol/L rotenone/antimycin A, OCRs were measured with extracellular flux analysis (Seahorse Biosciences) every 8 minutes.

## Statistical Analysis

The results are expressed as Mean ± SEM. One-way ANOVA plus the Student-Newman-Keuls test was used for statistical analysis.  $p < 0.05$  represents statistical significance.

## RESULTS

### *R. sacra* Alleviates HFD-Induced Muscle Atrophy in Mice as Exercise

Lipid infiltration induced muscle atrophy in HFD mice (Tong et al., 2019). Exercise has been considered as an effective therapy to limit muscle atrophy or sarcopenia associated with disuse or denervation. However, it remains unclear how exercise affects HFD-induced muscle atrophy. In our present study, following HFD feeding for 8 weeks, mouse body weights increased more profound than normal chow group (Figure 2A). However, the body weight gain was significantly inhibited in the HFD group accompanied with exercise. Interestingly, HFD+RS mice showed a decreased tendency of body weight gain when compared to HFD group, but there is no statistical difference. The visceral fat weight (% body weight) and serum free fatty acid in HFD mice were also increased following HFD. However, *R. sacra* or exercise decreased these two parameters (Figure 2B,1C). Gastrocnemius muscle weight was decreased following HFD feeding (Figure 2D) accompanied with a lower cross-sectional area of muscle fiber

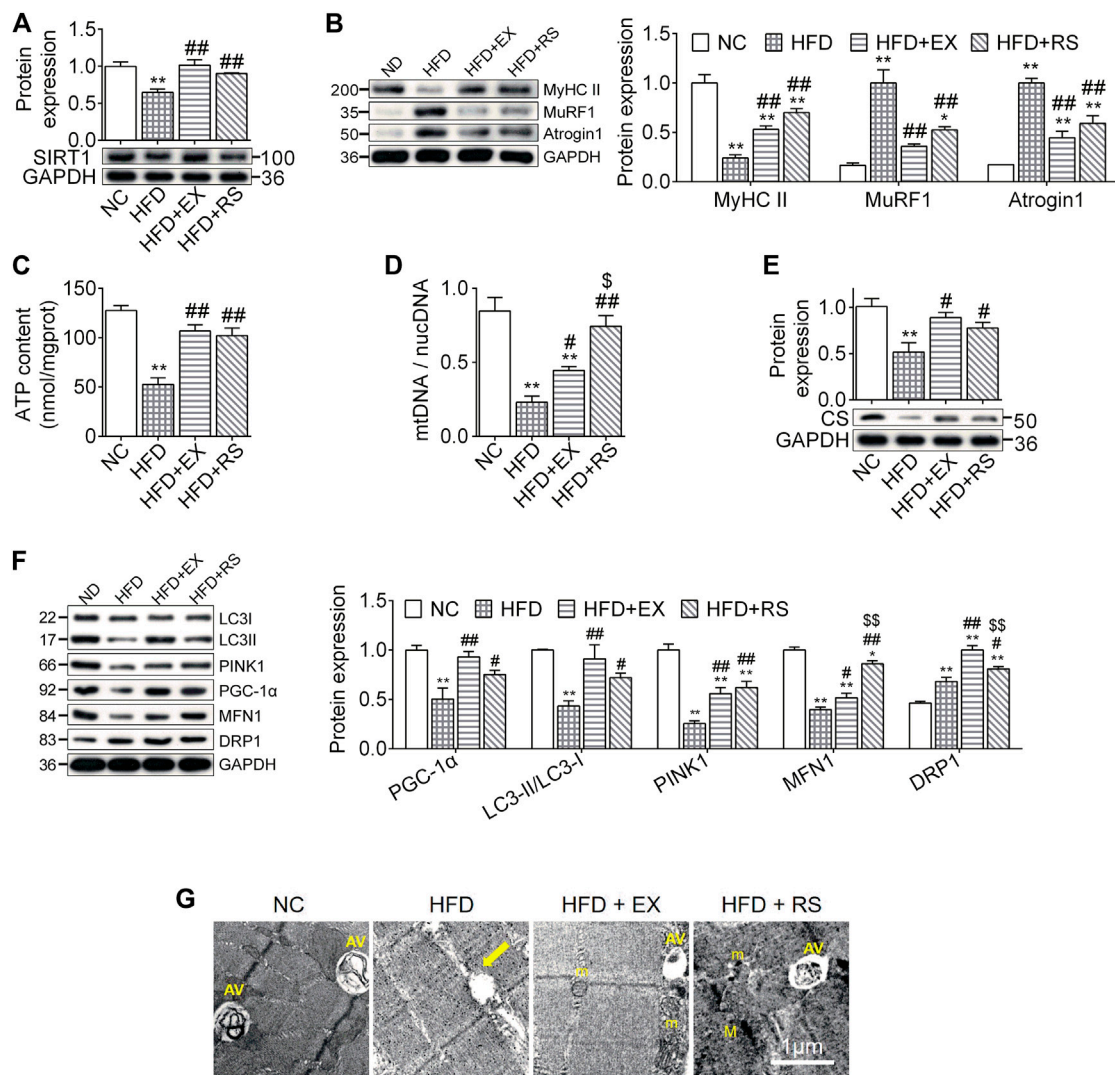

(Figure 2D). However, exercise training or *R. sacra* treatment significantly ameliorate these pathological conditions as showed in Figures 2D,E. These data collectively suggested that *R. sacra* treatment mimics exercise training to improve HFD-induced muscle atrophy.

### *R. sacra* or Exercise Improves Muscle Dysfunction in HFD Mice

We next performed inverted screen test and load swim test to assess muscle strength and endurance. The hanging time was decreased 50% in HFD group compared NC. However, accompanied with exercise or *R. sacra* treatment, the mice following HFD demonstrated a normal hanging time as NC group (Figure 3A). A similar result was also observed in the load swimming experiment (Figure 3B). Following load swimming, muscle damage was subsequently evaluated by electron microscopy. We found that in HFD group, muscle fiber consistency was disrupted, and mitochondrial membrane was ruptured (Figure 3E). In parallel, serum creatine kinase (CK) and BUN were also increased (Figures 3C,D). However, neither the morphologic changes in muscle cells nor CK and BUN release occur in HFD+EX or HFD+RS groups (Figures 3C–E), suggesting that exercise or *R. sacra* could improve muscle function deficiency induced by HFD.

### *R. sacra* Improves Atrophy Through Activating SIRT1 Signaling Pathway

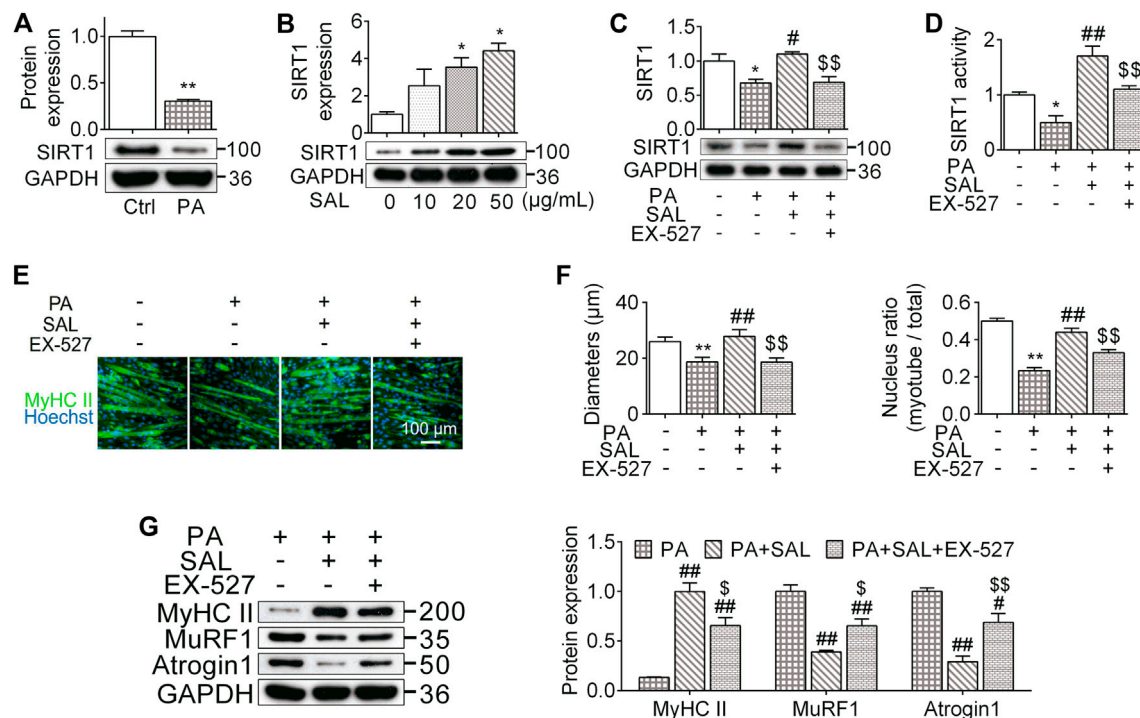

Atrophy is associated with protein degeneration, inflammation, and mitochondrial dysfunction. SIRT1, a key regulator in nutrients/energy metabolism and cell fate signaling, also

**FIGURE 4 |** *R. sacra* improves atrophy through activating sirt1 signaling pathway (**A,B**) 8 week-old mice were fed normal chow (NC) or high-fat diet (HFD) with either *R. sacra* treatment (RS) or exercise training (EX) for 8 weeks, then muscle samples were obtained and the relative protein expression of SIRT1, MyHC II, MuRF1, and Atrogin1 were assessed; (**C**) the ATP content is measured; (**D**) the ratio between mitochondrial DNA (mtDNA) and nuclear DNA (nucDNA) determined; (**E,F**) the relative protein expression of CS, PGC-1α, LC3, PINK1, MFN1, and DRP1 were assessed; (**G**) the morphology of muscle sample was observed by transmission electron microscope (TEM), and the damaged mitochondrion (yellow arrows), normal mitochondria (m), autophagic vacuoles (AV), as well as myofilament (M) were indicated in TEM images, scale bar = 1 μm. Data are expressed as Mean ± SEM,  $n = 3$ , \*, \*\* represent  $p < 0.05$ ,  $p < 0.01$  in comparison with NC; #, ## represent  $p < 0.05$ ,  $p < 0.01$  in comparison with HFD; \$, \$\$ represent  $p < 0.05$ ,  $p < 0.01$  in comparison with HFD+EX.

modulates atrophic genes and mitochondrial homeostasis (Tonkin et al., 2012). We found that SIRT1 protein levels were significantly decreased in skeletal muscle following HFD feeding, and this reduction was inhibited by exercise training or *R. sacra* treatment (**Figure 4A**). MyHC II content was lost almost 76% in muscles isolated from HFD group compared to NC ( $p < 0.01$ ). The protein expression of atrogenes including MuRF1 and atrogin1 were increased in HFD group (**Figure 4B**). All these changes were partially corrected in HFD+EX and HFD+RS groups. Interestingly, exercise training seems to have greater effects than *R. sacra* treatment although there is no statistical significance.

ATP content is an important parameter to evaluate mitochondrial functions. In our study, we found that ATP content was significantly reduced in skeletal muscle isolated from HFD group. This reduction was accompanied with a decrease in the expression of mtDNA/nucDNA and CS (**Figures 4C–E**), suggesting that HFD might induce muscle mitochondrial dysfunction. Exercise or *R. sacra* facilitated mitochondrial function recovery by increasing ATP content, mtDNA/nucDNA and CS. HFD skeletal muscle also demonstrated a reduction in protein expression of mitochondrial biogenesis marker, PGC-1α, mitophagy markers, LC3-II and PINK1, and fusion marker MFN1. The

**FIGURE 5 |** Salidroside prevents myotube atrophy through activating SIRT1 signaling. **(A)** The differentiated myotubes were vehicle (Ctrl) or 0.75 mmol/L palmitate (PA) for 24 hours, SIRT1 expression were subsequently measured; **(B)** the cells were incubated in different concentration of salidroside (SAL), then the protein expression of SIRT1 was measured; **(C,D)** the cells were treated with 50 µg/ml salidroside with or without 10 µmol/L EX-527 in the presence of 0.75 mmol/L palmitate for 24 hours, then the protein expression and activity of SIRT1 were measured; **(E,F)** the morphology of differentiated myotubes was observe by MyHC II immunofluorescence, meanwhile the diameters and nucleus ratio of myotubes were calculated; **(G)** the relative protein expression of MyHC II, MuRF1, and Atrogin1 were assessed. Scale bar = 100 µm. Data are expressed as Mean ± SEM,  $n = 3$ , \*\* represent  $p < 0.05$ ,  $p < 0.01$  in comparison with Ctrl; #, ## represent  $P < 0.05$ ,  $P < 0.01$  in comparison with PA; \$, \$\$ represent  $p < 0.05$ ,  $p < 0.01$  in comparison with PA+SAL.

fission marker DRP1 was increased. Exercise training or *R. sacra* treatment prevent these changes (**Figure 4F**). Eventually, by using TEM, we observed damaged mitochondria characterized with edema and reduction of cristae (yellow arrows) in HFD muscles but autophagic vacuoles (marked by AV) were hardly observed. Autophagic vacuoles were more abundant in NC, HFD+EX and HFD+RS.

## Salidroside Prevents Myotube Atrophy Through Activating SIRT1 Signaling

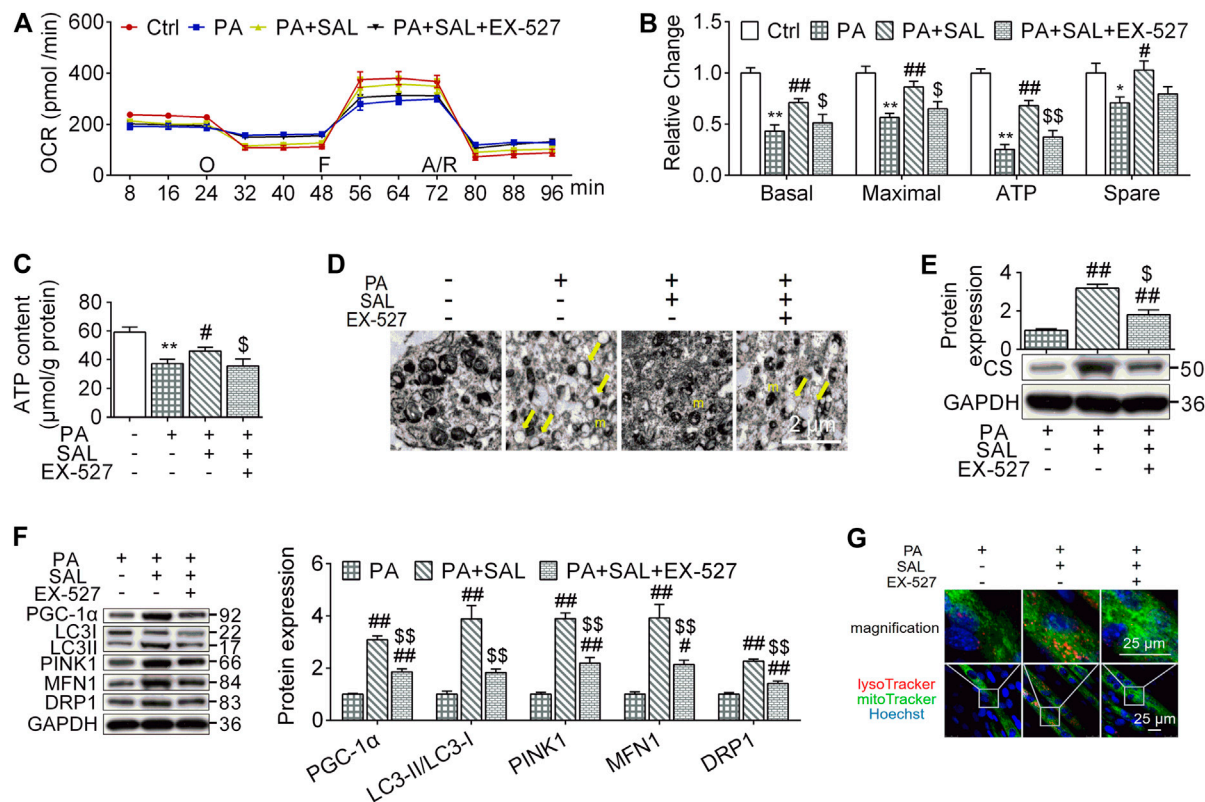

To further investigate the molecular mechanisms by which *R. sacra* prevents HFD-induced muscle dysfunction, C2C12 myotubes were incubated with a high palmitate treatment. We found that high palmitate significantly inhibited the protein expression of SIRT1 in C2C12 myotubes as we observed *in vivo*, suggesting that palmitate might be a direct factor in accelerating muscle cell atrophy (**Figure 5A**). Salidroside, as the major active ingredient of *R. sacra*, activated SIRT1 in myotubes in a dose-dependent manner (**Figure 5B**). We therefore used salidroside to treat C2C12 myotubes with palmitate. We found that salidroside significantly relieve the inhibition of SIRT1 in palmitate-treated cells (**Figures 5B–D**).

We also analyzed the morphology of myotubes following 0.75 mM palmitate treatment. High palmitate significantly decreased the diameter of myotubes around 29% ( $P < 0.01$ ) and reduced the number of nuclei located within the myosin heavy chain positive myotube by 44% ( $p < 0.01$ ) (**Figures 5E,4F**). Salidroside abated these morphological alterations. Salidroside also upregulated MyHC II and decreased atrogenes expression (**Figure 5G**). To further clarify the role of SIRT1 signaling pathway in the influences of salidroside, a SIRT1 signaling inhibitor, EX-527, was used with salidroside in the presence of high palmitate in C2C12 myotubes. EX-527 prevented the effects of salidroside on upregulating SIRT1 expression and activity (**Figures 5C,D**). Meanwhile, the effects of salidroside on the myotube morphology, nucleus ratio, MyHC II content, as well as atrogenes were also abolished by EX-527 (**Figures 5E–G**). These data together suggest that salidroside limits myotube atrophy probably through activating the SIRT1 signaling pathway.

## Salidroside Activates Mitochondrial Quality Control Through the SIRT1 Signaling

Mitochondria maintain muscle contractile function and remodeling (Gan et al., 2018). In order to evaluate whether

**FIGURE 6 |** Salidroside activates mitochondrial quality control through the SIRT1 signaling. **(A,B)** the cells were treated with 50  $\mu\text{g/ml}$  salidroside (SAL) with or without 10  $\mu\text{mol/L}$  EX-527 in the presence of 0.75mmol/L palmitate (PA) for 24 hours, oxygen consumption rate (OCR) was measured by seahorse XF analyzer whereas 1  $\mu\text{mol/L}$  oligomycin (O), 1  $\mu\text{mol/L}$  FCCP (F) and 1  $\mu\text{mol/L}$  rotenone/antimycin A (A/R) were added in order, then the basal respiration, maximal respiration, ATP respiration, and spare respiration were calculated from the OCR data; **(C)** ATP content were measured; **(D)** mitochondria in treated cells were directly observed by transmission electron microscope (TEM), and the normal mitochondria (m) as well as damaged mitochondria (yellow arrows) were indicated in TEM images, scale bar = 2  $\mu\text{m}$ ; **(E,F)** the protein expression of CS, PGC-1 $\alpha$ , LC3, PINK1, MFN1, and DRP1 were measured; **(G)** the treated cells were stained by lysoTracker and mitoTracker, scale bar = 25  $\mu\text{m}$ . Data are expressed as Mean  $\pm$  SEM,  $n = 3$ , \*, \*\* represent  $p < 0.05$ ,  $p < 0.01$  in comparison with Ctrl; #, ## represent  $p < 0.05$ ,  $p < 0.01$  in comparison with PA; \$, \$\$ represent  $p < 0.05$ ,  $p < 0.01$  in comparison with PA+SAL.

the beneficial effects of salidroside on skeletal muscle are associated with mitochondrial functions, we quantify mitochondrial functions and MQC-associated parameters. In this study, OCR levels, including basal respiration, maximal respiration, ATP production respiration, and spare respiration as well as ATP content were decreased in myotubes following palmitate-treatment. However, salidroside treatment prevented these reductions (**Figures 6A–C**). Similar results were observed in the expression of CS, the mitochondrial respiratory critical enzyme (**Figure 6E**). In morphology, we found that high palmitate induced a damage in mitochondrial structures characterized with edema and reduction of crista (yellow arrows). Salidroside treatment successfully mitigate the morphological changes in mitochondria (**Figure 6D**). However, EX-527 inhibited the improvement effects of salidroside on mitochondrial structure and functions evaluated by OCR levels, ATP content, CS expression, and TEM.

To explore how the activated SIRT1 signaling by salidroside regulates mitochondrial functions, we evaluated MQC. As shown in **Figure 6F**, salidroside treatment increased MQC quantified by PGC-1 $\alpha$ , LC3-II, PINK1, MFN1, and DRP1 compared to PA

group while EX-527 abolished this enhancement. Mitolysosome, a mitophagy marker, has been defined as the colocalization of LysoTracker and MitoTracker-stained organelles in cells. In the presence of SAL, Mitolysosomes were more abundant compared to palmitate-treated cells. However, addition of EX-527 reduced mitolysosomes content (**Figure 6G**). These results suggest that SIRT1 is a key regulator in modulating palmitate-induced MQC impairment and salidroside as an activator of SIRT1 might be a potential therapeutic treatment for HFD-induced muscle dysfunction.

## DISCUSSION

HFD-induced muscle dysfunction is an important clinical issue due to its prevalence and poor prognosis. Exercise training improves muscle functions against atrophy (Perry et al., 2016). Our present study indicated that a long-term exercise mitigated HFD-induced muscle dysfunction via inhibiting atrogenes and enhancing MQC. Interestingly, *R. sacra* mimics long-term exercise training to mitigate muscle dysfunction and it also

**FIGURE 7 |** Proposed pathway of Rhodiola effects on HFD-induced muscle dysfunction. Sirtuin1 (SIRT1) is the key regulator of atrophy via mediating atrogenes and mitochondrial hemostasis. During high-fat diet (HFD)-induced obesity, SIRT1 in muscle was inhibited and adversely alteration in atrogenes and mitochondrial quality control (MQC) were observed. However, our data shows exercise training or *R. Sacra* treatment suppress atrogenes and enhances MQC to alleviate HFD-induced muscle dysfunction through activating SIRT1 signaling. Thus, we conclude that *R. sacra* treatment might be a potential exercise mimic or supplement therapy against HFD-induced muscle dysfunction.

modulates SIRT1 signaling pathway, suggesting that *R. sacra* might be a new strategy to replace the long-term exercise training.

Diet containing 45% of fat (mainly lard) was used in this study to induce muscle dysfunction. It is long-chain saturated fatty acids (SFA) instead of unsaturated fatty acid described to be involved in lipotoxic pathways (Listenberger et al., 2003). Palmitate, as the most important SFA in lard (about 24%), was proposed to be an inducement of muscle mitochondrial dysfunction (Nisr et al., 2020). Thus, we used palmitate to establish dysfunctional C2C12 myotubes.

The NAD-dependent protein deacetylase, SIRT1, belongs to the sirtuin family and it performs a wide variety of functions in resisting metabolic disorders, cancer and cardiac stress etc. (Canto and Auwerx, 2012). Activation of SIRT1 by resveratrol also prevents muscle atrophy induced by mechanical unloading and dexamethasone (Lagouge et al., 2006; Momken et al., 2011). SIRT1 blocks FoxO1 and 3 and prevents the induction of key atrogenes atrogin1 and MuRF1 which are muscle-specific ubiquitin ligases contributing to proteolysis (Lee and Goldberg, 2013). Our present study found that SIRT1 activation also alleviates muscle dysfunction induced by HFD by reversing the upregulation of atrogenes in mice, suggesting that SIRT1 is an important signaling pathway in preventing or rescuing muscle dysfunction through the regulation of atrogenes.

Muscle dysfunction is associated with mitochondrial dysfunction (Gan et al., 2018), which is usually characterized with alteration of mitochondrial hemostasis, reduction of mitochondrial contents, and changed expression of mitochondrial genes which are responsible for oxidative metabolism in skeletal muscle (Joseph et al., 2012). Any cellular mechanism which improves mitochondrial functions would have important therapeutic potentials to resist the development of muscle dysfunction. SIRT1 activation protects mitochondrial oxidative functions. Supplementation of

nicotinamide riboside, an NAD<sup>+</sup> precursor, activates SIRT1 and upregulates mitochondrial energy metabolic genes in mice (Canto et al., 2012). Furthermore, an increase in mitochondrial respiration has been observed in permeabilized skeletal muscle fibers from human subjects following 2 weeks of supplementation with acipimox, another NAD<sup>+</sup> precursor (van de Weijer et al., 2015). SIRT1 also improves obesity-associated metabolic diseases through deacetylating and activating mitochondrial biogenetic marker, PGC-1 $\alpha$  (Lagouge et al., 2006). Thus, SIRT1-regulated mitochondrial biogenesis and oxidative metabolism may be another important mechanism to prevent or rescue muscle dysfunction.

Exercise counteracts deleterious muscle influence of aging and obesity via resisting lipid-induced protein degeneration or metabolic disorders in skeletal muscle (Heo et al., 2018). Thus, a 12-month exercise training increased thigh cross-sectional area and muscle mass in older-aged patient with diabetes mellitus (Mavros et al., 2014). Exercise also enhances mitochondrial oxidative functions via activating SIRT1 (Gurd, 2011). Indeed, our present study indicated that HFD decreased mitochondrial ATP content, DNA ratio, and CS expression in mouse muscle which are accompanied with attenuated mitochondrial functions. These effects were overcome by additional exercise training. MQC including mitochondrial biogenesis, autophagy, fusion, and fission is key to maintain mitochondrial homeostasis and oxidative function. MQC disorders result in mitochondrial dysfunction and pathological changes. Exercise enhances MQC and improves exercise capacity in healthy mice (Dun et al., 2017). Our present data suggest that MQC-related parameters, PGC-1 $\alpha$ , LC3-II, PINK1, DRP1, and MFN1 were inhibited, whereas exercise relieve the MQC impairment, suggesting that exercise training mitigate HFD-induced muscle dysfunction probably through mediating atrogenes and MQC.

Extracts from the root of *Rhodiola* have been traditionally used to improve hypoxic tolerance for the people who ascend to high altitudes (Kelly, 2001). *Rhodiola* also improves exercise performance and anti-stress ability of skeletal muscle in human subjects and animal models which are probably associated with enhanced mitochondrial functions in skeletal muscle (Abidov et al., 2003; Noreen et al., 2013). We previously indicated that *R. sacra* triggered MQC and ultimately improves the exercise capacity and anti-fatigue ability in healthy mice (Dun et al., 2017). However, it remains uncertain whether *R. sacra* is beneficial to HFD-induced muscle dysfunction. In the present study, muscle atrophy and SIRT1 inhibition occurred in HFD-induced obese mice which were significantly mitigate by *R. sacra* treatment or exercise training. In parallel, HFD-impacted mitochondrial function and MQC in obese mice were also improved by *R. sacra* treatment or exercise training, suggesting that *R. sacra* has similar therapeutic effect as exercise training on activating SIRT1 and enhancing mitochondrial functions.

Salidroside is an active ingredient from the roots of *R. sacra*. It ameliorates muscle atrophy in cachexia or denervation via activating mTOR signaling pathway or reducing expression of atrogenes, such as MuRF1 and Atrogin-1 (Chen et al., 2016; Wu et al., 2019). Our previous study also indicated that salidroside resists metabolic disorders in skeletal muscle via upregulating SIRT1-mediated mitochondrial quality control in mice (You et al., 2020). Our present study further showed that in skeletal muscle cells, salidroside abated palmitate-induced SIRT1 inhibition, atrogenes activation, and myotubes atrophy and these therapeutic effects were significantly attenuated by additional EX-527 pre-treatment. These results indicate that salidroside may counteract lipid accumulation-caused atrophic factors and mitochondrial alteration by activating SIRT1 signal pathway. As the LC-MS analysis shown, polyphenols are main bioactive compounds of *R. sacra* too. Moreover, Capó and his colleagues found that polyphenolic extract ameliorate muscle decline in by reducing oxidative stress and oxidative damage (Annunziata et al., 2020). Thus, polyphenols might be responsible for the biological effects of *R. sacra* in the study and could be another potential treatment for HFD-induced muscle atrophy, but more data is needed.

In summary, our present study indicated that *R. sacra* mimics exercise to alleviate HFD-induced muscle dysfunction via inhibiting atrogenes and enhancing MQC via SIRT1 pathway,

which was summarized in **Figure 7**. We believe that *R. sacra* treatment may be a potential substitute for long-term exercise training in clinical practice against muscle dysfunction in the future.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Medicine Animal Welfare Committee of Xiangya Medical School, Central South University.

## AUTHOR CONTRIBUTIONS

BY designed and performed most of the study and the wrote the paper; YD analyzed and interpreted the data; YD, SF, WZ, LQ and MX performed part of the study; DQ provided valuable suggestions and comments on the study design and critically revised and edited the manuscript; YD, YL and SL supervised and funded the study.

## FUNDING

This work was supported by grants from the National Natural Science Foundation of China (Grant number 81672262 to SL, 82002403 to YD, and 81702241 to YL), the Natural Science Foundation of Hunan Province (Grant number 2018JJ3847 to YL), and the National Development and Reform Commission (No. (201201521 to SL).

Effective therapies for stroke are still limited due to its complex pathological manifestations. QiShenYiQi (QSYQ), a component-based Chinese medicine capable of reducing organ injury caused by ischemia/reperfusion, may offer an alternative option for stroke treatment and post-stroke recovery. Recently, we reported a beneficial effect of QSYQ for acute stroke *via* modulation of the neuroinflammatory response. However, if QSYQ plays a role in subacute stroke remains unknown. The pharmacological action of QSYQ was investigated in experimental stroke rats which underwent 90 min ischemia and 8 days reperfusion in this study. Neurological and locomotive deficits, cerebral infarction, brain edema, and BBB integrity were assessed. TMT-based quantitative proteomics were performed to identify differentially expressed proteins following QSYQ treatment. Immunohistochemistry, western blot analysis, RT-qPCR, and ELISA were used to validate the proteomics data and to reveal the action mechanisms. Therapeutically, treatment with QSYQ (600 mg/kg) for 7 days significantly improved neurological recovery, attenuated infarct volume and brain edema, and alleviated BBB breakdown in the stroke rats. Bioinformatics analysis indicated that protein galectin-3 and its mediated inflammatory response was closely related to the beneficial effect of QSYQ. Specially, QSYQ (600 mg/kg) markedly downregulated the mRNA and protein expression levels of galectin-3, TNF- $\alpha$ , and IL-6 in CI/RI brain as well as serum levels of TNF- $\alpha$  and IL-6. Overall, our findings showed that the effective action of QSYQ against the subacute phase of CI/RI occurs partly *via* regulating galectin-3 mediated inflammatory reaction.

**Keywords:** qishenyiqi, cerebral ischemia/reperfusion injury, TMT-based quantitative proteomics analysis, inflammatory response, galectin-3

## INTRODUCTION

Stroke is recognized as one of the main leading causes of death and serious long-term disability, as well as cognitive functional impairment, worldwide (Benjamin et al., 2019). Of all strokes, ischemic stroke incidents account for approximately 87% (Benjamin et al., 2019). Although intensive basic and clinical research has uncovered multiple modifiable risk factors (such as high systolic blood pressure, high fasting plasma glucose, and high total cholesterol) (Feigin et al., 2016), and has revealed many potential molecular mechanisms (such as inflammatory response (Jin et al., 2013), oxidative stress (Li et al., 2018), blood-brain barrier dysfunction (Jiang et al., 2018), activation of apoptotic and autophagic pathways (Kalogeris et al., 2012), mitochondrial dysfunction (Yang et al., 2018), and complement activation of stroke (Ma et al., 2019), effective therapies are still limited. Currently, the standard clinical therapy for appropriate patients with acute ischemic stroke are tissue plasminogen activator (tPA)-mediated intravenous thrombolysis and executing intra-arterial thrombectomy to realize recanalization (Dong et al., 2017; Goda et al., 2020). However, the major problems of the relatively narrow therapeutic time window and a high risk of hemorrhagic transformation in tPA treatment should not be ignored (Dong et al., 2017; Puig et al., 2017). Reperfusion injury following the restoration of blood supply may also result in more adverse stroke outcomes *via* complicated pathological processes (Lin et al., 2016). It is believed that cerebral ischemia/reperfusion injury (CI/RI) has become an increasingly critical challenge for post-stroke recovery (Pan et al., 2007). Thus, it is crucial to discover novel and alternative therapies for ischemic stroke.

In China, herbal remedies have been historically applied in the treatment of stroke and stroke-associated symptoms based on the theory of traditional Chinese medicine (TCM) (Sun et al., 2015; Han et al., 2017a). Qishen Yiqi (QSYQ) formula, which is composed of *Astragalus membranaceus* (Fisch.) Bge. (Huangqi), *Salvia miltiorrhiza* Bge. (Danshen), *Panax notoginseng* (Burk.) F. H. Chen (Sanqi), and *Dalbergia odorifera* T. Chen (Jiangxiang), is a typical component-based Chinese medicine that was approved by the State Food and Drug Administration of China in 2003 for treatment of angina pectoris of coronary heart disease origin with Qi deficiency and blood stasis syndrome (Cao et al., 2017), and secondary prevention of myocardial infarction (Shang et al., 2013). Recently, the major active ingredients in QSYQ, such as astragaloside IV, calycosin, calycosin-7-O- $\beta$ -D-glycoside, formononetin, salvianolic acid A, salvianolic acid B, tanshinone IIA, notoginsenoside R1, ginsenoside Rg1, and ginsenoside Rb1 (Yu et al., 2017; Zhang et al., 2018), have been reported to have therapeutic potential in acute and subacute phases of ischemic stroke *via* various functional mechanisms, especially immune-inflammatory response related mechanism (Han et al., 2017b; Zhang et al., 2020). Furthermore, we have found the protective action of QSYQ against acute ischemic stroke *via* regulating neuroinflammatory network mobilization in a mouse model of cerebral ischemia and reperfusion (Wang et al., 2020).

At present, it is believed that immune-inflammatory response is an important endogenous mechanism involved in the pathophysiological process of CI/RI (Famakin, 2014). An anti-inflammatory strategy appears to be a favorite therapeutic target, given its pleiotropic roles in the acute damage to long term recovery phase of ischemic stroke (Peng et al., 2019). Galectin-3 is a unique chimera-type member of the galectin family and exerts various functions depending on cell type and cellular location (Yip et al., 2017). Recent studies suggested that galectin-3 may serve as a promising prognostic biomarker as well as a potential therapeutic target for cardiovascular and cerebrovascular diseases (Shen et al., 2016; Dong et al., 2018). Accumulated evidence has indicated that galectin-3 appeared to function as a significant regulator participating in the neuroinflammatory reaction caused by cerebral ischemia and reperfusion (Shin, 2013; Rahimian et al., 2018). Interestingly, Burguillos et al. reported that microglia-secreted galectin-3 acted as an endogenous ligand for Toll-like receptor 4 (TLR-4) activation and deteriorated typical TLR4-dependent inflammatory response after cerebral ischemia (Burguillos et al., 2015).

In the present study, we aimed to explore the pharmacodynamic effect of QSYQ against the cerebral injury induced by ischemic stroke in the subacute phase. Subsequently, tandem mass tag (TMT)-based quantitative proteomics analysis followed by experimental verification was executed to explain the galectin-3 mediated neuroinflammatory mechanism of QSYQ treatment in response to CI/RI of the subacute phase.

## MATERIALS AND METHODS

### Drugs and Reagents

QSYQ (drug approval number: Z20030139; batch number: 20160604), which was supplied by Tasly Pharmaceutical Group Co., Ltd. (Tianjin, China), was prepared according to the ratio of Huangqi: Danshen: Sanqi: Jiangxiang oil = 148.01: 70.35:70.35:11.97 and dissolved in ultrapure water to make a solution at concentrations of 15 mg/ml, 30 mg/ml, and 60 mg/ml for experiments. Nimodipine (Nim) (drug approval number: H14022821) was purchased from Yabao Pharmaceutical Group Co., Ltd. (Taiyuan, China). Chromatographic-grade methanol and acetonitrile were purchased from Merck (Darmstadt, Germany). Water was purified using the Millipore-Q water purification system (Millipore, Milford, MA, United States). Standards of tanshinol, calycosin-7-O- $\beta$ -D-glycoside, protocatechualdehyde, formononetin, and rosmarinic acid were purchased from the National Institutes for Food and Drug Control of China (Beijing, China). Standards of lithospermic acid, ononin, and calycosin were purchased from Tianjin Shilan Technology Co., Ltd. (Tianjin, China). Standards of salvianolic acid A, salvianolic acid B, salvianolic acid D, salvianolic acid T, and salvianolic acid U were obtained from Tianjin Tasly Pharmaceutical Group Co., Ltd. (Tianjin, China). The purities of the above standards were more than 98%. 2, 3, 5-Triphenyl-2H-Tetrazolium Chloride (TTC) solution (2%, G3005), paraformaldehyde (4%, P1110), RIPA lysis buffer (R0020), PMSF (100mM, P0100), BCA Protein Assay Kit

(PC0020–50T), and SDS-PAGE Gel Kit (P1200–50T) were purchased from Solarbio (Beijing, China). Evans Blue was purchased from Meilunbio (MB4680–5°g, Dalian, China). Isoflurane (Lot No. B506) was purchased from Ruiwode Lifescience Co., Ltd. (Shenzhen, China). Omnipaque (300 mg I/ml, drug approval number: H20000,595) was purchased from GE Pharmaceutical Co., Ltd. (Shanghai, China). Tandem mass tag (TMT) (6-plex) isobaric label reagents were purchased from Thermo Fisher Scientific (Waltham, MA, United States). Sodium dodecyl sulfate (SDS), DL-dithiothreitol (DTT), Iodoacetamide (IAA), Triethylamine borane (TEAB), and urea were obtained from Bio-Rad (Hercules, CA, United States). Trypsin was obtained from Promega (Madison, WI). Tris was obtained from Sigma (St. Louis, MO, United States). Anti-Galectin-3 antibody was purchased from the Abcam Company (ab53082, Cambridge, United Kingdom). Anti- $\beta$ -actin antibody was purchased from Cell Signaling Technology (8457S, Beverly, MA, United States). Goat anti-rabbit IgG H&L was purchased from Zhongshan Jingqiao Biotechnology, Inc. (ZB-5301, Beijing, China). Cytokine IL-6 and TNF- $\alpha$  ELISA kits were obtained from Shanghai Zhuocai Biotechnology Co., Ltd. (Shanghai, China).

## High Performance Liquid Chromatography Analysis

Mixed standards were prepared as follows: all standards were weighed accurately and dissolved in 10 ml of methanol. Mixed standards were then filtered using a 0.45  $\mu$ m filtration membrane before analysis. Samples were extracted as follows: One hundred fifty milligrams of QSYQ was accurately weighed and ultrasonically extracted with 10 ml of 50% (v/v) methanol by ultrasonication for 30 min. After replenishing the lost weight during extraction, samples were filtered using a 0.45  $\mu$ m filtration membrane for HPLC analysis.

The HPLC analysis of QSYQ was performed using an Agilent 1,290 Infinity LC, which was equipped with a photodiode array ultraviolet-visible detector. A Waters ACQUITY UPLC BEH Shield RP18 column (2.1  $\times$  100 mm, 1.7  $\mu$ m) was used to perform the chromatography separation using water (A) and acetonitrile (B) as mobile phases. The gradient elution was set as follows: 0–3 min, 15% B; 3–10 min, 15–20% B; 10–12 min, 20% B; 12–18 min, 20–40% B; 18–24 min, 40–70% B; 24–27 min, 70–95% B; and 27–28 min, 95–8% B. The column temperature was maintained at 25°C with an injection volume of 2  $\mu$ L and a flow rate of 0.4 ml/min for analysis. Dual-wavelength detection was applied in this analysis: channel A was set as 254 nm; channel B was set as 280 nm from 0 to 3 min and 325 nm from 3 to 28 min.

## Experimental Animals

Male Sprague-Dawley (SD) rats weighing 200–220 g were obtained from Beijing Vital River Lab Animal Technology Co., Ltd. (Beijing, China, Certificate No: SCXK [Jing] 2014-0013). Rats were housed under a 12 h light/dark cycle in polypropylene cages, which were well ventilated, and there was a controlled in-house temperature of 22  $\pm$  2°C as well as humidity of 40  $\pm$  5%. Commercial rodent chow (Beijing Vital River Lab Animal

Technology Co., Ltd.) and clean water were provided ad libitum. Before the surgery, animals were fasted for 12 h, but with free access to water. The behavioral assessment was executed during the rats' active periods.

## Middle Cerebral Artery Occlusion Model and Drug Treatment

Before the surgery, rats were anesthetized with 4% isoflurane in 70% nitrous oxide (N<sub>2</sub>O)/30% oxygen (O<sub>2</sub>). Then, isoflurane was lowered to 2.5% to maintain anesthesia using a small animal anesthesia machine (Matrix VIP 3,000; Midmark, United States). Throughout all surgical procedures, the animal was placed on a heating pad to keep body temperature at 37°C. Surgery was performed using transient MCAO technique as described elsewhere with proper modification (Uluc et al., 2011; Gubskiy et al., 2018; Lopez and Vemuganti, 2018). A ventral midline incision (~1 cm) was made at the sterile neck and the left common carotid artery (CCA), external cerebral artery (ECA), and internal cerebral artery (ICA) were orderly exposed. After temporarily blocking the left CCA and ICA using two microsurgical clips, two sterile 4–0 silk sutures were placed around the left ECA: one tight ligature was tied as distally as possible from the bifurcation and the other loose ligature was put near the bifurcation. Then, a small hole was created between two silk sutures on the left ECA with a microsurgical scissor and a 3.0–5.0 cm length of silicone-coated 4-0 nylon monofilament (diameter with coating 0.32  $\pm$  0.02 mm, Guangzhou Jialing Biotechnology Co., Ltd., Guangzhou, China) was inserted into the left ECA and gently guided toward the ICA. The microsurgical clip from the ICA was removed and advanced toward the monofilament until the tip occluded the origin of the left middle cerebral artery (MCA), resulting in a decline of local cerebral blood flow to 20% of baseline. After 90 min MCAO, the perfusion of blood flow was regained by withdrawing the monofilament. Before its closing, the wound area was moisturized with sterile saline and lidocaine was applied as a topical analgesic. Isotonic saline was intraperitoneally injected to prevent dehydration. After wound closure, bupivacaine was applied along the sutures and the animal was placed in a temperature-controlled recovery chamber to monitor its behavior for 1–2 h. Finally, the rat was put back to the housing cage and moistened rodent chow was placed on the bottom of the cage to facilitate eating. Sham-operated rats were handled in the same way like the model group, although the monofilament was not used to achieve the occlusion of MCA.

## Animal Grouping and Drug Treatment

After 22.5 h reperfusion, two independent observers, who were blinded to the experiment, tested the neurological deficits of the animals that had undergone MCAO surgery according to a five-point scale described previously by Longa et al. with a minor modification (Longa et al., 1989). The criteria were set as follows: score 0, no neurological deficit; score 1, mild focal neurological deficit (failure to fully extend contralateral forelimb); score 2, moderate focal neurological deficit (repetitive circling to the contralateral side); score 3, severe focal neurological deficit

(falling to the contralateral side); and score 4, unable to walk spontaneously with a depressed level of consciousness or death. A total of 130 rats with a score between 1 and 2 were selected for the present study. As shown in **Supplementary Figure S1**, apart from the Sham group, the selected experimental rats were randomly divided into five different groups, including I/R (model), Nim (positive control)+I/R, QSYQ low dose (150 mg/kg) + I/R, middle dose (300 mg/kg) + I/R, and high dose (600 mg/kg) + I/R groups. Rats in QSYQ (150 mg/kg, 300 mg/kg, 600 mg/kg) and Nim (12 mg/kg) groups were orally administered their respective dose once daily for 7 days. Meanwhile, the Sham-operated and I/R model groups were given 0.9% normal saline via gavage at a dose of 10 ml/kg.

## Neurological Deficits and Mortality Rate

For the evaluation of neurological function, a modified Neurological Severity Score (mNSS) was used on days 1, 3, 5, and 7, respectively after MCAO. The mNSS was a synthetic scale, including motor function, sensory disturbance, balance, and reflection tests, graded on a score of 0–18 (Chen et al., 2001). The details were shown in **Supplementary Table S1**. One point was defined as inability to complete the tasks or no response to tests, while higher scores represented more serious neurological deficit. All tests were assessed by two independent investigators who were blinded to the experimental groups. The mortality rate of each group was calculated for the whole period of the drug treatment.

## Behavioral Assay

Open field test was executed to evaluate the locomotor activity of experimental animals (Jin et al., 2015). On the 8th day after stroke, the rats were respectively placed in four open field locomotion chambers (50 cm in length × 50 cm in width × 40 cm wall height) made of plywood. The bottom of the chamber was actually divided by white drawn lines, composing nine equal-area grids. After 5 min adaption to the novel environment, the locomotor data of each rat was automatically recorded for 30 min and calculated using the ANY-maze software (version 4.82, Stoelting, United States). The following parameters were analyzed: total distance traveled by the animals and average speed. The behavioral assessment was performed in a quiet room, from 8:00–12:00 a.m., by two observers who were blinded to the animal experiment.

## Gait Analysis

For the gait test, CatWalk XT 9.1 (Noldus Information Technology, Wageningen, Netherlands), an automated quantitative gait analysis system, was performed in this study (Orgah et al., 2019). Prior to surgery, rats were trained for at least three consecutive days to adapt to the walkway in a quiet room. On the 8th day after the MCAO or sham-operation, post-surgery testing was executed in the same conditions as the training period. Each experimental animal was placed individually on the runway and allowed to freely run back and forth until three accepted runs were recorded. The subsequent data analysis was handled using the Catwalk XT 9.1 Software. The main gait parameters, including walking speed (the speed of rats across the runway), base of support (distance between girdle paw pairs), stride length (distance the paw traveled from one step to the next), and stand (time duration of the paw in contact

with the floor during a step cycle), were employed for assessing the effects of QSYQ on functional recovery. At least two observers who were blinded to the animal grouping carried out the CatWalk test and data analysis.

## Micro-CT Imaging and Analysis

After 8 days post-reperfusion, anesthetized rats were intra-arterially injected with a clinically available iodinated x-ray contrast agent (Omnipaque) at 2.0 ml over a period of 20 s. Subsequently, the micro-Computed Tomography (CT) imaging technique was used to visualize the blood-brain barrier (BBB) disruption and cerebral edema (Park et al., 2014; Orgah et al., 2018). In brief, brain micro-CT imaging was performed using a small animal micro-CT imager (Quantum FX; PerkinElmer, United States) with the following main imaging parameters: voltage for 90 kV, current for 180  $\mu$ A, field of view (FOV) for 40 mm, and scan for 4.5 min. BBB disruption was detected for Omnipaque leakage and cerebral edema was presented with position offset of midline. Next, the “VOL EDIT” module in Analyze 12.0 image analysis software (Analyze Direct, Overland Park, KS, United States) was applied to make 3D reconstructions of whole-cerebral slide images. The “ROI” measure module was used to calculate the mean micro-CT number (HU) of Omnipaque leakage and cerebral hemisphere volumes.

## TTC Staining and Quantification of Infarct Volume

After performing micro-CT imaging, brains were quickly removed. Six pieces of 2 mm-thick coronal cerebral slices were obtained using a rat brain matrix (Shenzhen RWD life technology Co., Ltd., Guangzhou, China) and stained with 2% TTC solution in the dark for 10 min at 37°C. After stained cerebral slices were photographed, ImageJ image processing software (ImageJ 1.51, Wayne Rasband, National Institutes of Health, United States) was applied to measure cerebral infarct area. Ratios of infarct volume were displayed as a percentage (%) of (total cerebral infarct volume/total brain volume) × 100 (Lin et al., 1993).

## Assessment of BBB Permeability

BBB permeability was examined by the extravasation of Evans Blue (EB) stain into the brain following the tail-vein injection. After 7 days post-reperfusion, rats were injected with 4% EB solution in 0.9% normal saline (2 ml/kg) via the tail vein. 24 h later, the brains suffering perfusion were cut into 2 mm-thick coronal slices. After recording the EB-stained cerebral sections, the Caliper IVIS Lumina K Series III system was used for fluorescent imaging detection [58]. Then, the Living Image® Software (version 4.3.1) was used to quantify the EB leakage via calculating a total radiant efficiency [(p/s)/( $\mu$ W/cm<sup>2</sup>)].

## TMT-Based Quantitative Proteomics Analysis

### Sample Preparation

According to the above experimental results, rats from the model group (n = 3) and QSYQ high dose group (n = 3) were screened to

further perform proteomic analysis. A total of eight days after MCAO, anesthetized rats were transcardially perfused with prechilled saline and then the brains were immediately removed. The infarcted cerebral hemisphere tissues were separated, snap frozen in liquid nitrogen, and stored at  $-80^{\circ}\text{C}$  until use. Protein extraction from the cerebral tissues were carried out referring to a method previously described (Zhu et al., 2014) with some modifications. In brief, all samples were homogenized in ice-cold lysis buffer. Subsequently, the homogenate was sonicated and boiled for 15 min. After centrifugation at 14,000 g for 40 min at  $4^{\circ}\text{C}$ , the supernatant was filtered with  $0.22\text{ }\mu\text{m}$  filters. Protein content was determined using the BCA protein assay kit.

### Protein Digestion Based on Filter-Aided Sample Preparation

Protein digestion was performed according to the method of filter-aided sample preparation (FASP) (Wisniewski et al., 2009). 200  $\mu\text{g}$  of proteins for each sample were incorporated into 30  $\mu\text{L}$  SDT buffer (4% SDS, 100 mM DTT, 150 mM Tris-HCl pH 8.0). The detergent, DTT, and other low-molecular-weight components were removed using UA buffer (8 M Urea, 150 mM Tris-HCl pH 8.0) by repeated ultrafiltration (Microcon units, 10 kD). Then 100  $\mu\text{L}$  iodoacetamide (100 mM IAA in UA buffer) was added to block reduced cysteine residues and the samples were incubated for 30 min in the dark. The filters were washed with 100  $\mu\text{L}$  UA buffer three times and then 100  $\mu\text{L}$  100 mM TEAB buffer twice. Finally, the protein suspensions were digested with 4  $\mu\text{g}$  trypsin (Promega) in 40  $\mu\text{L}$  TEAB buffer overnight at  $37^{\circ}\text{C}$ , and the resulting peptides were collected as a filtrate. The peptide content was estimated by UV light spectral density at 280 nm using an extinctions coefficient of 1.1 of 0.1% (g/L) solution that was calculated on the basis of the frequency of tryptophan and tyrosine in vertebrate proteins.

### TMT Labeling and Peptide Fractionation

According to the manufacturer's instructions, 100  $\mu\text{g}$  peptide mixture of each sample was labeled using tandem mass tags (TMT) isobaric label reagents (Thermo Fisher Scientific). Subsequently, pierce high pH reversed-phase peptide fractionation kit (Thermo Fisher Scientific, Waltham, MA, United States) was used to fractionate TMT-labeled digest samples into 15 fractions by an increasing acetonitrile step-gradient elution according to instructions (Wei et al., 2018). The fractions were dried, lyophilized, and stored at  $-80^{\circ}\text{C}$  until LC-MS/MS analysis.

### Reversed-Phase Liquid Chromatography-Tandem Mass Spectrometry

The NanoLC-MS/MS analysis of each fraction was performed using a Q Exactive mass spectrometer (Thermo Fisher Scientific) that was coupled to an Easy nLC1000 HPLC system (Thermo

Fisher Scientific). The labeled peptides were loaded onto a reverse phase trap column (Thermo Scientific Acclaim PepMap100,  $100\text{ }\mu\text{m}$  inner diameter  $\times$  2 cm, nanoViper C18) connected to the C18-reversed phase analytical column (Thermo Scientific Easy Column, 10 cm long,  $75\text{ }\mu\text{m}$  inner diameter,  $3\text{ }\mu\text{m}$  resin) in buffer A (0.1% formic acid) and eluted with a 60 min linear gradient - 0–50% buffer B (84% acetonitrile and 0.1% formic acid), 50 min; 50–100% buffer B, 5 min; 100%–100% buffer B, 5 min - at a flow rate of 300 nL/min controlled by IntelliFlow technology. The mass spectrometer was operated in positive ion mode. MS data was acquired using a data-dependent top 10 method dynamically choosing the most abundant precursor ions from the survey scan (300–1800 m/z) for high-energy collision dissociation (HCD) fragmentation. Automatic gain control (AGC) target value was set to  $3 \times 10^6$  with a maximum ion injection time of 10 ms. Dynamic exclusion duration was 40.0 s. The survey scans were acquired at a high resolution of 70,000 at m/z 200, resolution for HCD spectra was set to 17,500 at m/z 200, and isolation width was 2 m/z. Normalized collision energy was 30 eV and the underfill ratio, which specified the minimum percentage of the target value likely to be reached at maximum fill time, was defined as 0.1%. The instrument was run with peptide recognition mode enabled.

### Protein Identification and Quantification

The MS/MS spectra were searched using MASCOT engine (Matrix Science, London, United Kingdom; version 2.2) embedded into Proteome Discoverer 1.4 (Thermo Fisher Scientific). Trypsin was chosen as the enzyme, allowing up to two missed cleavage sites. Carbamidomethylation (C), TMT 6-plex (N-term), and TMT 6-plex (lysine, K) were chosen as fixed modification. Oxidation (methionine, M) was regarded as a variable modification. The peptide mass tolerances were set at 20 ppm for MS1 spectra acquired, and the fragment mass tolerance for MS2 spectra was set to 0.1 Da. In this study, only rank 1 peptide and a false discovery rate (FDR) of  $\leq 1\%$  were accepted. The protein ratios were calculated as the median of only unique peptides of the protein. All peptide ratios were normalized by the median protein ratio, and the median protein ratio should be 1 after the normalization. Comparisons of the protein identification and quantitation results were done between each QSYQ high dose (H) and the corresponding model (M) groups. Significantly regulated proteins between experimental groups were determined based on their *p*-value (*p*-value < 0.05). Only proteins with more than 1.20-fold or less than 0.833-fold change compared to control groups were considered differentially regulated.

### Bioinformatics Analysis

In this study, Cluster 3.0 (<http://bonsai.hgc.jp/~mdehoon/software/cluster/software.htm>) and Java Treeview software (<http://jtreeview.sourceforge.net>) were used to perform hierarchical clustering analysis. Euclidean distance algorithm for similarity measure and average linkage clustering algorithm (clustering uses the centroids of the observations) for clustering were selected when carrying out hierarchical clustering. The acquired protein relative expression data was visualized as a

tree heat map. Then, the data, including significantly differential protein name, *p*-value, and log(fold change), were imported into Ingenuity® Pathway Analysis (IPA) system (<http://www.ingenuity.com>) to execute further analysis. “Core analysis-Diseases and Functions” module was performed to obtain the top diseases and functions related to the significantly differential proteins. “Build-Connection” module was used to analyze protein-protein interaction (PPI) network.

According to the direct functional degree of each protein, the importance of the protein in the PPI network was displayed. “Path designer” module was used to polish the network images and graphs.

The algorithm of the IPA analysis was based on Fisher’s exact test with the enrichment score of *p*-value.

## Immunohistochemistry Analysis

After 8 days post-reperfusion, brain tissues were quickly obtained from euthanized rats and then fixed in 4% paraformaldehyde for at least 48 h. The fixed tissues were dehydrated and embedded in paraffin blocks to be cut into 5 µm cerebral coronal paraffin slices. Subsequently, the sections were dewaxed in xylene and rehydrated followed by incubation with 3% hydrogen peroxide at room temperature for 10 min to block intrinsic peroxidase activity. After performing antigen repair, the brain slices were treated with blocking buffer (10% bovine serum) at 37°C for 1 h to block any nonspecific antibody responses. Next step, the sections were incubated overnight at 4°C using anti-galectin-3 antibody diluted with blocking buffer (1:50), then sequentially incubated with secondary antibody (the biotin-conjugated goat anti-rabbit IgG) diluted with blocking buffer (1:200) for 40 min at 37°C. The immunoreactivity of galectin-3 protein was visualized using a DAB substrate kit, followed by counterstaining hematoxylin, differentiation with 1% hydrochloric acid alcohol, dehydration, and sealing. Finally, the optical microscope (Vectra 3, PerkinElmer, United States) was carried out to observe and photograph the brain slices. ImagePro Plus software (National Institutes of Health, Bethesda, MD, United States) was executed to quantify the expression of galectin-3 by calculating the average optical density (AOD) value.

## Western Blotting Analysis

The frozen post-ischemic hemisphere tissues (*n* = 3 per group) were collected in ice-cold RIPA lysis buffer containing serine proteases and acetylcholinesterase inhibitors. The lysates were centrifuged at 12,000 g for 10 min at 4°C. The BCA protein assay kit was used to measure the protein concentration. Equal amounts of 30 µg protein extracts were loaded and separated by 12% sodium dodecyl sulfate-polyacrylamide gels (SDS-PAGE) and transferred to polyvinylidene fluoride (PVDF) blotting membrane (GE Healthcare, Millipore, United States) using an electrophoresis apparatus (Tanon Science and Technology Co., Ltd., Shanghai, China). The membrane was blocked with a 5% non-fat milk-Tris-HCl-buffered saline and Tween 20 (TBST) solution for 3 h at room temperature, and then incubated overnight at 4°C with the antibodies of anti-Galectin-3 (1:1,000) and anti-β-actin (1:2,000). After washing three times with TBST, the membrane was incubated with goat anti-rabbit IgG

H&L (1:10,000) as the secondary antibody for 2 h at room temperature. After incubation finished, the membrane was washed three times (10 min each) and visualized using enhanced chemiluminescence detection reagents (TransGen Biotech Co., Ltd., Beijing, China). Western blotting bands were captured using the C-DiGit scanner with Image Studio (Version 5.2) imaging system. The quantification of band intensity was performed according to integrated density by ImageJ image processing software (ImageJ 1.42, Wayne Rasband, National Institutes of Health, United States).

## Quantitative Real-Time Polymerase Chain Reaction Analysis

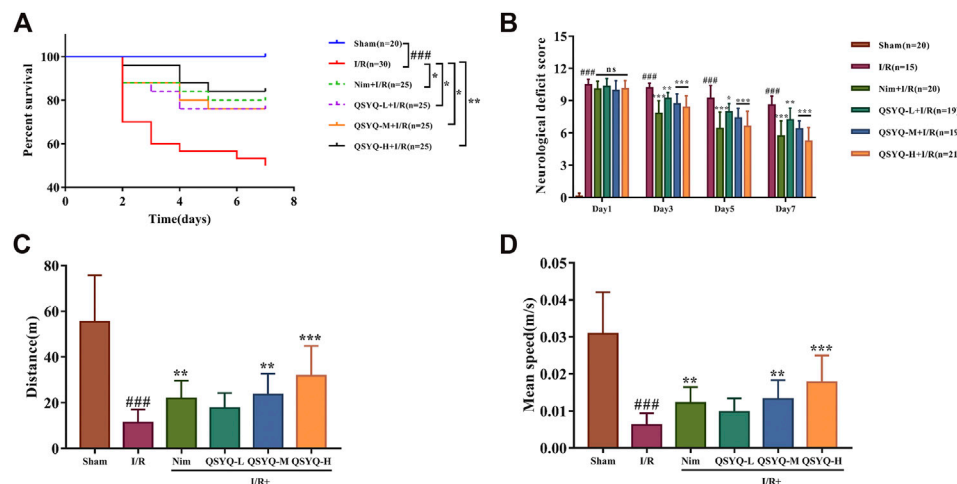

Total RNA samples from the post-ischemic hemisphere tissues were isolated using TRIzol® reagent (Invitrogen, Thermo Fisher Scientific, Inc., Waltham, MA, United States) according to the manufacturer’s protocol. Subsequently, the complementary DNA (cDNA) was synthesized from 1 µg total RNA in a 20 µL reaction using Transcriptor First Strand cDNA Synthesis Kit (Roche, Mannheim, Germany).

The Bestar® Sybr Green qPCR Master Mix (DBI® Bioscience, Ludwigshafen, Germany) was used in reverse transcription-quantitative real-time polymerase chain reaction (RT-qPCR) to quantify the mRNA expression levels of LGALS3 (galectin-3), TNF-α, and IL-6 with glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as an internal control. The designed gene-specific primers were obtained by Sangon Biotech (Shanghai, China) and the following oligonucleotide primer sequences were used: for LGALS3 forward 5'-GAG AAC AAC AGA AGA GTC ATC GTG-3', reverse 5'-GAC CTG TAT TTT GAA TGG TTT GCC-3'; for TNF-α forward 5'-GCG TGT TCA TCC GTT CTC TA-3', reverse 5'-CGT CTC GTG TGT TTC TGA GC-3'; for IL-6 forward 5'-ACC TGG AGT TTG TGA AGA ACA AC-3', reverse 5'-GGA AGT TGG GGT AGG AAG GA-3'; for GAPDH forward 5'-GGC CTT CCG TGT TCC TAC C-3', reverse 5'-CGC CTG CTT CAC CAC CTT C-3'. The amplification and analysis were performed using LightCycler® 480 Software Version 1.5.0.39 (Roche, Mannheim, Germany) for 45 cycles. The relative mRNA expression levels were calculated using 2<sup>-ΔΔCT</sup> method, following normalization to the housekeeping gene GAPDH.

## Enzyme-Linked Immunosorbent Assay

After 8 days post-reperfusion, the blood samples were collected from anesthetized rats. Then, blood samples were centrifuged at 10,000 rpm for 15 min at 4°C to separate and obtain the serum. In order to measure the expression levels of TNF-α and IL-6 in serum, the rat TNF-α ELISA kit (ZC-37624, ZCi Biotechnology Co., Ltd.) and rat IL-6 ELISA kit (ZC-36404, ZCi Biotechnology Co., Ltd.) were applied according to the manufacturer’s instructions. Finally, the protein concentrations of TNF-α and IL-6 in serum were calculated with the reference to the standard curve acquired from a gradient concentration standard substances provided by the assay kit.

Statistical analysis Statistical analysis was performed using Student’s two-tailed *t*-test for comparison between two groups

**FIGURE 1 |** Effect of treatment with QSYQ on survival rate and neurological as well as motor deficits caused by stroke. **(A)** The Kaplan-Meier survival curve of each group. Treatment with QSYQ at all doses or Nim improved the survival rate compared to the model group. **(B)** The mNSS scores on days 1, 3, 5, and 7 after I/R surgery. The model group exhibited serious neurological deficit among six groups on days 3, 5, and 7 after drug treatment, whereas QSYQ and positive control groups showed a distinct reduction in mNSS scores. **(C)** Bar graph representing results of traveled total distance ( $n = 15$ ). QSYQ at middle and high doses/Nim + I/R groups obviously improved the total traveled distance compared to the stroke rats. **(D)** Bar graph representing results of mean speed ( $n = 15$ ). QSYQ at middle and high doses/Nim + I/R groups significantly boosted the mean speed compared to the stroke rats. Data are expressed as the mean  $\pm$  SD.  $\#p < 0.05$ ,  $\#\#\#p < 0.001$  vs. the sham group;  $*p < 0.05$ ,  $**p < 0.01$ , and  $***p < 0.001$  vs. the model group. I/R, ischemia/reperfusion; Nim, Nimodipine; QSYQ-L, QSYQ 150 mg/kg-low dose; QSYQ-M, QSYQ 300 mg/kg-middle dose; QSYQ-H, QSYQ 600 mg/kg-high dose.

and using one-way analysis of variance (ANOVA) followed by Dunnett's t-test for comparisons between multiple groups. The mortality was analyzed using the Kaplan-Meier survival curve. A value of  $p < 0.05$  was defined as a statistically significant difference. Data from different experiments were expressed either as mean  $\pm$  SD or mean  $\pm$  SEM as indicated. GraphPad Prism 7 software (GraphPad Software, Inc., La Jolla, CA, United States) was used to generate all data graphs.

## RESULTS

### Chemical Profile of Major Ingredients in QSYQ by HPLC

To elucidate the main chemical components in QSYQ, HPLC analysis was performed in this study. A representative HPLC chromatogram was displayed in **Supplementary Figure S2**. Thirteen constituents in QSYQ were successfully identified according to the comparison of the retention times with standard substances, which was similar with the previous report (Zhang et al., 2018).

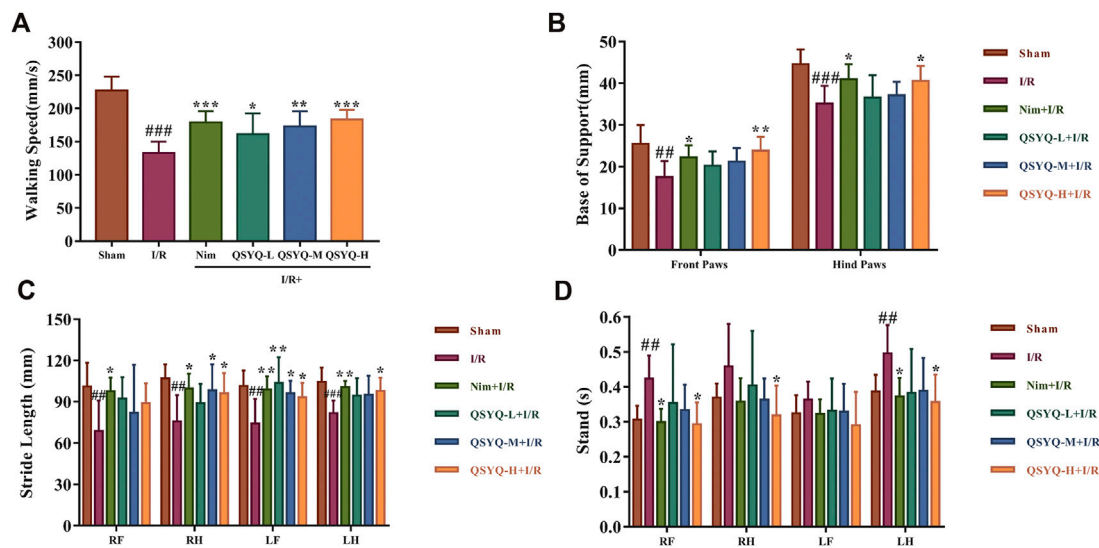

### QSYQ Improved the Survival Rate and Neurological Scores of Subacute Stroke Rats

The Kaplan-Meier survival curve showed the survival proportion of the stroke-induced rats (**Figure 1A**). Rats after MCAO significantly increased mortality, especially during the acute period of reperfusion (first 72 h), compared to the sham group within the 7 day period of data collection. As expected, MCAO

rats treated with low and middle doses of QSYQ or Nim obviously improved their survival rate ( $p < 0.05$ ). Furthermore, treatment with QSYQ at high doses (600 mg/kg) increased the survival rate from 50 to 84% ( $p < 0.01$ ; **Figure 1A**). As shown in **Figure 1B**, rats subjected to sham operation behaved normally without neurological deficit symptoms, however, the left side cerebral I/R surgery caused serious neurological deficit of rats in the model group. Compared with the model group, treatment with Nim or different doses of QSYQ markedly decreased scores with better neurological function. Moreover, QSYQ at middle and high doses had similar effects on neurological function to the Nim group (**Figure 1B**). In addition, we also carried out an open field test to measure the locomotor activity of experimental animals on post-stroke day 8. The data of total distance traveled by the animals and average speed within the 30 min indicated severe motor deficits in the model group (**Figures 1C,D**). Fortunately, the Nim, QSYQ middle dose (300 mg/kg), and QSYQ high dose (600 mg/kg) groups significantly enhanced the locomotor activity of stroke rats ( $p < 0.01$ ).

### QSYQ Ameliorated Motion Deficits of Subacute Stroke Rats

In this study, we applied CatWalk XT 9.1 system to conduct the gait test of rats in each group 8 days after the MCAO or sham-operation. The collected footprints of rats from each group were automatically labeled by the system as right front paw (RF), right hind paw (RH), left front paw (LF), and left hind paw (LH). Once auto-classification of labeled footprints was finished, we could obtain the corresponding gait parameters of each labeled paw. Then, a one-way between subjects ANOVA was used to compare

**FIGURE 2 |** Locomotive gait analysis and functional recovery of QSYQ treated subacute stroke rats. (A–D) Bar graph representation of main parameter statistics, including walking speed, BOS, stride length, and stand time, for estimating functional recovery of QSYQ-treated stroke rats ( $n = 8$ ). Left brain lesion induced by I/R resulted in a significant motion deficits of rats. Fortunately, QSYQ treatment could attenuate the abnormal motion function during the 8th-days post-reperfusion. Data are presented as the mean  $\pm$  SD.  $\#p < 0.05$ ,  $\#\#p < 0.01$ , and  $\#\#\#p < 0.001$  vs. the sham group;  $*p < 0.05$ ,  $**p < 0.01$ , and  $***p < 0.001$  vs. the model group. I/R, ischemia/reperfusion; Nim, Nimodipine; QSYQ-L, QSYQ 150 mg/kg-low dose; QSYQ-M, QSYQ 300 mg/kg-middle dose; QSYQ-H, QSYQ 600 mg/kg-high dose.

the effect of drugs on the function recovery of post-stroke motion impairment for walking speed, base of support (BOS), stride length, and stand time. In subacute phase of stroke, the rats subjected to MCAO significantly reduced walking speed, BOS, and stride length as well as increased stand time (Figure 2). Surprisingly, treatment with QSYQ could dose-dependently enhance walking speed (Figure 2A). Secondly, MCAO rats treated with QSYQ at high dose (600 mg/kg) obviously increased BOS of their front paws and hind paws (Figure 2B).

For the parameter of stride length, treatment with QSYQ at high dose (600 mg/kg) remarkably improved the impairment of RH, LF, and LH caused by stroke, while treatment with QSYQ at middle dose (300 mg/kg) only increased stride length in RH and LF (Figure 2C). Treatment with high doses of QSYQ positively reduced stand time of RF, RH, and LH (Figure 2D). As expected, treatment with Nim also obviously improved the deficit of locomotor function induced by cerebral ischemia and reperfusion (Figure 2).

## QSYQ Reduced Cerebral Infarction Volume and Cerebral Edema in Subacute Stroke Rat Brain

By calculating the cerebral infarction volume in TTC-stained slices and indirectly assessing the severity of brain edema in micro-CT imaging, the brain injury in different groups on the 8th day after MCAO surgery was evaluated. Compared with the sham-operated group, the infarct volume was significantly increased in the experimental ischemic stroke model group ( $25.87 \pm 2.88\%$  of the cerebral volume), whereas treatment with Nim, QSYQ middle dose (300 mg/kg), and high dose

(600 mg/kg) could exhibit a positive effect on reducing infarct volume induced by I/R injury (Figures 3A,B). According to the cerebral coronal image, we found that the model group presented the most obvious midline offset caused by cerebral edema, however, treatment with QSYQ at all three doses as well as Nim lessened the degree of midline offset (Figure 3C). Subsequently, Analyze 12.0 image analysis software was used to calculate the cerebral edema. Compared with the sham group, the ratio of the bilateral cerebral hemisphere volume markedly elevated on account of undergoing left MCAO surgical operation (Figure 3D). Similar to the result of Nim, treatment with QSYQ at three doses inhibited the ratio of the bilateral cerebral hemisphere volume, which confirmed that QSYQ treatment reduced cerebral edema in the subacute phase of the experimental animal model of ischemic stroke (Figure 3D).

## QSYQ Attenuated BBB Disruption in Subacute Stroke Rats

IVIS fluorescent imaging and brain micro-CT imaging techniques were integrated to detect and quantify the BBB integrity. As a control, no EB extravasation, Omnipaque leakage, and detectable spectrum were observed in the sham group, whereas a significant leakage (EB and Omnipaque) of the BBB was detected in the model samples (Figure 4). Notably, treatment with both Nim and QSYQ high dose (600 mg/kg) significantly lowered EB extravasation and Omnipaque leakage (Figure 4). Treatment with QSYQ at middle dose (300 mg/kg) also reduced Omnipaque leakage, whereas treatment with QSYQ at middle dose (300 mg/kg) attenuated EB leakage to some extent, but did not reach significance (Figures 4D,E). The results of EB and Omnipaque extravasation indicated that treatment

The infarct areas were in white, whereas normal areas were in red. **(B)** Quantitative analysis of cerebral infarction volumes of each group ( $n = 6$ ). QSYQ/Nim + I/R group significantly decreased the infarct volumes caused by MCAO. **(C)** Representative coronal cerebral slice image of each group. Yellow dotted line marks the cerebral midline and red arrows indicate offset distance of midline. **(D)** Quantitative analysis of the ratio of bilateral brain hemisphere volume of each group ( $n = 6$ ). Treatment with QSYQ at three doses as well as Nim decreased the raised values of the ratio of bilateral brain hemisphere volume due to left cerebral I/R injury. TTC staining and cerebral edema data are presented as the mean  $\pm$  SD.  $^{\#}p < 0.05$ ,  $^{##}p < 0.01$ , and  $^{###}p < 0.001$  vs. the sham group;  $^*p < 0.05$ ,  $^{**}p < 0.01$ , and  $^{***}p < 0.001$  vs. the model group. I/R, ischemia/reperfusion; Nim, Nimodipine; QSYQ-L, QSYQ 150 mg/kg-low dose; QSYQ-M, QSYQ 300 mg/kg-middle dose; QSYQ-H, QSYQ 600 mg/kg-high dose.

with QSYQ at high dose (600 mg/kg) or Nim observably reduced BBB disruption of model rats in the subacute phase of experimental stroke.

### Identification of Differentially Expressed Proteins Induced by QSYQ Treatment in the Brain of Subacute Stroke Rats.

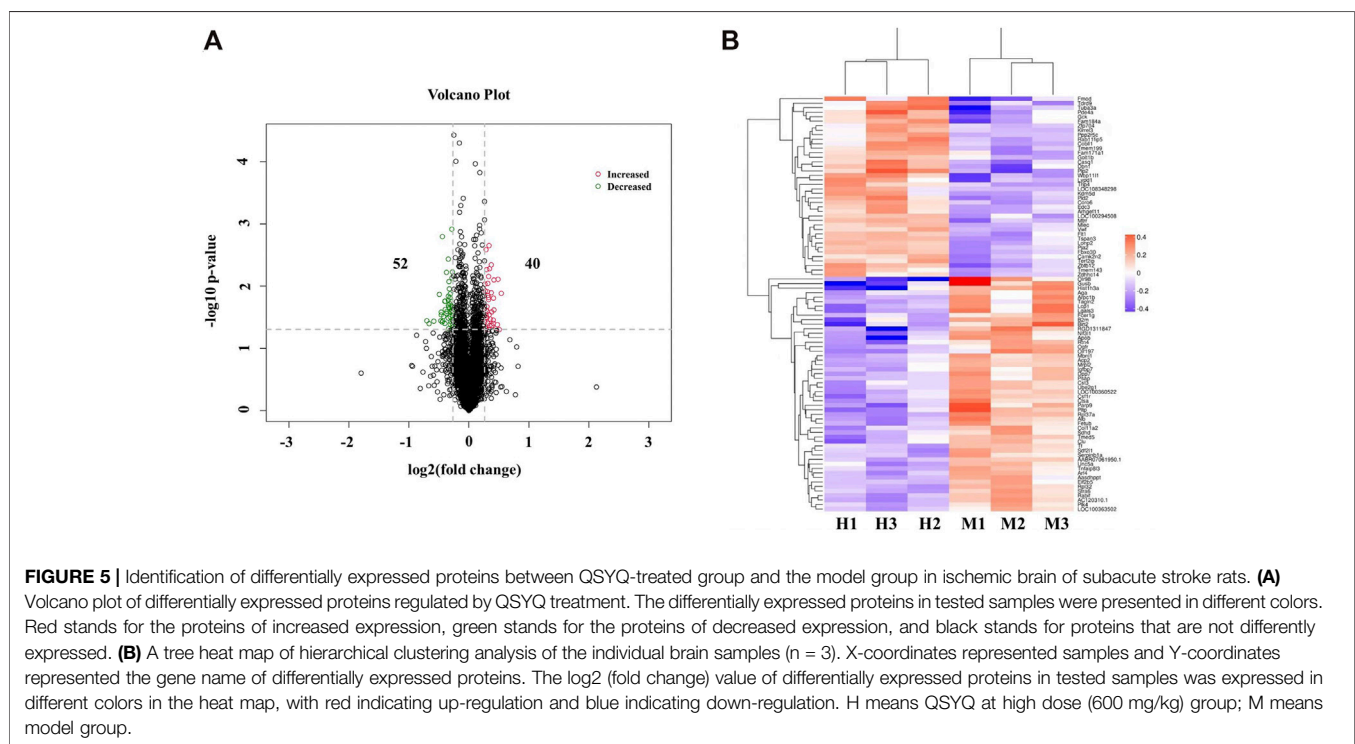

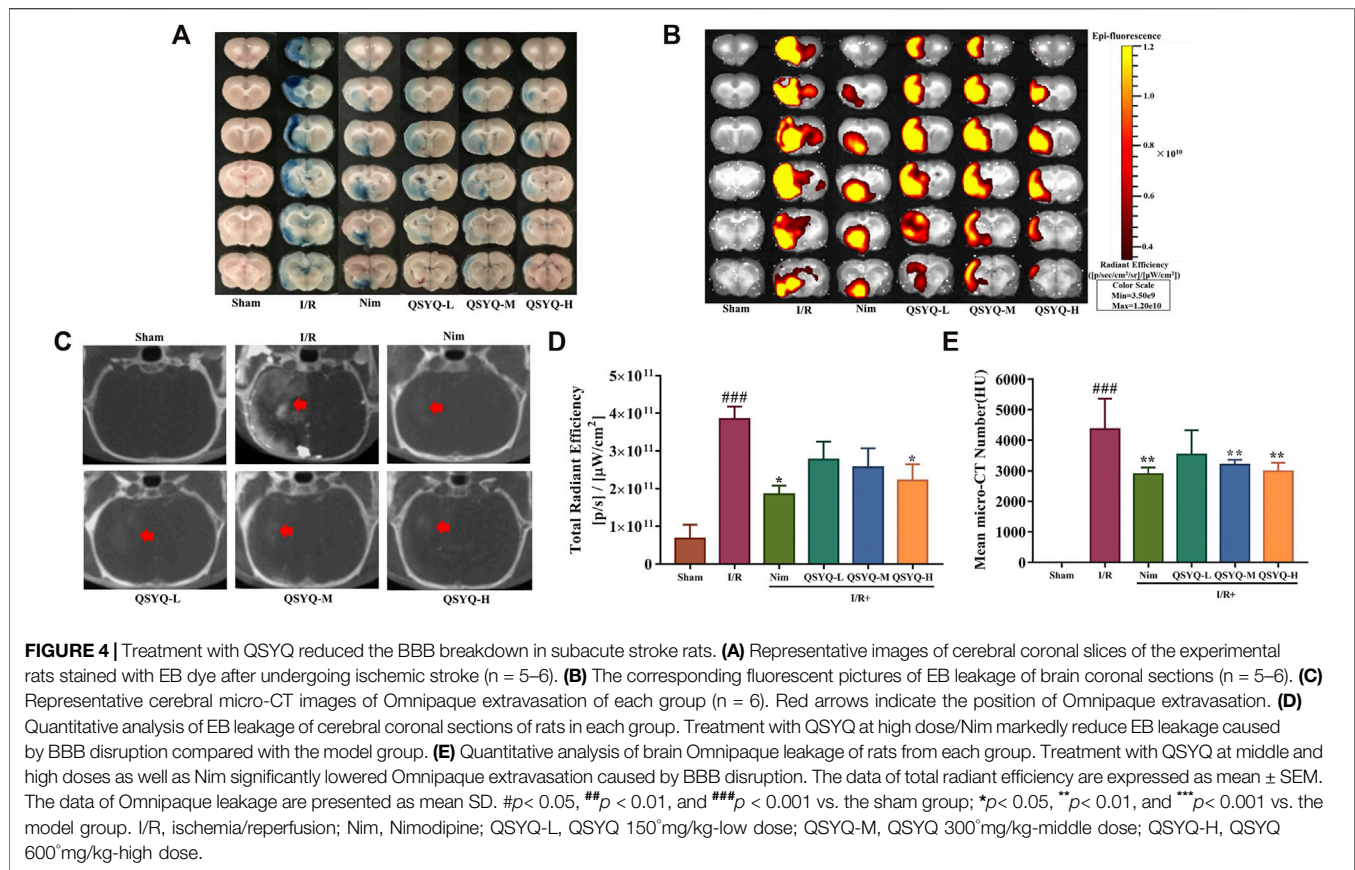

To reveal the underlying molecular mechanisms of subacute phase (1.5 h ischemia and 8 days reperfusion) stroke protection against cerebral injury by QSYQ, TMT-based quantitative proteomics analysis was employed on the proteins extracted from ischemic brain tissues of MCAO/reperfusion rats with or without QSYQ treatment. A total of 34,187 unique peptides were detected (only rank 1 peptides and FDR  $\leq 1\%$  were accepted) and 5,813 proteins were identified by one or more unique peptides. Using a strict criteria (fold change  $> 1.20$  or  $< 0.833$ ,  $p$ -value  $< 0.05$ ), a total of 92 differentially expressed proteins in ischemic brain tissues were detected between QSYQ (high dose)-treated and the model groups. Among them, the expression levels of 40 proteins were significantly elevated with a fold change more than 1.20 in H (QSYQ high dose group) vs. M (model group), whereas the expression levels of 52 proteins were dramatically reduced with a fold change less than 0.833 in H (QSYQ high dose group) vs. M (model group), as displayed in a volcano plot in **Figure 5A**. Hierarchical clustering analysis of the acquired protein relative expression data were

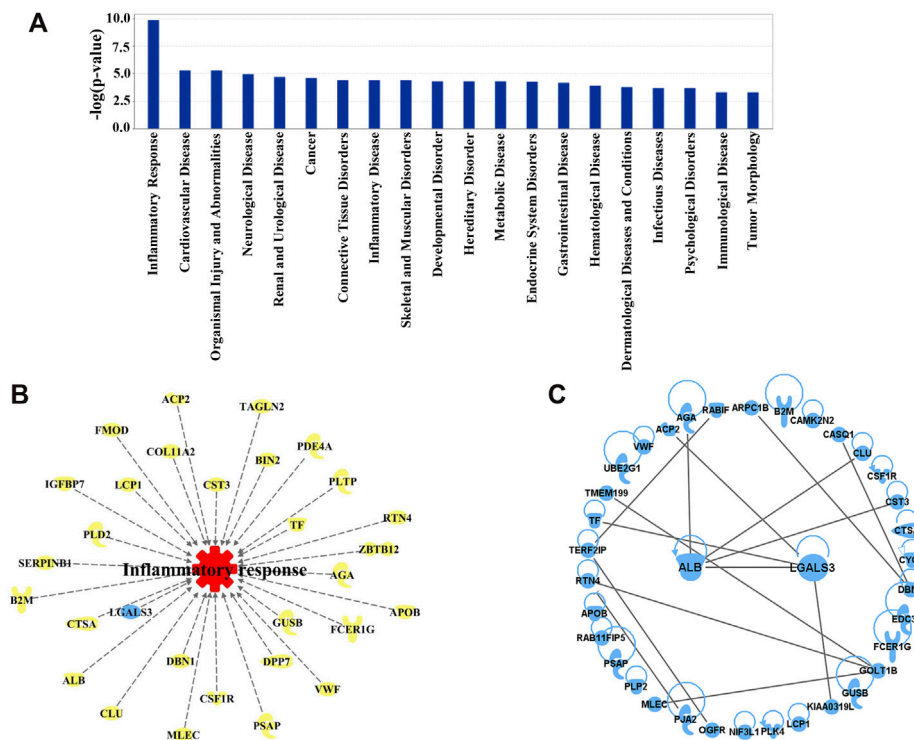

visualized in a tree heat map (**Figure 5B**), which supported the rationality of selecting differentially expressed proteins. The detailed information of significantly differentially expressed proteins was shown in **Supplementary Table S2**.

### Network Pharmacology Analysis Revealed Galectin-3 Mediated Neuroinflammation as a Key Mechanism of Subacute Stroke Protection by QSYQ.

To discover the molecular mechanisms accounting for the action of QSYQ treatment against ischemia and reperfusion injury, network pharmacology analysis was carried out using IPA system. The “Core analysis-Diseases and Functions” module was executed to gain the top diseases and functions strongly linked to the significantly differentially expressed proteins. Based on the Fisher’s exact test algorithm of IPA, the diseases as well as functions were ranked according to corresponding  $p$ -value scores so as to distinguish the relatedness or importance among these proteins and diverse diseases as well as functions. The top 10 diseases and functions influenced by QSYQ in the order of descending  $-\log(p\text{-value})$  score were inflammatory response, cardiovascular disease, organismal injury and abnormalities, neurological disease, renal and urological disease, cancer, connective tissue disorders, inflammatory disease, skeletal and muscular disorders, and developmental disorder. As the inflammatory response ranked the highest with a  $-\log$

**FIGURE 6 |** (A) Diseases and Functions affected by QSYQ were ranked according to the Fisher's exact test algorithm. Top 20 diseases and functions were displayed in descending order based on  $-\log(p\text{-value})$  score. Among them, inflammatory response ranked the highest with a  $-\log(p\text{-value})$  score. (B) 30 important proteins correlated with inflammatory response picked out from 92 differentially expressed proteins modulated by QSYQ. (C) PPI network of the differentially expressed proteins. From the network, galectin-3 (LGALS3) and albumin (ALB) directly interact with the greatest number of proteins.

(*p*-value) score (**Figure 6A**), the result indicated that the anti-inflammatory mechanism could be one of the most vital mechanisms to explain QSYQ effective action against experimental stroke. The corresponding differentially expressed proteins involved in inflammatory response determined by “Build-Grow-Diseases and Functions” module of IPA (**Figure 6B**) showed that 30 proteins, including galectin-3 (LGALS3), albumin (ALB), cathepsin A (CTSA), clusterin (CLU), and transferrin (TF), participated in the inflammatory response. PPI network analysis positioned galectin-3 (LGALS3) and albumin (ALB) as the core proteins regulated by QSYQ since they displayed the most interactions with other significantly differentially expressed proteins revealed by our differential proteomic analysis (**Figure 6C**). The detailed information of PPI network analysis was shown in **Supplementary Table S3**.

## QSYQ Reversed Galectin-3 Mediated Neuroinflammation in Subacute Stroke Brain Tissues

Based on the results of network pharmacology analysis, the differentially expressed protein of galectin-3 was found to act as a critical target involved in QSYQ-regulated inflammatory response during subacute stroke recovery. Both immunohistochemistry and western blotting were performed to confirm the results from the TMT-based quantitative proteomics analysis. As shown in **Figures**

**7A–D**, the protein expression level of galectin-3 was significantly increased in brain tissues of stroke rats in the subacute phase compared with the sham group. Treatment with high dose (600 mg/kg) of QSYQ markedly decreased galectin-3 expression compared to rats that underwent MCAO and reperfusion (**Figures 7A–D**). This was consistent with the above quantitative proteomic datasets. Since published literature reported that galectin-3 activated TLR-4 and downstream inflammatory targets like nuclear factor  $\kappa$ B (NF- $\kappa$ B), resulting in an increase in the release of pro-inflammatory cytokines following brain injury (Burguillos et al., 2015), we compared the mRNA expression of the following genes - LGALS3 (galectin-3), TNF- $\alpha$ , and IL-6 - in rat brain samples from the sham group, cerebral I/R injury model group, and model treated with QSYQ (600 mg/kg) group by RT-qPCR. Compared with the sham group, MCAO and reperfusion caused obvious inflammation, as indicated by significant upregulation of these mRNA levels (**Figures 7E–G**). Importantly, treatment with high dose (600 mg/kg) of QSYQ distinctly downregulated mRNA expression of these neuroinflammation-related genes compared to the model group (**Figures 7E–G**).

### QSYQ Reduced Proinflammatory Factors TNF- $\alpha$ and IL-6 in Serum

To gain an insight into the regulatory role of QSYQ on galectin-3 mediated inflammation in subacute ischemic stroke, serum levels

**FIGURE 7 |** The regulatory role of QSYQ on galectin-3 mediated neuroinflammation in response to cerebral ischemia and reperfusion injury. **(A)** Representative images of immunohistochemical staining of galectin-3 protein expression in brain tissue slices ( $\times 200$  magnification). **(B)** Quantification of immunohistochemical staining ( $n = 3$ ). **(C)** Representative images of western blotting of galectin-3. **(D)** The quantitative analysis of western blotting ( $n = 3$ ). Treatment with high doses of QSYQ significantly reduced the protein expression level of galectin-3 compared with the model group. Relative expression levels of cerebral LGALS3 **(E)**, TNF- $\alpha$  **(F)**, and IL-6 **(G)** mRNA were evaluated by RT-qPCR ( $n = 3$ ). Results were normalized to GAPDH expression. Treatment with high dose of QSYQ significantly decreased the mRNA expression of galectin-3-mediated inflammation related genes. Quantitative assessment the effect of QSYQ treatment on the release of TNF- $\alpha$  **(H)** and IL-6 **(I)** in rats serum following MCAO and reperfusion using ELISA kits ( $n = 6$ ). The data of western blotting and ELISA are expressed as mean  $\pm$  SD. Meanwhile, the data of RT-qPCR are presented as mean  $\pm$  SD.  $^{\#}p < 0.05$ ,  $^{##}p < 0.01$ , and  $^{###}p < 0.001$  vs. the sham group;  $^{*}p < 0.05$ ,  $^{**}p < 0.01$ , and  $^{***}p < 0.001$  vs. the model group. I/R, ischemia/reperfusion; QSYQ-H, QSYQ 600 mg/kg-high dose.

of TNF- $\alpha$  and IL-6 in different groups were determined by ELISA. As shown in **Figures 7H,I**, concentrations of TNF- $\alpha$  and IL-6 in serum were significantly higher in rats that underwent MCAO/reperfusion compared with that from sham-operated rats. As expected, treatment with QSYQ at high dose (600 mg/kg) markedly lowered the serum concentrations of TNF- $\alpha$  and IL-6 compared with the model group (**Figures 7H,I**).

## DISCUSSION

Recovery after stroke is a complex, dynamic, multifactorial, and multicellular process (Alawieh et al., 2018; Sadler et al., 2020). No drugs or therapies have been approved for stroke recovery to date, in part due to inappropriate experimental models and because screen strategies focusing on single targets and drug molecules were used (Cramer, 2015). Our current study tested a hypothesis that a multi-component medicine, such as QSYQ, targeting different biological pathways would be more effective for post-stroke recovery. At present, QSYQ with the function of Qi-tonifying and blood-activating has been widely used to treat cardiovascular disease in clinic (Han et al., 2019). In addition to the cardioprotection against ischemia/reperfusion injury, we recently also reported the protective effect of pretreatment with QSYQ against CI/RI, which may be partly related to the modulation of neuroinflammatory response in an acute stroke model (Chen et al., 2015; Wang et al., 2020).

However, questions remain on whether QSYQ contributes to the therapeutic post-stroke recovery and, if so, what the underlying mechanisms are.

To evaluate the efficacy of QSYQ for post-stroke recovery, we chose Nim as a positive control drug in the present study. Nim is a dihydropyridine calcium channel blocker and has been observed for its therapeutic application in stroke. Babu et al. showed that administration of Nim alleviated excitotoxicity and neurological deficits in experimental ischemic stroke rats (Babu and Ramanathan, 2011). Liu et al. found that Nim treatment reduced infarct volume and pathological damage and improved neurological function of subacute stroke animals (Liu et al., 2016). The beneficial effect of Nim on protecting BBB integrity has also been reported (Li et al., 2019). Since neurological and motor deficits are common in stroke patients, improvement of neural and behavioral outcomes are considered as necessary to estimate the action of anti-stroke drugs (Benjamin et al., 2019). Therefore, in addition to the parameters used in our previous acute CI/RI study, mNSS, open field test, and gait test were integrated to systematically evaluate the neuroprotective function of QSYQ on promoting post-stroke recovery in this work. Similar to Nim, the results indicated that treatment with QSYQ at middle (300 mg/kg) and high dose (600 mg/kg) markedly inhibited cerebral infarct volume as well as ameliorated neurological and behavioral impairment in subacute stroke rats (**Figures 1–3**), which revealed the beneficial effect of QSYQ on functional recovery.

BBB dysfunction, characterized by the structural disruption of tight junction protein complexes causing increased permeability, ion transporter dysfunction leading to cerebral edema, and further inflammatory damage induced by the infiltration and accumulation of peripheral immune cells and the activation of resident microglial cells, is a prominent pathological feature of ischemic stroke (Jiang et al., 2018). Damage to BBB permeability after cerebral ischemia and reperfusion is apparent in both the acute and subacute phases of ischemic stroke (~1–7 days) (Jiang et al., 2012). In response to CI/RI, multiple mechanisms may be involved in the restoration of BBB integrity, such as inflammatory response, oxidative stress, and angiogenesis (Jiang et al., 2018). The therapeutic strategies to promote BBB repair may enhance the functional recovery of the subject after ischemic stroke (Boese et al., 2018). In this study, the IVIS fluorescent imaging and brain micro-CT imaging techniques were respectively applied to measure BBB permeability. Significantly, treatment with QSYQ at high dose (600 mg/kg) and Nim obviously reduced the extravasation of EB and Omnipaque on account of BBB breakdown after ischemic stroke, which suggested the positive action of QSYQ against BBB disruption caused by ischemia and reperfusion (**Figure 4**). The data of micro-CT imaging also indicated decreased cerebral edema after three doses of QSYQ treatment, which could be observed in the subacute stage of CI/RI (**Figures 3C,D**).

Proteomics analysis takes a holistic approach to deciphering the complexity of biological systems and to characterizing protein interactions and biological networks that mediate physiological and pathological processes of diseases (Ji et al., 2015). In recent years, it has been increasingly applied to reveal the underlying mechanisms of TCM for multiple therapeutic effects on stroke treatment (Ning et al., 2012; Ji et al., 2015). TMT-based proteomics technique, employing chemical peptide labeling with amine-reactive isobaric tags, is a reliable method for large-scale multiplexed proteins relative quantification between multiple samples within a single experiment (Rauniyar et al., 2013). In this study, we applied TMT-based proteomics (TMT-LC-MS/MS) to label ischemic rat brain tissue samples to identify differentially expressed proteins following QSYQ treatment. As a result, a total of 5,813 proteins were identified, of which 92 were significantly differentially expressed (fold change >1.20 or <0.833,  $p$ -value <0.05) (**Figure 5A**). IPA analysis revealed that among the differentially expressed proteins, those with the highest  $-\log(p\text{-value})$  score were closely associated with inflammatory response, suggesting that post-stroke inflammation may be one of the main mechanisms underlying the beneficial action of QSYQ in enhancing functional recovery after CI/RI (**Figures 6A,B**). Importantly, subsequent PPI network analysis revealed that an inflammation-related protein named galectin-3 (LGALS3) could be tightly networked with other proteins (**Figure 6C**) and serve as a key player of QSYQ action at the subacute phase of stroke.

Inflammation has been recognized as a double-edged sword which could be either detrimental or beneficial depending on the particular stages after a stroke. In response to acute ischemic stroke, resident glial cells activation, infiltration of peripheral immune cells, release of pro-inflammatory cytokines and BBB disruption together orchestrate the post-stroke augmented

inflammatory response, which contribute to a series of long-term secondary brain damages and neurological behavioral deficits (Rajkovic et al., 2018; Wang et al., 2018). In the late repair phase of CI/RI, neuroinflammation fundamentally participates in multiple brain recovery processes, including post-stroke neurogenesis, neurovascular unit remodeling, post-stroke synaptogenesis, and axonal sprouting, which synergistically promote neurological behavioral outcomes (Wang et al., 2018). Currently, the regulation of inflammation is considered as a primary target for the development of stroke therapies.

Recently, growing evidence has suggested that galectin-3 could act as an endogenous regulator of brain injury-related inflammation (Shin, 2013; Rahimian et al., 2018). In response to cerebral damage induced by stroke, high level expression of galectin-3 was observed in activated microglial cells localized in the ischemic lesion (Lalancette-Hebert et al., 2012). Burguillos *et al.* showed that microglia-secreted galectin-3 acted as an endogenous ligand for TLR-4 activation to amplify the pro-inflammatory response and led to hippocampal degeneration in the injured brain caused by ischemia (Burguillos et al., 2015). However, galectin-3 deficiency reduced the expression of pro-inflammatory cytokines and exerted a neuroprotective effect (Yip et al., 2017). Prins *et al.* reported that the absence of galectin-3 attenuated neuroinflammation and ameliorated neurological functional recovery after spinal cord injury (Prins et al., 2016). These findings suggested that galectin-3 could be regarded as a major immunomodulatory molecule that played a significant role in the modulation of brain inflammation and neurodegeneration. In this study, we found that treatment with QSYQ (600 mg/kg) distinctly downregulated the high expression level of galectin-3 protein in brain tissues from MCAO/reperfusion rats according to the quantitative proteomics analysis results, which was verified with the methods of RT-qPCR, immunohistochemistry, and western blot analysis (**Figures 7A–E**). The results indicated that the neuroprotective function of QSYQ against the subacute phase of CI/RI might act partly through the regulation of galectin-3-mediated inflammatory response.

The inflammatory cytokines, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin-6 (IL-6), are generally considered to be representative contributors to neuroinflammation in ischemic stroke and are therefore promising potential targets in future stroke therapy (Lambertsen et al., 2019). In experimental stroke model of rodents, the increased expression levels of TNF- $\alpha$  mRNA and protein were observed in ischemic brain tissues (Berti et al., 2002; Haddad et al., 2006). In the subacute phase of CI/RI, the upregulated level of TNF- $\alpha$  and IL-6 contents could be detected in damaged brain tissues (Yang et al., 2019). The enhanced serum levels of TNF and IL-6 in stroke patients were tested on days 1, 3, and 7 after stroke when compared to the control group (Jiang et al., 2017). Furthermore, TNF- $\alpha$  was also reported to regulate neuronal networks involved in cognition and behavior (Baune et al., 2008). In the present work, we further showed that treatment with QSYQ (600 mg/kg) significantly reduced the mRNA levels of TNF- $\alpha$  and IL-6 in brain tissues of stroke rats after ischemia and reperfusion (**Figures 7F,G**). Moreover, the serum levels of TNF- $\alpha$  and IL-6

were markedly increased in the subacute phase of stroke, which were reversed by QSYQ (600 mg/kg) (**Figures 7H,I**). The data suggested that the beneficial effects of QSYQ on brain damage and neurological behavioral dysfunction induced by experimental stroke were partly *via* the modulation of galectin-3-mediated inflammatory reaction.

## LIMITATION AND FUTURE DIRECTIONS

Although we demonstrated the efficacy and mechanism of QSYQ for post-stroke recovery, there are still limitations to this study. First, the clinical relevance of the rat subacute stroke model we used needs to be tested in human studies. Secondly, models of longer-term recovery are to be established and optimized to evaluate drugs and treatments that will benefit real-time patients. Thirdly, differential contributions of Yiqi (Qi-benefitting, i.e., Huangqi) and Huoxue (Blood-activating, i.e., Danshen + Sanqi) components of QSYQ need to be distinguished and the active components involved needs defining.

## CONCLUSION

In summary, the current work provides the first evidence for the beneficial action of treatment with QSYQ against the subacute phase of CI/RI, which may be closely associated with its potential to inhibit MCAO/reperfusion-induced upregulation of brain-injury-related inflammatory regulator galectin-3, as well as the pro-inflammatory cytokines TNF- $\alpha$  and IL-6. The results suggest that QSYQ exerts a neuroprotective role in the damaged brain caused by experimental stroke probably through modulating the galectin-3-mediated inflammatory response. The fact that QSYQ can improve post-stroke outcome needs further clarification, and more thorough and reliable experimental data are required to support its clinical application. Our study may provide a novel therapeutic agent of ischemic stroke.

## DATA AVAILABILITY STATEMENT

All datasets generated for this study are included in the article and the **Supplementary Material**. Besides, the mass spectrometry proteomics data were deposited to the ProteomeXchange via the PRIDE partner repository with the dataset identifier PXD020936.

## ETHICS STATEMENT

All animal experiments were performed in accordance with the international regulations, following the guidelines of the

Laboratory Animal Ethics Committee of Tianjin University of TCM (Permit number: TCM-LAEC2016036) as well as Tianjin International Joint Academy of Biotechnology and Medicine (Permit number: TJAB-TJU20160024).

## AUTHOR CONTRIBUTIONS

YZ designed and funded the study. YW and GX carried out MCAO surgery and brain tissue TTC staining. YQZ prepared the extracts of QSYQ and YW performed drug administration. YW executed micro-CT and IVIS imaging studies. LZ and XL performed the evaluation of the neurological deficits and mortality rate. JO and ZL participated in the open field test and gait analysis. YW performed IPA analysis. XL carried out immunohistochemistry. YW and XD carried out western blotting analysis. YW and SH performed RT-qPCR experiment. YW and HD executed ELISA experiment. WZ and YQZ provided key materials and executed HPLC analysis. JO, YF, and BZ contributed to the review and interpretation of the data. YW wrote the draft manuscript. YZ and YW. edited the final manuscript. All authors have read and agreed with the submission of the manuscript.

## FUNDING

This work was supported by grants from the National Science Foundation of China (NSFC 81873037), the National Key Research and Development Plan (2018YFC1704502), the National Science and Technology Major Projects of China (2018ZX01031301), and the China Postdoctoral Science Foundation Grant (2020M681904).

## ACKNOWLEDGMENTS

We appreciated Shanghai Applied Protein Technology Co., Ltd. (Shanghai, China) for the technical support of TMT-based quantitative proteomics analysis. We would also like to thank Jian Yang, Pengzhi Dong, and Rui Shao for discussion and suggestions, and the members of our laboratory, particularly Shan Li and Kai Huang, for technical assistance in some experiments.

He J, Zhang Q, Ma C, Giancaspro GI,  
Bi K and Li Q (2021) An Effective  
Workflow for Differentiating the Same  
Genus Herbs of *Chrysanthemum*  
*morifolium* Flower and  
*Chrysanthemum indicum* Flower.  
Front. Pharmacol. 12:575726.  
doi: 10.3389/fphar.2021.575726

*C. morifolium* flower and *C. indicum* flower are two closely related herbal species with similar morphological and microscopic characteristics but are discriminated in edible and medicinal purpose. However, there is no effective approach to distinguish the two herbs. A novel workflow for quickly differentiating *C. morifolium* flower and *C. indicum* flower was developed. Firstly, the difference in anti-inflammatory effects for *C. morifolium* flower and *C. indicum* flower was characterized using lipopolysaccharide-treated rats. Then HPLC fingerprint analysis for 53 batches of *C. morifolium* flowers and 33 batches of *C. indicum* flower was carried out to deep profile the chemical components. The preliminary markers were screened out by OPLS-DA, identified by HPLC-ESI-QTOF-MS, and quantified by the improved SSDMC (single reference standard to determine multiple compounds) approach. Finally, multiple statistical data mining was performed to confirm the markers and a binary logistic regression equation was built to differentiate *C. morifolium* flower and *C. indicum* flower successfully. In general, the established workflow was rapid, effective and highly feasible, which would provide a powerful tool for herb identification.

**Keywords:** *Chrysanthemum morifolium* flower, *Chrysanthemum indicum* flower, comparative evaluation, anti-inflammatory, phytochemical analysis

## INTRODUCTION

*Chrysanthemum morifolium* flower [*Chrysanthemum x morifolium* (Ramat.) Hemsl.] and its wild relative, *Chrysanthemum indicum* flower (*Chrysanthemum indicum* L.), are commonly used as medicinal and edible cognate plants in Asia. *C. morifolium* flower and *C. indicum* flower have been widely used as food supplements, as well as herbal teas and health foods in China for 3,000 years (Lin and Harnly, 2010). Modern pharmacological studies indicate that both the two herbs possess various

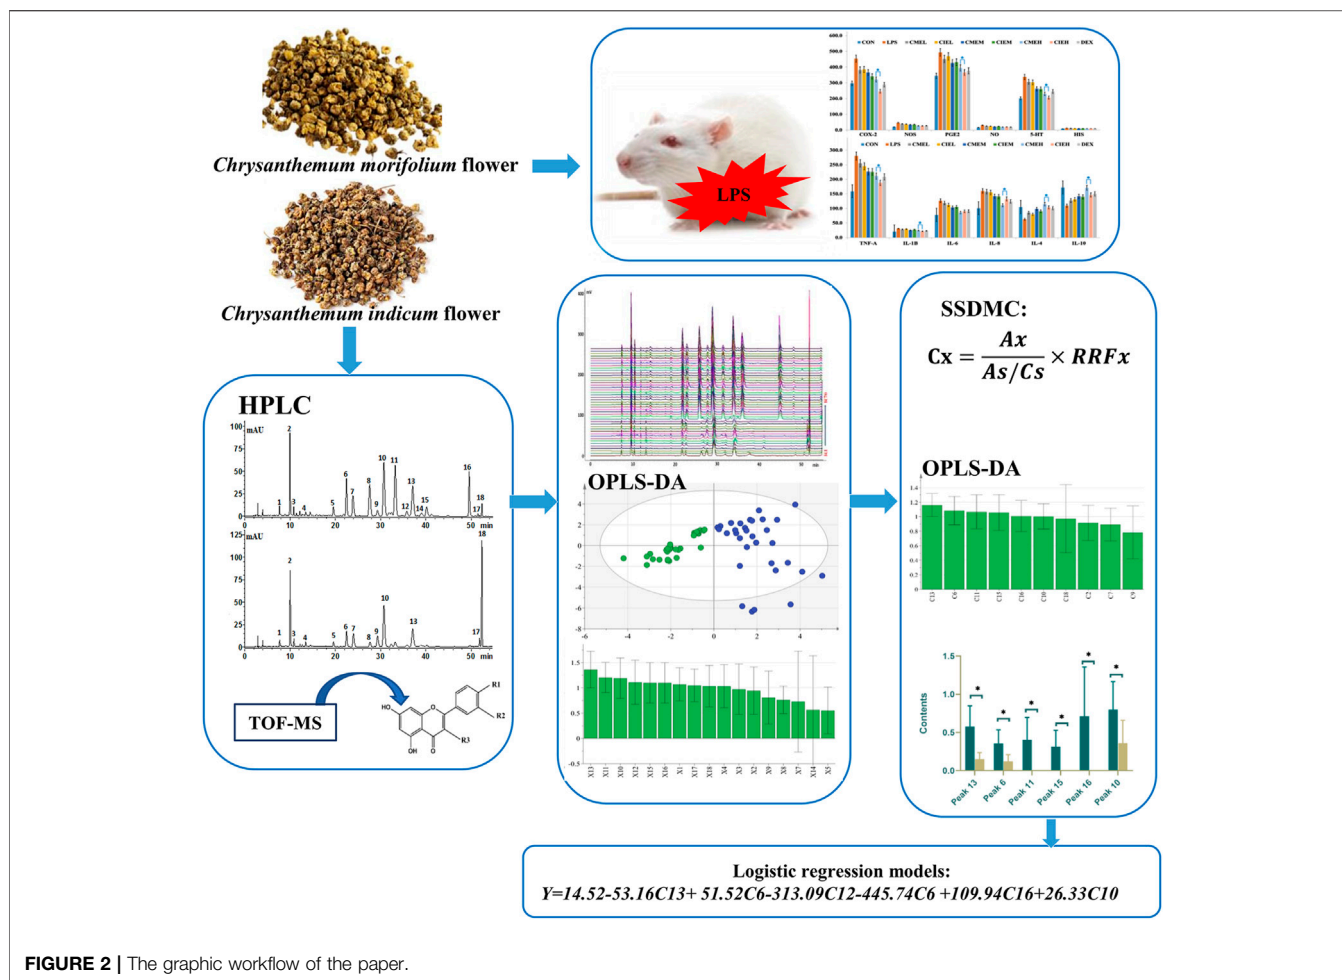

**FIGURE 1** | Representative photos of *C. morifolium* flower and *C. indicum* flower.

bioactivities, including anti-inflammation (Su et al., 2012; Han et al., 2015), antioxidation (Cui et al., 2012), cardiovascular protection (He et al., 2012), anticancer (Liu et al., 2018), etc.

In the Chinese Pharmacopoeia, *C. morifolium* flower is used for “scattering cold,” “cleaning heat and toxin,” and “brightening eyes,” and *C. indicum* flower is used to remove toxic heat (Chinese Pharmacopoeia Commission, 2020). Inflammation is the basic pathological changes of all these diseases. Inflammatory cytokines play an important role in the process, which is the interaction between pro-inflammatory cytokines like tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), prostaglandin E2 (PGE2), interleukin (IL)-2, IL-6, IL-17,

IL-23, and anti-inflammatory cytokines such as IL-4, IL-10, and IL-13 (Cheng et al., 2005). The dynamic change between pro-cytokines and anti-cytokines determines the ending and outcome of inflammation. Research on cytokines in inflammation especially in infective inflammation is meaningful as it may be the next breakthrough of a thorough cure in inflammatory disease (Gabay and Kushner, 1999; Kim et al., 2015). However, a comparative study of the anti-inflammatory activity of the two herbs remains to be investigated.

Though there are some differences between fresh *C. morifolium* flower and *C. indicum* flower, multiple batches of *C. morifolium* flower and *C. indicum* flower materials were easy to

**FIGURE 2 |** The graphic workflow of the paper.

confuse due to different harvest periods, different origins, different processing or other reasons, especially for non-professionals (Fang et al., 2012; Japanese Pharmacopoeia Commission, 2016; Chinese Pharmacopoeia Commission, 2020). In addition, the commercialized products of *C. morifolium* flower and *C. indicum* flower are often sold in processed form as powder or extract (shown in **Figure 1**), which is more likely to lead to species misidentification and subsequent substitution. Furthermore, the two closely related herbal species have similar chemical compositions but are discriminated in medicinal and tea use due to differences in the contents of active compounds (Committee, C. P. 2015). However, the two herbs are usually assessed independently for quality using one or several marker compounds (Wu et al., 2010; Liu et al., 2013; Committee, C. P. 2015). The markers detected might be not sufficient to distinguish between herbal drugs that have similar appearances and/or chemical compositions (Osathanunkul et al., 2016). Therefore, the development of comparative quality evaluation and characterization methods for *C. morifolium* flower and *C. indicum* flower is essential.

Therefore, the present study aimed to define the chemical composition and pharmacological characteristics for comparative evaluation of *C. morifolium* flower and *C. indicum* flower (shown

in **Figure 2**). First, the anti-inflammation activities of *C. morifolium* flower and *C. indicum* flower were systematically compared using lipopolysaccharide-treated rats. Then HPLC fingerprint analysis for 53 batches of *C. morifolium* flowers and 33 batches of *C. indicum* flower was carried out to deep profile the chemical components and differentiate the two herbs. The preliminary markers were screened out by OPLS-DA, identified by HPLC-ESI-QTOF-MS, and quantified by the improved SSDMC (single reference standard to determine multiple compounds) approach. Finally, multiple statistical data mining was performed to confirm the markers and a binary logistic regression equation was built to differentiate *C. morifolium* flower and *C. indicum* flower successfully.

## MATERIALS AND METHODS

### Chemicals, Reagents and Materials

Isochlorogenic acid A, isochlorogenic acid B, isochlorogenic acid C, chlorogenic acid, luteolin-7-O-glucoside, apigenin-7-O-glucoside, linarin, luteolin-7-O-glucuronide, diosmetin-7-O-glucoside, caffeic acid, neochlorogenic acid and cryptochlorogenic acid (purity > 98%) were purchased from

**TABLE 1** | Sample information of *C. morifolium* flower and *C. indicum* flower samples.

Group	Sample no	Chinese name	Origins	Morphological characteristics	Similarity (Mean ± SD)
I	G1~19	<i>Gongju</i>	Huangshan, Anhui	Flower	0.865 ± 0.031
	H1~9	<i>Hangbaiju</i>	Tongxiang, Zhejiang	Flower	0.884 ± 0.035
	H10~18	<i>Hangbaiju</i>	Tongxiang, Zhejiang	Flower buds	0.914 ± 0.032
II	K1~16	<i>Hangbaiju</i>	Lanxi, Zhejiang, etc.	Flower	0.838 ± 0.142
III	Y1-33	<i>Yejuhua</i>	Anhui etc.	Flower or flower buds	0.654 ± 0.121*

I: *C. morifolium* flower samples which were Genuine medicinal materials and purchased online or from markets; II: *C. morifolium* flower samples collected from the five introduction districts and provided by Zhejiang Conba Pharmaceutical Co., Ltd; III: *C. indicum* flower samples collected from 13 provinces which were summarized in a previous study (1). The significant difference in similarities between the two herbs was statistically evaluated by the Student's t-test (\* $p < 0.05$ ).

Chengdu Must Biological Technology Co. Ltd., (Chengdu, China). Water for HPLC was redistilled. Other chemical reagents were of HPLC grade. Dexamethasone sodium phosphate injection (DEX) (Specification: 1 ml: 2 mg) was purchased from Tianjin pharmaceutical Group Xinzheng Co. Ltd. Lipopolysaccharides (LPS) (*Escherichia coli* 055: B5) was purchased from Beijing Solaibao Biotechnology Co. Ltd., (Beijing, China). ELISA kits of rat 5-Hydroxytryptamine (5-HT), cyclooxygenase-2 (COX-2), Prostaglandin E2 (PGE2), nitric oxide (NO), nitric oxide synthase (NOS), tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ), Histamine (HIS), interleukin 1 $\beta$  (IL-1 $\beta$ ), IL-4, IL-6, IL-8, and IL-10 were purchased from Beijing Qisong Biotechnology Co. Ltd., (Beijing, China).

As listed in **Table 1**, 37 samples of *C. morifolium* flowers were purchased from herb markets, including the two cultivars of “*Gongju*” (from Huangshan City, Anhui Province) and “*Hangbaiju*” (from Tongxiang County, Zhejiang Province), which were considered as the genuine medicinal materials. From different farms owned by Zhejiang Conba Pharmaceutical Co. Ltd., 16 samples of *C. morifolium* flower were also collected. In addition, 33 batches of *C. indicum* flower samples were collected from different provinces in China as summarized in a previous study (He et al., 2016). All of these samples were authenticated based on analyses of microscopic and macroscopic characteristics by Professor Jia Ying and deposited at the Centre of Chinese Material Medica at Shenyang Pharmaceutical University.

## Apparatus and Chromatographic Conditions

HPLC analysis was performed using a Shimadzu 20A HPLC System (Shimadzu Corporation, Japan) composed of a binary solvent delivery system, an on-line degasser, an auto-sampler, a column temperature controller and a photodiode array detector coupled with Lab solution software. Additional different HPLC instruments were also used, including an Agilent 1260 HPLC system composed of a quaternary solvent delivery system, an on-line degasser, an auto-sampler, a column temperature controller and a photodiode array detector coupled with an analytical workstation. HPLC analysis was performed on a Luna C<sub>18</sub> column (4.6 × 250 mm, 5  $\mu$ m, Phenomenex Inc., CA, United States) with a sample injection volume of 10  $\mu$ l. The detection wavelength was set at 327 nm, the flow rate was

1.0 ml min<sup>-1</sup>, and the column temperature was maintained at 25°C. The mobile phase consisted of a mixture of solution A (0.1% glacial acetic acid in water) and solution B (acetonitrile) along a linear gradient as follows: 0–10 min (10–18% B), 10–14 min (18–19% B), 14–20 min (19–19% B), 20–35 min (19–20% B), 35–40 min (20–22% B), 40–45 min (22–25% B), 45–55 min (25–35% B), 55–60 min (95–95% B), 60–65 min (10–10% B).

LC-MS<sup>n</sup> analysis was performed on an Agilent 1260 HPLC system coupled with a Triple TOF<sup>TM</sup> 5600 (AB SCIEX, Foster City, CA) with an ESI interface. The mass range was set at  $m/z$  50–1,500. The optimum parameters of the MS/MS detector were set as follows: the ion spray voltage was 5000 V for positive ion mode and –4500 V for negative ion mode, the ion source temperature was set at 500°C, ion source gas 1 was set at 50 psi, ion source gas 2 was set at 50 psi, the curtain gas was set at 30 psi, and the declustering potential was set as 90 V. Peak View<sup>®</sup> Software V. 2.2 was used for data collection and processing.

## Sample Preparation for Bioassay

Fifty grams of *C. indicum* flower/*C. morifolium* flower powder was refluxed with 1250 ml of 75% EtOH for 2 h, and the extract solution was evaporated in vacuo to an adequate concentration. Then the extract powders were obtained with a freeze-drying method. The yields of *C. indicum* flower and *C. morifolium* flower extracts were 25 and 26%, respectively. For the vivo experiment on inflammatory response, both the *C. indicum* flower extract (CIE) and *C. morifolium* flower extract (CME) were suspended in 0.5% sodium carboxymethylcellulose at the concentration of 80, 40 and 20 mg/ml prior to use.

## Sample Preparation for Qualitative and Quantitative Analysis

The reference mixture solutions of chlorogenic acid (0.1782 mg/ml), luteolin-7-O-glucoside (0.1110 mg/ml), isochlorogenic acid B (0.1234 mg/ml), isochlorogenic acid A (0.1882 mg/ml), apigenin-7-O-glucoside (0.1338 mg/ml), isochlorogenic acid C (0.1122 mg/ml), and linarin (0.2458 mg/ml) were prepared in methanol. The mixed stock solutions were serially diluted to produce calibration standard solutions. All standard solutions were kept at 4°C.

Five hundred milligrams of *C. indicum* flower (No. Y29)/250 g *C. morifolium* flower (No. H5) powder was accurately weighed

and transferred into a flask, followed by the addition of 25 ml of 60% methanol and sonication for 30 min. The supernatant was collected and filtered through a 0.22 µm membrane for qualitative and quantitative analysis.

## Evaluation of the Anti-Inflammatory Activity *In Vivo*

Sprague Dawley (SD) rats (male, 16 weeks of age, 180–220 g) were provided by the Medical Experiment Animal Center of Shenyang Pharmaceutical University. They were housed under controlled temperature (23–25°C) and 12 h light/12 h dark cycle for a week before the experiment. Food and water were freely available. Experiments were conducted in accordance with the guidelines of the Guiding Principles for the Care and Use of Laboratory Animals approved by the Committee for Animal Experiments in Shenyang Pharmaceutical University.

For the experiment, rats were randomly assigned to nine groups (eight for each). CME (100, 200, and 400 mg/kg) and CIE (100, 200, and 400 mg/kg) were tube-fed for 7 days. The dose of linarin was selected based on previous report [20] and our preliminary study. The normal control, positive control group (DEX) and control group (LPS) were given equal amount of vehicle during this period. 0.5 h after final administration, all of the animals except for rats in normal control groups were injected intraperitoneally with 100 µg/kg LPS to induce acute inflammation. Rats in positive control group were injected with DEX (50 µg/kg) 0.5 h before LPS challenge. All of the animals were anesthetized with pentobarbital sodium and then the blood samples were collected from the abdominal aorta at 6 h after LPS injection. Blood samples were immediately centrifuged at 3,000 rpm for 10 min. Sera were collected, frozen, and kept at –80°C until analysis.

## Calculation of Relative Conversion Factors in SSDMC Approach

According to the HPLC test results for the reference compound mixture solutions obtained using the method described in *Apparatus and Chromatographic Conditions*, the relative response factor (RRF<sub>x</sub>) could be calculated using the ratio of the peak areas and the ratio of the concentration of the analyte and internal reference substance (Eq. 1) (Hou et al., 2014):

$$RRR_x = \frac{\sum \left( \frac{A_{si}}{C_{si}} \right) / \left( \frac{A_{xi}}{C_{xi}} \right)}{N} \quad i = 1 \sim n, \quad (1)$$

where  $A_{si}$  and  $A_{xi}$  are the peak areas of the internal reference substance and analyte, respectively, at the concentration level  $i$ . The variables  $C_{si}$  and  $C_{xi}$  are the concentrations (at level  $i$ ) of the internal reference substance and analyte, respectively.  $N$  represents the number of concentration levels, which was seven in this work.

With the results of RRF<sub>x</sub>, the concentration of analyte ( $C_x$ ) in the samples was calculated based on the following equation:

$$C_x = \frac{A_x}{A_s/C_s} \times RRF_x, \quad (2)$$

where  $A_x$  and  $A_s$  are the peak areas of the analyte and reference component, respectively.  $C_x$  and  $C_s$  are the concentrations of the analyte and reference compound in the *sample solution* and *standard solution*, respectively. RRF<sub>x</sub> is the relative response factor of the analyte vs. the reference compound.

## Validation of the Quantitative Analysis Method

Analytical method validation ensures the suitability and ruggedness of the method as a quality measure for use across multiple laboratories. The method developed for quantitative analysis of the major caffeoylquinic acids and flavone glycosides in *C. morifolium* flower and *C. morifolium* flower was validated by tests of linearity, limits of detection (LODs), limits of quantification (LOQs), accuracy, precision (intra- and inter-day variability), robustness and stability.

## RESULTS AND DISCUSSION

### Anti-inflammatory Activity of *C. morifolium* Flower and *C. indicum* Flower Extract in Lipopolysaccharide-treated Rats

Gram-negative bacterial endotoxins or LPS, are associated with tissue injury and fatal outcome in septic shock (Girish, 2013). It has been demonstrated both experimentally and clinically that sepsis causes the production of a series of proinflammatory cytokines (IL-1β, TNF-α, IL-8, and IL-6), anti-inflammatory cytokines (IL-4 and IL-10), inflammatory mediators (NO, HIS, 5-HT, PGE<sub>2</sub>), and related enzymes (iNOS, COX-2), which determine the ending and outcome of inflammation (Gouwy et al., 2005; Chen et al., 2018; Dickson and Lehmann, 2019).

In the present study, levels of serum inflammatory cytokines, inflammatory mediators and related enzymes were measured by ELISA at 6 h after LPS injection based on pilot experiments results and the previous reports who demonstrated peaks in serum cytokines concentrations at 4–6 h after LPS injection (Kim et al., 2014). As shown in **Figure 3**, ELISA results displayed that all extracts of *C. morifolium* flower and *C. indicum* flower can cause a dose-dependent decrease in pro-inflammation cytokines, inflammatory mediators and related enzymes, and a dose-dependent increase in anti-inflammatory cytokines for anti-inflammatory effects. Moreover, high dose groups (400 mg/kg) of *C. morifolium* flower and *C. indicum* flower exhibited significant difference in inhibition or promotion of inflammatory mediators (NO, HIS, 5-HT, PGE<sub>2</sub>), and related enzymes (iNOS, COX-2) serum cytokines ( $p < 0.05$ ), while low (100 mg/kg) and moderate (200 mg/kg) dose groups of *C. morifolium* flower and *C. indicum* flower showed no significant variation was observed between each other. Comparatively, high dose group of *C. indicum* flower reflected stronger inhibitory effects for COX-2, PEG2, 5-HT, TNF-α, IL-β in serum. While,

**FIGURE 3 |** Anti-inflammation effect of *C. morifolium* flower extract (CME) and *C. indicum* flower extract (CIE) in lipopolysaccharide-induced rats. The data are expressed as the mean  $\pm$  S.D. The significant difference between groups of CME and CIE with different dose was statistically evaluated, respectively, by the Student's *t*-test ( $p < 0.05$ ).

high dose group of *C. morifolium* flower appeared to show stronger promoting effects for IL-4 and IL-10. In addition, all the groups with the same dose of *C. morifolium* flower and *C. indicum* flower showed no significant difference in expression of NOS, NO, HIS, and IL-6.

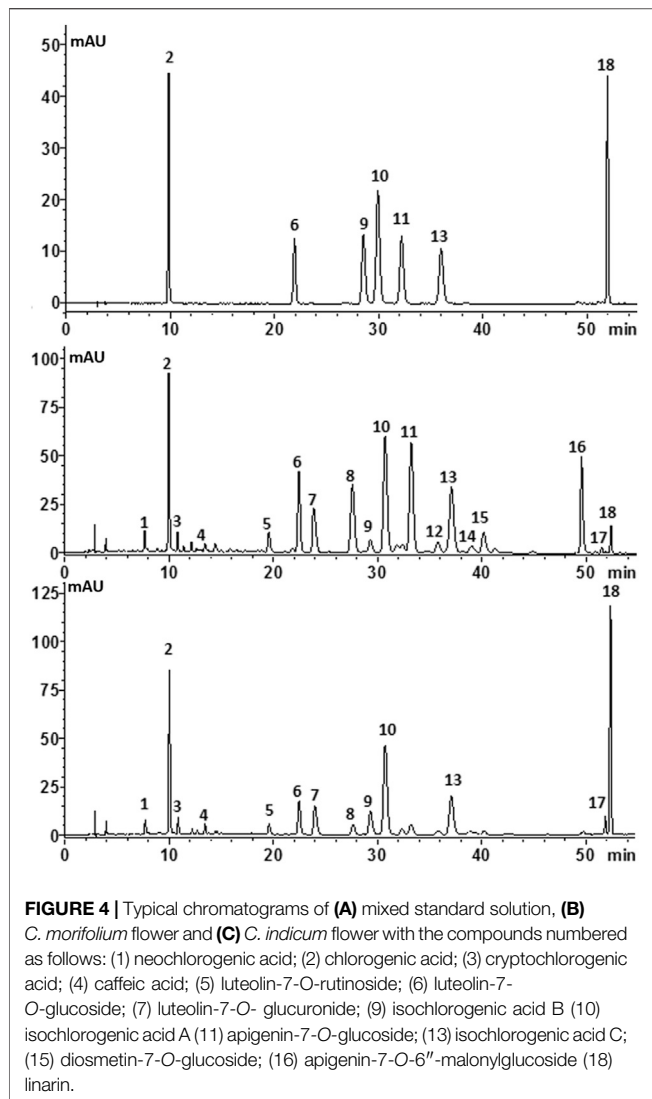

### HPLC Fingerprint Analysis

In the present work, the HPLC fingerprint analysis was validated and considered to be effective and reliable. Then, 53 batches of *C. morifolium* flower (“Hangbaiju” and “Gongju”) and 33 batches of *C. indicum* flower samples from different regions (Table 1) were analyzed under the optimized HPLC conditions. Figure 4 shows typical fingerprinting chromatograms of *C. morifolium* and *C. indicum* flowers. Eighteen common peaks, which moderately existed in all chromatograms from the samples and indicated similarity among the various samples, were collected from *C. morifolium* flower samples by comparison of the UV spectra and retention times. Chromatograms of *C. indicum* flower confirmed the abundance of peak 18 but showed a deficiency of peaks 11, 12, 14, 15, and 16 compared with the spectra of *C. morifolium* flower samples.

CFDA suggests that all herbal chromatograms should be evaluated in terms of similarity based on a calculation of the

correlation coefficient and/or angle cosine value of the original data (Zhao et al., 2011). The similarities (Table 1) between the mean chromatogram (both *C. morifolium* flower and *C. indicum* flower) and each herb sample were within a range of 0.341–0.805 (*C. indicum* flower) and 0.816–0.947 (*C. morifolium* flower). These preliminary examinations showed that it was possible to discriminate *C. morifolium* and *C. indicum* flower samples by calculating the correlation coefficients of the main secondary metabolite profiles. It also demonstrated that *C. indicum* flower samples from numerous wild regions had a large fluctuation in quality, while the chromatograms of *C. morifolium* flower samples considered to be genuine were comparatively stable and consistent. In addition, *C. morifolium* flower (“Hangbaiju”) samples from Zhejiang Province (samples considered to be genuine) had higher correlation coefficients of similarity (0.833–0.947), while samples (K10–15) from Jiangsu and Hubei Provinces (introduction areas) had lower correlation coefficients of similarity (0.624–0.886). The results indicated that there were differences in the internal quality of “Hangbaiju” between samples grown in Zhejiang and those grown in the other two provinces of Jiangsu and Hubei.

OPLS-DA was used to preliminarily screen out the markers for differentiating *C. morifolium* and *C. indicum* flower samples

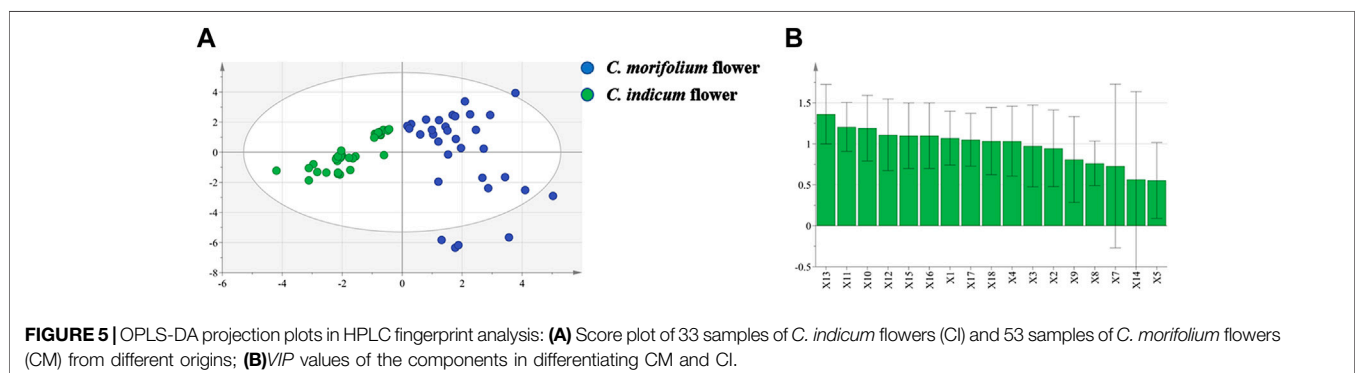

based on the relative peak areas (RPAs) of common peaks. The score plot (Figure 5A) showed that *C. morifolium* flower and *C. indicum* flower were separated clearly ( $R^2X$  0.736,  $R^2Y$  0.756,  $Q^2$  0.725). Combined VIP value (Figure 5B) of OPLS-DA (VIP > 1.0) and  $p$  value of Student's  $t$ -test ( $p < 0.05$ ), potential marker

pool was generated, which contained peaks 13, 11, 10, 12, 15, 16, 1, 17, 18, 4.

### Identification of Potential Markers Between *C. morifolium* and *C. indicum* Flowers

Based on HPLC-DAD and HPLC-ESI-QTOF-MS analysis, 14 detected peaks in *C. morifolium* and *C. indicum* flowers were identified or tentatively characterized using the chemical reference standards by comparing UV spectra, retention times, precursors and fragment ion ( $m/z$ ) values. The UV spectrums and extracted ion chromatograms of CM and CI were shown in **Supplementary Figures S1, S2** in Supporting Information. The structures and detailed MS data of the identified components were summarized in **Table 2**. Compounds 1, 2 and 3 yielded  $[M-H]^-$  peaks at  $m/z$  353.0876 (calculated for  $C_{16}H_{18}O_9$ , 353.0873) and fragment ions at  $m/z$  191.0559 due to the cleavage of the caffeoyl band, suggesting that monocaffeoylquinic acids were present. Compounds 9, 10, and 13 showed  $[M-H]^-$  peaks at  $m/z$  515.1645 (calculated for  $C_{25}H_{24}O_{12}$ , 515.1645), which produced two successive neutral losses from caffeic acid that yielded two stable fragment ions at 353.0845  $[M-H-C_9H_6O_3]^-$  and 191.0536  $[M-H-2C_9H_6O_3]^-$ , suggesting that dicaffeoylquinic acids were also present. Compound 4 produced  $[M-H]^-$  peaks at  $m/z$  179.0351 (calculated for  $C_9H_8O_4$ ), which produced a stable ion fragment at 135.0451  $[M-H-CO_2]^-$ , suggesting that this compound was caffeic acid. Then, the seven compounds numbered 1, 2, 3, 4, 9, 10, and 13 were unambiguously identified as neochlorogenic acid, chlorogenic acid, cryptochlorogenic acid, caffeic acid, isochlorogenic acid B, isochlorogenic acid A, and isochlorogenic acid C, respectively, based on comparison of the experimental retention times, UV spectra and MS<sup>n</sup> data with those of the standards.

Seven major flavonoids were identified in the two herbal medicines, five of which (peaks 6, 7, 13, 15, and 18) were unambiguously identified by comparing the obtained data with those from the reference standards. The produced ions  $[M-H-308]^-$  at  $m/z$  287.0393 ( $[M-H-glucose]^-$ ) from compound 5  $[M-H-162]^-$  at  $m/z$  287.0393 ( $[M-H-glucoside]^-$ ) from compound 6, and  $[M-H-176]^-$  at  $m/z$  285.0380 ( $[M-H-glucuronide]^-$ ) from compound 7 were indicative of the glucuronide, glucoside and glucuronide of luteolin, respectively. Compound 11 produced an  $[M-H]^-$  ion at  $m/z$  431.0954  $[M-H]^-$  (calculated for  $C_{21}H_{20}O_{10}$ ,

465.1033), and moderately abundant [M-H-162]<sup>−</sup> product ions at *m/z* 269.0437 were formed through the neutral losses of glucose, indicating that this compound was apigenin-7-*O*-glucoside. Compound 16 produced [M-H-248]<sup>−</sup> and [M-H-86]<sup>−</sup> fragments due to the loss of malonyl-glucose and malonyl (−COCH<sub>2</sub>COO−) from their molecular ions, suggesting that this compound was the malonyl glucoside of apigenin. The fragment ions [M-H-162]<sup>−</sup> at *m/z* 299.0540 produced from compound 15 were indicative of the glucosides of diosmetin, and the fragment ions at *m/z* 284.0300 were formed by the neutral losses of CH<sub>3</sub>. The fragment ions ([M-H-rutinoside]<sup>−</sup>) at *m/z* 283.0586 from compound 18 were indicative of the rutinoside of acacetin. The fragment ion at *m/z* 151.0021 yielded through the loss of CH<sub>3</sub> showed the existence of a 3'-OCH<sub>3</sub> group. In general, these compounds were identified as glycosylated derivatives of apigenin, luteolin, diosmetin and acacetin.

### Quantitative Analysis of Potential Markers Between *C. morifolium* and *C. indicum* Flowers

Considering that all potential markers between *C. morifolium* and *C. indicum* flowers belong to caffeoylquinic acids (Peak 13, 10, 1, and 4) or flavone glycosides (Peak 11, 15, 16, and 18), quantitative analysis was conducted for the two types of compounds in the tested samples by improved SSDMC and standard calibration methods.

### Calculation of Relative Response Factors and Relative Retention Times

The SSDMC method was mainly developed to simultaneously identify a group of compounds with similar polarity

characteristics, UV spectra and chromatographic behaviors (Wang et al., 2015). In this work, chlorogenic acid and luteolin-7-*O*-glucoside, which were stable, accessible, and abundant in the samples, were selected as internal reference substances to determine the other three caffeoylquinic acids (isochlorogenic acid A, isochlorogenic acid B, and isochlorogenic acid C) and two flavone glycosides (apigenin-7-*O*-glucoside and linarin). Based on the series of standard solutions, the final RRF of each analyte was calculated using the average of several RRFs detected from the series of concentrations and calculated according to Eq. 1. The calculation of RRT was necessary to identify the peaks using only the internal standard for the SSDMC method. To develop an SSDMC method with general applicability, it was essential to evaluate the ruggedness of the RRT and RRF on different columns (different batches of Luna C<sub>18</sub>) and equipment. As summarized in Table 3, the RRFs for each analyte were quite similar at the detection wavelength of 327 nm across different HPLC instruments, indicating a good consistency of the RRFs. The RRT for each analyte was stable with the RSDs, with deviations of less than 2.0%, and was found to be suitable for use in the identification.

In addition, previous studies showed that the RRFs of flavones presenting the same or similar skeletons and different substituent groups were correlated with molecular weights (Cui et al., 2016). Due to a lack of reference standards, the RRFs of the three flavone glycosides luteolin-7-*O*-glucuronide, diosmetin-7-*O*-glucoside and apigenin-7-*O*-6''-malonylglucoside were calculated based on analytes with highly similar molar absorptivities and molecular weights. For example, the structures of luteolin-7-*O*-glucuronide (*M<sub>r</sub>* = 462.3) and diosmetin-7-*O*-glucoside (*M<sub>r</sub>* =

**TABLE 3 |** Ruggedness of the RRT and RRF of marker components in *C. morifolium*/*C. indicum* flower,  $n = 7$ .

<sup>a</sup>or luteolin-7-*O*-glucoside.

<sup>b</sup>as internal reference substances.

462.3) were similar to that of luteolin-7-*O*-glucoside ( $M_r = 448.3$ ). Thus, the RRFs of the two analytes were both obtained as 1.03 ( $RRF = 462.3/448.3 \times 1.00$ ). The RRF of apigenin-7-*O*-6''-malonylglucoside ( $M_r = 518.1$ ), which possessed a structure similar to that of apigenin-7-*O*-glucoside ( $M_r = 432.8$ ), was determined to be 0.91 ( $RRF = 518.1/432.8 \times 0.76$ ). Though the results of the three RRFs may deviate from the true value and are only an approximation, the method was validated as an effective alternative for the quality control of *C. morifolium* flower and *C. indicum* flower when lacking of the sufficient chemical standard substances.

### Validation of the Quantitative Analysis Method

For the ESM method, all of the reference standards solutions related to the analytes to be examined should be prepared first. In contrast, only the internal reference solutions were needed for the SSDMC method. The results calculated via the SSDMC method in this experiment were compared to the results obtained with ESM (shown in **Supplementary Tables S1–S8**).

The linearity equation was constructed using a series of standard solutions. The calibration curves calculated by plotting the peak area  $Y$  against the concentration  $x$  ( $\mu\text{g/ml}$ ) of each compound were  $Y_1 = 2.564 \times 10^4 x + 5.208 \times 10^3$ ,  $Y_2 = 2.006 \times 10^4 x + 0.745 \times 10^3$ ,  $Y_3 = 2.756 \times 10^4 x + 1.954 \times 10^3$ ,  $Y_4 = 3.129 \times 10^4 x + 0.973 \times 10^3$ ,  $Y_5 = 2.628 \times 10^4 x + 7.102 \times 10^3$ ,  $Y_6 = 2.918 \times 10^4 x + 3.478 \times 10^3$ , and  $Y_7 = 1.918 \times 10^4 x + 7.238 \times 10^3$  for Peak 2, 9, 10, 13, 6, 11, and 18, respectively. The calibration curves exhibited good linearity ( $r^2 > 0.9993$ ) within the test range. The LOD ( $S/N = 3$ ) was 0.49–0.79 ng/ml and the LOQ ( $S/N = 10$ ) was 1.64–2.65 ng/ml for the seven compounds.

Repeatability was assessed by examining three replicate solutions prepared at three different concentrations (high, medium and low). The RSD values for the seven components in samples (H5, Y29) were less than 5.4%. The precision of the method was analyzed by using different operators and performing the analysis on different days, equipment and columns. The RSD values were found to be in the range of 1.2–4.2% (in S3–S7 in Supporting Information). The results showed no remarkable differences between the precision of the two methods, SSDMC and ESM, according to the F-test ( $p = 0.113 > 0.05$ ).

The method accuracy was determined using a recovery test by assaying the known added amount of analyte in the sample at three concentration levels (75, 100, and 125%). Three replicates of each concentration in samples (H5, Y29) were examined. Recoveries were in the range 95.0–102.0% with RSDs less than 3.2% for the seven analytes in the samples (H5, Y29) (shown in S8–S9 in Supporting Information). The recoveries between the ESM and SSDMC methods showed no remarkable differences using the paired  $t$ -test ( $p = 0.174 > 0.05$ ).

The stability of the sample solutions (H5, Y29) was examined by comparing the peak areas of the same sample solutions after storage for different times. The results demonstrated that the sample solutions were stable for almost 24 h with the RSDs of peak areas less than 2.6%.

### Workflow for Differentiating *C. morifolium* Flower and *C. indicum* Flower

Four caffeoylquinic acids (Peak 2, 9, 10, and 13) and three flavone glycosides (Peak 6, 11, and 18), in the tested samples were simultaneously determined by SSDMC and standard calibration methods. The quantitative results from the two methods were accordant using the  $t$ -test ( $p = 0.376$ ,  $p > 0.05$ ). Meanwhile, the other three flavone glycosides (Peak 7, 15, and 16) were determined by the RRFs calculated as described in *Calculation of Relative Response Factors and Relative Retention Times*. All of the results are summarized in **Supplementary Tables S9–S11** in the Supporting Information. Contents of the ten components in the different samples varied greatly, with the total contents of four caffeoylquinic acids ranging from 0.684 to 3.445% in *C. morifolium* flower and 0.166–2.112% in *C. indicum* flower, while the total contents of six flavone glycosides ranged from 0.315 to 4.161% in *C. morifolium* flower and 0.144–2.078% in *C. indicum* flower. The average amount of Peak18 (linarin, 0.636%) in *C. indicum* flower was much higher (approximately six-fold) than that in *C. morifolium* flower but varied significantly among the different samples due to the numerous regions of origin and the variation of wild resources. In contrast, the other five flavone glycosides were detected at significantly lower levels in *C. indicum* flower. Furthermore, the absolute contents of the four caffeoylquinic acids in *C. morifolium* flower samples were

significantly higher than those in *C. indicum* flower samples, but the content ratios of the four caffeoylquinic acids were similar in both *C. morifolium* flower and *C. indicum* flower.

Based on the quantitative results, Student's *t*-test and OPLS-DA ( $R^2X$  0.822,  $R^2Y$  0.764,  $Q^2$  0.715) were used to further screen out markers for differentiating *C. morifolium* flower and *C. indicum* flower. Combined *VIP* value and *p* value, peaks 13, 16, 11, 15, 16 and 10 were identified as the markers, whose contents were shown as **Figure 6**. Then to effectively distinguish the two herbs from the same genus, a binary logistic regression equation was established as  $Y = 14.52 - 53.16C_{13} + 51.52 C_6 - 313.09C_{11} - 445.74 C_6 + 109.94C_{16} + 26.33C_{10}$  ( $C_x$  represents the content of peak  $x$ ). When the contents of the six markers were substituted into the equation, the sample was determined as *C. morifolium* flower if the result was negative and on the contrary for *C. indicum* flower. The established method was tested with multiple batches of samples collected from different regions, and the accuracy rate was 100%, which proved the robustness of the model.

## CONCLUSION

In summary, we demonstrated a systematic study for comparing *C. morifolium* flower and *C. indicum* flower from chemical composition to pharmacological characteristics. The difference in anti-inflammatory activity between the two herbs was firstly characterized. Potential markers for distinguishing *C. morifolium* flower from *C. indicum* flower were preliminarily screened out by HPLC fingerprint analysis combined with statistical methods and

identified by HPLC-ESI-QTOF-MS. An improved SSDMC approach was used for quantifying the potential markers of four caffeoylquinic acids and six flavone glycosides. Finally, a binary logistic regression equation based on the contents of markers was built to differentiate *C. morifolium* flower and *C. indicum* flower successfully. The workflow for differentiating *C. morifolium* flower and *C. indicum* flower was effective and would provide a powerful tool for herb identification.

Acute-on-chronic liver failure (ACLF) is described as a characteristic of acute jaundice and coagulation dysfunction. Effective treatments for ACLF are unavailable and hence are urgently required. We aimed to define the effect of Yi-Qi-Jian-Pi Formula (YQJPF) on liver injury and further examine the molecular mechanisms. In this study, we established CCl<sub>4</sub>-, LPS-, and D-galactosamine (D-Gal)-induced ACLF rat models *in vivo* and LPS- and D-Gal-induced hepatocyte injury models *in vitro*. We found that YQJPF significantly ameliorates liver injury *in vivo* and *in vitro* that is associated with the regulation of hepatocyte necroptosis. Specifically, YQJPF decreased expression of receptor-interacting protein kinase 1 (RIPK1), receptor-interacting protein kinase 3 (RIPK3) and pseudokinase mixed lineage kinase domain-like (MLKL) to inhibit the migration of RIPK1 and RIPK3 into necrosome. YQJPF also reduces the expression of inflammatory cytokines IL-6, IL-8, IL-1 $\beta$ , and TNF- $\alpha$ , which were regulated by RIPK3 mediates cell death. RIPK1 depletion was found to enhance the protective effect of YQJPF. Furthermore, we showed that YQJPF significantly downregulates the mitochondrial reactive oxygen species (ROS) production and mitochondrial depolarization, with ROS scavenger, 4-hydroxy-TEMPO treatment recovering impaired RIPK1-mediated necroptosis and reducing the expression of IL-6, IL-8, IL-1 $\beta$ , and TNF- $\alpha$ . In summary, our study revealed the molecular mechanism of protective effect of YQJPF on hepatocyte necroptosis,

## INTRODUCTION

Acute-on-chronic liver failure (ACLF) is a syndrome characterized by acute decompensation of chronic liver disease, which has a high short-term mortality rate, and it seriously threatens the lives of patients with chronic liver disease (Xiang et al., 2020). However, the pathogenesis of ACLF remains poorly understood. Among Asian countries, the prevalence of hepatitis in China is still high. There are approximately 97 million hepatitis B virus (HBV) carriers and one million hepatitis C virus (HCV)-infected patients in China. Chronic viral hepatitis is still the basis in ACLF (Xie et al., 2019). Virus replication and bacterial infection are the main causes of liver failure. However, no effective therapy for liver failure beyond supportive treatment is currently available; hence, a new treatment or medicine against liver failure is needed. Previous studies have suggested that ACLF develops in patients with cirrhosis as a consequence of precipitating events leading to acute decompensation and multi-organ failure (Sarin and Choudhury, 2016). Despite variations in the definition of ACLF in different regions, progressive, unrelenting hepatocyte injury and death are common hallmarks of ACLF, which have been well-documented as pathobiology of ACLF. Effective treatments to target hepatocyte injury and death due to ACLF are lacking and thus are urgently required. Unlike apoptosis and pyroptosis, necroptosis is a caspase-independent death program (Asrani et al., 2019). The dying cells exhibit none of the morphological characteristics of apoptosis, instead these cells display the swelling associated with necrosis; the dying cell can trigger an innate immune response, cause the release of inflammatory cytokines, and exacerbate tissue damage (Wang et al., 2014). The inhibitors of necroptosis could have therapeutic potential.

Traditional Chinese medicines have received attention worldwide in last few decades because of their satisfactory therapeutic effects, facile availability, and cost-effectiveness (Bajaj et al., 2018; Engelmann et al., 2020). Our previous study confirmed that the treatment with Yi-Qi-Jian-Pi Formula (YQJPF) composed of Huangqi, Taizishen, Baizhu, Chenpi, Danggui, Fulin, Huangqin, and Gancao can ameliorate HBV-ACLF. *Corethrodedendron multijugum* (Maxim.) B. H. Choi and H. Ohashi (Huangqi in Chinese) and *Pseudostellaria Radix*, *Pseudostellaria heterophylla* (Miq.) Pax (Taizishen in Chinese) are Monarch drugs; *Angelica Sinensis Radix*, *Angelica sinensis* (Oliv.) Diels (Danggui in Chinese), *Wolfiporia extensa* (Peck) Ginns (Fulin in Chinese), *Atractylodes lancea* (Thunb.) DC (Cangzhu in Chinese) and *Atractylodes macrocephala* Koidz (Baizhu in Chinese) are Ministerial drugs; and *Citrus Reticulata*, *Citrus × aurantium* L. (Chenpi in Chinese), *Scutellariae Radix* *Scutellaria baicalensis* Georgi (Huangqin in Chinese), and licorice, *Glycyrrhiza uralensis* Fisch. ex DC., *G. glabra* L., and *G. inflata* Batalin (Gancao in Chinese) are adjuvants. A retrospective cohort study on 60 patients with HBV-

ACLF reported that YQJPF could prevent the development of liver failure and improve the Model for End-Stage Liver disease score (Zhang Z. et al., 2014; Lian et al., 2015). However, the regulation mechanism of its effect has not been elucidated. Atractylone is the main sesquiterpenic constituent of *Atractylode japonica*, which is a necessary component of YQJPF. *Atractylode japonica* was used to treatment of several diseases such as rheumatic diseases, digestive disorders, hepatic protection and influenza for a long history in China. Additionally, atractylone was reported to have anti-inflammatory and anti-hepatotoxic effects (Cheng et al., 2019).

In the present study, we developed *in vivo* and *in vitro* models with D-galactosamine (D-gal)/LPS injection that recapitulate some features of clinical ACLF. In these models, we assessed the features of ACLF in laboratory settings. Further, ACLF models were treated with YQJPF to assess its effect on liver injury. Additionally, we explored the role of inflammation infiltration and hepatocyte necroptosis and the potential mechanisms for the treatment of liver injury in ACLF.

## MATERIALS AND METHODS

### Reagents and Antibodies

Methylprednisolone was obtained from the Nanjing Hospital affiliated to Nanjing University of Chinese Medicine (Nanjing, Jiangsu China) and was dissolved in PBS to a concentration of 30 mg/ml and was stored at 4°C. Necrotatin-1 (Nec-1) and 4-hydroxy-TEMPO (Tempol) were bought from Sigma-Aldrich (St Louis, MO, United States). Dulbecco's modified essential medium (DMEM), fetal bovine serum (FBS), Opti-MEM medium, phosphate-buffered saline (PBS), and trypsin-EDTA were purchased from GIBCO (Grand Island, NY, United States). The antibodies against  $\beta$ -actin (20536-1-AP), RIPK1 (17519-1-AP), and RIPK3 (17563-1-AP) were purchased from Proteintech Group, Inc (Rosemont, IL, United States). Caspase-3 (#9662), cleaved-caspase-3 (#9664), caspase-8 (#9746), cleaved-caspase-8 (#9748), TNF- $\alpha$  (#11948), IL-18 (#54943), IL-1 $\beta$  (#12242), and IL-6 (#12153) were procured from Cell Signaling Technology (Danvers, MA, United States). Mixed lineage kinase domain-like protein (MLKL; ab243142) were purchased from Abcam Technology (Abcam, Cambridge, United Kingdom).

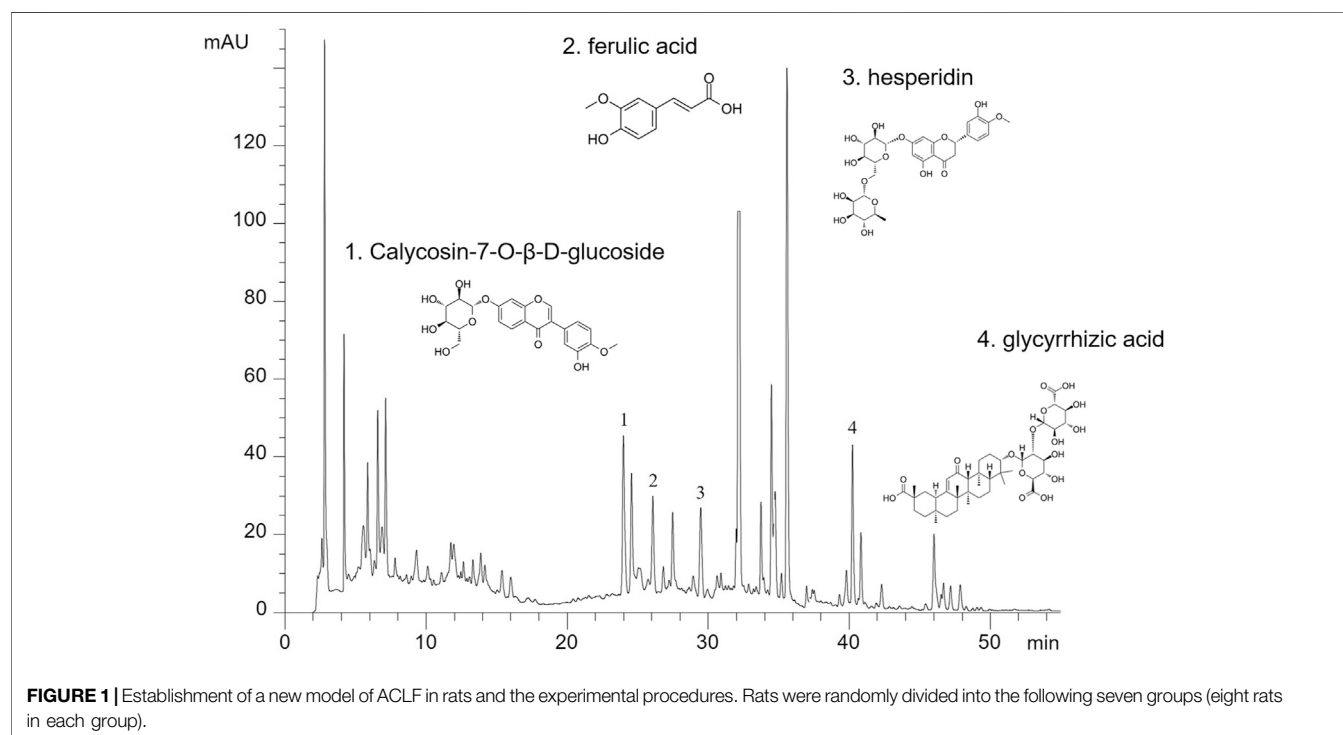

### Preparation and High-Performance Liquid Chromatography of YQJPF for Quality Control

YQJPF was provided by Nanjing University of Chinese Medicine, Nanjing Hospital Affiliated to Nanjing University of Chinese Medicine. YQJPF was prepared from nine commonly used Chinese herbal medicines (Table 1). All the herbal

**TABLE 1 |** The composition of traditional Chinese medicine in Yi-Qi-Jian-Pi Formula (YQJPF).

Components	Latin name	Medical parts	Amount used (g)	Percentage (%)
Huangqi	<i>Corethroedendron multijugum</i> (Maxim.) B. H. Choi and H. Ohashi	Root	30	19.6
Taizishen	<i>Pseudostellaria heterophylla</i> (Miq.) Pax	Root	30	19.6
Danggui	<i>Angelica sinensis</i> (Oliv.) Diels	Rhizome	30	19.6
Baizhu	<i>Atractylodes macrocephala</i> Koidz	Root	15	9.8
Fulin	<i>Wolfiporia extensa</i> (Peck) Ginns	Sclerotium	15	9.8
Cangzhu	<i>Atractylodes lancea</i> (Thunb.)DC	Fruit	10	6.5
Chenpi	<i>Citrus × aurantium</i> L.	Pericarp	10	6.5
Huangqin	<i>Scutellaria baicalensis</i> Georgi	Root	10	6.5
Gancao	<i>Glycyrrhiza uralensis</i> Fisch. ex DC., <i>G. glabra</i> L., and <i>G. inflata</i> Batalin	Root, hizome	3	2.1

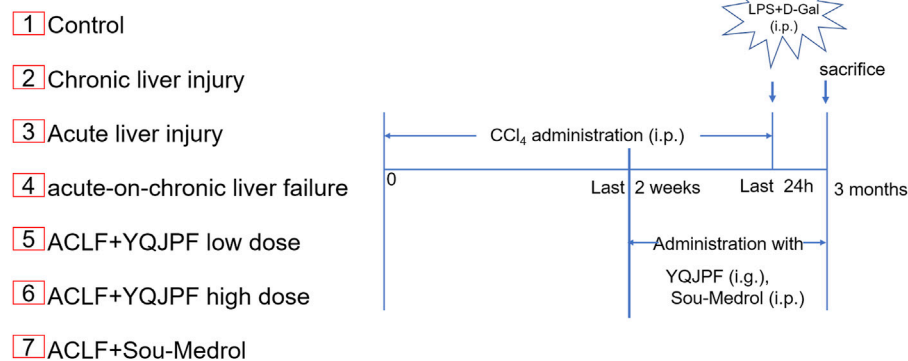

constituents were obtained from the Beijing Tong Ren Tang Co. Ltd. (Beijing, China). Huangqi, Taizishen, Baizhu, Chenpi, Danggui, Fulin, Huangqin, and Gancao were mixed in the ratio 30:30:30:10:15:15:3:10:10.

Then, all herbs were decocted twice and the decoction liquids were concentrated to a density of 2.86 g/ml and was stored at 4°C. For quality control, HPLC analysis was used as previously described (Yao et al., 2018). YQJPF were assessed using an Agilent 1,260 liquid chromatography system (United Kingdom). Briefly, 10 µl YQJPF solution was injected into an apparatus with an auto sampler. Chromatographic separation was implemented at a flow rate of 1 ml/min with an Agilent C18 column (4.6 mm × 250 mm, 5 µm). The separation phase was composed of 0.2% phosphoric acid (A) and acetonitrile (B). The linear concentration solution gradually increases from 2 to 72% of solvent B over the course of 45 min. The separation

temperature was 40°C, with a detection wavelength of 254 nm. The results are shown in **Figure 1**.

## Animals and Experimental Design

A total of 56 male Sprague-Dawley rats, with the body weight of 180–220 g, were purchased from Beijing Vital River Laboratory Animal Technology Co. Ltd (Beijing, China). All animals were housed with laboratory chow and tap water at 22 ± 2°C under 55 ± 5% humidity-controlled environment and a 12-h light–dark cycle. The experimental design was approved by the Institutional and Local Committee on the Care and Use of Animals of Nanjing University of Chinese Medicine (Nanjing, China). All animals were provided care in compliance with the National Institutes of Health (United States) guidelines. A mixture of CCl<sub>4</sub> and olive oil [1:1 (w/v)] was used to induce liver cirrhosis in rats (1.5 ml/kg body weight). LPS (100 µg/kg) and D-Gal (400 mg/kg) were

**FIGURE 2 |** The major components in YQJPF were assessed using HPLC. Calycosin-7-O- $\beta$ -D-glucoside, ferulic acid, hesperidin, and glycyrrhizic acid were found to be in the amounts of 0.3676, 0.6639, 2.442, and 0.4028 mg/ml, respectively.

used to induce acute liver injury. The mice were randomly divided into seven groups ( $n = 8$  for each group). The experimental groups were as follows (**Figure 2**):

Group 1: control group; i. p. with olive oil.

Group 2: chronic liver injury model group; i. p. with CCl<sub>4</sub> for 12 weeks.

Group 3: acute liver injury model group; i. p. with LPS and D-Gal once.

Group 4: ACLF model group; i. p. with CCl<sub>4</sub> for 12 weeks followed by i. p. with LPS and D-Gal once.

Group 5: YQJPF low-dose treatment group; i. p. with CCl<sub>4</sub> for 12 weeks and i. g. with YQJPF (14.3 g/kg) for 2 weeks followed by i. p. with LPS and D-Gal once.

Group 6: YQJPF high-dose treatment group; i. p. with CCl<sub>4</sub> for 12 weeks and i. g. with YQJPF (28.6 g/kg) for 2 weeks followed by i. p. with LPS and D-Gal once.

Group 7: methylprednisolone treatment group; i. p. with CCl<sub>4</sub> for 12 weeks and i. p. with methylprednisolone (15 mg/kg) for 2 weeks followed by i. p. with LPS and D-Gal once.

## Cell Culture

Human LO2 cell line was obtained from the Cell Bank of Chinese Academy of Sciences (Shanghai, China). Cells were cultured in DMEM with 10% FBS and 1% antibiotics and were incubated in 5% CO<sub>2</sub> and 95% air humidified atmosphere at 37°C.

## Liver Histopathology

Liver hematoxylin and eosin (H&E) and Masson and Sirius Red staining were performed as per the previously described methods (Jin et al., 2016). Representative pictures of liver sections were displayed.

## Serum Biochemistry

Blood samples were collected and incubated at room temperature for 1 h, and extracted serum was collected after centrifugation. Levels of alkaline phosphatase (ALP), aspartate aminotransferase (AST), and alanine aminotransferase (ALT) in serum were

measured using enzyme-linked immunosorbent assay kits (Nanjing Jinteng Bioengineering Institute, Nanjing, China) according to the manufacturer's protocols.

## Determination of Hepatic mtDNA, ATP, Malondialdehyde, and Superoxide Dismutase Levels

Liver tissues were treated according to the treatment regimen mentioned earlier. After treatment, hepatic mtDNA, ATP, malondialdehyde (MDA), and superoxide dismutase (SOD) were quantified using corresponding kits (Nanjing Jinteng Bioengineering Institute, Nanjing, China) according to the manufacturer's instructions.

## Immunohistochemistry

Immunohistochemical staining of liver tissue was performed using antibodies against caspase 8, MLKL, RIPK1, and RIPK3, as previously described (Zhang F. et al., 2014). Representative pictures of liver sections were displayed.

## Cell Viability Assay

To assess the effects of different treatments on cell proliferation, Cell viability analysis was performed using MTT. In brief, The LO2 cells were seeded into 96-well plates at a density of  $3 \times 10^3$  cells per well. After incubating for 24 h, the cells were treated with LPS (10  $\mu$ g/ml) and D-Gal (10 mg/ml) for 4 h for the hepatocyte injury model. Further, the cells were treated with serial concentration gradients of YQJPF and atracyclone for another 24 h, with triplicates for each concentration. Then 5 mg/ml MTT was added in cells, and cells were incubated at 37°C for 4 h, and the absorbance was measured at a wavelength of 490 nm. Independent experiments were performed in triplicates.

## Trypan Blue Staining

Cell death was determined using the trypan blue staining assay (Beyotime Biotechnology, Shanghai, China). In brief, after YQJPF treatment, the cells were digested using trypsin without EDTA

**TABLE 2 |** Primers used for human LO2 cells.

Gene	Forward sequence	Reverse sequence
IL-6	GCTTCCCTCAGGATGCTTGT	ATTAAGTGGGGTGCCTGCTC
TNF- $\alpha$	GAGACAGATGTGGGGGGTGTGAG	TCCTAGCCCTCCAAGTTCCA
IL-1 $\beta$	AGCCATGGCAGAAGTACCTG	TGAAGCCCTTGTCTGAGTGG
IL-18	CGAGGGAGTGAAGACCCTG	TGGGCGTAAGCTTGAATGT
GAPDH	TGTCATGGCAGAAGTACCTG	GTAACTGGGGAGCCTGCTC

followed by centrifugation. The cells were further washed twice with PBS and were resuspended in PBS. Cell suspension and trypan blue solution were mixed gently in 1:1 ratio and allowed to stand for 3 min. A few of the stained cells were counted with a hemocytometer, and photographs were taken in a blinded fashion at random fields. Stained blue cells represented dead cells.

## RNA Isolation and Real-Time PCR

Total RNA was extracted from liver tissues and LO2 cells by using Trizol reagent according to the manufacturer's protocol (Sigma-Aldrich, St. Louis, MO, United States) and further reverse-transcribed into cDNA by using PrimeScript RT reagent kit (TaKaRa Biotechnology, Beijing, China). Real-time PCR was performed using the SYBR Green I fluorescent dye (TaKaRa Biotechnology, Beijing, China), according to the manufacturer's protocol. Glyceraldehyde phosphate dehydrogenase (GAPDH) served as an invariant control, and mRNA levels were expressed as fold changes after normalizing to GAPDH. The experiment was performed in triplicates. Primers (Genscript, Nanjing, China) are listed in **Table 2** below.

## Western Blot

Cells and liver samples were lysed using a mammalian lysis buffer (Sigma St. Louis, MO, United States) and were denatured in SDS loading buffer. Then, western blot analysis was performed according to the manufacturer's instructions (Bio-Rad, Hercules, CA, United States). Thereafter, Cells and liver samples were incubated overnight with antibodies against caspase 3, cleaved-caspase-3, caspase 8, cleaved-caspase-8, MLKL, RIPK1, RIPK3, IL-6, IL-18, IL-1 $\beta$ , and TNF $\alpha$  at 4°C. Protein detection, band visualization, and quantification were performed as per the manufacturer's instructions. Anti- $\beta$ -actin antibody (Danvers, MA, United States) was used as a loading control.

## Immunoprecipitation Assay

The immunoprecipitation assay was performed using co-immunoprecipitation (Co-IP) kit (Thermo) as per manufacturer's instructions. Briefly, the cell lysates were incubated with anti-RIPK1 and anti-RIPK3 antibodies. Protein G-agarose beads were added and incubated overnight to precipitate the protein complexes. Western blot analysis was performed to detect the protein complexes expression.

## Immunofluorescence Analysis

LO2 cells were seeded on 24-well plates and cultured in DMEM with 10% FBS. Afterward, they were treated with corresponding reagents for 24 h. Then, the cells were fixed with 4% PFA for 30 min at 37°C, permeabilized with PBS-T (0.1% Triton x-100 dissolved in PBS), and blocked with PBS-B (4% BSA dissolved in

PBS). The cells were stained with the corresponding antibody (1:200 dilution) overnight at 4°C, followed by incubation with FITC-labelled goat anti-rabbit IgG (1:100 dilution) for 2 h. Finally, 4',6-diamidino-2-phenylindole (DAPI) staining was performed by incubation in dark for 5 min, and the fluorescence was observed using a fluorescence microscope (Nikon, Tokyo, Japan) to visualize the nuclei.

## Enzyme-Linked Immunosorbent Assay (ELISA)

Levels of IL-6, IL-8, IL-1 $\beta$ , and TNF- $\alpha$  in serum were measured using ELISA kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer's instructions.

## Intracellular ROS Assay

The level of intracellular ROS was determined using an oxidation-sensitive fluorescent probe, 2',7'-dichlorodihydrofluorescein diacetate (DCFH-DA) (Beyotime Biotechnology, Shanghai, China). Briefly, LO2 cells were seeded in a 24-well plate and pre-treated with ROS scavenger Tempol (10  $\mu$ M) for 1 h before exposing to YQJPF or selective RIPK1 inhibitor Nec-1. DCFH-DA probe was subsequently incubated with LO2 for 30 min. Subsequently, ROS levels were detected according to the manufacturer's instructions.

## Determination of Mitochondrial ROS

We determined mitochondrial ROS production by using a fluorescent probe, MitoSOX, which is a red mitochondrial superoxide indicator for live cell imaging (Molecular Probes; Life technologies). Briefly, LO2 cells were treated with YQJPF or selective RIPK1 inhibitor Nec-1. Further, LO2 cells were incubated with MitoSox reagent (5  $\mu$ M) for 10 min at 37°C and washed with PBS. The red fluorescence density was detected using a fluorescence microscope (Nikon, Tokyo, Japan) with the rhodamine channel.

## Mitochondrial Membrane Potential Assay

The mitochondrial membrane potential (MMP) was determined using 5,5',6,6'-tetrachloro-1,1',3,3'-tetraethylbenzimidazolylcarbocyanine iodide (JC-1) (Beyotime Biotechnology, Shanghai, China) staining as per the manufacturer's protocol. LO2 cells were washed with PBS and incubated with JC-1 working solution at 37°C in dark for 20 min. After removing JC-1 solution, the cells were washed with PBS, and images were taken using a fluorescence microscope (Nikon, TiE, Japan) with both red and green channels. The MMP is represented by the average red/green fluorescence intensity ratio.

## Transmission Electron Microscopy

LO2 cells were seeded in six-well plates (14,000 cells/well). After the corresponding treatment, transmission electron microscopy (TEM) images were obtained using a JEM 1010 transmission electron microscope (JEOL, Tokyo, Japan). Briefly, LO2 cells were fixed in Karnovsky fixative solution (2% paraformaldehyde and 2.5% glutaraldehyde in 0.15 mol/L sodium cacodylate buffer, pH 7.1–7.3) during 1 h and then washed three times in a

cacodylate buffer for 15 min. Then pellets were embedded into 2% agar and postfixed in 1% osmium tetroxide in a cacodylate buffer during 1 h. Samples were then dehydrated in 50, 70, 95, and 100% of acetone for 2, 10, 30, and 60 min, respectively, and embedded into Durcupan ACM (Fluka, Analytical Sigma-Aldrich; Switzerland). And the ultrathin sections (70 nm) were placed on nickel grids and examined at 100 keV. For each group, electromicrographs were recorded at a microscope magnification of  $\times 10,000$ .

## Flow Cytometer Analysis

FITC Annexin V apoptosis detection kit (BD Pharmingen™, BD Biosciences) was used for detection of cell apoptosis. Briefly, LO2 cells were seeded in six-well plates in complete medium and allowed to attach for 24 h. Then, cells were treated as indicated. Cells were further incubated for 24 h, in 5% CO<sub>2</sub> at 37°C. After that, cells were trypsinized, washed in PBS and stained according to kit according to the manufacturer's instructions. Stained cells were analyzed using BD Accuri C6 flow cytometer (BD Pharmingen™, BD Biosciences) and data was processed with FlowJo\_v10.6.2 software. Each sample was assessed using a collection of 10,000 events. The mean values and standard deviations were calculated from three independent experiments.

## Statistical Analysis

Two-tailed Student's tests and one-way ANOVA analysis were performed using GraphPad Prism software v. 7.0 (Graph Pad Software Inc., San Diego, CA). The values and data are presented as the mean  $\pm$  SEM from three independent experiments. A *p* value of  $<0.05$  was considered statistically significant.

# RESULTS

## YQJPF Alleviated Liver Injury *In Vivo*

The ACLF rat model was pre-established through intraperitoneal injection of CCL<sub>4</sub> for 12 weeks. Further, acute liver injury was induced by using a combination of LPS and D-Gal. And YQJPF was given for 2 weeks to investigate the protective effect on ACLF rats. In addition, methylprednisolone (Sou-Medrol) was used as a positive control drug, which has been confirmed as a therapeutic agent for ACLF (Zhao et al., 2012; Jia et al., 2020). And the establishment of a new model of ACLF in rats and the experimental procedures as shown in **Figure 2**. The livers in ACLF model became small and hard accompanied by necrosis, with small nodules on their surface; however, YQJPF and methylprednisolone were found to effectively ameliorate the liver morphology. Pathological examinations were used to manifest the effects of YQJPF on hepatic injury. As shown in H&E staining, YQJPF and methylprednisolone ameliorated the disordered hepatic structure (**Figure 3A**). The effect of YQJPF on liver injury was evaluated. Detection of serum biochemical indicators indicated improvement in liver injury indices such as TBil, ALT, and AST contents after

2 weeks of YQJPF and methylprednisolone treatment in rats with ACLF (**Figures 3B–E**). In summary, YQJPF and methylprednisolone significantly ameliorated liver injury in ACLF model rats.

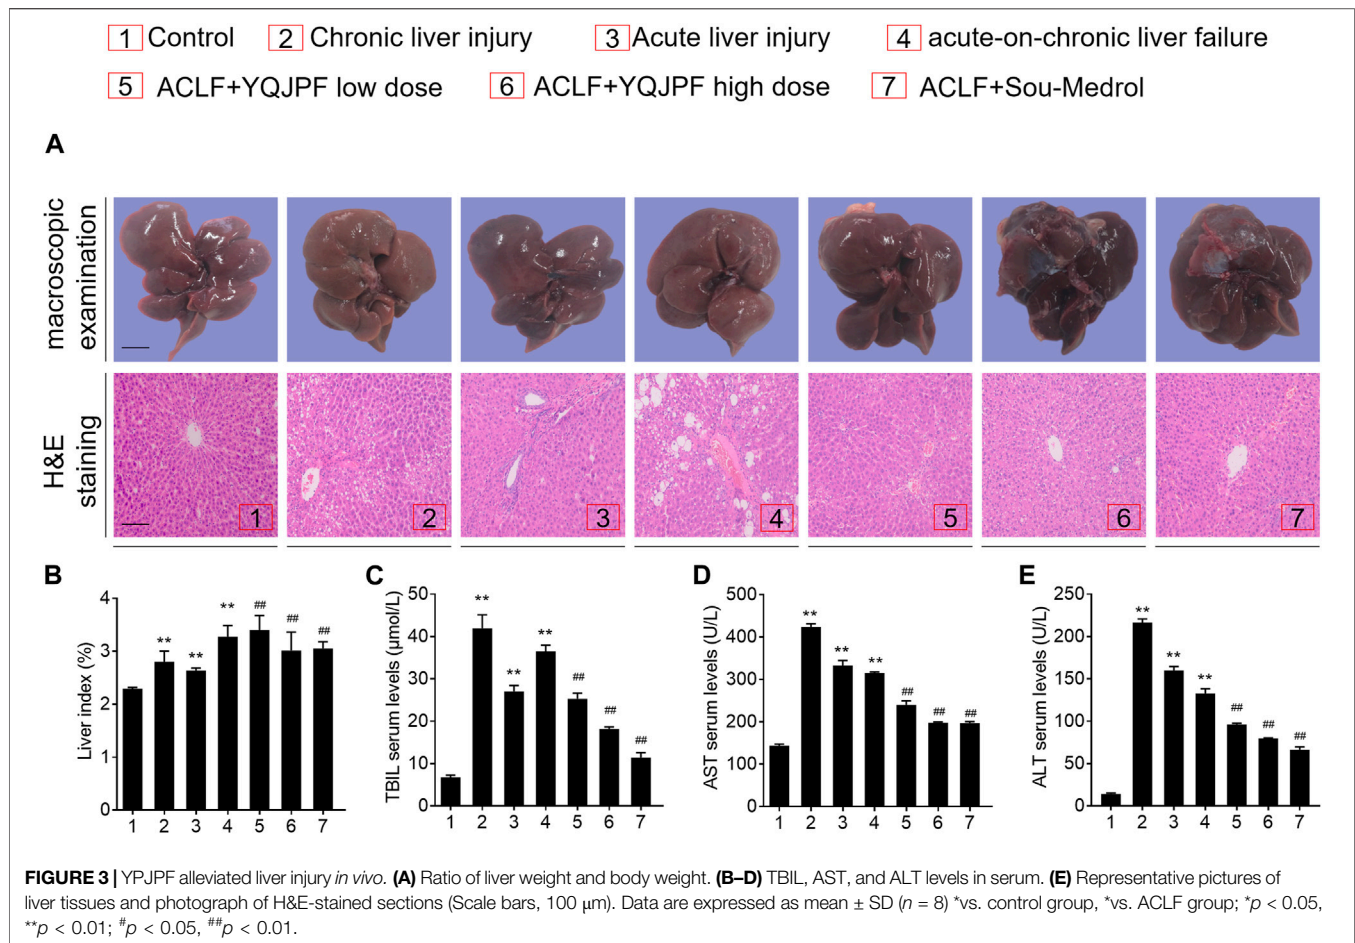

## Protective Effect of YQJPF on LPS- and D-Gal-Induced Hepatocyte *In Vitro*

Generally, massive hepatocyte death is implicated in ACLF. Here, we used LPS (10  $\mu$ g/ml) and D-Gal (10 mg/ml) to induce liver injury in LO2 cells. MTT assay showed that LPS and D-Gal inhibit cell viability, whereas YQJPF and atractylone could promote cell viability in a dose-dependent manner. YQJPF above 10  $\mu$ g/ml and atractylone at 5  $\mu$ M showed a significant effect (**Figures 4A,B**). Light microscopy indicated that the adherent LO2 cells are swollen, and the cell morphology changed after LPS and D-Gal treatment for 4 h. YQJPF and atractylone could improve microscopic performance (**Figure 4C**). Levels of AST and ALT were detected to assess the hepatocytic damage. The levels of ALT, AST, and LDH in the supernatant of cultured LO2 cells were detected by ELISA. Results showed significantly increased levels of ALT, AST, and LDH in the model group and decreased levels of those in YQJPF and atractylone treatment groups (**Figures 4D–F**). Thus, YQJPF and atractylone exerted a protective effect on LPS- and D-Gal-induced hepatocytic injury.

## YQJPF Inhibited Necroptosis but Not Apoptosis on LPS- and D-Gal-Induced Hepatocytic Injury *In Vitro*

Necrosis and apoptosis are the most common pathways of death during liver injury (Schwabe and Luedde, 2018). Hence, we first examined which pathway plays a significant role in LPS- and D-Gal-induced hepatocytic injury. The result of the TUNEL assay indicated that YQJPF (10, 20, and 40  $\mu$ g/ml) and atractylone (5  $\mu$ M) have no effect on apoptosis (**Figure 5B**). The protein expression of key indicators such as caspase 3, caspase 8, and the cleaved caspase-3 and caspase-8 did not change after LPS and D-Gal treatment (**Figure 5C**). Then, the cell apoptosis was determined by flow cytometry, and results indicated that YQJPF and atractylone have no effect on apoptosis (**Figure 5D**). Therefore, LPS- and D-Gal-induced cell death was not dependent on apoptosis because no obvious apoptotic features could be observed. YQJPF and atractylone prevented cell death without influencing apoptosis. Next, we assessed whether necroptosis plays a role in this process. Positive result in trypan blue staining indicated that membrane permeability is altered by LPS and D-Gal. YQJPF or atractylone treatment significantly decreased the number of dead cells (**Figure 5A**). To confirm our findings, we used TEM analysis to observe cell morphology and structure. The cells exhibited a typical necrotic cell death morphology, including swelling of organelles (especially mitochondria), condensation of chromatin into small, irregular patches, and chromatin margination, after LPS and D-Gal treatment (**Figure 5E**). YQJPF could restore cell morphology

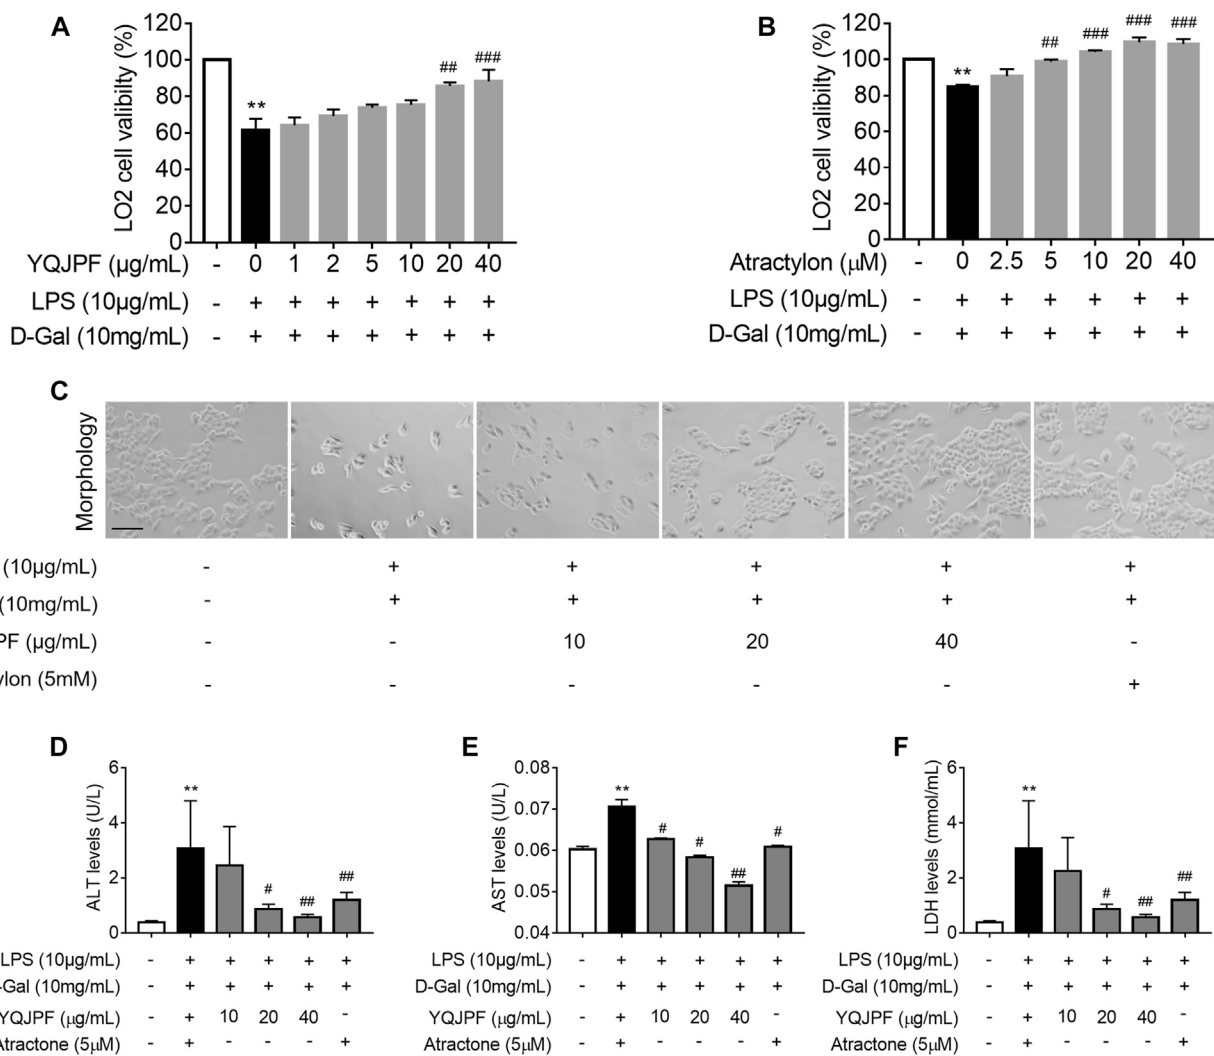

and structure in a dose-dependent manner. Atractylone exhibited the same effect. Necroptotic cells underwent organelle breakdown, leading to the leakage of intracellular contents consequently triggering inflammation (Weinlich et al., 2017). Further, we examined some inflammation-associated biomarkers. mRNA and protein levels of pro-inflammatory cytokines IL-1 $\beta$ , IL-6, TNF- $\alpha$ , and IL-18 were detected using RT-qPCR, ELISA, and western blot analysis (Figures 6A–I). The results showed that pro-inflammatory cytokines are decreased in YQJPF and atractylone treatment groups compared with the LPS- and D-Gal-induced model group. Above all, we demonstrated that LPS and D-Gal induce hepatocyte necroptosis but not apoptosis and that YQJPF and its active ingredient atractylone could protect hepatocytes from necroptosis by reducing the expression of inflammatory cytokines in hepatocytes.

### The RIPK1/RIPK3 Complex Is Required for YQJPF to Inhibit Necroptosis *In Vitro*

The RIPK1/RIPK3 signaling pathway has been reported to be involved in the induction of necroptosis (Lin et al., 2016; Newton et al., 2016). Thus, we investigated using western

blot and ELISA whether YQJPF and atractylone alter the expression of RIPK1, RIPK3 and MLKL. As shown in (Figures 7A–E), YQJPF or atractylone treatment downregulated the expression of RIPK1, RIPK3 and MLKL. Immunofluorescence staining of RIPK1 and RIPK3 further validated these results. The association between RIPK1 and RIPK3 was analyzed using immunoprecipitation, which indicated that YQJPF and atractylone could inhibit the interaction between RIPK1 and RIPK3 (Figure 7F). To identify whether YQJPF and atractylone are dependent on RIPK1/RIPK3-mediated necroptosis, we used the RIPK1 kinase inhibitor necrostatin-1 (Nec-1) to verify the effect of YQJPF and atractylone. The results indicated that Nec-1 and YQJPF work together, and they had the most significant inhibitory effect on LO2 necroptosis induced by LPS and D-Gal (Figures 8A–E). We further investigated the interaction between RIPK1 and RIPK3 in YQJPF-treated LO2 cells through immunoprecipitation. RIPK1 and RIPK3 were significantly immunoprecipitated in LPS- and D-Gal-induced cells, which could be impaired by YQJPF and RIPK1 inhibitor Nec-1 (Figure 8F). Overall, YQJPF could downregulate the expression of RIPK1 and RIPK3, inhibit their aggregation to form necrosome, and eventually reduce

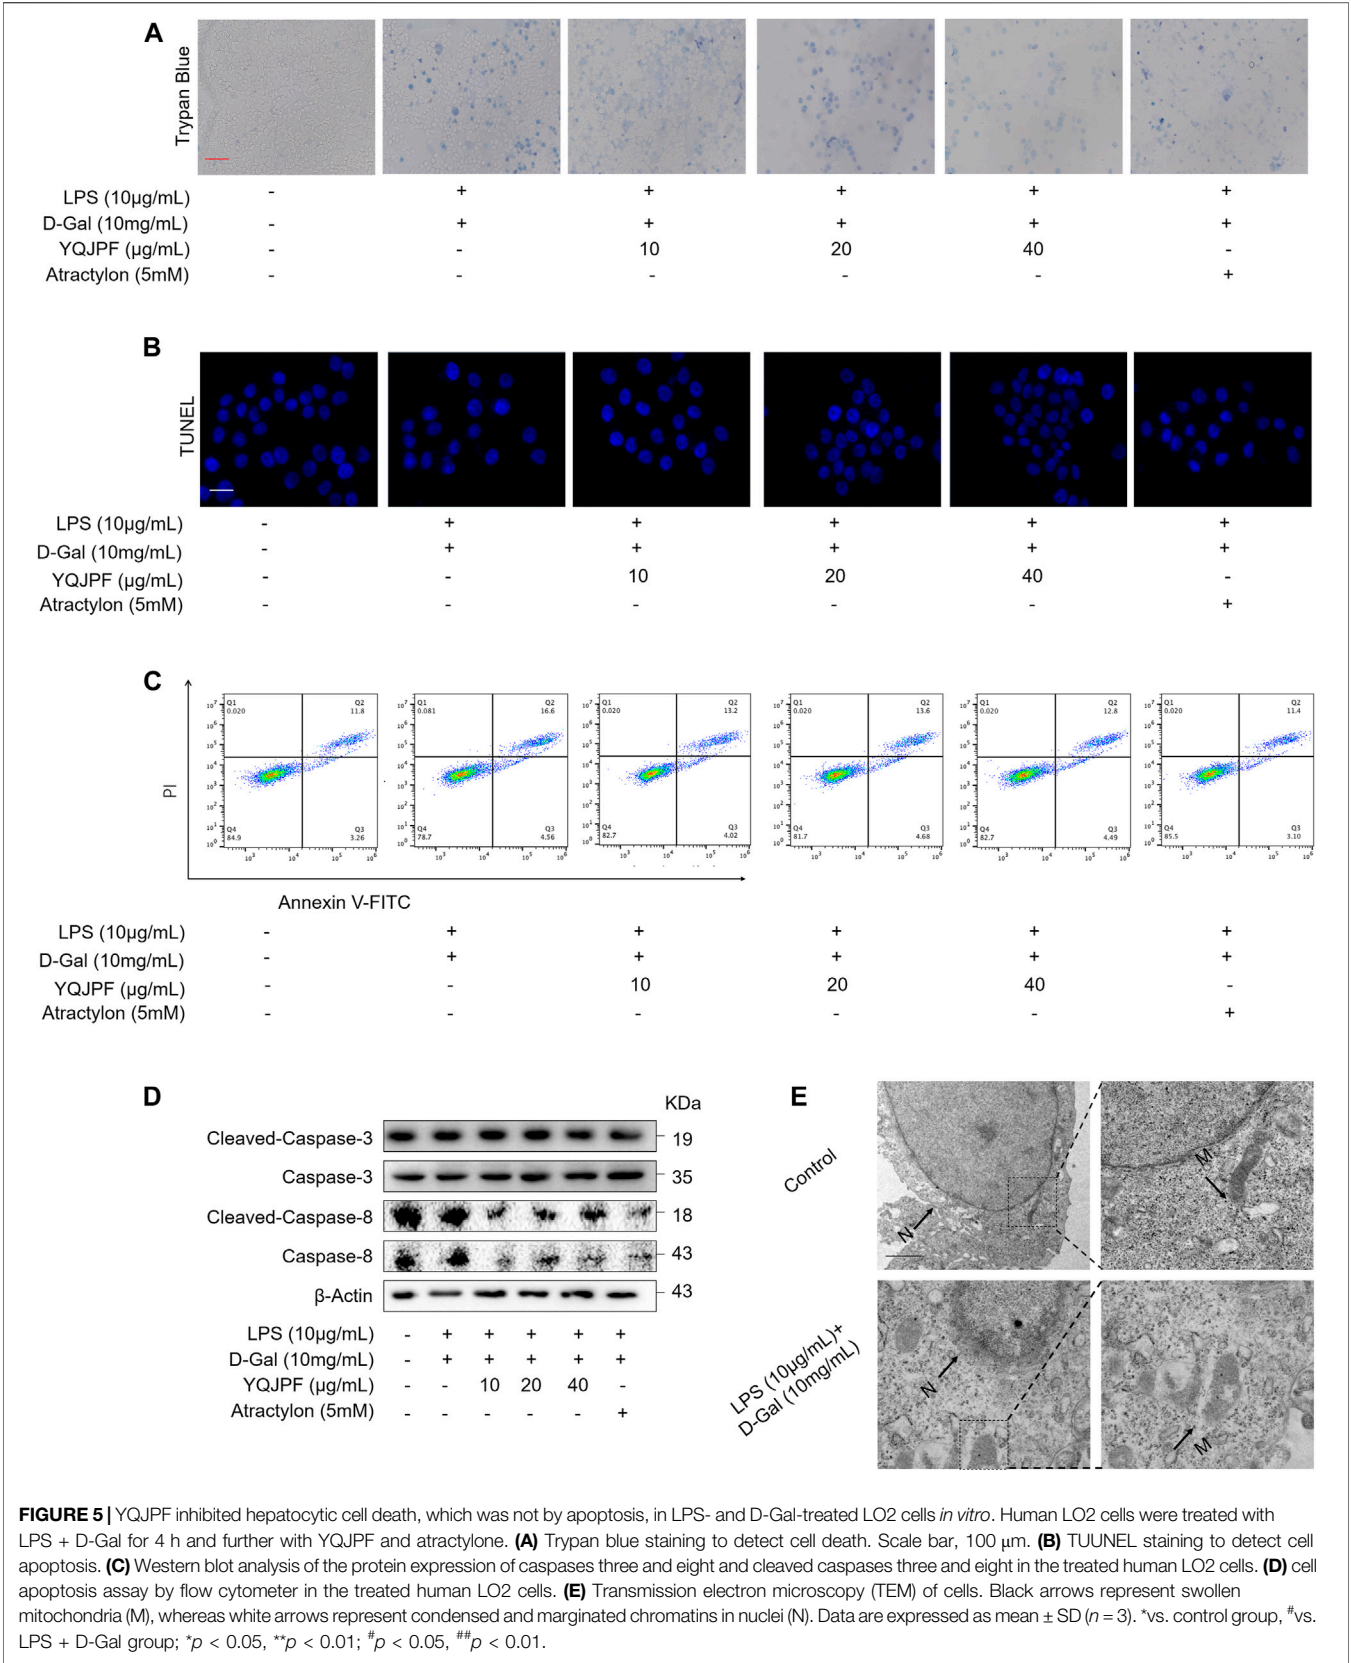

**FIGURE 4 |** Protective effect of YQJPF on LPS- and D-Gal-treated hepatocytes *in vitro*. Human LO2 cells were treated with LPS + D-Gal for 4 h and further treated with YQJPF and atractylone at indicated concentrations. **(A,B)** MTT assay to study LO2 cell viability. **(C)** Cell morphology assessment. Scale bar, 200 μm. **(D-F)** ALT, AST, and LDH levels in LO2 cell culture. Data are expressed as mean ± SD (*n* = 6). \*vs. control group, #vs. LPS + D-Gal group; \**p* < 0.05, \*\**p* < 0.01; #*p* < 0.05, ###*p* < 0.01.

the expression of pro-inflammatory cytokines by inhibiting RIPK1/RIPK3-mediated necroptosis.

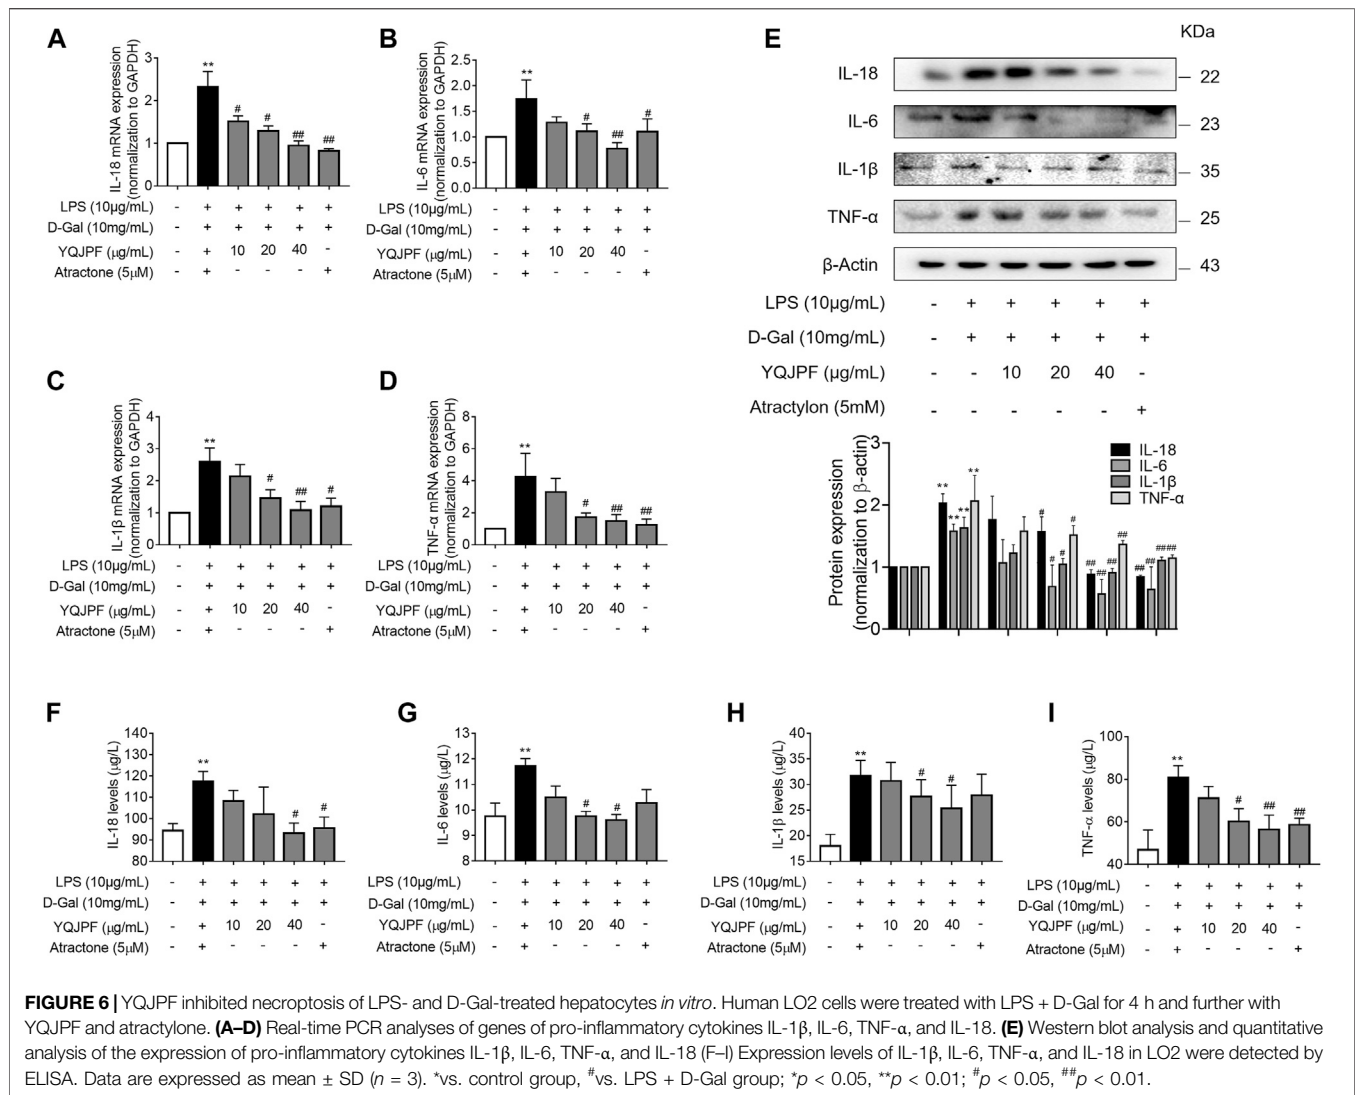

## YQJPF Inhibited Hepatocyte Necroptosis Through Inhibition of Mitochondrial ROS Generation and Depolarization *In Vitro*

Numerous studies have shown that ROS production is necessary for necroptosis in several cell lines such as macrophages (Koike et al., 2019), fibrosarcoma L929, HeLa, and human embryonic kidney (HEK) 293 T (Luedde et al., 2014; Zhang et al., 2017). To investigate whether YQJPF reduces ROS production in hepatocytes, we first analyzed the effect of YQJPF on intracellular ROS levels. Observation using fluorescence microscope revealed that YQJPF treatment decreases the ROS level in LO2 cells (Figures 9B,C). MitoSox Red staining was used

to evaluate the mitochondrial ROS production. As shown in Figure 9A, YQJPF caused a significant decrease in mitochondrial superoxide, which had the same effect as selective RIPK1 inhibitor Nec-1. In addition, we found that pre-treatment of cells with YQJPF or Nec-1 significantly reversed LPS- and D-Gal-induced reduction in intracellular GSH and SOD levels. Additionally, YQJPF or Nec-1 inhibited MDA formation (Figures 9D-F). The effect of YQJPF on MMP was assessed using JC-1 staining, where a high ratio of red/green indicates an increase in MMP. The result indicated that YQJPF or Nec-1 upregulates MMP, recovers LPS- and D-Gal-induced MMP dissipation, and ameliorates mitochondrial depolarization (Figure 9G). The overproduction of ROS triggers serious damages in various cells. We observed that when the cells are pre-treated with ROS scavenger Tempol (10 μM), it could restore necroptosis-associated cell morphology and structure and inhibit

**FIGURE 5 |** YQJPF inhibited hepatocytic cell death, which was not by apoptosis, in LPS- and D-Gal-treated LO2 cells *in vitro*. Human LO2 cells were treated with LPS + D-Gal for 4 h and further with YQJPF and atractylone. **(A)** Trypan blue staining to detect cell death. Scale bar, 100 μm. **(B)** TUNEL staining to detect cell apoptosis. **(C)** Western blot analysis of the protein expression of caspases three and eight and cleaved caspases three and eight in the treated human LO2 cells. **(D)** cell apoptosis assay by flow cytometer in the treated human LO2 cells. **(E)** Transmission electron microscopy (TEM) of cells. Black arrows represent swollen mitochondria (M), whereas white arrows represent condensed and marginated chromatin in nuclei (N). Data are expressed as mean ± SD (n = 3). \*vs. control group, #vs. LPS + D-Gal group; \*p < 0.05, \*\*p < 0.01; #p < 0.05, ##p < 0.01.

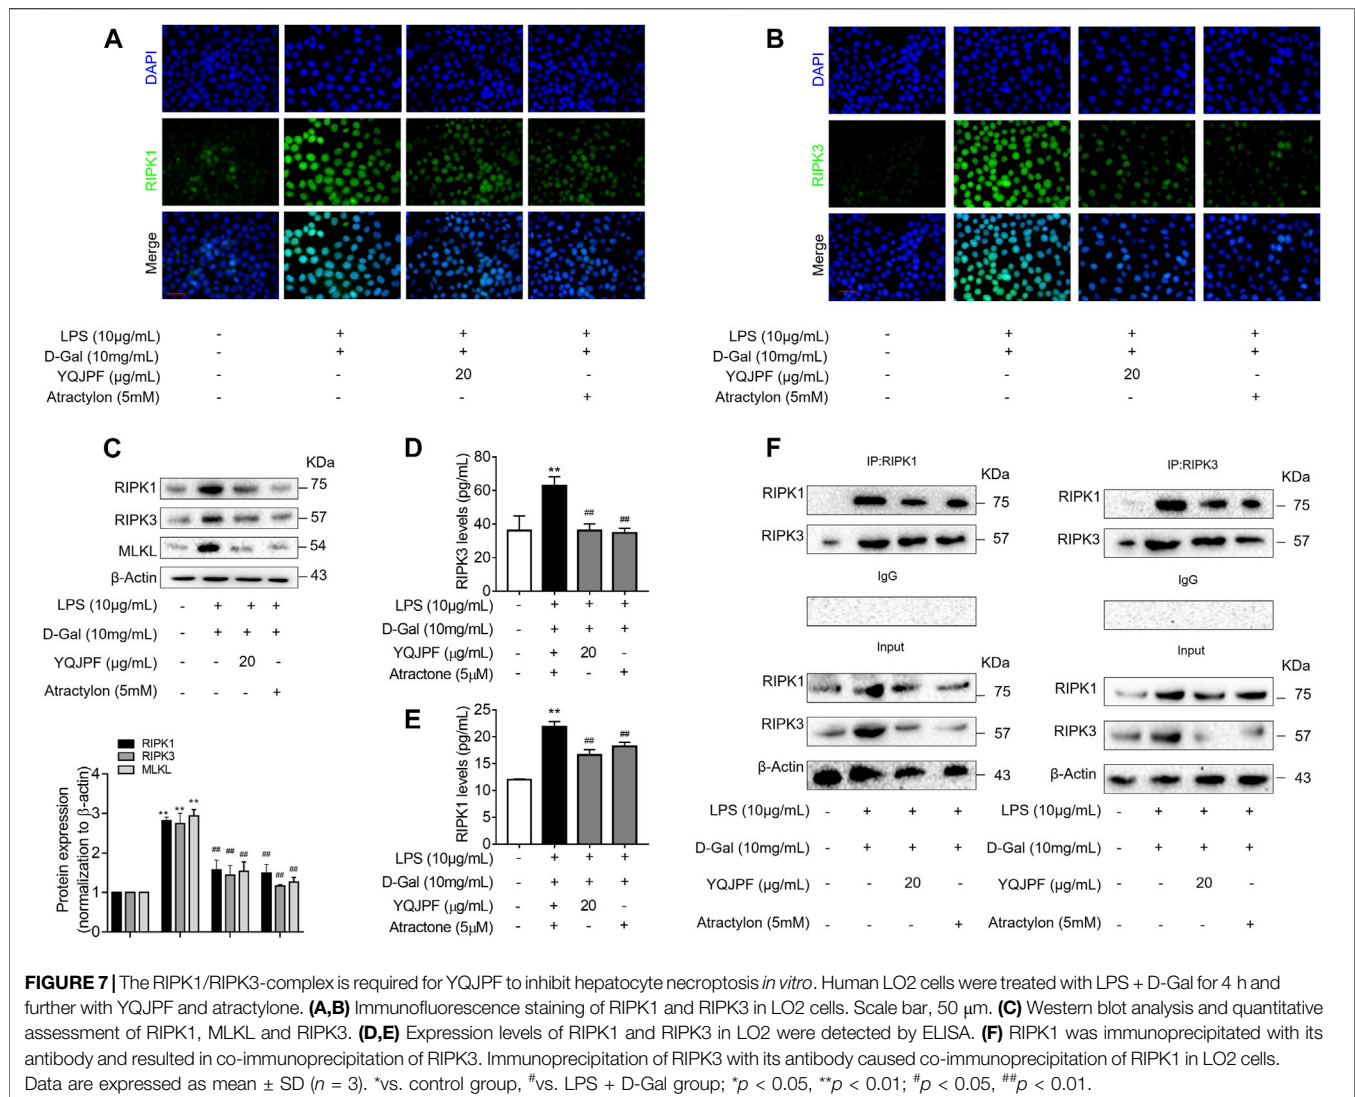

the expression of pro-inflammatory cytokines IL-1 $\beta$ , IL-6, TNF- $\alpha$ , and IL-18, as revealed by western blot (Figure 9H), which had the same effect as that of YQJPF. This suggested that YQJPF reduces the level of ROS in hepatocytes and thus plays a critical role in inhibiting cell death. Collectively, these results suggested that YQJPF inhibits necroptosis by reducing the level of mitochondrial ROS and stabilizing MMP in hepatocytes.

### Disruption of Hepatocyte Necroptosis, Instead of Apoptosis, Was Associated with YQJPF Treatment *In Vivo*

The results of *in vivo* studies on the effect of YQJPF on hepatocyte necroptosis were the same as those of *in vitro* results. Protein levels of key caspases did not change under YQJPF treatment. Therefore, reduction in cell death due to YQJPF was independent of apoptosis. Further, we proceeded to investigate whether YQJPF could disrupt hepatocytic death by regulating necroptosis. Western blot analysis of RIPK1, RIPK3, and MLKL, which

governed necroptosis, indicated that necroptosis is increased in ACLF *in vivo* (Figure 10E). However, it was weakened by YQJPF treatment. Furthermore, immunochemical staining of RIPK1, RIPK3, and MLKL showed that YQJPF reduces hepatocytic RIPK1, RIPK3, and MLKL levels, which were upregulated in chronic liver injury, acute liver injury, and ACLF model (Figure 10F). Overall, these results demonstrated that YQJPF decreases the levels of RIPK1, RIPK3, and MLKL and decreases ATP production to ameliorate hepatocyte necroptosis instead of apoptosis in ACLF model. Our previous study revealed that JNK1/2-ROS signaling is involved in HSC necroptosis (Jia et al., 2018). To investigate the role of anti-oxidant response in YQJPF-ameliorated hepatocyte necroptosis, we analyzed the effect of YQJPF on SOD and MDA levels in the liver, which are produced during lipid peroxidation. Observation using SOD and MDA detection kits showed that YQJPF treatment increases the anti-oxidant response in the liver (Figure 10A). Interestingly, the levels of ATP and mtDNA decreased significantly in chronic liver injury, acute liver injury, and ACLF model (Figure 10B).

Collectively, these results suggest that anti-oxidant response contributes to the effect of YQJPF on hepatocyte necroptosis. Similar to the *in vitro* results, we observed a significant increase in the serum levels of TNF- $\alpha$ , IL-18, IL-1 $\beta$ , and IL-6 in ACLF rats, but the effect was altered in a concentration dependent-manner by YQJPF treatment (Figures 10G–J). These results indicated that YQJPF attenuates hepatic inflammation and liver injury by disrupting hepatocyte necroptosis instead of apoptosis *in vivo*.

## DISCUSSION

The pathobiology of ACLF is characterized by hepatic and systemic inflammation; progressive, unrelenting hepatocyte injury; and hepatocyte death. Hepatocyte death typically follows two patterns: necrosis and apoptosis (Vanlangenakker et al., 2008). In our study, we developed ACLF rat models by administering high dose (1.5 ml/kg body weight) of 1:1 (w/v) mixture of CCl<sub>4</sub> and olive oil for 3 months followed by 100  $\mu$ g/kg

LPS and 400 mg/kg D-Gal injection. Hepatocyte injury and cell death index were obvious in the *in vivo* model. Through the successful establishment of the disease model, we first confirmed the protective effect of YQJPF on ACLF liver injury. YQJPF could ameliorate CCl<sub>4</sub>-, LPS-, and D-Gal-induced liver injury. Liver tissue morphology improved and serum levels of hepatic ALT, AST, and Tbil decreased after YQJPF treatment. The protective effect of YQJPF was consistent in the *in vitro* experiments. To further clarify the mechanism of action of YQJPF, an *in vitro* hepatocyte injury model was established using LPS (10  $\mu$ g/ml) and D-Gal (10 mg/ml). YQJPF and atractylone (the main component of YQJPF) could restore the damage to cell viability induced by LPS and D-Gal and decrease ALT, AST, and LDH levels in cell supernatant. These data clearly indicated that YQJPF confers protection against ACLF.

Liver failure is characterized by massive loss of parenchymal cells, and cell death can occur in this pathophysiological context (Schwabe and Luedde, 2018). Necroptosis is defined as the third type of programmed cell death in addition to apoptosis and

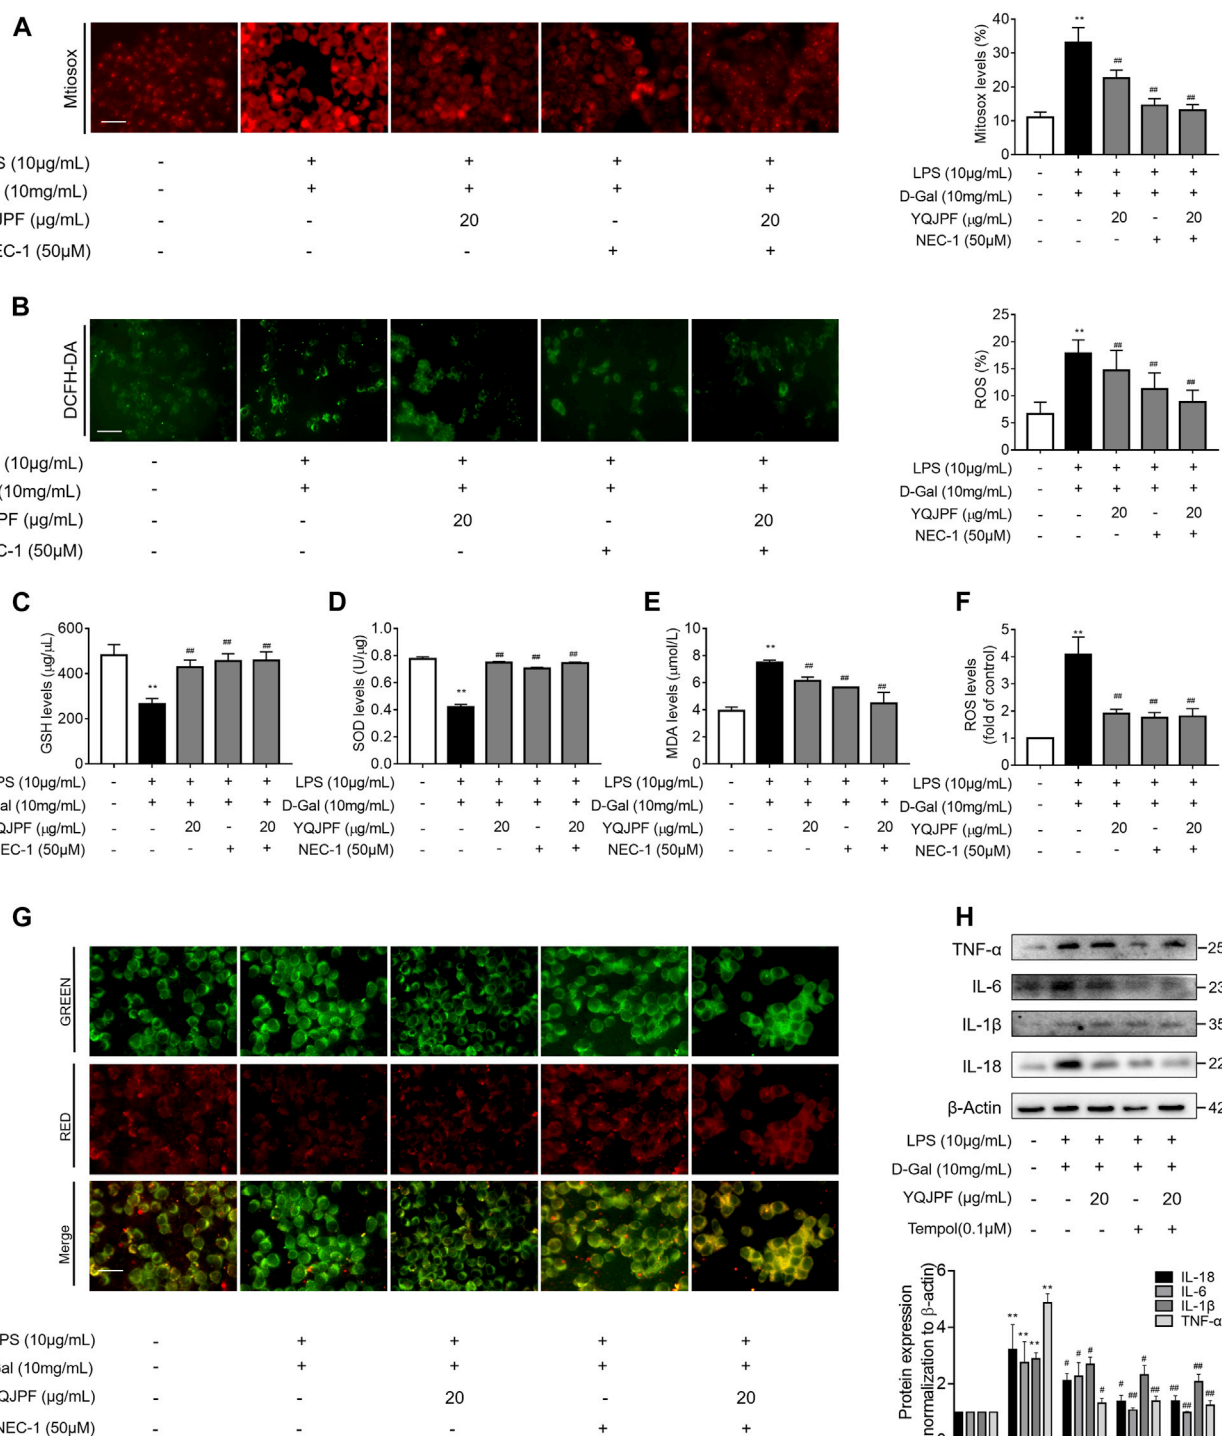

**FIGURE 8** | YQJPF inhibited hepatocyte necroptosis in RIPK1-dependent manner *in vitro*. Human LO2 cells were treated with LPS + D-Gal for 4 h and further pre-treated with 50 μM Nec-1 for 1 h, followed by YQJPF or atractylone treatment for 24 h. **(A–D)** Expression levels of IL-1β, IL-6, TNF-α, and IL-18 in LO2 cells were detected by ELISA. **(E)** Western blot and quantitative analysis of IL-1β, IL-6, TNF-α, and IL-18. **(F)** RIPK1 was immunoprecipitated with its antibody and resulted in co-immunoprecipitation of RIPK3. Immunoprecipitation of RIPK3 with its antibody caused co-immunoprecipitation of RIPK1 in LO2 cells. Data are expressed as mean ± SD (*n* = 3). \*vs. control group, #vs. LPS + D-Gal group; \**p* < 0.05, \*\**p* < 0.01; #*p* < 0.05, ##*p* < 0.01.

necrosis (Galluzzi and Kroemer, 2008). It is also known as programmed necrosis or caspase-independent cell death. Necroptosis is believed to trigger a massive inflammatory response that can cause substantial collateral damage to neighboring cells. Findings of a clinical study indicated that circulating RIPK3 is significantly increased in patients with HBV-ACLF and is associated with a clinical outcome (Chen et al., 2020). However, very few studies on drugs inhibiting necroptosis in the liver are available. This study found that YQJPF could attenuate hepatocyte death but has no effect on the inhibition of the caspases three and eight activity. Therefore, YQJPF-induced hepatocytic cell death inhibition did not result from apoptosis. Moreover, a typical cell necroptosis morphology could be identified, and RIPK3 mediates cell death and regulates inflammatory responses (Zhao et al., 2017). Our study showed that the levels of TNF-α, IL-18, IL-1β, and IL-6 were found to be significantly increased in LPS (10 μg/ml)- and D-Gal (10 mg/ml)-induced models. The effect was altered in a concentration-dependent manner after YQJPF treatment. RIPK1, RIPK3, and MLKL were identified as necroptosis regulators (Wang et al., 2012). Further, we assessed expressions of RIPK1 and RIPK3. Western blot analysis, ELISA, and immunochemical staining of RIPK1 and RIPK3 demonstrated that YQJPF decreases hepatocytes necroptosis in the ACLF model. Moreover, YQJPF inhibited the combination expression of RIPK1 and RIPK3 and blocked the formation of necrosome. As expected, YQJPF-induced inhibition of inflammatory cytokines and necrosome formation were enhanced when RIPK1 activity was inhibited by pharmacological inhibitor

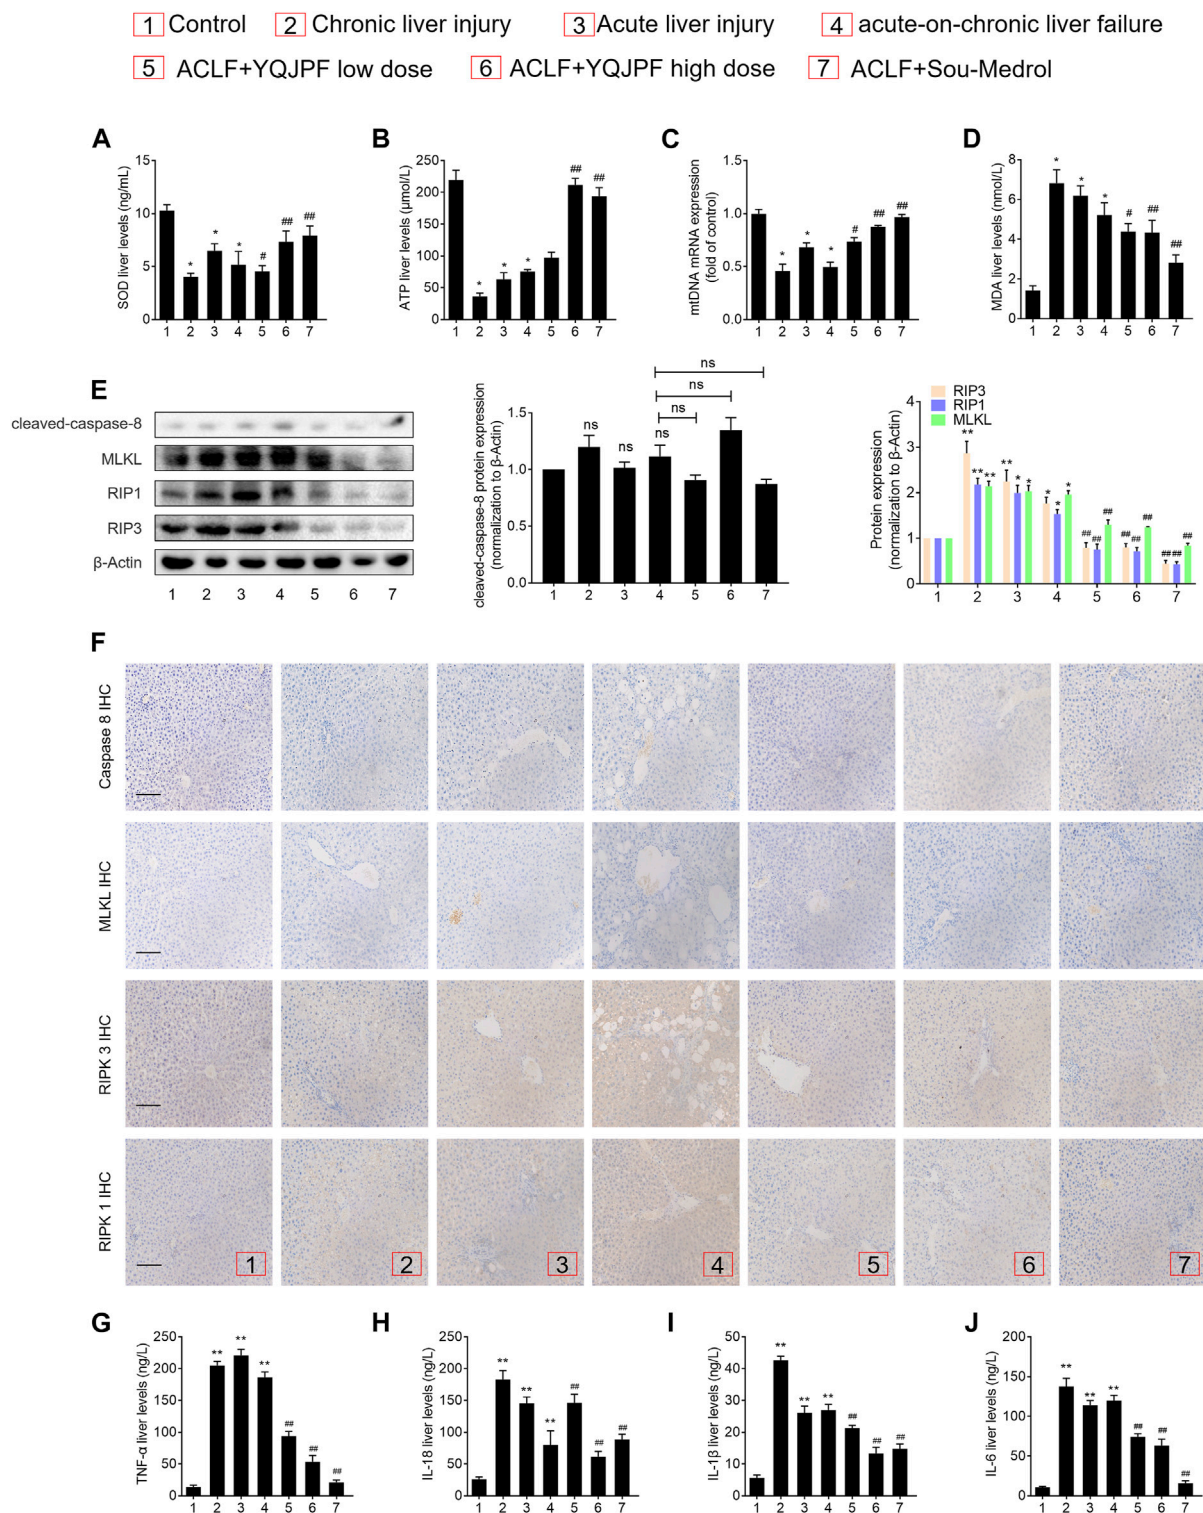

Nec-1. Obviously, YQJPF inhibited RIPK1/RIPK3-complex-dependent necroptosis in human LO2 cells.

Oxidative stress, a major contributor of liver injury, can be induced by excessive ROS. Studies have shown that ROS may be considerably involved in the pathogenesis of liver diseases (Chen et al., 2016). ROS have a significant effect on necroptosis, particularly the mitochondrial ROS generated in response to TNF/TNFR1 engagement. Conversely, ROS accumulation is also gradually regarded as the executioner and mediator of necroptosis (Zhu et al., 2018). ROS is mainly produced in mitochondria that in turn leads to the damage of organelles or even cell death. In this study, we found significantly decreased levels of intracellular and mitochondrial ROS after YQJPF treatment. Following pre-treatment with the ROS scavenger-Tempol, the YQJPF-induced inhibition of cell inflammatory cytokines was significantly enhanced. Thus, YQJPF could inhibit ROS accumulation. The association between RIPK1 and RIPK3 upregulation and mPTP opening has been illustrated in several studies (He et al., 2011). ROS has been reported as the primary factor that activates mPTP opening and has been implicated in the process of necroptosis. In addition, RIPK1-RIPK3 interaction could upregulate ROS levels and enhance mitochondrial superoxide production. Hence, we identified that the inhibition of RIPK1 with Nec-1 markedly enhances YQJPF-induced alteration of mitochondrial superoxide. Cellular anti-oxidant machinery mainly includes SOD, MDA, and GPx that can effectively scavenge free radicals (Riordan and Williams, 2003). In this study, SOD,

**FIGURE 9 |** YQJPF inhibited hepatocyte necroptosis through the inhibition of mitochondrial ROS generation and depolarization *in vitro*. Human LO2 cells were treated with LPS + D-Gal for 4 h and further pre-treated with 50 μM Nec-1 for 1 h, followed by YQJPF or atractylone treatment for 24 h. **(A)** Mitochondrial superoxide was detected and quantified through immunofluorescence by using MitoSox Red staining. Scale bar, 50 μm. **(B)** ROS production was assessed and quantified by DCFH-DA staining, Scale bar, 50 μm. **(C–E)** MDA, SOD, and GSH levels were measured by corresponding test kits. **(F)** ROS levels were assessed using ROS test kit. **(G)** Mitochondrial membrane potential was detected by JC-1 staining. Scale bar, 50 μm. **(H)** Western blot and quantitative analysis of the expression of IL-1β, IL-6, TNF-α, and IL-18. Data are expressed as mean ± SD (*n* = 3). \*vs. control group, #vs. LPS + D-Gal group; \**p* < 0.05, \*\**p* < 0.01; #*p* < 0.05, ##*p* < 0.01.

**FIGURE 10 |** Disruption of hepatocyte necroptosis, and not apoptosis, was required for the action of YQJPF *in vivo*. **(A–D)** MDA, ATP, GSH, and SOD levels in the rat livers were measured. **(E)** Western blot and quantitative analysis of cleaved caspase 8, MLKL, RIP1, and RIP3 expression in the rat livers. **(F)** Immunohistochemical staining and quantitative analysis of caspase 8, MLKL, RIPK1, and RIPK3 expression in liver tissues. Scale bar, 100 μm. **(G–J)** Expression levels of IL-1β, IL-6, TNF-α, and IL-18 in the rat livers were detected by ELISA. Data are expressed as mean ± SD (*n* = 8) \**p* vs. control group, #*p* vs. ACLF group; \**p* < 0.05, \*\**p* < 0.01; #*p* < 0.05, ##*p* < 0.01.

GSH, and MDA levels were assessed, and the results suggested that the anti-oxidant response contributes to the effect of YQJPF on hepatocyte necroptosis. Inhibition of RIPK1 by Nec-1 enhanced the effect. Additionally, these findings were confirmed in the rat models.

Traditional Chinese medicine (TCM) pattern is a physiological regulation network, which contains a regulation center, overall effective target, material basis and functional unit. Its mechanism needs to be indicated by means of TCM pattern prevention and treatment characteristics, multiple organ integration effectiveness, and functional unit network so as to guide clinical practice as well as for inspiring basic research. It is urgently to exploring the efficacy mechanism and regulation with the molecular biology and systems biology. In our research, we conducted a deep study of the pathogenesis, TCM pattern feature and efficacy evaluation of TCM in ACLF. And results showed that YQJPF attenuates liver injury in ACLF. Recently, Chen et al.' reported that flavonoids have been to possess a wide variety of biological activities such as antioxidant activity, anti-inflammatory activity, hepatoprotective effect, antibacterial activity, antiviral activity, anticancer activity, and antidiabetic activity (Chen et al., 2018). Chen et al.' reported that raspberry treatment could ameliorate H<sub>2</sub>O<sub>2</sub>-induced oxidative stress in HepG2 cells *via* Keap1/Nrf2 pathway (Chen et al., 2019). In our study, we found that atracylone (one component of YQJPF) has the similar effect with YQJPF, and inhibited necroptosis of hepatocytes *in vitro*. Which revealed the main component of YQJPF could play such effect.

In summary, YQJPF attenuates liver injury by inhibiting hepatic inflammation and necroptosis of hepatocytes *in vivo* and *in vitro*. Mechanistically, YQJPF inhibits hepatocyte necroptosis by blocking the RIPK1/RIPK3 complex formation followed by relieving mitochondrial dysfunction, which ultimately prevents hepatocytic cell death. Most importantly, we confirmed that YQJPF can be used as a medicine for ACLF treatment and provided a scientific basis for the research on the application of YQJPF in ACLF.

Licorice (*Glycyrrhiza* spp.).  
Front. Pharmacol. 12:590477.  
doi: 10.3389/fphar.2021.590477

Licorice (*Glycyrrhiza* spp.) is used widely in traditional Chinese medicine (TCM) due to its numerous pharmacologic effects. However, the mechanisms of action of the chemical constituents of licorice and their structure–function relationships are not fully understood. To address these points, we analyzed the chemical compounds in licorice listed in the TCM Systems Pharmacology database and TCM Integrated database. Target proteins of the compounds were predicted using Integrative Pharmacology-based Research Platform of TCM v2.0. Information on the pharmacologic effects of licorice was obtained from the 2020 *Chinese Pharmacopoeia*, and disease-related genes that have been linked to these effects were identified from the Encyclopedia of TCM database. Pathway analyses using the Kyoto Encyclopedia of Genes and Genomes database were carried out for target proteins, and pharmacologic networks were constructed based on drug target–disease-related gene and protein–protein interactions. A total of 451 compounds were analyzed, of which 211 were from the medicinal parts of the licorice plant. The 241 putative targets of 106 bioactive compounds in licorice comprised 52 flavonoids, 47 triterpenoids, and seven coumarins. Four distinct pharmacologic effects of licorice were defined: 61 major hubs were the putative targets of 23 compounds in heat-clearing and detoxifying effects; 68 were targets of six compounds in spleen-invigorating and qi-replenishing effects; 28 were targets of six compounds in phlegm-expulsion and cough-suppressant effects; 25 compounds were targets of six compounds in spasm-relieving and analgesic effects. The major bioactive compounds of licorice were identified by ultra-high-performance liquid chromatography–quadrupole time-of-flight–tandem mass spectrometry. The anti-inflammatory properties of liquiritin apioside, liquiritigenin, glycyrrhizic acid and isoliquiritin apioside were demonstrated by enzyme-linked immunosorbent assay (ELISA) and Western blot analysis. Liquiritin apioside, liquiritigenin, isoliquiritin, isoliquiritin apioside, kaempferol, and kumatakenin were the main active flavonoids, and 18 $\alpha$ - and 18 $\beta$ -glycyrrhetinic acid were the main active triterpenoids of licorice. The former were associated with heat-clearing and detoxifying effects, whereas the latter were implicated in the other three pharmacologic effects. Thus, the compounds in licorice have

distinct pharmacologic effects according to their chemical structure. These results provide a reference for investigating the potential of licorice in treatment of various diseases.

**Keywords:** licorice, flavonoid, triterpenoid, pharmacologic effects, network pharmacology

## INTRODUCTION

Licorice (referred to in Chinese as “GanCao”) is a food and dietary supplement that has been used widely in traditional Chinese medicine (TCM) for ~4,000 years. According to the 2020 *Chinese Pharmacopoeia*, licorice refers to the dried root and rhizome of *Glycyrrhiza uralensis* Fisch. ex DC., *G. inflata* Bat., or *G. glabra* L.

As indicated in *Shennong’s Materia Medica Classic* (Shennong Bencao Jing), licorice is used predominantly to treat spleen dysfunction, stomach weakness, fatigue, lack of strength, palpitation, dyspnea, cough, profuse sputum, acute pain in the abdominal cavity, limb contracture, carbuncles, and sores, as well as to alleviate drug toxicity (Chinese Pharmacopoeia Commission, 2020). Because of its ability to “harmonize” the effects of different medicines, licorice is an ingredient in nine out of 10 herbal formulations.

The genus *Glycyrrhiza* comprises ~30 species that are native to Eurasia and which have been cultivated in Europe (e.g., Spain, Italy, France), the Middle East (e.g., Syria, Iran, Turkey, Iraq) and Asia (e.g., China) (Chen J. et al., 2019). Eight species in the Leguminosae family are found in China: *G. uralensis* Fisch. ex DC.; *G. inflata* Bat.; *G. glabra* L.; *G. eurycarpa* P.C.Li; *G. aspera* Pall.; *G. yunnanensis* P.C.Li; *G. pallidiflora* Maxim.; *G. squamulosa* Franch. (Zeng et al., 1991; Karami et al., 2015). These species have various chemical constituents, such as flavonoids, triterpenoids, coumarins, and stilbenoids (Zhang and Ye, 2009; Cheng et al., 2012; Qiao et al., 2015).

There have been several reports on the pharmacologic effects and bioactive constituents of licorice, which are mainly flavonoids and triterpenoids (Wang et al., 2020). *In vivo* and *in vitro* experiments have shown that these classes of compound have anti-inflammatory, antimicrobial, antiviral, antioxidant, and antitumor effects. Recent studies have focused on the pathways regulating the pharmacologic effects of the metabolites of flavonoids and triterpenoids in licorice (Hosseinzadeh and Nassiri-Asl, 2015). However, given the diversity and complexity of the bioactive compounds in licorice, high-throughput and network-based approaches are needed to fully elucidate their pharmacologic properties and mechanisms of action.

Network pharmacology is an emerging discipline based on systems biology, analysis of biological networks, and identification of specific network nodes as targets in drug design (Hopkins, 2007; Li and Zhang, 2013). In general, treatment of diseases using TCM is based on integrative and holistic principles as well as the synergistic effects of multiple compounds and herbal formulations (Zhang et al., 2013). Network pharmacology adopts a similar holistic approach in a paradigm shift from “one target, one drug” to “network target, multi-compound” therapeutics (Li et al., 2014). Thus, network pharmacology is used widely to investigate the molecular

mechanisms underlying the pharmacologic effects of TCM formulations (Li H. et al., 2014; Xiong et al., 2018; Piao et al., 2019); appropriate TCM prescriptions for the treatment of specific diseases (Li et al., 2007; Li X. et al., 2014; Shi et al., 2014; Ke et al., 2016; Fang et al., 2017a, 2017b; Hu and Sun, 2017; Dai et al., 2018; Shi et al., 2019); bioactive components of medicines (Lv et al., 2014; Zhang Y.-F. et al., 2019; Ma et al., 2019; Song et al., 2019; Guo et al., 2020).

Network pharmacology has been applied to studies on the mechanisms of action of TCM formulations containing licorice such as Sini, Shaoyao-Gancao, Guizhi-Shaoyao-Zhimu, Yinchensini, and Maxing-Ganshi decoctions, among others (Chen S. et al., 2014; Chen G. et al., 2018; Song et al., 2018; Zhang Q. et al., 2019; Zhu et al., 2019) as well as analyses of licorice constituents and their functions (Liu et al., 2013; Chen M. et al., 2019). The molecular mechanisms of licorice components in the context of diseases have also been studied (Li Y. et al., 2019). Those reports focused on compounds present in the overground and underground parts of the plant, which differ considerably (Wang, 2004; Zhou, 2015; Ran, 2019). The medicinal properties of licorice are associated mainly with the underground parts (roots and rhizomes).

Here, we classified the different types of bioactive compounds in the underground parts of the licorice plant. We also analyzed the mechanisms of action underlying the pharmacologic effects of licorice.

## MATERIALS AND METHODS

### Chemicals, Reagents, and Materials

Ultra-high-performance liquid chromatography–mass spectrometry (UHPLC–MS)–grade acetonitrile and formic acid were supplied by Fisher Scientific (Fairlawn, NJ, United States). Ultrapure water (18.2M $\Omega$ ) was prepared with a Milli-Q™ water-purification system (Millipore, Milford, MA, United States). All other reagents were of analytical grade and purchased from Sinopharm Chemical Reagents (Shanghai, China).

The reference compounds schaftoside (number 1; lot number, 111,912–201703; purity, 95.60%), calycosin 7-O- $\beta$ -D-glucopyranoside (4; 111,920–201907; 96.80%), liquiritin (5; 111,610–201908; 95.00%), kaempferol (15; 110,861–202013; 93.20%), formononetin (17; 111,703–201504) and glycyrrhizic acid monoammonium salt (18; 110,731–202021; 96.20%) were supplied by National Institutes for Food and Drug Control (NIFDC; Beijing, China).

The reference compounds neoliquiritin (2; PRF20060,941; 97.88%), liquiritinapioside (3; PRF9050224; 99.95%), isoliquiritin apioside (6; PRF9101021; 97.04%), isoliquiritin (7; PRF20040,923; 98.23%), ononin (8; PRF20060,944; 99.58%), neoisoliquiritin (9; PRF20060,942; 99.25%), licochalcone B (10; PRF8031021; 99.10%), liquiritigenin (11; PRF20042,742;

99.50%), calycosin (12; PRF10072945; 99.70%), naringenin (13; PRF10030641; 99.67%), echinatin (14; PRF10122621; 99.81%), isoliquiritigenin (16; PRF20060,943; 99.87%), licoflavone A (19; PRF8050422; 99.94%), glycycomarin (20; PRF20060,921; 99.77%), kumatakenin (21; PRF10120925; 99.28%), licochalcone A (25; PRF8041841; 98.65%), 18 $\alpha$ -Glycyrrhetic acid (29; PRF10101201; 99.02%) and 18 $\beta$ -Glycyrrhetic acid (30; PRF9100841; 99.46%) were purchased from Chengdu BiopurifyPhytochemicals (Chengdu, China).

The reference compounds licoisoflavone A (23; PS010124; 98.46%), glycyrol (26; PS010089; 98.71%) and licoisoflavone B (28; PS200618–01; 98.02%) were obtained from Chengdu Push Biotech (Chengdu, China).

The reference compound licoflavonol (27; MUST-20041,311; 98.86%) was purchased from Chengdu Must Biotechnology (Chengdu, China). The reference compound licoricone (24; 200313G; 99.46%) was obtained from Nanjing Dasf Biotechnology (Nanjing, China). The reference compound licoflavone C (22; P29A9F68905; 99.30%) was purchased from Shanghai Yuanye Biotechnology (Shanghai, China).

Licorice materials were obtained from Elion Resources Group (Inner Mongolia, China) and Gansu JinYoukang Pharmaceutical Technology (Gansu, China). Licorice materials were authenticated as the dried roots of *Glycyrrhiza uralensis* Fisch. ex DC. by Professor Nanping Zhang (NIFDC, Beijing, China). The voucher numbers of licorice from Inner Mongolia were N2-4-1 to N2-4-10, and from Gansu were G1-5-1 to G1-5-10. Voucher specimens were deposited in the Museum of Chinese Traditional Drugs within the NIFDC (Li X. et al., 2019).

## Preparation of Standard and Sample Solutions

Thirty reference compounds were prepared by completely dissolution in 70% methanol and their concentration (in mg/mL) was (compound 1) 0.266; 2) 0.187; 3) 0.178; 4) 0.416; 5) 0.258; 6) 0.186; 7) 0.269; 8) 0.299; 9) 0.166 (10) 0.155 11) 0.277 12) 0.189 13) 0.279 14) 0.222 15) 0.257 16) 0.214 17) 0.431 18) 0.227 19) 0.144 (20) 0.124 21) 0.144 22) 0.233 23) 0.263 24) 0.164 25) 0.221 26) 0.230 27) 0.186 28) 0.164 29) 0.172 (30) 0.337. All solutions were stored at 4°C before analyses.

All samples were pulverized and screened through the 50-mesh sieve. The dried powder (0.5g) was weighed accurately into a 100-ml conical flask with a stopper, and extracted by ultrasonication in 50ml of methanol (70%) for 0.5h. The mixture was centrifuged at 12,000rpm for 10min at room temperature. Finally, the supernatant was filtered through 0.22- $\mu$ m membrane before injection into aUHPLC–MS/MS system.

## Ultra-High-Performance Liquid Chromatography–Quadrupole Time-of-Flight–Tandem Mass spectrometry(UHPLC–QTOF–MS/MS)

Chromatography was undertaken using an Acquity UHPLC HSS T3 C18 column (2.1mm i. d.  $\times$  100mm, 1.8 $\mu$ m) within an Acquity

UHPLC system (Waters, Milford, MA, United States). The column temperature was maintained at 35°C. The mobile phase (at a flow rate of 0.4ml/min) consisted of solvent A (0.1%formic acid/water) and solvent B (acetonitrile). The conditions of gradient elution were optimized as: 5% B (0–1min), 5–18% B (1–3min), 18–30% B (3–13min), 30–45% B (13–18min), 45–50% B (18–21min), 50–75% B (21–29min), 75–95% B (29–31min), 95–5% B (31–31.5min) and held at 5% B for 3.5min to equilibrate the column. The injection volume was 2 $\mu$ L.

A Synapt<sup>TM</sup> G2-S QTOF mass spectrometer (Waters MS Technologies, Manchester, UK) was combined with the UHPLC system via the electrospray-ionization source in positive-ion mode. The desolvation-gas rate was set as 600L/h at 500°C. The source temperature was set as 120°C. The capillary voltage was 3 kV and the sample cone voltage was set at 30V. Centroided data were acquired from 50 to 1,000Da. Mass data were acquired using LockSpray<sup>TM</sup> to ensure the mass was recorded accurately. Leucine-enkephalin at a charge/mass ratio ( $m/z$ ) 556.2771 was selected as the lock-mass in positive mode. The accurate mass and composition of precursor ions and fragment ions were calculated using MassLynx V4.1 (Waters), that incorporated with the instrument solution for the acquisition of accurate mass.

## Preparation of Bioactive Compounds

Four reference bioactive compounds, liquiritin apioside, liquiritigenin, glycyrrhizic acid and isoliquiritin apioside were prepared by completely dissolution in 0.1% DMSO/water and their concentration were 2mg/ml. The dried licorice extract powder (1.0g) was weighed accurately into a 100-ml conical flask with a stopper, and completely dissolved in 50ml of ultrapure water. All solutions were stored at –20°C before analyses.

## Cell Culture and Treatments

Murine macrophage RAW264.7 cells, a widely used *in vitro* model for studies of macrophage and inflammatory cascades, were obtained from the China National Collection of Authenticated Cell Cultures (Shanghai, China). Cells were maintained at 37°C under 5% CO<sub>2</sub> in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum. RAW264.7 cells were treated with 1 $\mu$ g/ml lipopolysaccharide (LPS; Sigma-Aldrich; Merck KGaA, Darmstadt, Germany) for 24h at 37°C. The cells were rinsed with phosphate buffer saline (PBS) and stimulated with LPS (1 $\mu$ g/ml) to induce pyroptosis. Conditioned cells were collected for measurement of protein expression levels by ELISA and western blot analysis.

## ELISA Assay for Cytokines

Interleukin (IL)-1 $\beta$  and tumor necrosis factor (TNF)- $\alpha$  expression levels in the supernatant of treated cells were measured by ELISA assays (IL-1 $\beta$ : Mouse: ml063132-C; TNF- $\alpha$ : Mouse: ml002095-C; Enzyme-linked Biotechnology Co., Ltd., Shanghai, China) according to the manufacturer's instructions.

## Western Blot Analysis

The protein expression in RAW264.7 cells were detected by Western blot. Cells ( $1.6 \times 10^5$  cells/well) were plated overnight and then treated with the indicated concentrations of bioactive compounds. After 1h, 1 $\mu$ g/ml LPS were added. Then, the supernatant and precipitation of cells were collected 24h later. Immunoblotting was performed using antibodies against the target proteins, including AKT1 (1:2,500; ab89402; Abcam, Cambridge, MA, United States), p-AKT1 (1:5,000; ab81283; Abcam, Cambridge, MA, United States), PI3K (1:1,000; 4,249; Cell Signaling Technology, Inc., Danvers, MA, United States), p-PI3K (1:1,000; bs-3332R; Bioss Antibodies, Biotechnology, Inc., Beijing, China), NF $\kappa$ B-p65 (1:1,000; sc-8008; Santa Cruz Biotechnology, Inc., Dallas, TX, United States), p-NF $\kappa$ B-p65 (1:1,000; YP0191; Immuno Way, Biotechnology, Inc., Plano, TX, United States). The blots were developed with an enhanced chemiluminescence kit (ECL, Amersham Biosciences, Buckinghamshire, United Kingdom) and measured by using a luminescent image analyzer (LAS-3000, Fuji Photo Film Co. Ltd., Japan).

## Statistical Analyses

All experimental values were presented as the mean  $\pm$  standard error of the mean. Statistical comparison between two groups was performed by Student's *t*-test, and one-way analysis of variance followed by Bonferroni *post hoc* analyses was performed among multiple groups for parametric data. *P* < 0.05 was considered to indicate a statistically significant difference.

## Chemical Compounds in Licorice

Candidate chemical compounds in licorice were searched in two phyto chemical databases: Traditional Chinese Medicine Systems Pharmacology (TCMSP; <http://tcmspw.com/tcmsp.php>) (Ru et al., 2014) and Traditional Chinese Medicines Integrated database (TCMID; [www.megabionet.org/tcmid/](http://www.megabionet.org/tcmid/)). Components of the underground parts of the licorice plant were screened from candidate compounds by reviewing the literature. National Center for Biotechnology Information (NCBI) PubMed (<https://pubmed.ncbi.nlm.nih.gov/>) and China National Knowledge Infrastructure (CNKI; [www.cnki.net/](http://www.cnki.net/)) databases were used to find the underground parts of licorice. In the PubMed database, "licorice chemical composition" were used as keywords to search for studies from 2000 to 2020. In the CNKI database, we searched for doctor altheses from 2000 to 2020 under the keyword of "licorice". Two-dimensional (2D) chemical structures were obtained from NCBI PubChem (<https://pubchem.ncbi.nlm.nih.gov/>) and SciFinder Scholar (<https://scifinder.cas.org/scifinder/>) databases. If a structure could not be retrieved from these databases, the original research article describing the identification or purification of the compound was searched for. ChemBioDraw Ultra v12.0 (PerkinElmer, Waltham, MA, United States) was used to draw structures, which were saved in sdf or mol2 formats (Xiong et al., 2019).

## Putative Targets of Bioactive Compounds in Licorice

The sdf or mol2 files were uploaded to Integrative Pharmacology-based Research Platform of Traditional Chinese Medicine

(TCMIP) v2.0 ([www.tcmip.cn/](http://www.tcmip.cn/)). The putative targets of the compounds in licorice were predicted using the drug target-prediction tool of TCMIP. We selected only pairs of compound-putative targets in which the structural similarity score of the compound to known drugs was >0.80 (moderate-high similarity). Detailed information on putative targets are shown in **Supplementary Table S1**.

## Disease-Related Genes Associated with Thepharmacologic Effects of Licorice

Disease-related genes associated with the pharmacologic effects of licorice were identified from the Encyclopedia of Traditional Chinese Medicine database ([www.nrc.ac.cn:9090/ETCM](http://www.nrc.ac.cn:9090/ETCM)) (Xu et al., 2019). The genes related to "immune inflammation" imbalance and some psychiatric symptoms were obtained as disease/symptom gene sets corresponding to heat-clearing and detoxifying effects. The genes related to anemia, low resistance, mental disorders, organ dysplasia, reproductive capacity and other symptoms were obtained as disease/symptom gene sets corresponding to spleen-invigorating and qi-replenishing effects. The genes related to the throat, trachea, bronchus, inflammation, lung disease, asthma and other symptoms were obtained as disease/symptom gene sets corresponding to phlegm-expulsion and cough-suppressant effects. The genes related to the chest, abdomen, limb-spasm pain and neurological diseases were obtained as the disease/symptom gene sets corresponding to spasm-relieving and analgesic effects.

## Network of Interactions Between Drug Targets and Disease-Related Genes

Networks of interactions between drug targets and disease-related genes were constructed based on the relationships between the putative targets of compounds in licorice and disease-related genes associated with the pharmacologic effects of licorice. Construction and analyses of such networks were carried out with TCMIP v2.0 ([www.tcmip.cn/](http://www.tcmip.cn/)). Visualization of such networks was done using Navigator v2.2.1 (Krembil Research Institute, Toronto, ON, Canada). Hubs with a degree greater than two fold the median value of all node degrees were screened, and a network was constructed based on direct interactions between hubs. Three topologic properties of the hub network (degree, betweenness, and closeness) were calculated to identify targets of topologic importance. Major hubs were identified as those with network topology values that were higher than the corresponding median values.

## Analyses of Pathway Enrichment

Pathway-enrichment analyses were done using database Visualization and Integrated Discovery v6.7 (<http://david.abcc.ncifcrf.gov/home.jsp>) based on pathway data obtained from the Kyoto Encyclopedia of Genes and Genomes (KEGG) database ([www.genome.jp/kegg](http://www.genome.jp/kegg); updated on 18 November 2016) (Kanehisa and Goto, 2000; Dennis et al., 2003). Only functional annotations with enrichment *P*-values corrected

with Bonferroni and Benjamini algorithms ( $p < 0.05$ ) were selected for further analyses.

## RESULTS AND DISCUSSION

### Analyses of Licorice Composition and Compound Screening

A total of 451 compounds were screened from TCMSP and TCMID (Supplementary Table S2). Of these, 211 were identified by literature review as compounds present in the medicinal portion of the licorice plant: 134 flavonoids, 49 triterpenoids, 18 coumarins, and 10 stilbenoids (Supplementary Table S3). Most network-pharmacology studies on licorice have used a single database to identify its chemical constituents. We compared compounds in TCMSP and TCMID, which are used widely in TCM research and provide the names and 2D structures of compounds. We found that some were common to both databases whereas others were unique. Some compounds were duplicated in the same database. We obtained 604 compounds from the initial search (280 from TCMSP and 324 from TCMID). We found that 26 compounds were duplicated in TCMID and, therefore, there were actually 298 chemical compounds; 127 were common to both TCMSP and TCMID. Compared with earlier network-pharmacology studies of licorice, our screen of the chemical constituents of licorice was more comprehensive and allowed more accurate prediction of molecular mechanisms. The compounds were grouped according to their 2D structure for further analyses of the relationship between the type of compound and pharmacologic effects of licorice.

### Putative Targets of Compounds in Licorice

Based on their structural similarity to known chemical compounds, 241 putative targets were identified for 106 chemical compounds in licorice: 52 targeted by flavonoids, 47 by triterpenoids, and seven by coumarins. Detailed information on the bioavailability of these chemical compounds is provided in Supplementary Table S4 (Ru et al., 2014; Daina et al., 2017; Xu et al., 2019). Enrichment analyses based on the biological pathways in the KEGG database revealed that the putative targets were mainly involved in neuromodulation [neuroactive ligand–receptor interactions ( $P = 3.90 \times 10^{-10}$ ), long-term potentiation ( $P = 0.001$ ), and gap junctions ( $P = 0.03$ )], energy production and metabolic pathways (nitrogen metabolism ( $P = 7.84 \times 10^{-10}$ ), linoleic-acid metabolism ( $P = 1.30 \times 10^{-7}$ ) and oxidative phosphorylation ( $P = 9.47 \times 10^{-4}$ ) and inflammation/immune-system regulation (Fc epsilon RI ( $P = 0.01$ ), toll-like receptor (TLR;  $P = 0.01$ ) and nucleotide-binding and oligomerization domain-like receptor (NLR;  $P = 0.02$ ) signaling pathways.

### Pharmacologic Mechanisms of Compounds in Licorice

#### Pharmacologic Mechanisms of Heat-Clearing and Detoxifying Effects

Of the 241 putative targets, 37 were disease-related genes involved in the heat-clearing and detoxifying effects of licorice. The

network of interactions of drug target–disease-related genes contained 985 nodes and 3,974 interactions. A total of 299 major hubs were identified based on the values of three topologic features of the network (node degree, betweenness, and closeness). Of these, 61 hubs were the putative targets of 23 chemical compounds in licorice: echinatin, glabrolide, glycycomarin, glycyrol, glycyrrhizic acid, isoliquiritin, kumatakenin, licoaryl coumarin, licochalcone B, licoricesaponin A3, licoricesaponin B2, licoricesaponin C2, licoricesaponin D3, licoricesaponin E2, licoricesaponin F3, licoricesaponin G2, licoricesaponin J2, licoricesaponin K2, liquiritigenin, liquiritin, methyl glycyrrhetate, neoisoliquiritin, and ononin.

To investigate the mechanisms underlying the heat-clearing and detoxifying effects of licorice, a network was constructed based on direct interactions between major hubs that was divided into four functional modules.

The first nodule was regulation of the balance between inflammation and the immune system. This comprised the genes involved in nuclear factor-kappa B (NF- $\kappa$ B) (Zhang et al., 2015), tumor necrosis factor (TNF) (Graßmann et al., 2017), TLR (Belforte et al., 2013), and NLR signaling pathways (Luan et al., 2018), as well as inflammatory regulation of transient receptor potential (TRP) channels (Sahoo et al., 2019).

The second nodule was modulation of the nervous system. This comprised the genes involved in retrograde endocannabinoid signaling (Musella et al., 2017), neuroactive ligand–receptor interactions (Schüle et al., 2014),  $\gamma$ -aminobutyric acid [GABA]ergic (Streeter et al., 2010) as well as serotonergic synapses and neurotrophin signaling pathways (Kashyap et al., 2018).

The third nodule was regulation of energy production and metabolism. This comprised the genes involved in adipocytokine (Kita et al., 2019) and thyroid-hormone signaling pathways (Mullur et al., 2014).

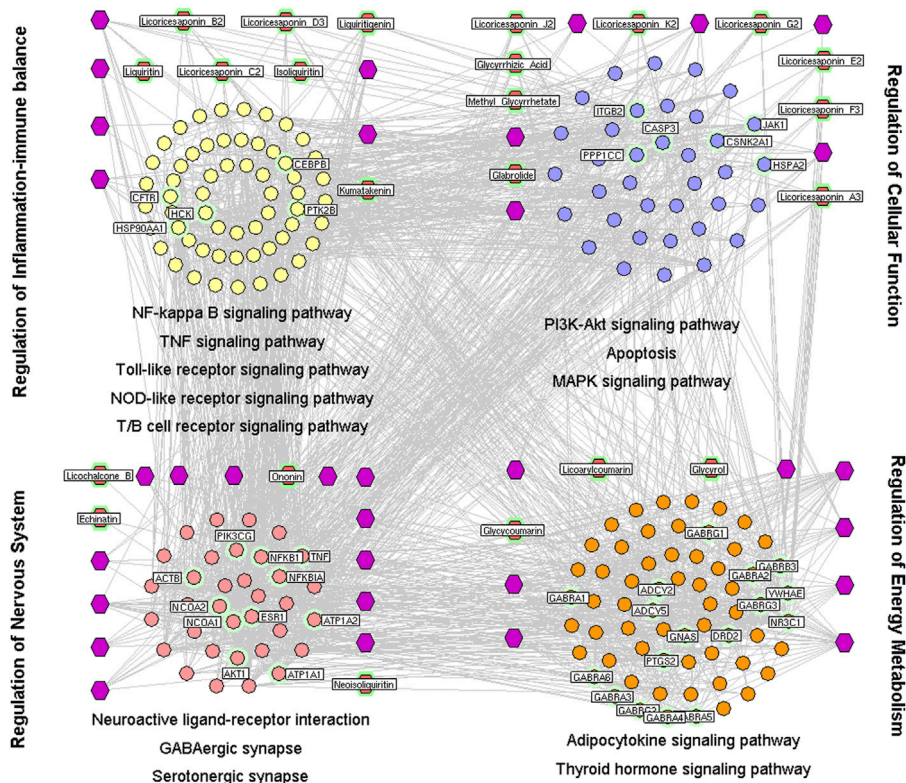

The fourth nodule was cellular functions. This comprised genes involved in phosphoinositide 3-kinase/protein kinase B ([PI3K/AKT) (Hong et al., 2016) and mitogen-activated protein kinase (MAPK) signaling pathways (Park, 2018) and apoptosis (Kawamoto et al., 2016) (Figure 1).

### Pharmacologic Mechanisms of Spleen-Invigorating and Qi-Replenishing Effects

Of the 241 putative targets, 78 were disease-related genes associated with the spleen-invigorating and qi-replenishing effects of licorice. The network of interactions of drug target–disease-related genes contained 1,729 nodes and 9,181 interactions. Based on the node degree, betweenness, and closeness values, 534 major hubs were identified, of which 68 were the putative targets of six compounds (18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid, isoliquiritin apioside, kumatakenin, licoaryl coumarin, and liquiritin apioside).

We wished to investigate the mechanisms underlying the spleen-invigorating and qi-replenishing effects of licorice. Hence, a major hub network was constructed based on the direct interactions between major hubs that were divided into four functional modules.

**FIGURE 1 |** Interaction network of chemical compounds containing licorice and the corresponding major targets associated with its heat-clearing and detoxifying effects. To investigate the mechanisms underlying the heat-clearing and detoxifying effects of licorice, a network was constructed based on direct interactions between major hubs that was divided into four functional modules. Purple hexagons represent chemical components, red hexagons denote representative the chemical components of licorice, yellow circles denote the core targets related to regulation of balance of inflammation and the immune system, and blue circles represent the core targets related to cellular functions. The pink circle represents the core target related to modulation of the nervous system, the orange circle represents the core target related to regulation of energy production and metabolism.

The first functional node was regulation of balance of inflammation and the immune system. This comprised genes involved in PI3K/AKT, MAPK, TNF, Fc epsilon RI (Ben Mkaddem et al., 2019), and NF- $\kappa$ B signaling pathways, and inflammatory regulation of TRP channels.

The second functional node was regulation of energy production and metabolism. This was composed of genes involved in thyroid hormone, cyclic (c)AMP (Alqurashi et al., 2016), insulin (Guo and Guo, 2017), adipocytokine, and 5' AMP-activated protein kinase (Ke et al., 2018) signaling pathways.

The third functional module was modulation of the nervous system. This comprised genes involved in the neurotrophin signaling pathway, gap junctions (Dong et al., 2018), long-term potentiation/depression (Bliss and Cooke, 2011), and neuroactive ligand-receptor interactions.

The fourth functional module was regulation of angiogenesis and circulation. This comprised genes involved in Ras-associated protein (Rap)1 (Rho et al., 2017), hypoxia-inducible factor (HIF)-1 (Semenza, 2014), and vascular endothelial growth factor (VEGF) signaling pathways (Gianni-Barrera et al., 2014) as well as contraction of vascular smooth muscle and platelet activation (Starlinger et al., 2011) (Figure 2).

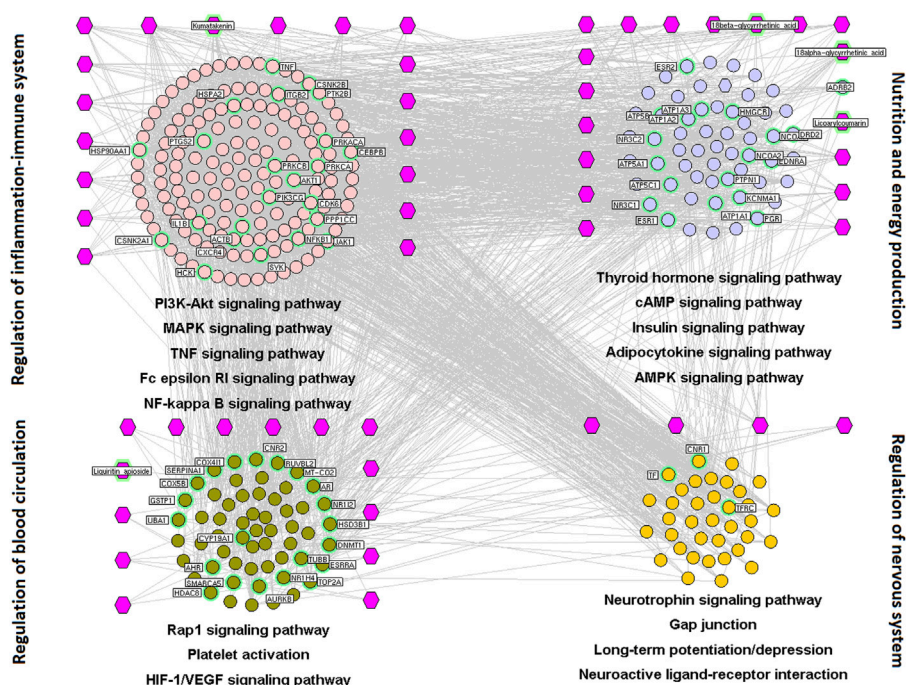

## Pharmacologic Mechanisms of Phlegm Expulsion and Cough-Suppressant Effects

Of the 241 putative targets, nine were disease-related genes involved in the phlegm-expulsion and cough-suppressant effects of licorice. The network of interactions between drug targets and disease-related genes contained 301 nodes and 851 interactions. Ninety-seven major hubs were identified based on the values of the node degree, betweenness, and closeness in the network. Of these, 28 were the putative targets of six compounds in licorice (18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid, isoliquiritin apioside, kumatakenin, licoaryl coumarin, and liquiritin apioside).

We wished to investigate the mechanistic basis of the phlegm-expulsion and cough-suppressant effects of licorice. A major hub network was constructed based on the direct interactions between major hubs that was divided into three functional modules.

The first functional nodule was regulation of the balance between inflammation and the immune system. This comprised the genes involved in: TNF, NF- $\kappa$ B, T-/B-cell receptors (Lee and Korner, 2019), NLR, and TLR signaling pathways; leukocyte transendothelial migration (Nourshargh and Alon, 2014); tuberculosis (Khader et al., 2019); pertussis (Murphy et al., 2020).

**FIGURE 2 |** Interaction network of chemical compounds containing licorice and the corresponding major targets associated with spleen-invigorating and qi-replenishing effects. We wished to investigate the mechanisms underlying the spleen-invigorating and qi-replenishing effects of licorice. Hence, a major hub network was constructed based on the direct interactions between major hubs that were divided into four functional modules. Purple hexagons represent chemical components, pink circles denote core targets related to regulation of balance of inflammation and the immune system, blue circles represent core targets related to nutrition and energy production, green circles denote core targets related to regulation of blood circulation, and the orange circle represents the core target related to modulation of the nervous system.

The second functional nodule was regulation of energy production and metabolism. This was composed of the genes involved in thyroid hormone, cAMP, adipocytokine, and glucagon signaling pathways (Kleinert et al., 2019); regulation of lipolysis in adipocytes (Shin et al., 2017) as well as asthyroid-hormone synthesis.

The third functional nodule was modulation of the nervous system. This comprised genes involved in GABAergic synapses (Babaev et al., 2018); retrograde endocannabinoid (Lu and Mackie, 2017) and chemokine (Zigmond and Echevarria, 2019) signaling pathways, as well as neuroactive ligand–receptor interactions (MacKenzie EM et al., 2007) (Figure 3).

### Pharmacologic Mechanisms of Spasm-Relieving and Analgesic Effects

Of the 241 putative targets, 29 were disease-related genes linked to the spasm-relieving and analgesic effects of licorice. The network of interactions of the drug target and disease-related genes contained 689 nodes and 2,682 interactions. Based on the network topology values of node degree, betweenness, and closeness, 200 major hubs were selected, of which 25 were the putative targets of six compounds in licorice (18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid, isoliquiritin apioside, kumatakenin, licoaryl coumarin, and liquiritin apioside).

We wished to investigate the mechanisms associated with the spasm-relieving and analgesic effects of licorice. Hence, a network was constructed based on the direct interactions between major hubs that were divided into three functional modules.

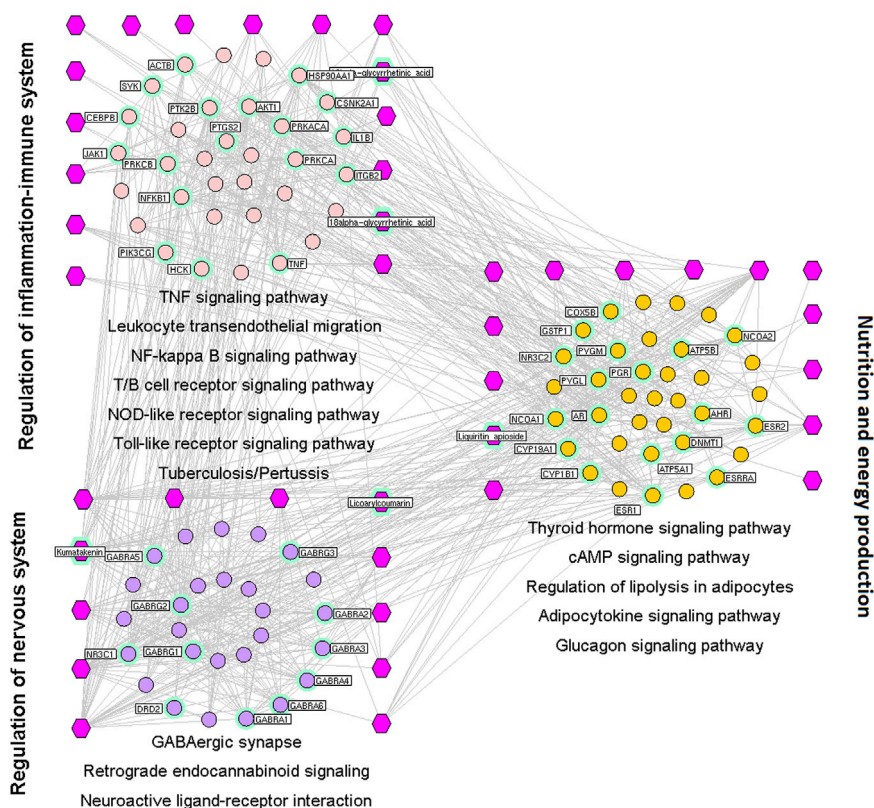

The first functional module was modulation of neuroinflammation and neuropathologic pain. This comprised the genes involved in MAPK, calcium (Navakkode et al., 2018), TNF, and TLR signaling pathways, as well as neuroactive ligand–receptor interactions (Salvalaio et al., 2017).

The second functional module was regulation of energy production and metabolism. This was composed of the genes involved in cAMP and adipocytokine signaling pathways, regulation of lipolysis in adipocytes, and oxidative phosphorylation (Bald et al., 2017).

The third functional module was regulation of angiogenesis and circulation. This comprised the genes involved in Rap1, HIF-1 and VEGF signaling pathways as well as contraction of vascular smooth muscle and platelet activation (Figure 4).

### Analyses of the Main Bioactive Ingredients of Licorice

The main bioactive components of licorice could be detected by UHPLC–TOF–MS/MS (Figure 5). Thirty bioactive compounds were identified by comparing the retention time and quasi-molecular ions with reference standards, respectively. The structures of these compounds are shown in Figure 6. Information such as retention time (min), CAS number, molecular formula,  $m/z$ , and MS<sup>2</sup> fragments is offered in Supplementary Table S5.

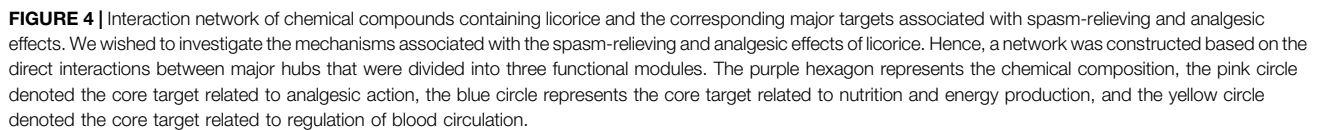

**FIGURE 3 |** Interaction network of chemical compounds containing licorice and the corresponding major targets associated with phlegm-expulsion and cough-suppressant effects. We wished to investigate the mechanistic basis of the phlegm-expulsion and cough-suppressant effects of licorice. A major hub network was constructed based on the direct interactions between major hubs that was divided into three functional modules. Purple hexagons represent chemical components, pink circles denote core targets related to regulation of balance of inflammation and the immune system, light purple circles represent core targets related to modulation of the nervous system, and orange circles denote core targets related to nutrition and energy production.

Liquiritin apioside and liquiritigenin were the main flavonoids, and 18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid were the main triterpenoids, in licorice. These compounds were found to be implicated in the various pharmacologic effects of licorice. Liquiritin apioside, which was also present at a high level in licorice, can be used as a marker for the quality assessment of *Glycyrrhiza* species (Jiang et al., 2016). The phlegm-expulsion and cough-suppressant effects of liquiritin apioside have been reported (Kuang et al., 2018; Wei et al., 2020). Also, liquiritin apioside has been linked to TNF, NF- $\kappa$ B, NLR, TLR, and adipocytokine signaling pathways, which have important roles in anti-inflammatory immune activity, energy production, and metabolism (Guan et al., 2012).

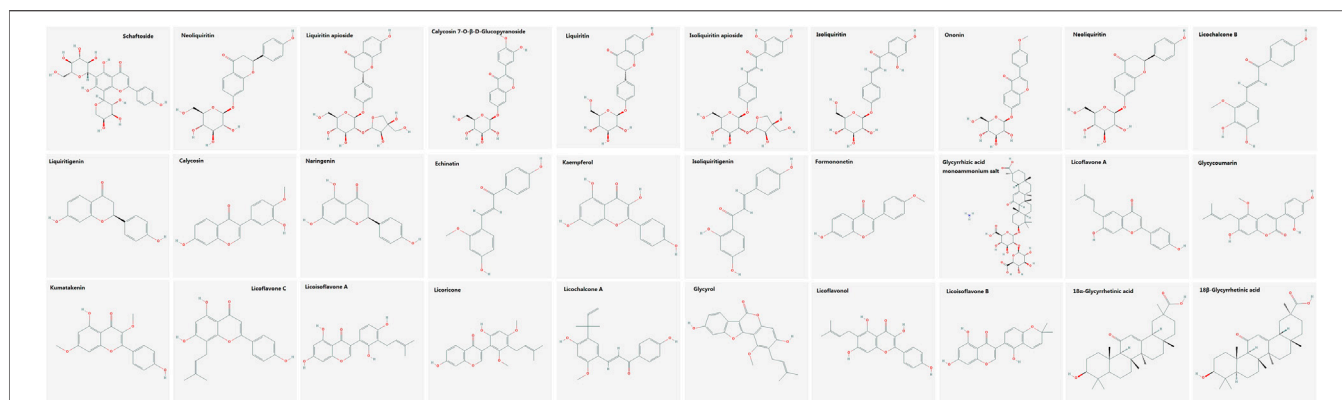

Liquiritigenin has potent pharmacologic activity, including inhibitory effects on fibrogenesis and inflammation in the liver (Huang et al., 2019; Lee et al., 2019). We predicted the following proteins to be the putative targets of liquiritigenin in the heat-clearing and detoxifying effects of licorice: AKT1, cyclin-dependent kinase 6, heat-shock protein (HSP)90AA1, HSPA2, Janus kinase, phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit  $\gamma$ , casein kinase 2 $\alpha$ 1, CCAAT enhancer-binding protein  $\beta$ ,  $\beta$ -actin, estrogen receptor 1, nuclear receptor coactivator (NCOA)1, and NCOA2. Our analyses suggested that liquiritigenin exerts heat-clearing and detoxifying effects *via* regulation of PI3K/AKT

(Shi et al., 2015; Tao et al., 2016; Meng and Lin, 2019), MAPK (Tu et al., 2019), NF- $\kappa$ B (Zhu et al., 2018), TNF (Yu et al., 2015), and neurotrophin (Liu et al., 2009) signaling pathways and apoptosis (Bae et al., 2018).

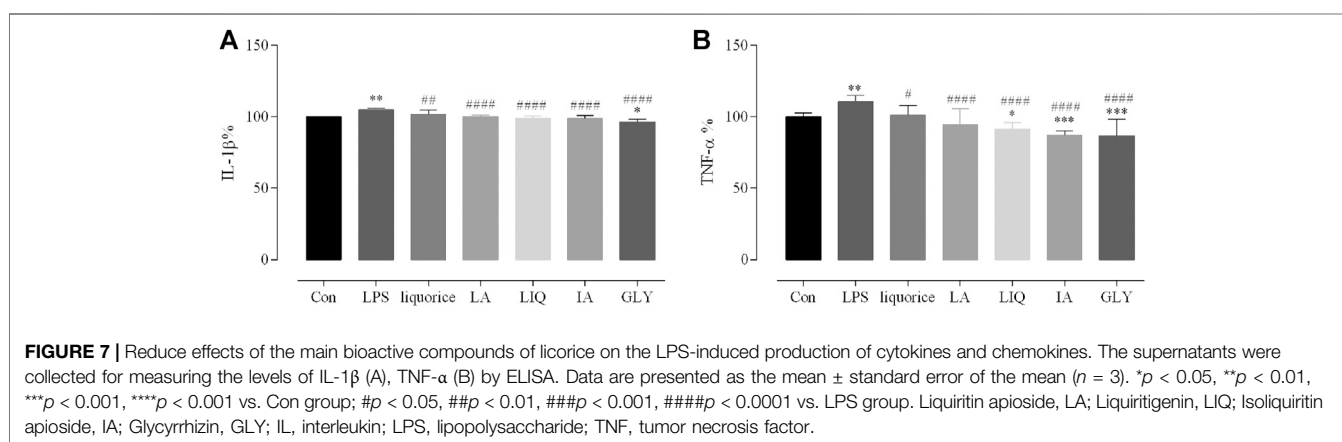

18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid are representative triterpenoid saponins present in high concentrations in licorice (Wang and Yang, 2007). They have anti-inflammatory, antiviral, hepatoprotective, and anti-tumor effects. We predicted the following proteins to be the putative targets of 18 $\alpha$ - and 18 $\beta$ -glycyrrhetic acid in the spleen-invigorating and qi-replenishing effects of licorice: NF- $\kappa$ B subunit 1, estrogen receptor1, NCOA1, NCOA2, 3-myoxy-3-methylglutaryl-coA reductase, integrin subunit  $\beta$ 2, and nuclear receptor subfamily 3 group C member 1. These proteins constituted two functional modules. The first functional module was regulation of balance of inflammation and the immune system, with genes involved in PI3K/AKT (Kao et al., 2010; Wang et al., 2011), MAPK (Chen X. et al., 2018; Zhang Y. et al., 2019), TNF (Zhou and Wink, 2019) and NF- $\kappa$ B (Cao et al., 2017) signaling pathways. The second functional module was regulation of energy production and metabolism (Chang et al., 2010; Chen et al., 2014a), with genes involved in thyroid hormone, cAMP, and adipocytokine signaling pathways (Shamsa et al., 1991; Rastegari et al., 2019).

**FIGURE 6 |** Two-dimensional chemical structures of the bioactive compounds in licorice.

**FIGURE 7 |** Reduce effects of the main bioactive compounds of licorice on the LPS-induced production of cytokines and chemokines. The supernatants were collected for measuring the levels of IL-1 $\beta$  (A), TNF- $\alpha$  (B) by ELISA. Data are presented as the mean  $\pm$  standard error of the mean ( $n = 3$ ). \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ , \*\*\*\* $p < 0.0001$  vs. Con group; # $p < 0.05$ , ## $p < 0.01$ , ### $p < 0.001$ , #### $p < 0.0001$  vs. LPS group. Liquiritin apioside, LA; Liquiritigenin, LIQ; Isoliquiritin apioside, IA; Glycyrrhizin, GLY; IL, interleukin; LPS, lipopolysaccharide; TNF, tumor necrosis factor.

Liquiritin and glycyrrhizic acid are the main representative chemical components of licorice (Chinese Pharmacopoeia Commission, 2020). We found that liquiritin and glycyrrhizic acid had putative targets, but the number of their putative targets were not as high as those of liquiritin apioside, 18 $\beta$ -glycyrrhizic acid or other chemical components. The pharmacologic effects of the chemical components of licorice were related not only to the strength of biological activity but also to their concentration. Chemical components with strong biological activity but very low concentration contributed little to the pharmacologic effect. However, the chemical components with moderate activity but very high concentration contributed considerably to the pharmacologic effect. Biological activity and concentration are the most important factors for selecting quality control (QC) markers. We believe that liquiritin and glycyrrhizic acid should be used as QC markers for licorice.

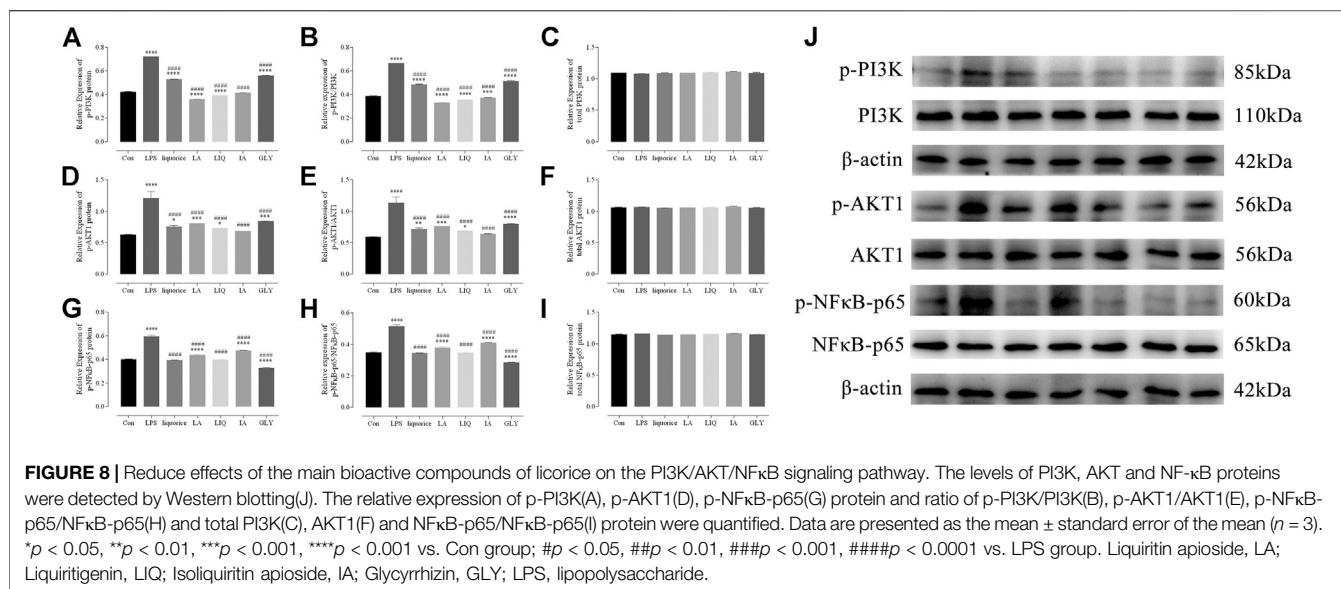

## Main Bioactive Ingredients of Licorice Reduce the Inflammatory Responses

Based on the result of network pharmacology, liquiritin apioside, liquiritigenin and isoliquiritin apioside were found as the main bioactive components of licorice. Liquiritin

apioside and isoliquiritin apioside comprised the genes involved in NF- $\kappa$ B, TNF and IL-1 $\beta$ , while liquiritigenin comprised the genes involved in PI3K/AKT. Glycyrrhizic acid is the main representative chemical components of licorice which comprised the genes involved in NF- $\kappa$ B and TNF. All of these genes have important roles in anti-inflammatory immune activity.

To determine whether the main bioactive components of licorice can reduce the inflammatory response, the levels of TNF- $\alpha$  and IL-1 $\beta$  were measured in RAW 264.7 by ELISA analysis. Liquiritin apioside, liquiritigenin, glycyrrhizic acid and isoliquiritin apioside were chosen as representative bioactive components. In the vitro experiment, the levels of TNF- $\alpha$  and IL-1 $\beta$  in RAW 264.7 were significantly increased after stimulation with LPS compared with those in the blank control ( $P < 0.01$ ). The LPS group showed higher levels of TNF- $\alpha$  and IL-1 $\beta$  than those of the four bioactive components-treated and licorice-treated LPS group ( $P < 0.05$ ), indicating that the excessive secretion of TNF- $\alpha$  and IL-1 $\beta$  induced by LPS could be reduced by liquiritin apioside, liquiritigenin, glycyrrhizic acid, isoliquiritin apioside and licorice (Figure 7). According to these results, we found that the inflammatory responses could be reduced by the main bioactive components of licorice treatment.

In order to investigate the mechanisms underlying the anti-inflammatory activities of bioactive components of licorice, Western blotting analysis was used to verify the regulatory effects of the main bioactive components. The results of Western blotting revealed that bioactive components are able to markedly suppressed the PI3K/AKT/NFκB signaling pathway, mediated by p-PI3K (Figure 8A), p-AKT1 (Figure 8D), p-NFκB-p65 (Figure 8G), p-PI3K/PI3K (Figure 8B), p-AKT1/AKT1 (Figure 8E) and p-NFκB-p65/NFκB-p65 (Figure 8H) in LPS-activated macrophages.

The PI3K/AKT/NFκB signaling pathway plays an important role in the regulation of signal transduction and biological processes such as cell proliferation, apoptosis, metabolism and angiogenesis. The regulatory mechanisms and biological functions of the PI3K/AKT/NFκB signaling pathway are important in many human diseases, including ischemic brain injury, neurodegenerative diseases, and tumors and play an important role in erythropoiesis and glycolysis (Xie et al., 2019; Xu et al., 2020). Nuclear factor-kappaB (NF-κB) proteins constitute a family of transcription factors that are

stimulated by pro-inflammatory cytokines, chemokines, stress-related factors and extracellular matrix (ECM) degradation products, which has long been considered a prototypical proinflammatory signaling pathway (Toby, 2009; Stella and Athanasios, 2013). These results indicate that the main bioactive components of licorice inhibit the expression of TNF- $\alpha$  and IL-1 $\beta$  in the downstream through the PI3K/AKT/NF $\kappa$ B signaling pathway. Our results further demonstrate that the main bioactive components of licorice have anti-inflammatory properties.

## Functions of Different Types of Compound in the Pharmacologic Effects of Licorice

We analyzed the major targets of the chemical compounds associated with the pharmacologic effects of licorice. We showed that the activities of the compounds varied according to their chemical structure, with flavonoids and triterpenoids having the most important role, data that are consistent with results from the work of Wang and colleagues (Wang et al., 2020).

We constructed a network for the heat-clearing and detoxifying effects of licorice comprising four functional modules: cellular functions; modulation of the nervous system; balance between inflammation and the immune system; regulation of energy production and metabolism. Triterpenoids were the predominant type of compound in the first three modules, whereas flavonoids had a leading role in regulation of energy production and metabolism (accounting for 83.73% of compounds within this module). Triterpenoids participated to varying degrees in the different functional modules. In the spleen-invigorating and qi-replenishing effects of licorice, they were important for modulation of the nervous system (69.97%). In the phlegm-expulsion and coughing-suppressant effects, they were responsible for regulating the balance between inflammation and the immune system (66.51%). In the spasm-relieving and analgesic effects, they played a major part in neuroinflammation and neuropathologic pain (67.13%) (Figure 9).

## CONCLUSION

The pharmacologic effects of licorice arise from the combined action of various types of compounds. Triterpenoids and flavonoids make the greatest contribution, but coumarins are also important. Each pharmacologic effect of licorice comprised multiple functional modules. This finding is consistent with the general premise of TCM that therapeutic mechanisms involve many compounds and targets. We suggest that, for invigorating the spleen and replenishing qi, expelling phlegm and suppressing

cough, or relieving spasm and pain, licorice with a higher triterpenoid content may be used. Licorice with higher levels of flavonoids may be more appropriate for heat-clearing and detoxification. Our results provide a reference for the QC of licorice and for investigating its therapeutic potential in the treatment of specific symptoms or diseases.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

## AUTHOR CONTRIBUTIONS

JC was responsible for the conception and design of the study, data acquisition and analyses, and manuscript drafting. XH and LL assisted with data collection and manuscript revision. FW aided the conception and design of the study. SM aided the conception and design of the study, as well as data analyses and interpretation. All authors approved the final version of the manuscript for submission.

## FUNDING

This study was supported financially by the 12th Five-Year China National Significant New Drugs Creation Feature Subjects–Traditional Chinese Medicine Quality Safety Evaluation and Risk Control Technology Platform (2014ZX09304307-002) and National Key Research and Development Plan (2019YFC1711500; “Research and Application of Key Technologies and Intelligent Equipment for Clean Cutting of Traditional Chinese Medicine Materials”).

## ACKNOWLEDGMENTS

We acknowledge Dr. Xian-Long Cheng from the Institute for Control of Chinese Traditional Medicine and Ethnic Medicine, National Institutes for Food and Drug Control, for his technical assistance in UHPLC-QTOF-MS/MS and processing of MS data.

**Background:** Qing-Yi Decoction (QYD) is a classic precompounded prescription with satisfactory clinical efficacy on acute pancreatitis (AP). However, the chemical profile and overall molecular mechanism of QYD in treating AP have not been clarified.

**Methods:** In the present study, a rapid, simple, sensitive and reliable ultra-performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry (UHPLC-QTOF-MS)-based chemical profile was first established. An integration strategy of network pharmacology analysis and molecular docking based identified ingredients was further performed to screen out the potential targets and pathways involved in the treatment of QYD on AP. Finally, SD rats with acute pancreatitis were constructed to verify the predicted results through a western blot experiment.

**Results:** A total of 110 compounds, including flavonoids, phenolic acids, alkaloids, monoterpenes, iridoids, triterpenes, phenylethanoid glycosides, anthraquinones and other miscellaneous compounds were identified, respectively. Eleven important components, 47 key targets and 15 related pathways based on network pharmacology analysis were obtained. Molecular docking simulation indicated that ERK1/2, c-Fos and p65 might play an essential role in QYD against AP. Finally, the western blot experiments showed that QYD could up-regulate the expression level of ERK1/2 and c-Fos, while down-regulate the expression level of p65.

**Conclusion:** This study predicted and validated that QYD may treat AP by inhibiting inflammation and promoting apoptosis, which provides directions for further experimental studies.

**Keywords:** Qing-Yi decoction, acute pancreatitis, chemical profile, network pharmacology, molecular docking, p65, ERK1/2, c-fos

## INTRODUCTION

Acute pancreatitis (AP) is a common clinical disease caused by a variety of factors, including cholelithiasis, excessive drinking, obesity, smoking, etc (Sadr-Azodi et al., 2012; Yadav and Lowenfels, 2013; Lankisch et al., 2015; Forsmark et al., 2016), which is manifested by acute epigastric pain, nausea, vomiting and fever (Lankisch et al., 2015). The overall incidence rate of AP is 13–45 per 100,000 persons and is increasing year by year (Yadav and Lowenfels, 2013; Lankisch et al., 2015).

At present, the western medicine treatment of AP is mainly focused on spasmolysis, pain relief, inhibition of pancreatin secretion and fluid resuscitation. In severe cases, surgical treatment will be used (Lankisch et al., 2015; Brunschot et al., 2018). However, the therapeutic effect of these schemes is limited because they can only control the symptoms without an ultimate cure. Furthermore, there is no specific drug available yet. Therefore, it is imperative to develop safer and more effective drugs to treat AP. Traditional Chinese medicine (TCM), which has a history of clinical application for thousands of years in China, has been gradually accepted in the treatment of AP in view of its characteristics of holism concept and pattern differentiation (Wang and Zhang, 2017) as well as advantages of less side effects and systemic regulation.

Qing-Yi Decoction (QYD) is a classic precompounded prescription that consists of eight herbs, namely, *Rheum officinale* Baill. (da-huang in Chinese), *Bupleurum chinense* DC. (chai-hu in Chinese), *Scutellaria baicalensis* Georgi (huang-qin in Chinese), *Paeonia lactiflora* Pall. (bai-shao in Chinese), *Aucklandia costus* Falc. (mu-xiang in Chinese), *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu (yan-hu-suo in Chinese), *Gardenia jasminoides* J. Ellis (zhi-zi in Chinese) and *Natrii Sulfas* (mang-xiao in Chinese). Previous studies reported that it could treat AP by reducing the production of various inflammatory mediators, blocking inflammatory signaling pathways, and improving intestinal mucosal barrier and motility effectively (Zhang et al., 2015). In clinical practice, QYD is more widely used than similar prescriptions such as Da-Cheng-Qi Decoction because of its advantages of targeting symptomatic infection by heat-clearing, detoxifying and removing stasis by purgation. (Qu et al., 2007; Chen et al., 2015). However, there are some shortages in the current research on QYD. For one thing, the pharmacodynamic material basis and quality evaluation system related to drug efficacy of QYD have not been established. For another, the current reports are mostly limited to a single target, which is difficult to reflect the “holism” characteristics of QYD as a compound preparation with multiple constituents, multiple targets and multiple pathways, and lacks convincing power. The above problems hindered the development and application of QYD. Therefore, it is necessary to characterize and reveal its chemical constituents and overall mechanism systematically.

Network pharmacology was proposed by Andrew Hopkins in 2007. Its core idea is to optimize treatment strategies depends on a biological network formed by disease features, bioactive agents

and drug targets that connect to each other (Hopkins, 2007). It has been introduced to evaluate the constituents and action mechanisms of TCM in view of its systematic and holistic coincides (Li et al., 2011; Li and Zhang, 2013; Cai et al., 2018a). Molecular docking is a technology of drug design and screening based on computer data simulation through the interaction and affinity between receptor macromolecules and drug micromolecules (Chen et al., 2014; Lionta et al., 2014; Saikia and Bordoloi, 2019; Reddyrajula and Dalimba, 2020). At present, their combined use has been successfully applied in the research of Traditional Chinese medicine and their compound preparation (Liang et al., 2019; Wang et al., 2019).

In this study, we systematically expounded the possible targets and related pathways of QYD in treating AP by integrating the ultra-performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry (UHPLC-QTOF-MS), network pharmacology, molecular docking analysis and experimental evaluation using molecular biology. The schematic diagram of this study was shown in **Figure 1**.

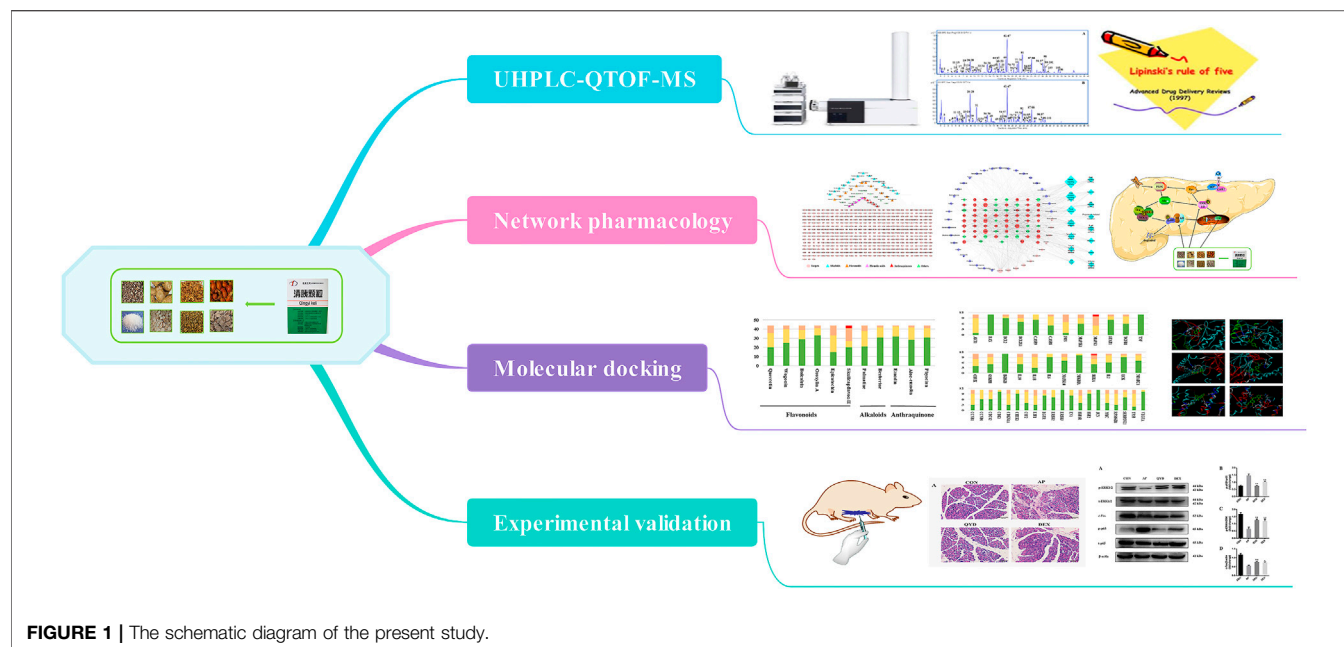

## MATERIALS AND METHODS

### Chemicals, Reagents and Materials

Methanol and acetonitrile of HPLC grade were purchased from Merck Company Inc. (Darmstadt, Germany). The chemical of formic acid was MS grade and purchased from Fisher Scientific Company Inc. (Fairlawn, NJ). All other reagents were of analytical grade and supplied by Tianjin Concord Technology Co., Ltd. (Tianjin, China). Ultra-pure water (18.2 MΩ) was prepared daily with a Milli-Q water purification system (Millipore, Milford, MA, United States).

Gallic acid (**3**), catechin (**18**), chlorogenic acid (**19**) (+)-epicatechin (**28**), scutellarin (**36**), tetrahydropalmatine (**47**), jatrorrhizine (**48**), baicalin (**62**), palmatine (**72**), baicalein (**88**), aloe-emodin (**93**), rhein (**94**), saikosaponin a (**96**), wogonin (**97**), emodin (**104**), chrysophanol (**107**), and physcion (**108**) were obtained from the National Institutes for Food and Drug Control (Beijing, China). Syringin (**22**), albiflorin (**29**), paeoniflorin (**31**), rutin (**35**) and benzoylpaeoniflorin (**85**) were purchased from Chengdu Pufei De Biotech (Chengdu, Sichuan, China). The purity of each reference standard was above 98%.

All the eight herbs of QYD, including *Rheum officinale* Baill. (batch No. 160702), *Bupleurum chinense* DC. (batch No. 170509), *Scutellaria baicalensis* Georgi (batch No. 170505), *Paeonia lactiflora* Pall. (batch No. 170308), *Aucklandia costus* Falc. (batch No. 170503), *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu (batch No. 170307), *Gardenia jasminoides* J. Ellis (batch No. 170305) and *Natrii Sulfas* (batch No. 170609) were purchased from the First Affiliated Hospital of Dalian Medical University (Dalian, Liaoning Province, China), and authenticated by Professor Aijing Leng (Department of Chinese medicine, The First Affiliated Hospital of Dalian Medical University). Their voucher specimens were deposited at the author's laboratory.

## Preparation of Qing-Yi Decoction Extract and Standard Solution

Raw herbs for the formula (containing *Bupleurum chinense* DC., 15 g; *Scutellaria baicalensis* Georgi, 12 g; *Paeonia lactiflora* Pall., 15 g; *Aucklandia costus* Falc, 15 g; *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu, 15 g; and *Gardenia jasminoides* J. Ellis, 15 g) was soaked and extracted by boiling with 10-fold mass of water (870 ml) for 1 h. After filtered with six-layer absorbent gauze, the residue was re-extracted with 8-fold mass of water in the same way for 0.5 h. Then *Rheum officinale* Baill. (20 g) was added into the extract and boiled for additional 0.5 h. After being filtered with six-layer absorbent gauze and added by *Natrii Sulfas* (10 g) when solution was hot, the two filtrates were combined and concentrated under vacuum to 120 ml (equal to 1 g crude herb/ml), and finally the concentrate was subjected to freeze-dry. The extract was obtained with a yield of 29.5% and kept in the desiccator before use.

A 1.0 g of the freeze-dried powder was accurately weighted and extracted with 50 ml of methanol/water (1:1, v/v) for 30 min under ultrasound. The extract solution was centrifuged at 13,000 rpm for 10 min at 4°C and the supernatant was filtered through a 0.22 μm membrane filters. Finally, 1.0 μl of filtrate was injected into UHPLC-QTOF-MS for analysis.

## Ultra-Performance Liquid Chromatography Coupled With Quadrupole Time-of-Flight Mass Spectrometry Condition

Chromatographic separation was carried out on an Agilent 1,290 Infinity LC system (Agilent, United States) using an Agilent Zorbax Eclipse Plus C18 column (100 × 2.1 mm i.d., 3.5 μm) at 40°C with a flow rate of 0.3 ml/min. The mobile phase consisted of water containing 0.1% formic acid (solvent system A) and acetonitrile

(solvent system B) were performed with gradient elution program as follows: 0–5 min, 3–10% B; 5–13 min, 10–18% B; 13–20 min, 18–25% B; 20–35 min, 25–70% B; 35–40 min, 70–99% B; 40–42 min, 99–3% B; 42–45 min, 3% B. 2 μl of sample solution was injected for analysis.

Mass detection was performed using an Agilent 6530b Accurate-Mass Quadrupole Time-of-Flight (Q-TOF) mass spectrometer (Agilent Corp., United States) equipped with a Dual AJS ESI source operating in both positive and negative mode with the following operating parameters: drying gas (N<sub>2</sub>) flow rate, 10.0 L/min; drying gas (N<sub>2</sub>) temperature, 350°C; nebulizer, 35 psig; sheath gas (N<sub>2</sub>) temperature, 400°C; fragmentor voltage, 120 V; skimmer voltage, 65 V; Octopole RF, 750 V. The capillary voltage was set at 4 kV or –3.5 kV under positive or negative mode, respectively. The nozzle voltage was set at +500 V or –1000 V, respectively; The quasi-molecular ions [M – H]<sup>–</sup> and [M + H]<sup>+</sup> were selected as precursor ions and subjected to target-MS/MS analyses with different collision energies ranging from 10 to 60 V to acquire sufficient product ions. MS spectra were recorded over the m/z range of 50–1,100. All data was processed by MassHunter workstation software version B.06.00 (Agilent Technologies, Germany).

## Network Pharmacology Analysis Establishment of Component Target Database for Qing-Yi Decoction

Briefly, the constituents contained in QYD identified by UHPLC-QTOF-MS were input into the Molinspiration Smiles database (<https://www.molinspiration.com/cgi-bin/properties>), and the active constituents were screened out through the Lipinski's rule of five (Lipinski et al., 2001). Then, the Canonical SMILES structure formats of these constituents were obtained from Pubchem database (<https://www.ncbi.nlm.nih.gov/pubmed/>), and the component targets were found out by inputting them into Swiss

Target Prediction Database (<http://www.swisstargetprediction.ch/>). To obtain more target information, the names of the ingredients were also input into Traditional Chinese Medicine Systems Pharmacy Database and Analysis Platform (TCMSP) (<http://LSP.nwu.edu.cn/tcmsp.php>). Finally, the UniProt Knowledgebase (<http://www.uniprot.org/>) was used to convert the protein names into official gene symbols (*Homo sapiens*).

### Establishment of Therapeutic Target Database for Acute Pancreatitis

The information of therapeutic target was searched by using “acute pancreatitis” as the keyword. After integration of search-derived target data and elimination of the repeated genes, the therapeutic targets database can be obtained. The databases that used in this study were shown below.

- 1) OMIM database (<http://omim.org/>)
- 2) GeneCards database (<https://www.genecards.org/>)
- 3) DisGeNET database (<http://www.disgenet.org/web/DisGeNET/menu>)
- 4) GAD database (<https://geneticassociationdb.nih.gov/>)

### The Protein-Protein Interactions Network Analysis

To clarify the relationship between intersection targets, an intersection targets protein-protein interactions (PPI) network of acute pancreatitis and QYD component was constructed and analyzed using STRING database (<https://string-db.org/>). Species were defined as *Homo sapiens*. PPIs with a confidence score greater than 0.95 were selected and topology analyses were carried out to ensure the accuracy of the results. Finally, targets with a degree value greater than twice the median were chosen for subsequent network construction and analysis (Lu et al., 2017; Li et al., 2018a).

### Enrichment Analysis

In order to clarify the signaling pathways related to key targets, Kyoto Gene and Genome Encyclopedia (KEGG) enrichments analysis was performed based on Database for Annotation, Visualization and Integrated Discovery (DAVID, <https://david.ncifcrf.gov/home.jsp>, ver. 6.8) (Huang et al., 2009).

### Network Construction and Analysis

To visualize the research data, we process the data by employing the network visualization software Cytoscape 3.2.1 (Demchak et al., 2014), which supplies a method for data integration, analysis, and visualization for complex network analysis. The two networks were constructed as follows: 1) constituents-putative targets network of QYD; 2) active constituents-intersection target PPIs-pathways network. In these network diagrams, constituents, targets, and pathways were all represented by nodes, while the edges indicate the interactions between different nodes. The “degree” of a node was determined by the number of connected edges.

### Molecular Docking

The Surflex-docking module in SYBYL-X 2.0 (Boström, 2001) was performed to evaluate the binding ability between the screened core constituents and targets. First of all, the 2D structure of the compound was obtained from the PubChem database (<https://www.ncbi.nlm.nih.gov/pubmed/>) in SDF format and then converted into the 3D structure in mol2 format by SYBYL-X 2.0 software for the preparation of micromolecule ligand compounds.

Next, the protein crystal structure of core targets was obtained from the RCSB Protein Data Bank database (<http://www.rcsb.org>) after searching PDB ID in the uniprot database (<http://www.uniprot.org/>). Finally, a series of treatments include removing water molecules and original ligands, adding hydrogen, repairing amino acids and forming binding pockets were performed to complete the preparation of macromolecular receptor target proteins. “Total Score” given by software was used as the indicator for docking results. The higher the score, the stronger the binding effect.

## Experiments Evaluation

### Animals and Drug Treatments

Twenty four male Sprague-Dawley (SD) rats (240 ± 10 g body weight about 6–8 weeks-old) purchased from the Laboratory Animal Center of Dalian Medical University (License number: SCXK (Liao) 2018-0003) were maintained in a breeding room under controlled temperature (22 ± 2°C), humidity (55 ± 5%) and lighting (12 h light-dark cycles) conditions. To be acclimatized, rats were allowed food and water *ad libitum* for one week before the experiments. All experimental protocol was approved by the Ethics Review Committee for Animal Experimentation of Dalian Medical University.

SD rats were randomly divided into four groups including the control (CON) group, acute pancreatitis (AP) group, Qing-Yi Decoction-treated (QYD) group and dexamethasone-treated (DEX) group ( $n = 6$  in each group). AP model was induced by retrograded injection of 3.5% sodium taurocholate (STC) into the pancreatic duct according to the previous report (Huang et al., 2017). For the CON group, only the traction of the duodenum was conducted, and injection of the drug wasn't given. QYD extract was orally administrated to rats at a dosage of 10 g crude drug/kg/day when awakening after modeling. DEX that dissolved with normal saline by ultrasound was used as a positive drug at a dose of 10 mg/kg by intravenous tail injection. QYD and DEX were given repeated 12 h later. Rats in the control and model group were given physiological saline, which had the same volume as QYD and DEX.

After modeling for 24 h, rat serum was collected by centrifugation at 3,000 rpm for 10 min at 4°C. Meanwhile, part of pancreatic tissues was collected and fixed in 4% paraformaldehyde solution for histopathological staining. The remaining ones were immediately frozen and stored at -80°C for western blot analysis.

### Histopathological Examination and Biochemical Analysis

Pancreatic was observed under an optical microscope (Olympus, Japan) with a magnification of 200 times after embedded in paraffin and stained with hematoxylin and eosin. Finally, the previous scoring system was used to evaluate the damage degree of pancreatic tissue with edema, inflammation and vacuolation as indexes (Rongione et al., 1997). Also, the serum of rats was diluted 100 times, and then the amylase level was determined according to the instructions of the kit (Jiancheng, Nanjing, China).

**FIGURE 2 |** Representative base peak chromatogram (BPC) of QYD in the positive and negative ions mode, respectively.

## Western Blot Analysis

Total protein was extracted from pancreas tissues with cold lysis buffer and PMSF protease inhibitor. Next, the protein concentration was determined using the BCA protein assay kit. The protein samples were fractionated by SDS-PAGE (8–10%) and then transferred to PVDF membranes. The membranes were blocked with 5% non-fat milk for 1.5 h and incubated overnight at 4°C with the following primary antibodies: p65, p-p65, ERK1/2, p-ERK1/2, c-Fos,  $\beta$ -actin (1:1,000 dilution). The membranes were incubated 1 h at room temperature with secondary antibodies and protein expression was probed with an ECL method and placed in a Tanon-5200 Imaging System (Tanon, Shanghai, China).

## Statistical Analysis

Statistical analysis was carried out with SPSS 20.0 software. All the data in the experiment are expressed as mean  $\pm$  standard deviation. F-test was used to analyze the variance homogeneity of the data. Then one-way ANOVA's "LSD test" or "Games-Howell test" was used to compare the differences between the two groups according to the results. Values of  $p < 0.05$  were considered statistically significant.

## RESULTS

### Chemical Profile of Qing-Yi Decoction by Ultra-Performance Liquid Chromatography Coupled With Quadrupole Time-of-Flight Mass Spectrometry

Under the optimized conditions, a total of 110 constituents including 28 flavonoids, 16 phenolic acids, 15 alkaloids, 15

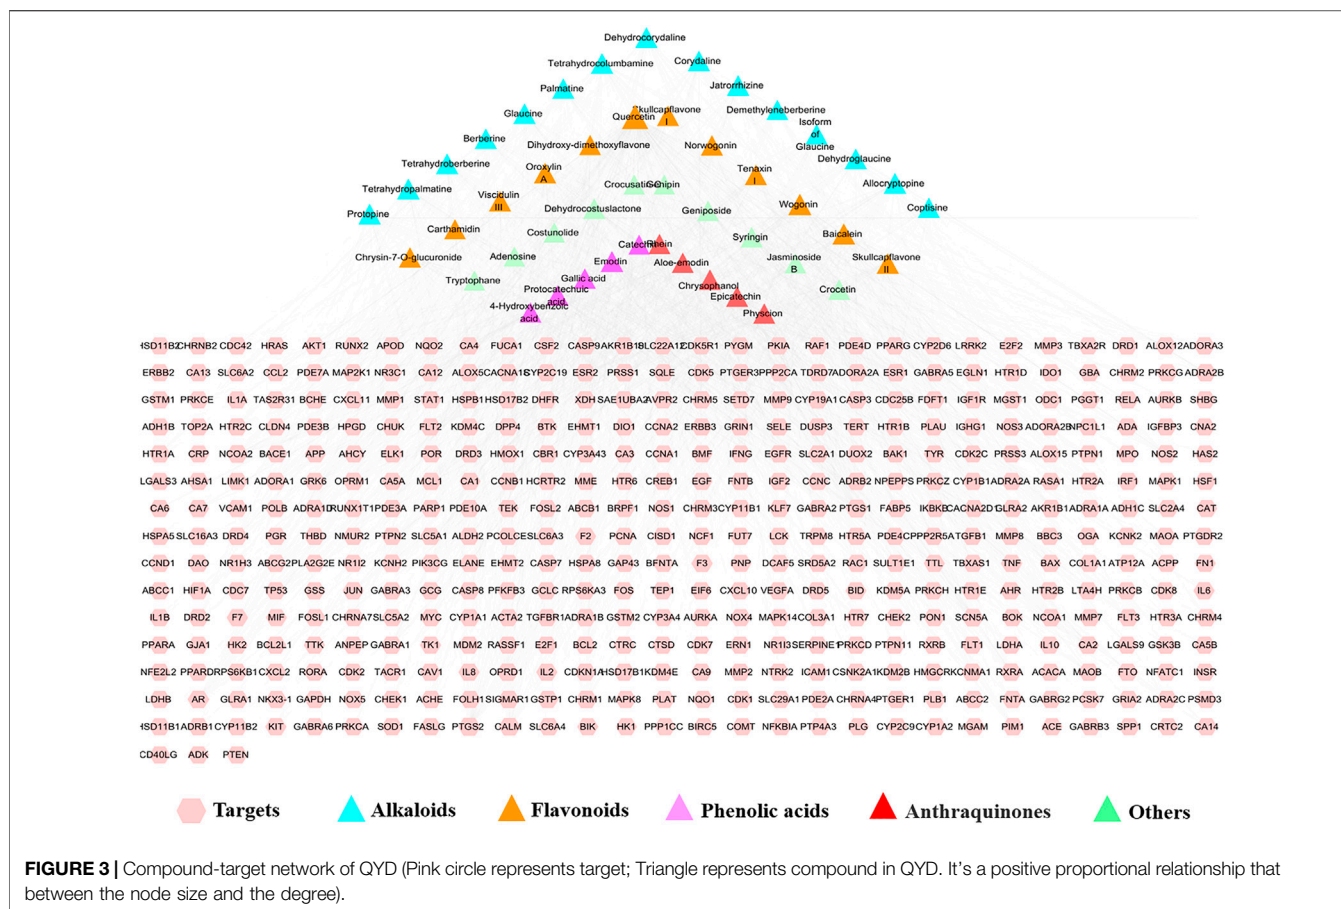

monoterpenes, 11 iridoids, eight triterpenes, five phenylethanoid glycosides, five anthraquinones and seven miscellaneous compounds that originate from seven herbs were identified or tentatively characterized according to the in-house constituents database established for QYD (**Figure 2**, **Supplementary Table S1**). While the typical constituents of *Natrii Sulfas* ( $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ ) were not detected.

Among them, 22 compounds (compounds **3**, **18**, **19**, **22**, **28**, **29**, **31**, **35**, **36**, **47**, **48**, **62**, **72**, **85**, **88**, **93**, **94**, **96**, **97**, **104**, **107** and **108**) were identified as gallic acid, catechin, chlorogenic acid, syringing (+)-epicatechin, albiflorin, paeoniflorin, rutin, scutellarin, tetrahydropalmatine, jatrorrhizine, baicalin, palmatine, benzoylpaeoniflorin, baicalein, aloe-emodin, rhein, saikosaponin a, wogonin, emodin, chrysophanol and physcion by comparing the retention time, quasi-molecular ions with authentic standards, respectively. While the others were tentatively deduced based on their high-accurate quasi-molecular ion such as  $[\text{M} - \text{H}]^-$ ,  $[\text{M} + \text{HCOO}]^-$ ,  $[\text{M} + \text{Cl}]^-$ ,  $[\text{M}]^+$ ,  $[\text{M} + \text{H}]^+$  and  $[\text{M} + \text{Na}]^+$  with those of the known published compounds recorded in the in-house library. Information regarding the 110 constituents, such as  $t_R$  (min), identification, formula, negative ion ( $m/z$ ), positive ion ( $m/z$ ) and botanical source, is offered in **Supplementary Table S1**.

## Network Pharmacology Analysis

### Qing-Yi Decoction Component Targets Network and Acute Pancreatitis Related Therapeutic Targets

Based on the chemical profile of QYD characterized by UHPLC/QTOF-MS, 541 targets associated with the 110 constituents were predicted as potential targets of QYD (**Supplementary Table S2**, **Supplementary Figure S1**). In order to focus on more important information, a total of 47 active constituents were screened out

according to the Lipinski's rule of five. Correspondingly, the potential targets of the constituents were reduced to 423. The active constituents-potential targets network of QYD for AP was constructed and shown in **Figure 3**. Similarly, 6593AP-related targets obtained from OMIM, GeneCards, DisGeNET and GAD databases were collected after searching, integrating and deduplicating steps. (**Supplementary Table S3**).

### Acquisition of Candidate Targets and Core Constituents for Qing-Yi Decoction Against Acute Pancreatitis

For the acquisition of the core targets for QYD against AP, the constituents-targets and disease-targets databases were intersected by Cytoscape 3.2.1 software, and 350 intersection targets were obtained. The PPI network of intersection targets was analyzed by the STRING database (<https://string-db.org/>) and the targets with confidence score >0.95 were screened for network construction. As a result, 236 nodes and 666 edges were involved in this network. More crucial targets were obtained based on the degree value of network topology analysis. Among them, 69 targets with degree values greater than twice the median were considered as candidate targets (**Supplementary Figure S2**). Forty constituents that had direct effects on 69 candidate targets were screened out for further identified as the key active constituents of QYD in treating AP. Among them, 11

constituents including quercetin (33), wogonin (97), baicalein (88), emodin (104), epicatechin (28), aloe-Emodin (93), berberine (71), palmatine (72), oroxylin A (101), phycion (108) and skullcapflavon II (100) were considered to be the key active constituents because their degree value was more than twice the median value.

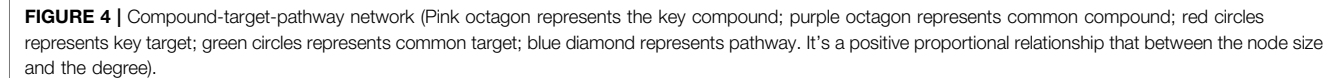

### Analysis of Related Pathways of Potential Targets

DAVID website was used to carry out KEGG pathway enrichment analysis on potential targets and 63 pathways were obtained. Of which 59 were statistically significant ( $p < 0.05$ ). Associations among active constituents, potential targets and the top 15 pathways (excepted cancer pathways) were shown in **Figure 4**. It could be seen that 11 key active ingredients could regulate relevant pathways by acting on 47 targets, and the MAPK signaling pathway, T cell receptor signaling pathway, Focal adhesion, Toll-like receptor signaling pathway and Apoptosis were involved. The details of their interactions were listed in **Supplementary Table S4**.

### Molecular Docking Analysis

RCSB Protein Data Bank database was used to investigate the relationship between active constituents and potential targets by collecting the crystal structure of the target (**Supplementary Table S5**), and SYBYL-X 2.0 platform was applied to analyze

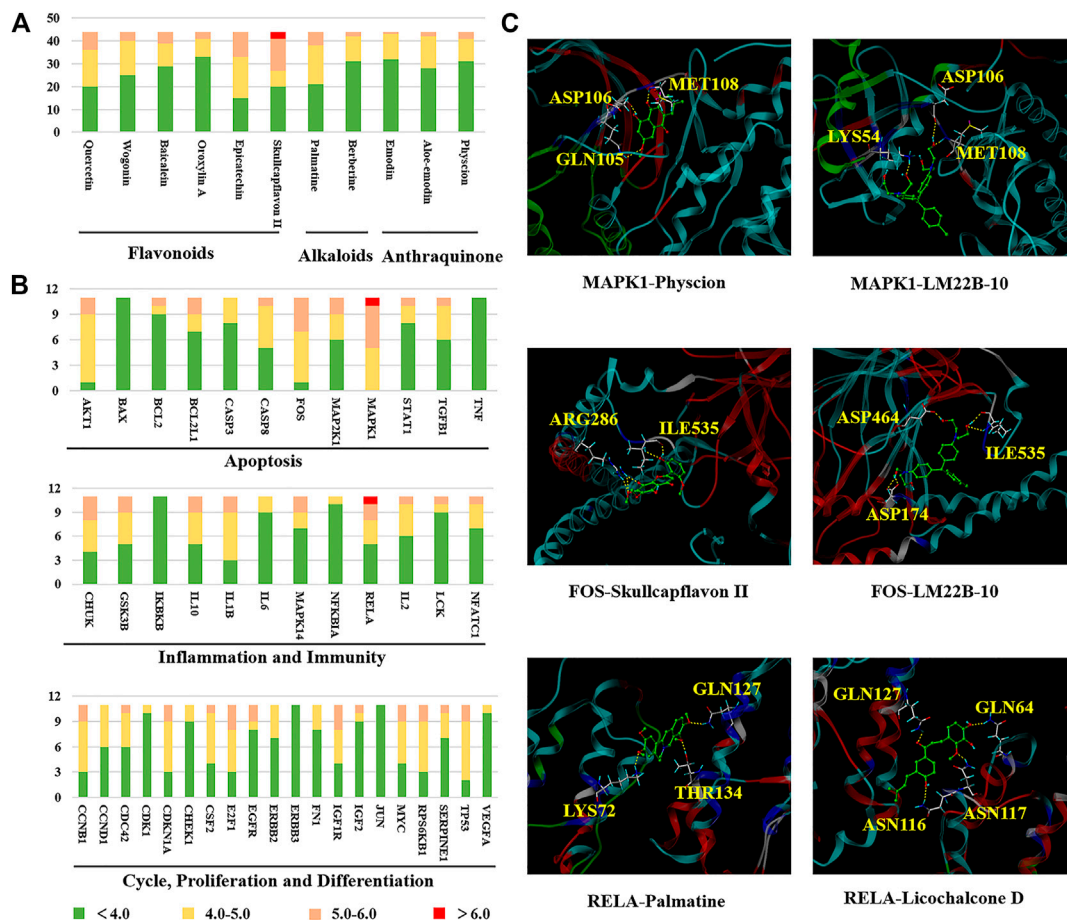

It was seen that there are four hydrogen bonds between MAPK1 and physcion (**108**), and three of which are the interaction between hydroxyl and MET108, ASP106 and GLN105, the other one is the interaction between MET108 and carbonyl. Three interactions consist in the combination of MAPK1 and the positive drug LM22B-10, namely MET108, ASP106 and LY654. In addition, in the binding pocket of FOS and skullcapflavon II (**100**), five hydrogen bonds formed by two amino acid residues (ARG286 and ILE535) and phenolic hydroxyl groups were found. Similarly, five hydrogen bonds were also found between FOS and the positive drug

## Experimental Evaluation

### Histopathological Examination and Biochemical Analysis

In pancreatic tissue of AP rats, the acinar cell injury, vacuolation, hemorrhage and inflammatory cell infiltration occurred was observed. When compared with the AP group, different degrees of improvement in QYD and DEX treatment groups were seen, and the QYD group possess a better effect. As shown in **Figure 6A**, edema and hemorrhage were not observed between the cells; the structure of the pancreatic lobules was clear and without infiltrated by inflammatory cells in the CON group. For the AP group, obvious edema among histiocytes was observed, a large number of red blood cells was overflowed, and the pancreatic tissue was infiltrated by numerous neutrophils and lymphocytes. The structure of pancreatic lobules was fuzzy and uniform, and a large quantity of necrotic pancreatic cells was found. In the QYD group, there was mild edema among tissue cells, the pancreas was infiltrated by a small number of inflammatory cells, and some areas were calcified. As for the DEX group, there was edema between cells, the pancreas was infiltrated by a few inflammatory cells, and the infiltration was

**FIGURE 5 |** The binding modes of key compounds with related proteins were analyzed by SYBYL-X 2.0 software. **(A)** Component docking score; **(B)** Target docking score; **(C)** Representative docking combinations.

distributed in the lesion. Calcification was seen in some areas, and a small number of red blood cells are spilled around the blood vessels. Also, its histopathological score is shown in **Figure 6B**.

Besides, an abnormal increase of serum amylase level is an essential basis for the diagnosis of AP. In this experiment, the serum amylase level of rats was detected by the starch-iodine colorimetric method. The results showed (**Figure 6C**) that amylase levels in the AP group were significantly higher than those in the CON group ( $p < 0.01$ ). In addition, compared with the AP group, QYD treatment could significantly inhibit the activity of amylase ( $p < 0.01$ ).

## Western Blot Analysis

The western blotting analysis was used to evaluate related protein levels in the pancreas. As shown in **Figure 7**, p-p65 expression was markedly up-regulated, and p-ERK1/2 and c-Fos expression were notably down-regulated in AP rats following STC infusion ( $p < 0.01$ ). As expected, QYD and DEX treatment significantly increased p-ERK1/2 and c-Fos levels and decreased p-p65 levels compared to the AP group ( $p < 0.01$ ), and QYD treatment group possesses a better effect. The results suggest that the therapeutic effect of QYD on AP may be related to

inhibiting the expression of p-p65 and promoting the expression of p-ERK1/2 and c-Fos.

## DISCUSSION

As a common critical disease of the digestive system, AP should attract our attention. Although the pathogenesis and clinical treatment of AP has been widely developed in recent basic and clinical research, satisfactory results are still not obtained. Therefore, it has become a significant challenge in clinical and scientific research to explore the mechanism of AP occurrence and development and provide new treatment suggestions for AP patients.

According to TCM theory, the pathogenesis of AP belongs to the category of Yang ming fu-viscera excess syndrome, which should be treated following the principles of soothing liver, regulating qi, clearing heat, detoxifying and removing stasis by purgation. QYD is developed based on the classic prescription Da-Cheng-Qi decoction of “Shang Han Lun”, which is composed of eight herbs and obtained a significant effect in the clinical treatment of AP. However, its material basis and the overall mechanism of action

**FIGURE 6 |** Histopathological examination and biochemical analysis. **(A)** Histopathological observation of pancreatic tissue in four groups (HE,  $\times 200$ ); **(B)** Histological score of pancreatic tissue in four groups (HE,  $\times 200$ ). **(C)** Serum amylase level in rats. Data are presented as the mean  $\pm$  SD ( $n = 3$ ),  $^{**}p < 0.01$  vs. AP group.  $^{##}p < 0.01$  vs. CON group.

**FIGURE 7 |** QYD extracts protect pancreas tissue of SD rats by regulated inflammation and cell apoptosis. **(A)** Effects of QYD extracts on p-p65, t-p65, p-ERK1/2, t-ERK1/2, c-Fos protein levels in STC-induced acute pancreatitis model based on the western blotting assay; **(B–D)** Statistical analysis of the effects of QYD extracts on protein expressions levels. Data are presented as the mean  $\pm$  SD ( $n = 3$ ),  $^{**}p < 0.01$  vs. AP group.  $^{##}p < 0.01$  vs. CON group.

remain a mystery. In this study, a combined strategy of phytochemistry, network pharmacology, molecular docking and basic experiment was used to assess the active constituents and potential molecular mechanisms of QYD on AP step by step. Firstly, the chemical composition of QYD was characterized by UHPLC-QTOF-MS for the first time. A total of 110 constituents were identified, of which 47 conform to the Lipinski's rule of five and mainly belong to alkaloids, flavonoids, and anthraquinones. Next, 11

key components were further filtered through network pharmacology, which contained six flavonoids that mainly from *Scutellaria baicalensis* Georgi [quercetin (33), wogonin (97), baicalein (88), epicatechin (28), oroxylin A (101), skullcapflavon II (100)], three anthraquinones that mainly from *Rheum officinale* Baill. [emodin (104), aloe-emodin (93), physcion (108)], and two alkaloids that mainly from *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu [berberine (71),

palmitate (72)]. Interestingly, the effects of *Scutellaria baicalensis* Georgi, *Rheum officinale* Baill. and *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu in TCM are similar to the primary efficacy of QYD, which suggests that these three drugs play a significant role in QYD treatment of AP. This makes the prediction results of network pharmacology more convincing. Also, the main components of these three herbs have been preliminarily explored in the treatment of AP. Two previous studies found that baicalein (88) and quercetin (33) from *Scutellaria baicalensis* Georgi could alleviate the symptoms of AP by promoting cell apoptosis and inhibiting inflammation (Zheng et al., 2018; Pu et al., 2019). In addition, emodin (104) from *Rheum officinale* Baill. played an antioxidant and anti-inflammatory role in AP (Xia et al., 2019). Moreover, berberine (71) from *Corydalis yanhusuo* (Y. H. Chou and Chun C. Hsu) W. T. Wang ex Z. Y. Su and C. Y. Wu had analgesic effects, which involved relieving the pancreatic pain of QYD on AP (Choi et al., 2016). The above discussion fully affirmed the therapeutic potential of QYD in AP.

Apoptosis, inflammatory response, immune regulation, cell proliferation and differentiation are essential characteristics of AP development (Xiang et al., 2017). In this study, KEGG pathway enrichment analysis showed that 11 key components in the QYD regulate the information transmission of 15 signaling pathways by targeting 47 targets. Combined the results of KEGG and molecular docking, we found that the top targets in docking scores were near related to apoptosis and inflammation.

As is known to all, the AP's development process is related to apoptosis and necrosis of pancreatic acinar cells, the MAPK signaling pathway and Apoptosis signaling pathway were enriched by apoptosis-related proteins such as AKT1, CASP3, FOS, etc. Our molecular docking results showed that a high overall score existed in MAPK1 (ERK1/2) and FOS (c-Fos) when docking with 11 key components, which suggested that they may play an essential role in QYD against AP. Previous studies have confirmed that ERK1/2 is a crucial target for MAPK signaling pathways. It is an important carrier that transfers transmitting signals from cell surface receptors to the nucleus, which could be activated by upstream signaling molecules and regulate corresponding biological functions like cell proliferation and apoptosis (Ma et al., 2013; Tanaka and Iino, 2015; Li et al., 2018b). Some other researchers have found that the process of apoptosis could be regulated by promoting phosphorylation of ERK1/2 (Damiano et al., 2018; Kim et al., 2019). Similarly, apoptosis could be promoted after c-Fos being activated, which is a downstream target of ERK1/2 (Pandey and Wang, 1995; Wagner, 2010; Ren et al., 2013). It has also been reported that accelerating apoptosis is beneficial to the disease remission in the early stage of AP because it delays the process of cell necrosis to some extent (Cai et al., 2018b). Consistent with this, our molecular biology experiments showed that there was a significantly decreased in the expression of ERK1/2 and c-Fos when AP occurred, while QYD restored their expression to some extent. Other critical proteins related to apoptosis, such as BCL-2 and caspase family, were also predicted (Morishima et al., 2002). It suggested that QYD treatment of AP may be partially achieved by promoting the process of apoptosis.

The NF-KB signaling pathway is one of the typical inflammatory response pathways and the inflammatory response is a typical feature of AP. Although this pathway did not show in the results

of KEGG pathway enrichment analysis, it exists in the multiple signal pathways that have been enriched and play a vital role in them, such as MAPK signal pathway, T cell receptor signal pathway, Toll-like receptor signal pathway, and NOD-like receptor signaling pathway. RELA (p65) is an essential molecule in NF-KB signaling pathways who is responsible for the expression of proinflammatory mediators (Jakkampudi et al., 2016). When docking with critical components, it exhibited high binding activity. In some studies, inflammatory cascade reaction shows the importance to aggravate AP. The binding of p65 and IKB is inhibited under normal conditions. However, when something stimulates the cell, IKB will be degraded by IKK, p65 will be released and enter the nucleus quickly to binding with the DNA so that the transcription is initiated and a large number of inflammatory cells factors such as TNF- $\alpha$ , IL-6 and IL-1B are released. Then, the p65 is further activated, and the inflammatory response is gradually amplified (Hayden and Ghosh, 2008; Rotstein, 2014). Hence, we can see that inhibition of p65 expression could attenuate the severity of the inflammatory response and alleviate the symptoms of AP, which was also supported by the results of our experiment. In addition, other targets such as CHUK and GSK3B were also involved in inflammation and the AP process.

In recent years, more and more researches have focused on the human immune system. A study found that the disturbance of the immune regulation mechanism is one reason that aggravates the severity of AP and even leads to death (Kylänpää et al., 2010). AP could be improved by timely adjustment of the immunosuppressive state because it will urge a dynamic balance between the proinflammatory and anti-inflammatory responses (Munir et al., 2020). Other studies had shown that IL2, NFATC1 and LCK played a vital role in the T cell receptor signaling pathway. Among them, IL2 is necessary for T cell proliferation and other immune regulation, and it could stimulate B cells, monocytes and natural killer cells. And NFATC1 is very important for the induction of IL2 gene transcription. The differentiation and apoptosis of T cells was regulated by it (Chuvpilo et al., 1999). Besides, Lck is an src-related protein tyrosine kinase, which regulates T cells' survival status by binding to CD4 molecules and the inflammatory response of AP (Bai et al., 2014; Bozso et al., 2020).

It is worth noting that among the targets predicted in this study, some proteins were related to the cell cycle, cell proliferation and cell differentiation. Among the multiple proteins, the CCNB1, CDC42, CDKN1A, E2F1, EGFR, MYC, and TP53 had a higher docking score. Previous studies believed that inflammation was closely related to immunity and the unfavorable supervision of the immune system is an advantage for tumorigenesis (Padoan et al., 2019). Meanwhile, repeated episodes of AP can lead to chronic pancreatitis, and scholars such as Kleeff J believed that chronic pancreatitis is an important risk factor for pancreatic ductal adenocarcinoma. Moreover, obvious binding effects between key components and tumor-related proteins suggested that QYD may have unexpected effects in preventing the transformation of pancreatitis from inflammation to cancer (Kleeff et al., 1965; Tarasiuk and Fichna 2019).

There are still two shortcomings in this study. On one hand, in terms of the research dimension, there is a lack of the validation from clinical and cellular molecular aspects. On the other hand, in

terms of the research technology, network pharmacology ignores the dose-effect relationship of multi-components in formula when they exert the therapeutic effects. These deficiencies will be improved in subsequent studies.

In conclusion, our molecular biology experiments showed that QYD could reduce the expression of p-p65 and promote the expression of p-ERK1/2 and c-Fos significantly, which is consistent with the results of the prediction of network pharmacology and molecular docking. Based on this, we propose a plausible molecular mechanism for the multi-target effects of QYD on AP, namely, QYD may protect the pancreas from injury by promoting apoptosis and inhibiting inflammation (Figure 8).

## CONCLUSION

Chinese medicine plays a crucial role in preventing and treating AP. In this study, 110 chemical components of QYD were identified by UHPLC-QTOF-MS for the first time, and then 11 important components and 47 key targets were screened based on network pharmacological analysis. Molecular docking showed that QYD may influence the process of apoptosis and inflammation by regulating the expression of ERK1/2, c-Fos and p65, thus protecting pancreatic injury caused by AP. This result has been confirmed in molecular biology experiments. To sum up, our research not only provides a comprehensive understanding of the active components and molecular mechanism of QYD, but also provides experimental basis and new idea for further development and clinical application of QYD.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Animal Care and Welfare Committee of Dalian Medical University. Written informed consent was obtained from the owners for the participation of their animals in this study.

## AUTHOR CONTRIBUTIONS

T-FW and LZ are the co-first author and performed all the experiments like identification of traditional Chinese medicine components, network pharmacological analysis, molecular docking analysis and animal experiments, etc. PH, F-LH, J-YJ, K-LX and Z-ZW helped the first author in different steps of experiments. J-LQ and DS designed the experiments, analyzed and supervised the results and corrected the manuscript. All the authors read and approved the final version of the manuscript.

## FUNDING

This work was financially supported by grants from National Natural Science Foundation of China (Nos. 81703675, 81873156), National Key Research and Development Program of China (No. 2018YFE0195200) and Dalian Municipal Medical Research Foundation (No. 17Z2001).

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2021.590994/full#supplementary-material>.

Evaluation of the Efficacy and Safety of  
Chinese Herbal Injection Combined  
With Trimetazidine for Viral Myocarditis:  
A Network Meta-Analysis.  
Front. Pharmacol. 12:630896.  
doi: 10.3389/fphar.2021.630896

**Background:** Viral myocarditis (VMC) is a common emergency of cardiovascular disease. Current treatment for VMC includes the prohibition of exercise plus supportive and symptomatic treatment, given the lack of specific antiviral therapeutic options and insufficient evidence for the use of novel immunosuppressive therapies. Trimetazidine, a drug used to improve myocardial energy metabolism, is frequently used for the treatment of viral myocarditis. In China, Chinese herbal injections (CHIs) are often used in combination with trimetazidine. Therefore, we evaluate the efficacy and safety of CHI combined with trimetazidine in the treatment of VMC through the method of network meta-analysis.

**Methods:** We searched PubMed, the Cochrane Library, Embase, China National Knowledge Infrastructure (CNKI), Wanfang Database, Chinese Scientific Journals Full-text Database (VIP), and China Biology Medicine Database (CBM) databases from inception to September 1, 2020, to identify eligible randomized controlled trials. The Cochrane risk of bias tool was used to assess the risk of bias among selected studies and the Stata 16.0 software was used to perform the network meta-analysis.

**Results:** A total of 29 studies were included, representing data from 2,687 patients. The effectiveness rate, level of myocardial injury marker, and the adverse reaction rate were evaluated. Compared with conventional treatment or conventional treatment combined with trimetazidine, CHIs combined with trimetazidine appeared to have a better therapeutic effect, with higher effectiveness rate and better reduction of the levels of creatine kinase, creatine kinase-MB, and lactate dehydrogenase. Based on surface under the cumulative ranking, Shenmai injection combined with trimetazidine appeared to be superior in terms of effective rate, while *Astragalus* injection or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection combined with trimetazidine appeared most effective in

**Abbreviations:** VMC, viral myocarditis; CHI, Chinese herbal injection; TCM, traditional Chinese medicine; RCTs, randomized controlled trials; CNKI, China National Knowledge Infrastructure; VIP, Chinese Scientific Journals Full-Text Database; CBM, China Biology Medicine; CK, creatine kinase; CK-MB, creatine kinase-MB; LDH, lactate dehydrogenase; cTnI, cardiac troponin I; OR, odds ratios; SMD, standard mean difference; CI, confidence intervals; IF, inconsistency factors; SUCRA, surface under the cumulative ranking.

reducing myocardial injury markers. There was no significant difference in safety between the interventions. However, a lack of safety monitoring in some selected studies meant that the safety of some interventions could not be fully evaluated.

**Conclusion:** CHIs combined with trimetazidine may have therapeutic value in the treatment of viral myocarditis, and Shenmai injection, *Astragalus* injection, and *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection may represent the most effective CHIs. Further clinical investigation is required to confirm these results.

**Keywords:** randomized controlled trials, network meta-analysis, viral myocarditis, trimetazidine, Chinese herbal injection

## INTRODUCTION

Viral myocarditis (VMC) is a localized or diffuse myocardial inflammatory lesion caused by viral infection. Its clinical manifestations vary widely, from asymptomatic in mild cases to heart failure and even sudden cardiac death in severe cases. The most common manifestations are chest pain, heart failure, and fatigue dyspnea (Grün et al., 2012; Society of Cardiovascular Diseases, China Association of Chinese Medicine, 2020). Viral infection is believed to be the main cause of VMC, and the common viruses are coxsackievirus B, parvovirus B19, herpesvirus, and so on (Leone et al., 2019). Relevant epidemiological data show that the incidence of VMC is about 10–22 per 100,000 people, and the population is mainly young and middle-aged (Global Burden of Disease Study 2013 Collaborators, 2015; Olejniczak et al., 2020). As severe cases of VMC can lead to heart failure and sudden cardiac death, which seriously affect the life of patients, the timely treatment of it is very important. Current treatment for viral myocarditis remains founded on the prohibition of exercise plus supportive and symptomatic treatment, given the lack of specific antiviral therapeutic options and insufficient evidence for the use of novel immunosuppressive therapies (Tschöpe et al., 2019).

Trimetazidine, an oxidation inhibitor of free fatty acids, is often used in the treatment of heart disease with the effect of improving myocardial energy metabolism and protecting myocardium (Marzilli et al., 2019). Some studies have shown that trimetazidine has a curative effect in the treatment of VMC, which can increase the clinical effectiveness rate, improve clinical symptoms, and promote the recovery of myocardial zymogram (Yu et al., 2014). In China, traditional Chinese medicine (TCM) also has significant advantages in the treatment of VMC, showing good therapeutic effects in anti-inflammation, protecting myocardium, enhancing immune function and so on (Cao et al., 2015). Chinese herbal injection (CHI), the product of the combination of traditional Chinese medicine and modern technology, is a kind of innovative preparation with high bioavailability and good curative effect (Li et al., 2017). It is an innovative application of Chinese medicine and has been widely used in the treatment of VMC. In recent years, a large number of clinical practices have combined trimetazidine with CHI in the treatment of VMC, showing a better therapeutic effect. Liu et al (2015) conducted a meta-analysis of the efficacy and safety of *Astragalus* injection combined with trimetazidine for VMC, and

the results showed that compared with conventional treatment or conventional treatment combined with trimetazidine, *Astragalus* injection combined with trimetazidine improved the clinical efficacy and reduced the cardiac zymogram level significantly. Cheng (2015) researched the efficacy of trimetazidine combined with Shenmai injection in the treatment of VMC, and the results showed that the combination could significantly shorten the improvement time of clinical symptoms and signs, and reduced B-type natriuretic peptide (BNP) and C-reactive protein (CRP) levels. Wang (2019) showed that trimetazidine combined with *Breviscapine* injection in the treatment of acute VMC is superior to trimetazidine alone in controlling the level of inflammatory cytokines, improving myocardial zymogram and relieving symptoms and so on.

Although a variety of CHIs have shown considerable efficacy in the treatment of VMC, previous studies have only explored the efficacy and safety of a single CHI combined with trimetazidine. To date, no direct or indirect comparison of different CHIs combined with trimetazidine has been reported for the treatment of VMC, meaning that it remains unclear which CHIs are most effective in the treatment of this condition. In view of this, the study aims to indirectly compare the efficacy and safety of different CHIs combined with trimetazidine in the treatment of VMC through network meta-analysis and hopes to provide some reference for clinical treatment.

## MATERIALS AND METHODS

### Inclusion Criteria

All published clinical randomized controlled trials (RCTs) of CHI combined with trimetazidine in the treatment of VMC were selected. No restrictions were imposed on nationality, age, gender, and race. The control group was treated with conventional treatment or conventional treatment combined with trimetazidine. Conventional treatment included one or more of the following therapies: rest, sedation, antiarrhythmic therapy, myocardial protection, antioxidant therapy, antiviral therapy, and so on. The experimental group was treated with trimetazidine and CHI on the basis of the conventional treatment used in the control group. All the included literature should report any one of the primary or secondary outcome indicators. The primary outcome indicator was the effectiveness rate. The main reference criteria were as follows: markedly effective:

clinical symptoms improved or disappeared, myocardial injury markers (myocardial zymogram or cardiac troponin) returned to normal; effective: clinical symptoms relieved, myocardial injury markers improved partially, but did not fully return to normal; invalid: clinical symptoms did not improve or even further worsened, myocardial injury markers did not improve. Effectiveness rate =  $N$  (the number of markedly effective and effective cases)/ $N$  (total number of cases)  $\times$  100%. The secondary outcomes were as follows: 1) myocardial injury markers: creatine kinase (CK), creatine kinase-MB (CK-MB), lactate dehydrogenase (LDH), and cardiac troponin I (cTnI); 2) adverse reactions.

## Exclusion Criteria

1) Studies on treatment combined with other TCM-related treatment measures, such as TCM decoction, Chinese patent medicines, and acupuncture were excluded; 2) participants complicated with other diseases, such as coronary heart disease and diabetes; 3) literature works published with duplicate data; 4) the reported data were incomplete and impossible to be acquired; 5) the reported data were inconsistent with the conclusion.

## Search Strategies

To obtain RCTs of CHI combined with trimetazidine in the treatment of VMC, we searched PubMed, the Cochrane Library, Embase, China National Knowledge Infrastructure (CNKI), Wanfang database, Chinese Scientific Journals Full-Text Database (VIP), and China Biology Medicine Database (CBM) from inception to September 1, 2020. The search terms in English database were as follows: “Viral myocarditis,” “Myocarditides,” “Carditis,” “Myocarditis,” “Trimetazidine,” “Centrophène,” “Trimetazidine Dihydrochloride,” “Dihydrochloride,” “Trimetazidine,” “Vastarel,” “Trimetazidine Irex,” “Vasartel,” and “Idaptan.” The search terms in Chinese database included “bing du xing xin ji yan,” “qu mei ta qin,” “yan suan qu mei ta qin,” “wan shuang li,” and “san jia yang bian qin.” The search strategy of each database is shown in **Supplementary Table S1**.

## Literature Screening and Data Extraction

After literature retrieval, two evaluators independently conducted literature screening according to the inclusion and exclusion criteria. A preliminary screening was carried out according to the title and abstract, and then rescreening was carried out by reading the full text. Any differences in the screening results of the two evaluators were resolved by discussion with a third evaluator. After determining the included studies, the data of literature was extracted as follows: title, authors, year of publication, baseline status, methodological information, sample size, intervention measures, the course of treatment, and outcomes.

## Bias Risk Assessment

Two evaluators independently assessed the risk of bias in the included studies by using the Cochrane risk of bias tool (Higgins et al., 2011), which consisted of the following items: 1) random

sequence generation; 2) allocation hiding; 3) blinding of outcome evaluators; 4) blinding of patients and trial personnel; 5) incomplete result data; 6) selective reporting; and 7) other biases. The risk assessment criteria are divided into low, high, and uncertain bias risk. Any differences in the assessment results of the two evaluators were resolved by discussion with a third evaluator. The bias risk assessment results of the included studies were visualized by RevMan5.3 software.

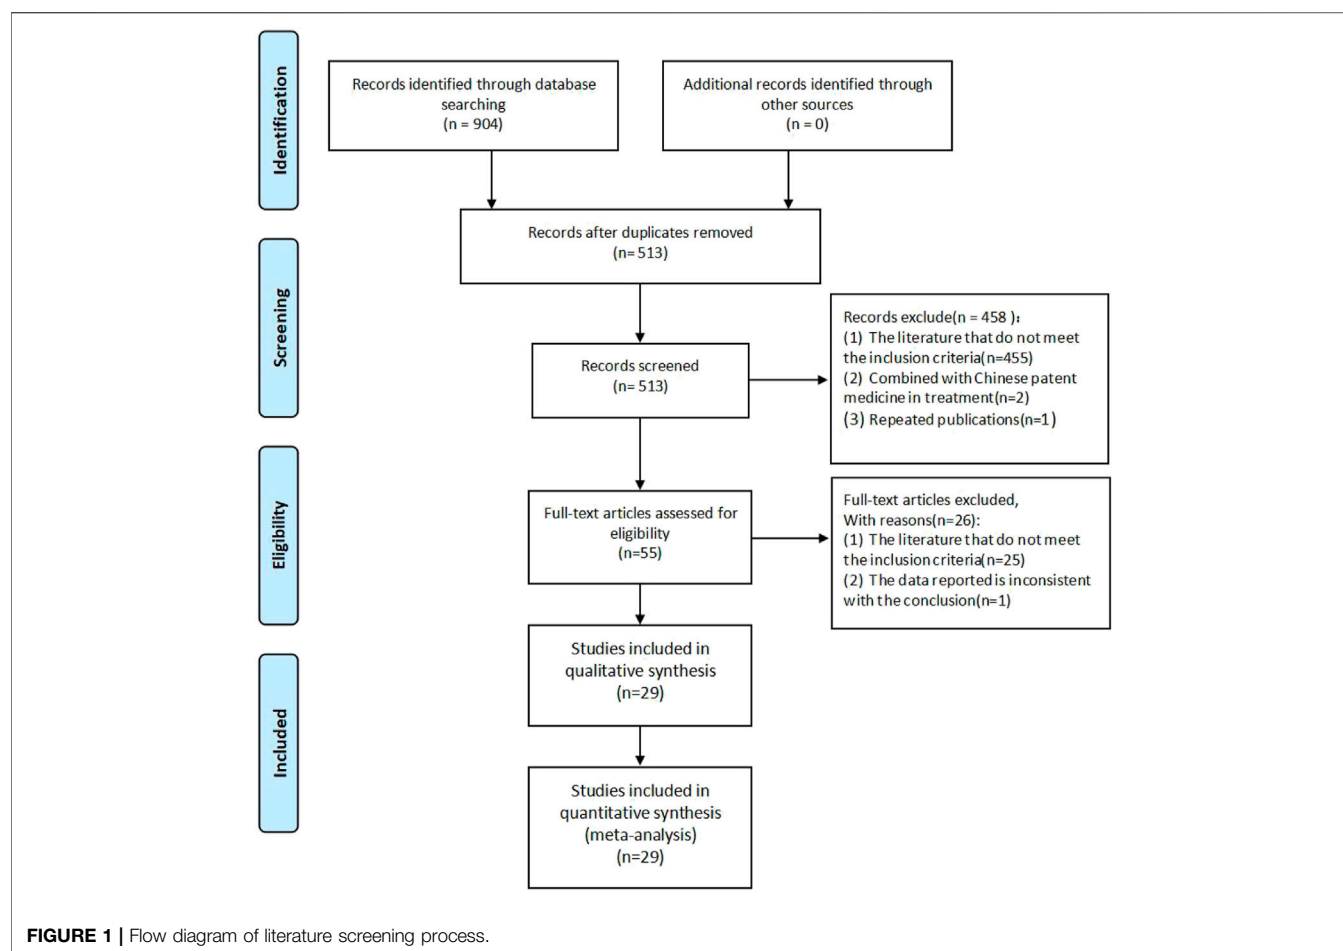

## Statistical Analysis

All statistical analysis was performed using Stata 16.0 software (Stata Company). For dichotomous variables (effectiveness rate and adverse reaction rate), odds ratios (OR), and 95% confidence intervals (CI) were used to assess effect size, whereas the effect size of continuous variables (myocardial injury markers) was assessed using the standard mean difference (SMD) and 95% CI. Considering the expected heterogeneity in the included studies, a random-effects model was used for statistical analysis. If the data could not be meta-analyzed, we would conduct a descriptive analysis. Based on the classical frequency, the random-effects model was selected under the “Network” command in the analysis software to perform the network meta-analysis. A network diagram of interventions was constructed to show the relationships between interventions. Where no closed loop was formed, the consistency model was used for analysis. When a closed loop was observed, an overall inconsistency check was performed. If  $p$  value  $> 0.05$ , it indicated that the overall inconsistency was not significant, otherwise, it indicated that the overall inconsistency was significant. At the same time, the inconsistency test of the loop was carried out to determine inconsistency between direct and indirect evidence by calculating the absolute difference between these types of evidence, expressed as an inconsistency factor (IF). Whereas 95% CI of the IF values contained 0, and the inconsistency of direct and indirect evidence was considered not significant. Otherwise, the inconsistency was deemed significant. When no inconsistency was apparent, the consistency model was used for analysis. Otherwise, the inconsistency model was selected for analysis. The value of surface under the cumulative ranking (SUCRA) was subsequently calculated and the number of iterations set at 5,000. Intervention measures were sorted based on SUCRA value. The larger the SUCRA value, the higher the ranking, indicating that the intervention was more likely to be the best intervention. Funnel plots were used to evaluate publication bias in the included studies.

## RESULTS

### Literature Search and Screening

A total of 904 literature works were obtained. Among them, there were 3 from PubMed, 7 from the Cochrane Library, 4 from Embase, 453 from CNKI, 172 from Wanfang database, 135 from VIP, and 130 from CBM. After screening, a total of 29 studies were included. The literature screening process is shown in **Figure 1**.

## Basic Characteristics of Included Studies

29 studies enrolled a total of 2,687 patients. All the included studies were conducted in China, and the literature was published from 2009 to 2020. The baselines of all studies were comparable between the experimental and control groups. In terms of intervention measures, the control groups of 18 studies were treated with conventional treatment alone, whereas the experimental groups were treated with CHI and trimetazidine on the basis of the control groups. Among them, 14 studies were combined with *Astragalus* injection, 3 studies combined with Shenfu injection, and 1 study combined with Shenmai injection. In the other 11 studies, the control groups were treated with conventional treatment combined with trimetazidine, whereas the experimental groups were treated with CHI on the basis of the control group. Among them, 4 studies combined with *Astragalus* injection, 4 studies combined with *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection, 2 studies combined with *Brevicapsine* injection, and 1 study combined with Shenmai injection. The detailed information of CHIs used in included studies and the chemical analysis of them are shown in **Supplementary Tables S2, S3**. In the course of treatment, the shortest was 2 weeks and the longest was 8 weeks. In the outcome indicators, 25 studies reported the effectiveness rate, 10 studies reported the level of CK, 12 studies reported the level of CK-

MB, 13 studies reported the level of LDH, 8 studies reported the level of cTnI, and 20 studies reported the adverse reactions during treatment. The basic characteristics of included studies are detailed in **Table 1**. For the convenience of description, A refers to conventional treatment, B refers to conventional treatment combined with trimetazidine and *Astragalus* injection, C refers to conventional treatment combined with trimetazidine and Shenfu injection, D refers to conventional treatment combined with trimetazidine and *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection, E refers to conventional treatment combined with trimetazidine and *Brevicapsine* injection, and G refers to conventional treatment combined with trimetazidine and Shenmai injection. The network diagrams of the seven interventions in different outcome indicators are shown in **Figure 2**.

## Bias Risk Assessment of Included Studies

The methodological quality of the included studies was generally low. In the generation of random sequences, 9 studies used random number tables, and 1 study used lottery randomization, so they were at low bias risk. Other studies only mentioned randomness and did not describe random methods, so they were at uncertain bias risk. None studies

**TABLE 1 |** Basic characteristics of the included studies.

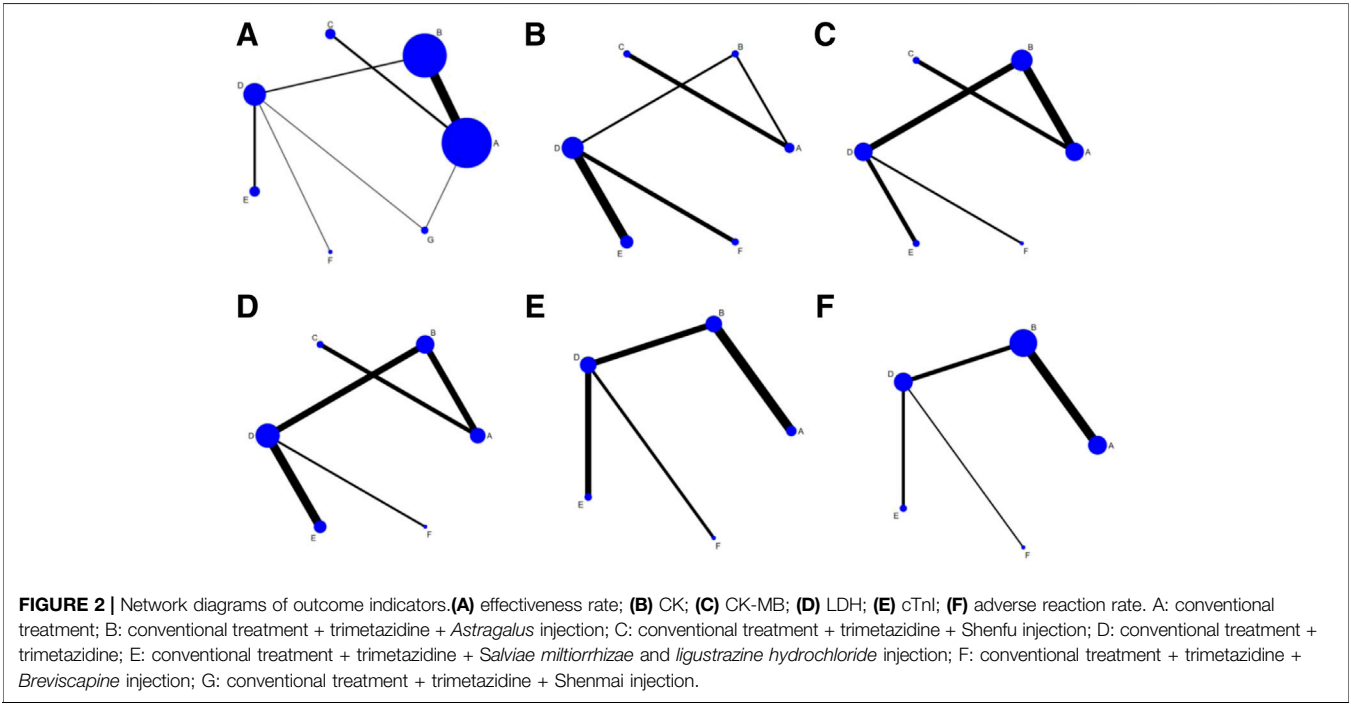

Study	Age (mean or range)	Sample size	Intervention		Courses	Outcome
	C/E	C/E	C	E

OR, odds ratio; SMD, standardized mean difference; CI, confidence interval; A, conventional treatment; B, conventional treatment + trimetazidine + Astragalus injection; C, conventional treatment + trimetazidine + Shenfu injection; D, conventional treatment + trimetazidine; E, conventional treatment + trimetazidine + *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection; F, conventional treatment + trimetazidine + *Breviscapine* injection; G, conventional treatment + trimetazidine + Shenmai injection.

combined in the analysis. The remaining 23 studies constituted 7 pairs of direct comparisons, which involved 5 types of CHIs. Four types of intervention measures (A and G) formed a quadrilateral closed loop, as shown in **Figure 2A**. The overall inconsistency test result had a  $p$  value = 0.891, indicating that the inconsistency was not significant, as shown in **Figure 4**. The inconsistency test of the loop resulted in an IF = 0.26 and 95% CI (0.00, 4.03), indicating that the inconsistency between the direct and indirect evidence was not significant, as shown in **Figure 5**. The consistent model was therefore adopted for network meta-analysis.

A total of 21 pairs were compared among the 7 intervention measures, 9 of which showed statistically significant differences ( $p < 0.05$ ). On the basis of conventional treatment, combining with *Astragalus* injection and trimetazidine [OR = 4.83, 95% CI (3.30, 7.09)], or Shenfu injection and trimetazidine [OR = 5.96, 95% CI (2.50, 14.23)], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection and trimetazidine [OR = 6.38, 95% CI (1.96, 20.77)], or *Breviscapine* injection and trimetazidine [OR = 4.46, 95% CI (1.34, 14.80)], or Shenmai injection and trimetazidine [OR = 15.17, 95% CI (2.41, 95.25)] was superior to conventional treatment alone with respect to effectiveness rate. In addition to the Shenfu injection, on the basis of conventional treatment plus trimetazidine, combining with *Astragalus* injection [OR = 2.58, 95% CI (1.14, 5.86)], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection [OR = 3.40, 95% CI (1.58, 7.34)] or *Breviscapine* injection [OR = 2.38, 95% CI (1.07, 5.28)], or Shenmai injection [(OR = 8.09, 95% CI (1.38, 47.59)] was superior to conventional treatment plus trimetazidine in terms of effectiveness rate. The comparisons

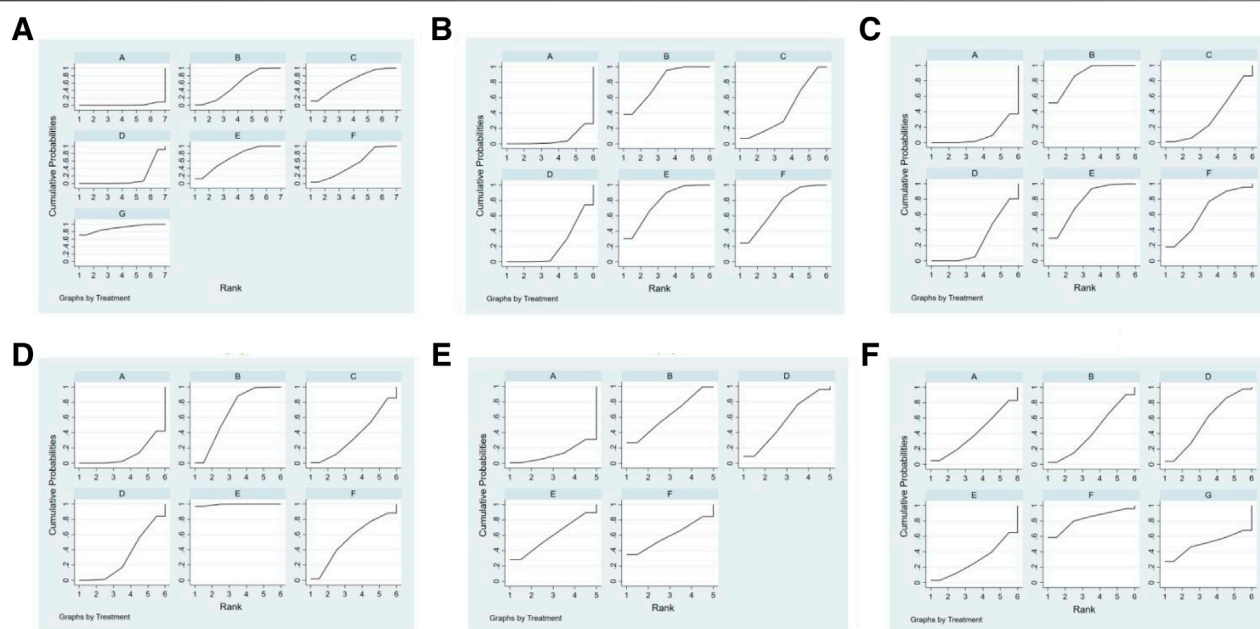

among the 5 types of injections and between conventional treatment and conventional treatment plus trimetazidine showed no statistically significant difference ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Ranking the 5 types of injections according to the SUCRA resulted in the following hierarchy: Shenmai injection (89.2%), *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (69.1%), Shenfu injection (65.5%), *Astragalus* injection (55.2%), and *Breviscapine* injection (52.3%), as shown in **Figure 6A**.

### Creatine Kinase

A total of 10 studies reported the level of CK, which constituted 5 pairs of direct comparisons, involved 4 types of CHIs and 6 types of intervention measures. The network diagram formed is shown in **Figure 2B**. Since it did not form a closed loop, no inconsistency test was carried out.

A total of 15 pairs were compared among the 6 intervention measures, 6 of which showed statistically significant differences ( $p > 0.05$ ). On the basis of conventional treatment, combining with *Astragalus* injection and trimetazidine [SMD = −2.94, 95% CI (−4.79, −1.09)], or Shenfu injection and trimetazidine [SMD = −1.59, 95% CI (−2.78, −0.40)], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection and trimetazidine [SMD = −2.90, 95% CI (−5.55, −0.24)] was superior to conventional treatment alone on reducing the level of CK. On the basis of conventional treatment plus trimetazidine, combining with *Astragalus* injection [SMD = −2.10, 95% CI (−3.81, −0.39)], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection

**FIGURE 6 |** SUCRA of outcome indicators. (A): effectiveness rate; (B): CK; (C): CK-MB; (D): LDH; (E): cTnl; (F): adverse reaction rate. A: conventional treatment; B: conventional treatment + trimetazidine + *Astragalus* injection; C: conventional treatment + trimetazidine + Shenfu injection; D: conventional treatment + trimetazidine; E: conventional treatment + trimetazidine + *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection; F: conventional treatment + trimetazidine + *Breviscapine* injection; G: conventional + treatment + trimetazidine + Shenmai injection.

[SMD =  $-2.06$ , 95% CI ( $-2.90$ ,  $-1.22$ )] or *Breviscapine* injection [SMD =  $-1.90$ , 95% CI ( $-3.07$ ,  $-0.72$ )] was superior to conventional treatment plus trimetazidine on reducing the level of CK. The comparisons among the 4 types of injections and between conventional treatment and conventional treatment plus trimetazidine showed no statistically significant difference ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Ranking the 4 injections based on the SUCRA value, the results were as follows: *Astragalus* injection (79.5%), *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (77.1%), *Breviscapine* injection (71.7%), and Shenfu injection (44.5%), as shown in **Figure 6B**.

### Creatine Kinase-MB

A total of 12 studies reported the level of CK-MB, which constituted 5 pairs of direct comparisons, involved 4 types of CHIs and 6 types of intervention measures. The network diagram formed is shown in **Figure 2C**. It did not form a closed loop, so there was no inconsistency test.

A total of 15 pairs of comparisons were formed among the 6 intervention measures, 5 of which were statistically significant ( $p < 0.05$ ). On the basis of conventional treatment, combining with *Astragalus* injection and trimetazidine [SMD =  $-3.49$ , 95% CI ( $-4.80$ ,  $-2.17$ )], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection and trimetazidine [SMD =  $-3.07$ , 95% CI ( $-5.78$ ,  $-0.36$ )] was superior to conventional treatment alone on reducing the level of CK-MB. On the basis of conventional treatment plus trimetazidine, combining with *Astragalus*

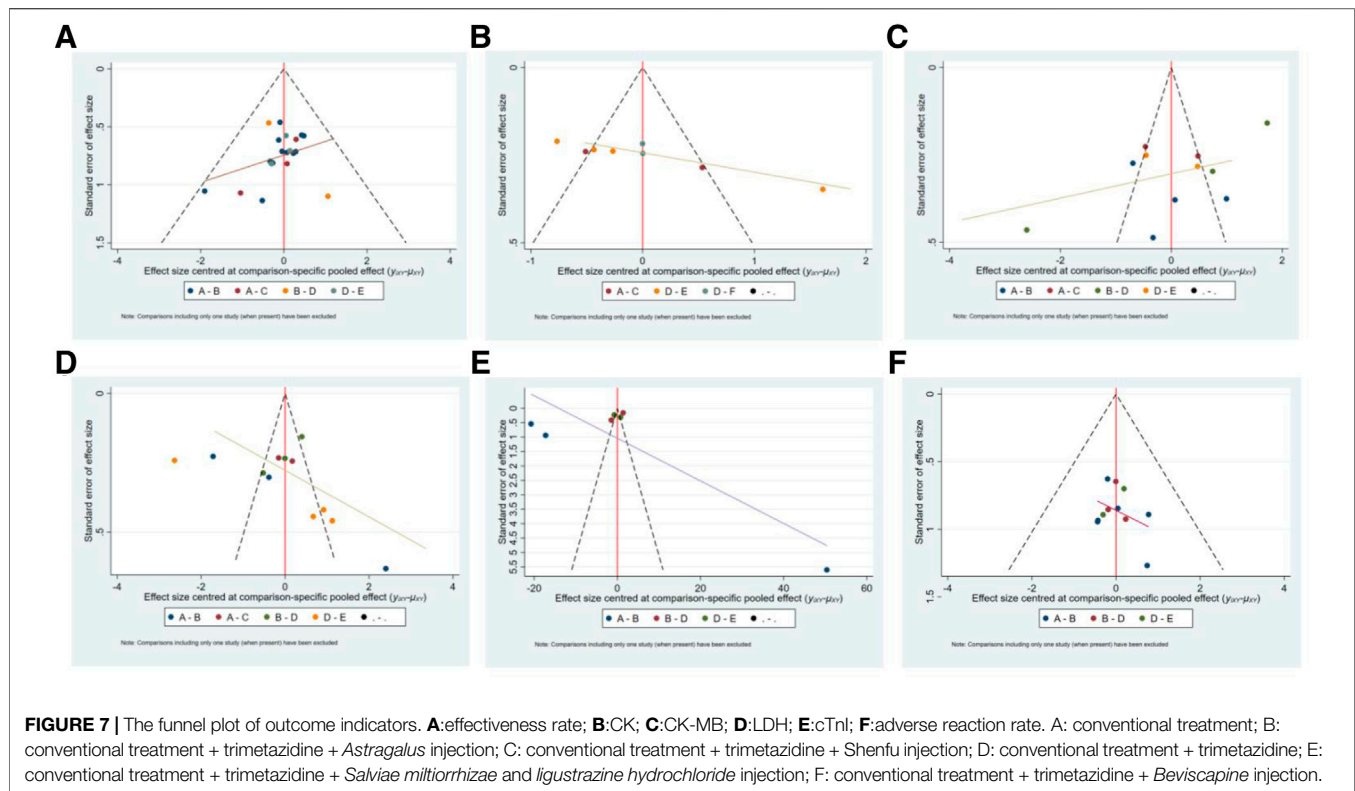

injection [SMD =  $-2.73$ , 95% CI ( $-4.23$ ,  $-1.22$ )], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection [SMD =  $-2.31$ , 95% CI ( $-4.13$ ,  $-0.48$ )] was superior to conventional treatment plus trimetazidine on reducing the level of CK-MB. The comparisons among the 4 types of injections showed that on the basis of conventional treatment plus trimetazidine, combining with *Astragalus* injection was superior to Shenfu injection [SMD =  $-2.58$ , 95% CI ( $-0.33$ ,  $-4.82$ )] on reducing the level of CK-MB. The other 10 pair comparisons showed no statistically significant difference ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Based on the SUCRA value, the 4 types of injections were ranked as follows: *Astragalus* injection (87.5%), *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (77.9%), *Breviscapine* injection (64.3%), and Shenfu injection (33.9%), as shown in **Figure 6C**.

### Lactate Dehydrogenase

A total of 13 studies reported the level of LDH, which constituted 5 pairs of direct comparisons, involved 4 types of CHIs and 6 types of intervention measures. The network diagram formed is shown in **Figure 2D**. No closed loop was constituted and no inconsistency test was performed.

A total of 15 pairs of comparisons were formed among the 6 intervention measures, 6 of which were statistically significant ( $p < 0.05$ ). On the basis of conventional treatment, combining with *Astragalus* injection and trimetazidine [SMD =  $-2.25$ , 95% CI ( $-3.97$ ,  $-0.53$ )], or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection and trimetazidine [SMD =  $-5.40$ , 95%

CI (−8.23, −2.58)] was superior to conventional treatment alone on reducing the level of LDH. On the basis of conventional treatment plus trimetazidine, combining with *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection [SMD = −4.49, 95% CI (−5.97, −3.00)] was superior to conventional treatment plus trimetazidine on reducing the level of LDH. The comparisons among the 4 types of injections showed that on the basis of conventional treatment plus trimetazidine, combining with *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection was superior to *Astragalus* injection [SMD = −3.16, 95% CI (−5.40, −0.92)] or Shenfu injection [SMD = −4.45, 95% CI (−7.94, −0.96)] or *Breviscapine* injection [SMD = −3.52, 95% CI (−6.77, −0.27)] on reducing LDH. The other 9 pairs comparisons were not statistically significant ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Ranking the 4 injections based on the SUCRA value, the results were as follows: *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (99.4%), *Astragalus* injection (66.7%), *Breviscapine* injection (54.3%), and Shenfu injection (36.4%), as shown in **Figure 6D**.

### Cardiac Troponin I

A total of 8 studies reported the level of cTnI, which constituted 4 pairs of direct comparisons, involved 3 types of CHIs and 5 types of intervention measures. The network diagram formed is shown in **Figure 2E**. Since it did not constitute a closed loop, the inconsistency test was not performed.

The results showed that there were no statistically significant differences among 10 pairs of comparisons of the

5 intervention measures ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Based on the SUCRA value, the 3 injections were ranked as follows: *Astragalus* injection (63.2%), *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (59.4%), and *Breviscapine* injection (59.4%), as shown in **Figure 6E**.

### Adverse Reaction Rate

Eight studies reported no adverse reactions during treatment, and 12 studies reported the number of cases of adverse reactions. The adverse reactions mainly include dizziness, headache, abdominal discomfort, nausea and vomiting, poor appetite, diarrhea, and rash. In terms of the adverse reaction rate, 12 studies consisted 4 pairs of comparisons, involved 3 types of CHIs and 5 types of intervention measures. The network diagram formed is shown in **Figure 2F**. Since it did not constitute a closed loop, the inconsistency test was not performed. The results showed that there were no statistically significant differences among 10 pairs comparisons of the 5 intervention measures ( $p > 0.05$ ). The above results are detailed in **Table 2**.

Ranking the three injections based on the SUCRA value, the results were as follows: *Breviscapine* injection (90.4%), *Astragalus* injection (39.3%), and *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection (26.1%), as shown in **Figure 6F**.

### Assessment of Publication Bias

The funnel plots have poor symmetry, indicating that there was some publication bias in the included studies, which may be caused by small sample effects, as shown in **Figure 7**.

## DISCUSSION

In the present study, we conducted a search of the RCTs of CHIs combined with trimetazidine in the treatment of VMC, and adopted a network meta-analysis approach to evaluate the clinical efficacy and safety of different CHIs combined with trimetazidine. A total of 29 RCTs were included in this analysis, representing 7 types of intervention measures and 5 types of CHIs. Our findings indicate that, in terms of effectiveness rate and reduction of the CK and CK-MB levels, *Astragalus* injection or *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection combined with trimetazidine was superior to conventional treatment alone or conventional treatment combined with trimetazidine. Moreover, *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection combined with trimetazidine was also superior to conventional treatment or conventional treatment combined with trimetazidine in reducing the level of LDH, and *Astragalus* injection combined with trimetazidine was also superior to conventional treatment in reducing the level of LDH. Shenmai injection or *Breviscapine* injection combined with trimetazidine was better than conventional treatment or conventional treatment combined with trimetazidine in terms of effectiveness rate. *Breviscapine* injection combined with trimetazidine was superior to conventional treatment combined with trimetazidine in reducing the level of CK. Shenfu injection combined with trimetazidine was superior to conventional treatment alone in terms of effectiveness rate and reduction of CK level. The comparison of different CHIs showed that *Astragalus* injection was superior to Shenfu injection in reducing the level of CK-MB. In reducing the level of LDH, *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection was superior to *Astragalus* injection, Shenfu injection, and *Breviscapine* injection. In terms of safety, there was no significant difference among different interventions. Based on the ranking of the SUCRA value, Shenmai injection may be superior to other injections in terms of effectiveness rate, *Astragalus* injection and *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection may be superior to other injections in reducing myocardial injury markers. However, different CHIs have different properties. Some tend to replenish qi, some tend to activate blood circulation, some tend to tonify yang, and some tend to nourish yin. Therefore, for the selection of CHI, it is better to choose based on the performance of patients and syndrome differentiation of traditional Chinese medicine in clinical practice, which may be able to harvest a better clinical efficacy.

As a myocardial metabolic agent, trimetazidine can optimize the oxidation of fatty acids and glucose, improve myocardial metabolism, inhibit cardiomyocyte apoptosis, reduce cardiac remodeling, improve cardiac function and so on, which is often used in the treatment of cardiovascular diseases (Li et al., 2020). *Astragalus* injection is extracted from the root of *Astragalus mongholicus* Bunge. Previous studies have shown that the application of *Astragali Radix* can improve the survival rate and relieve the pathological changes of mice with VMC induced by coxsackievirus B3 (Chen et al., 2006). Astragaloside IV plays a cardioprotective role in experimental animals with VMC through

a variety of signal pathways, such as antimyocardial remodeling, antivirus, anti-oxidation, anti-inflammation, anti-apoptosis, and reducing myocardial fibrosis (Zhuang et al., 2019). *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection is a compound preparation composed of *ligustrazine hydrochloride* and the extract of *Salvia miltiorrhiza* Bunge. *Salviae miltiorrhizae Radix et Rhizoma* is a standard Chinese herbal medicine for promoting blood circulation and removing blood stasis, and is thus widely used in the treatment of cardiovascular diseases. Previous studies have shown that several active components of *Salviae miltiorrhizae Radix et Rhizoma* have significant anti-inflammatory and antioxidant activities (MEIm et al., 2019). Tanshinone IIA can reduce myocardial apoptosis and myocardial remodeling caused by overload (Feng et al., 2016) and has been shown to alleviate cardiac dysfunction in septic mice by inhibiting inflammatory response (Huang et al., 2015). Tanshinol enhances antioxidant activity by activating serine/threonine kinase/extracellular signaling-regulated kinase1/2/nuclear factor erythroid-2-related factor 2 (Akt/ERK1/2/Nrf2) signal pathway, thus exerting a cardioprotective function (Yu et al., 2015). *Ligustrazine hydrochloride* can reduce cardiomyocyte apoptosis and injury in coxsackievirus B3-induced VMC by downregulating the expression of membrane surface molecules in mouse cardiomyocytes (Jiang et al., 2014). *Breviscapine* injection, which is extracted from *Erigeron breviscapus* (Vaniot.) Hand-Mazz., has been shown in previous studies to have pharmacological effects, such as anti-inflammation, endothelial protection, myocardial protection, and reduction of cardiac remodeling, leading to its widespread use in the treatment of cardiovascular disease (Gao et al., 2017). Shenmai injection is derived from *Panax ginseng* C. A. Mey. and *Ophiopogon japonicus* (Thunb.) Ker Gawl., and has been shown in systematic reviews to be of use in the treatment of VMC (Lu et al., 2014). Ginsenoside Rb3, an active components of *Ginseng Radix et Rhizoma*, can inhibit endothelial to mesenchymal transformation of cardiac microvascular cells following coxsackievirus B3 infection through protein-rich tyrosine kinase 2-phosphoinositide-3-kinase/serine/threonine kinase (Pyk2-PI3K-AKT) signal pathway (Yang et al., 2019). Finally, Shenfu injection is derived from *Panax ginseng* C. A. Mey. and *Aconitum carmichaeli* Debeaux, and is widely used in China for the treatment of acute and critical cardiovascular diseases. Studies have shown that Shenfu injection may play a role in antiviral myocarditis by regulating multiple metabolic pathways, such as sphingolipid metabolism, glycerophospholipid metabolism, arachidonic acid metabolism, tryptophan metabolism, amino acyl RNA biosynthesis, and the citrate cycle (Tan et al., 2018).

Although the present study compared the efficacy and safety of different types of CHIs combined with trimetazidine in the treatment of VMC by network meta-analysis and provided some reference for the selection of CHI in clinic, there are still some limitations in this study. First, the methodological quality of the included studies was generally low. The method of generating random sequences in most studies is not clear, and all studies have no random allocation hiding, which may lead to selective bias in the determination of subjects. Almost all the included studies have not blinded the patients, trial personnel, and outcome evaluator, which may lead to expectation bias due

to the influence of subjective factors in the evaluation of outcome indicators. Second, there may be some clinical heterogeneity because of some differences in the age of participants, drug dosage, and course of treatment in the included studies. Some studies do not monitor safety, leading to the failure to assess the safety of some CHIs. In addition, there may be a small sample effect, resulting in some publication bias in the included study. In view of the above limitations, we suggest that more high-quality, large-sample, standardized clinical randomized controlled trials should be carried out in the future, to provide strong evidence for the efficacy and safety of CHIs combined with trimetazidine for the treatment of VMC.

## CONCLUSION

The results of our network meta-analysis showed that CHI combined with trimetazidine may have therapeutic effect in the treatment of VMC. Compared with conventional treatment alone or conventional treatment combined with trimetazidine, the clinical effectiveness rate of CHI combined with trimetazidine is higher, with a greater effect on reducing myocardial zymogram level and no significant difference in safety. Among these CHIs evaluated in our analysis, Shenmai injection, *Astragalus* injection, and *Salviae miltiorrhizae* and *ligustrazine hydrochloride* injection may be the most effective. Given the limitations in the design of the included studies, our conclusions require further verification in larger, multicenter, and randomized controlled trials.

**Background:** Gegen Qinlian decoction (GGQLD) is a typical traditional Chinese medicine (TCM) prescription documented in *Shang Han Lun*. Clinically, GGQLD has been utilized to manage the inflammatory symptoms of metabolic diseases and to protect against renal damage in China. In the present study, a hypothesis was proposed that the multi-target solution of GGQLD produced anti-inflammatory effects on ameliorating hyperuricemia (HUA).

**Methods:** A total of 30 primary HUA patients receiving GGQLD treatment (two doses daily) for 4 weeks were selected. Then, differences in uric acid (UA) levels and expression of peripheral blood mononuclear cells (PBMCs) and urinary exosomes before and after treatment were analyzed. The therapeutic indexes for the active ingredients in GGQLD against HUA were confirmed through pharmacological subnetwork analysis. Besides, the HUA rat model was established through oral gavage of potassium oxonate and treated with oral GGQLD. In addition, proximal tubular epithelial cells (PTECs) were stimulated by UA and intervened with GGQLD for 48 h. Subsequently, RNA-seq, flow cytometry, and confocal immunofluorescence microscopy were further conducted to characterize the differences in UA-mediated inflammation and apoptosis of human renal tubular epithelial cells pre- and post-administration of GGQLD. In the meanwhile, quantitative real-time PCR (qPCR) was carried out to determine gene expression, whereas a western blotting (WB) assay was conducted to measure protein expression.

**Results:** Our network analysis revealed that GGQLD treated HUA via the anti-inflammatory and antiapoptotic pathways. Additionally, NLRP3 expression significantly decreased in PBMCs and urinary exosomes of HUA patients after GGQLD treatment. *In vivo*, GGQLD treatment alleviated HUA-induced renal inflammation, which was associated with decreased expression of NLRP3 inflammasomes and apoptosis-related mRNAs. Moreover, GGQLD promoted renal UA excretion by inhibiting the activation of GSDMD-

dependent pyroptosis induced by NLRP3 inflammasomes and by reducing apoptosis via the mitochondrial apoptosis signaling pathway *in vitro*.

**Conclusion:** This study indicates that GGQLD efficiently reduces inflammatory responses while promoting UA excretion in HUA. Our findings also provide compelling evidence supporting the idea that GGQLD protects against the UA-mediated renal tubular epithelial cell inflammation through the mitochondrial apoptosis signaling pathways. Taken together, these findings have demonstrated a novel therapeutic method for the treatment of HUA.

**Keywords:** Gegen Qinlian decoction, hyperuricemia, NLRP3, apoptosis, pharmacological network analysis

## INTRODUCTION

Hyperuricemia (HUA) is a factor that independently predicts the risk of kidney diseases (Prasad and Qing, 2015; Srivastava et al., 2018; Tsai et al., 2018). Generally, HUA is manifested as macrophage infiltration, tubular damage, and upregulated inflammatory mediator levels (Zhou et al., 2012; Xiao et al., 2018; Braga et al., 2020). The renal proximal tubule plays a pivotal role in transporting renal urate, which is a major site of urate reabsorption (Lipkowitz, 2012) and exerts a remarkable role in HUA occurrence and development. In our previous study, soluble uric acid (UA) triggers NLRP3 inflammasome production, IL-1 $\beta$  expression, and caspase-1 activation in human PTECs, which could thus induce the secretion of pro-inflammatory cytokines and activate the innate immunity (Xiao et al., 2015; Xiao et al., 2016). Therefore, it is of importance to develop a treatment against HUA to prevent renal tubular injury in the future. Till the present, numerous patients have experienced a relapse after the withdrawal of anti-hyperuricemic drugs such as benzbromarone.

For thousands of years, combination therapy has been promoted in traditional Chinese medicine (TCM) to treat different disorders. Among them, Gegen Qinlian decoction (GGQLD), one of the typical TCM prescriptions, was originally documented in the *Treatise on Exogenous Febrile Disease* in the Han Dynasty (202 BC–220 CE). GGQLD comprises *Pueraria montana* var. *lobata* (Gegen), *Scutellaria baicalensis* Georgi (Huangqin), *Glycyrrhiza uralensis* Fisch. ex DC (Gancao), and *Coptis chinensis* Franch (Huanglian). It has been extensively utilized for the clinical treatment of gastrointestinal diseases for approximately 2,000 years, in particular for damp-heat syndrome-related diarrhea (Bi et al., 2013; Tian et al., 2016). Moreover, the clinical efficacy of GGQLD in treating ulcerative colitis (UC) has been verified (Zhao et al., 2020). Experiments *in vitro* and *in vivo* suggest that some active ingredients in GGQLD, like berberine, baicalin, and puerarin, obviously mitigate oxidative stress (OS) and inflammation (Dinesh and Rasool, 2017; Guarino et al., 2017; Yu et al., 2021). We previously discovered that GGQLD exerted diabetes-mitigating (Xu et al., 2011; Li et al., 2013; Zhang et al., 2013) and anti-inflammation effects through its active ingredients (Tian et al., 2013; Ryuk et al., 2017; Wu et al., 2019). Besides, inflammatory response, lipid, and glucose metabolic disorders are also important for HUA. Therefore, guided by the TCM theory of “treating different diseases with

the same therapy,” GGQLD can be sometimes used to treat HUA. However, the underlying mechanism of action has not been clarified.

By network pharmacology, we discovered that GGQLD might treat HUA via the anti-inflammatory and antiapoptotic pathways. Further experiments showed that GGQLD alleviated the inflammatory state of HUA patients and improved renal inflammation in HUA rats. Moreover, *in vitro* experiment confirmed that GGQLD played a role in the inflammation and apoptosis of PTECs induced by UA.

## MATERIALS AND METHODS

### Materials and Reagents

Cell culture medium and human primary renal PTECs were provided by ScienCell (San Diego, CA, United States). Anti-SLC2A9 (URAT1) antibodies, TSG101, CD63, caspase-1, GSDMD, IL-1 $\beta$ , caspase-3, caspase-8, caspase-9, cytochrome c, Bcl-2, and Bax were purchased from ABclonal (Wuhan, China). Oxonic acid (OA) and UA were provided by Sigma (St. Louis, MO, United States). CIAS1/NALP3, GAPDH, and anti-GLUT9 were provided by Abcam (Cambridge, United Kingdom). In addition, the CCK-8 assay kit was provided by Jiwei Biological Technology (Shanghai, China).

### Preparation of GGQLD

GGQLD, a famous decoction documented in the *Treatise on Exogenous Febrile Disease* around 1,900 years ago, was used and approved by the Huadong Hospital Affiliated to Fudan University. The dried herbs, including *Pueraria montana* var. *lobata* (Gegen), *Scutellaria baicalensis* Georgi (Huangqin), *Glycyrrhiza uralensis* Fisch. ex DC (Gancao), and *Coptis chinensis* Franch (Huanglian), in the ratio of 8:3:3:2 (w/w/w/w), were first soaked in distilled water with 15-fold volumes of herbs (v/w) for 30 min and then extracted by decoction twice, 2 h for the first time and 2 h for the second time, with 8-fold volumes of water to herbs (v/w). After filtration, the solution was evaporated under reduced pressure to a suspension with a final density of 1 g/ml and stored at 4°C for further use (Xie et al., 2006).

### High-Performance Liquid Chromatography (HPLC)

Puerarin, baicalin, liquiritin, and berberine (all purities >98%) were provided by Shanghai Yuanzhi Biotechnology Co., Ltd.

(Shanghai, China). **Supplementary Figure S1** presents the chemical structures of the ingredients. Acetonitrile, formic acid, and methanol of HPLC grade were provided by Merck Company (Darmstadt, Germany). The Milli-Q system (Millipore, Milford, MA, United States) was utilized to obtain deionized water. Other reagents of analytical grade were acquired from commercial sources. To identify the components of GGQLD, we performed HPLC analysis using an Agilent 1260 Infinity brand chromatographic chain with a C18 chromatographic column (250 × 4.6 mm, 5 μm, Thermo Fisher Scientific, NY, United States), along with a column oven, a binary pump, a diode array detector, and an autosampler (Agilent 1100 series). Thereafter, 20 ml ethanol extract was added to the column. Throughout the whole chromatographic analysis process, the column injector was maintained at 25°C. The mobile phase comprised the ammonium formate solution (10 mmol/l, pH 3.0, A) and acetonitrile. For the components, their detection wavelength was set at 270 nm. Subsequently, we identified each compound according to the pure standard absorbance spectra and retention time (Guo et al., 2019).

## Systemic Pharmacological Analysis of GGQLD

We searched the active ingredients of Gegen, Huangqin, Huanglian, and Gancao in GGQLD against the TCMSP database (<http://tcmsp.com/index.php>) by the thresholds of druglikeness (DL, also known as the similarity between the known medicines and the components) ≥0.18 and oral bioavailability (OB, medicine component oral availability) ≥30%. Based on the TCMSP database (Yao et al., 2013; Liu et al., 2020), we aligned the GGQLD active ingredients with the candidate targets separately, then retrieved targets of diverse origins against the UniProt database (<http://www.uniprot.org>), and acquired the official target gene symbols to perform subsequent assays. A total of 196 HUA-associated targets were identified from the DisGeNET (<http://www.disgenet.org>) and NCBI databases. Cytoscape 3.8.0 software is the openly accessible bioinformatics platform used to visualize the molecular interaction networks (Deng et al., 2020). In the current study, we adopted Cytoscape to construct the active ingredient–target–disease–medicine interaction network. GO functional annotations and KEGG pathway analyses on the critical therapeutic targets in GGQLD against HUA were analyzed by adopting the DAVID 6.8 database (Komada et al., 2018).

## Participants and Setting

From January 1st, 2020 to October 31st, 2020, a total of 30 male patients with asymptomatic hyperuricemia were enrolled from the Inpatient and Outpatient Departments of the Huadong Hospital Affiliated to Fudan University (Shanghai, China). The patient inclusion criteria are shown below, those aged 18–75 years with a diagnosis of HUA (serum uric acid, SUA > 420 μmol/l). For patients receiving anti-HUA treatment, they should receive washout for 2 weeks, and we only enrolled patients with SUA > 420 μmol/l post-washout. The patient exclusion criteria were as

follows: 1) those with an allergic physique or previous allergic history to benzbromarone or TCM, 2) serum creatinine >1.5 mg/dl, 3) two-fold elevation of ALT compared with the normal upper limit, 4) serious stiffness or deformity due to gouty arthropathy, 5) clinically significant arrhythmia, and 6) alcohol abuse history. In addition, patients confirming to any one of the following conditions were also excluded: 1) those having serious concurrent diseases in the hematopoietic system, liver, cerebrovascular system, or kidney, mental diseases, or malignant cancers; 2) those taking salicylate or aspirin (>325 mg/d)-containing medications; 3) those taking hypouricemic medications, 6-mercaptopurine, or azathioprine; and 4) those who had been involved in additional clinical trials in the last 3 months.

In this study, 30 patients were given GGQLD treatment (two doses daily for 4 weeks). SUA and urine uric acid (UUA) were adopted for evaluating the therapeutic efficacy (**Table 1**). The Local Ethical Committee of Huadong Hospital Affiliated to Fudan University approved our study protocols (No. 20190037).

## Peripheral Blood Mononuclear Cell Isolation by Ficoll-Paque Density Gradient Centrifugation

The Local Ethical Committee of Huadong Hospital Affiliated to Fudan University approved our experimental protocols on human blood (No. 20190037). To be specific, whole blood was centrifuged at 500 × g for 5 min at room temperature to separate the plasma. Thereafter, the equivalent amount of 1× PBS (under ambient temperature) was used to dilute the rest blood samples, followed by Ficoll-Paque underlaying (under ambient temperature) and 30 min of centrifugation (2,000 rpm, 21°C) using a Heraeus Multifuge X3R (Thermo Fisher Scientific), with the deceleration and acceleration being set at 0 and 5, respectively. Afterward, we obtained PBMCs from the interface between plasma and Ficoll-Paque in the 15 ml tube and used 1× PBS to wash the cells twice for 10 min (1,500 rpm, 4°C).

## Purification and Characterization of Urine Exosomes and Pellets

We collected urinary exosomes from 8 controls and 8 GGQLD-intervened HUA patients. Later, 40 ml freshly prepared urine samples were collected to obtain urinary cell pellets. Thereafter, the supernatants were subjected to 30 min of centrifugation at 12,000 × g, followed by standing to isolate the urinary exosomes. ExoQuick-TC for tissue culture media and urine (Exiqon, Woburn, MA, United States) was used to isolate urinary exosomes in accordance with specific protocols. To validate the protocols for exosome purification, we performed cryo-transmission electron microscopy to analyze the size, shape, and morphology of urinary exosomes. The isolation of exosomes was characterized by WB using NanoSight.

## Animal Model and Measurement

A total of 15 male SPF SD rats (age, 8 weeks; weight, 200–250 g) were raised at the Animal Center of Shanghai

Rat and Mouse Biotech Co., Ltd. Then, all animals were randomized into three groups, including the 1) Cont, 2) OA (8-week administration of OA at 750 mg/kg/day), and 3) OA + GGQLD (8-week administration of OA at 750 mg/kg/day + 4-week administration of GGQLD at 10 ml/kg/day initiating in week 5) groups, with five in every group. At the end of week 8, each animal was terminated. The 24-h urine was sampled from animals in metabolic cages. Subsequently, the levels of sUA, uUA, serum creatinine (Scr), blood urea nitrogen (BUN), and urinary creatinine (Ucr) were measured through the enzymatic colorimetric assay using a fully automatic chemistry analyzer (MODULAR D/P, Roche). Afterward, the freshly prepared renal cortical samples were obtained immediately after the animals were terminated to measure UA in accordance with specific protocols. Part of the tissues was stained with hematoxylin–eosin (HE) or Masson's trichrome stain for light microscopy. Next, the dissected tissue samples were preserved at  $-80^{\circ}\text{C}$  to carry out immunoblotting and RT-PCR assays. Each animal experiment was approved by the Animal Care and Use Committee of Shanghai Rat and Mouse Biotech Co., Ltd. following guidelines of the National Institutes of Health (NIH Pub. No. 85-23, revised 1996).

## Cell Culture

The epithelial cell medium, which was supplemented with basal medium (500 ml), fetal bovine serum (10 ml, FBS), penicillin/streptomycin (5 ml), and epithelial cell growth supplement (5 ml), was used to culture human primary PTECs. Then, we incubated cells under  $37^{\circ}\text{C}$  and 5%  $\text{CO}_2$  conditions. A 24-h “growth arrest” period was observed within the serum-free medium before stimulation in each experiment.

## Soluble UA Preparation

Previously, we dissolved UA into 1M NaOH to the final concentration of 50 mg/ml (Xiao et al., 2015). Then, we examined the solution so as to ensure that there was no mycoplasma and also filtered the solution (pore size,  $22\ \mu\text{m}$ ) prior to use. No detectable crystal was observed under polarizing microscopy or in the process of cell incubation.

## Cell Viability Assay on Cells Treated With Different Doses of GGQLD

A Cell Counting Kit-8 (CCK-8, Beijing Solarbio Science and Technology Co., Ltd.) assay was conducted to assess cell viability after GGQLD treatments at diverse doses. Cells ( $1 \times 10^4$  cells/well) were cultivated within the 96-well plate for 24–48 h. The microplate reader was used to measure absorbance (OD) at 450 nm. All experiments were conducted thrice.

## RNA Sequencing

After GGQLD treatment, we harvested PTECs and washed them twice with ice-cold PBS. We collected six samples altogether, among which three were from the GGQLD group while three were from the control group. Trizol reagent (Takara, Dalian, China) was employed to extract total RNA in accordance with

**TABLE 1 |** Clinical data of HUA patients before and after GGQLD treatment.

	Before treatment with GGQLD Mean $\pm$ SD	After treatment with GGQLD Mean $\pm$ SD	p value <sup>#</sup>
SUA	497.70 $\pm$ 39.47	418.93 $\pm$ 69.64	<0.001
UUA	424.81 $\pm$ 157.10	641.62 $\pm$ 272.83	0.0128
Scr	85.84 $\pm$ 14.28	83.88 $\pm$ 12.34	0.3699
BUN	5.37 $\pm$ 1.28	5.84 $\pm$ 2.42	0.3518
eGFR	85.38 $\pm$ 17.35	87.33 $\pm$ 13.34	0.4198
TG	2.22 $\pm$ 1.08	1.81 $\pm$ 0.69	0.0263
TC	4.59 $\pm$ 1.04	4.34 $\pm$ 0.95	0.1458
IL1 $\beta$	9.13 $\pm$ 1.06	4.67 $\pm$ 1.15	0.0005
IL6	7.43 $\pm$ 5.80	2.35 $\pm$ 0.70	0.0389
IL8	20.58 $\pm$ 13.35	6.40 $\pm$ 0.77	0.0206
ALT	35.22 $\pm$ 33.16	24.96 $\pm$ 17.38	0.0380
AST	26.46 $\pm$ 15.28	20.87 $\pm$ 9.02	0.1043

specific protocols. Libraries were constructed and mRNA was sequenced by Nuohe Zhiyuan Technology Company (Beijing, China). In addition, DESeq (version 1.30.0) was utilized to identify differentially expressed genes (DEGs). The false discovery rate (FDR) was applied to adjust p value, and the significance thresholds of fold change (FC)  $\geq 2$  and  $p < 0.05$  were applied.

## Annexin V-FITC/PI Double-Labeled Flow Cytometry

Flow cytometric analysis was conducted with an Annexin V-FITC apoptosis detection kit (DOJINDO; Kyushu, Japan) to analyze cell apoptosis under specific instructions. After UA and GGQLD treatments, PTECs were harvested and rinsed with ice-cold PBS, followed by staining using the binding buffer that contained Annexin V-FITC/PI at  $4^{\circ}\text{C}$  for 15 min in the dark. Finally, flow cytometric analysis (Beckman Coulter, Fullerton, CA, United States) was performed to record cells.

## Confocal Immunofluorescence Microscopy

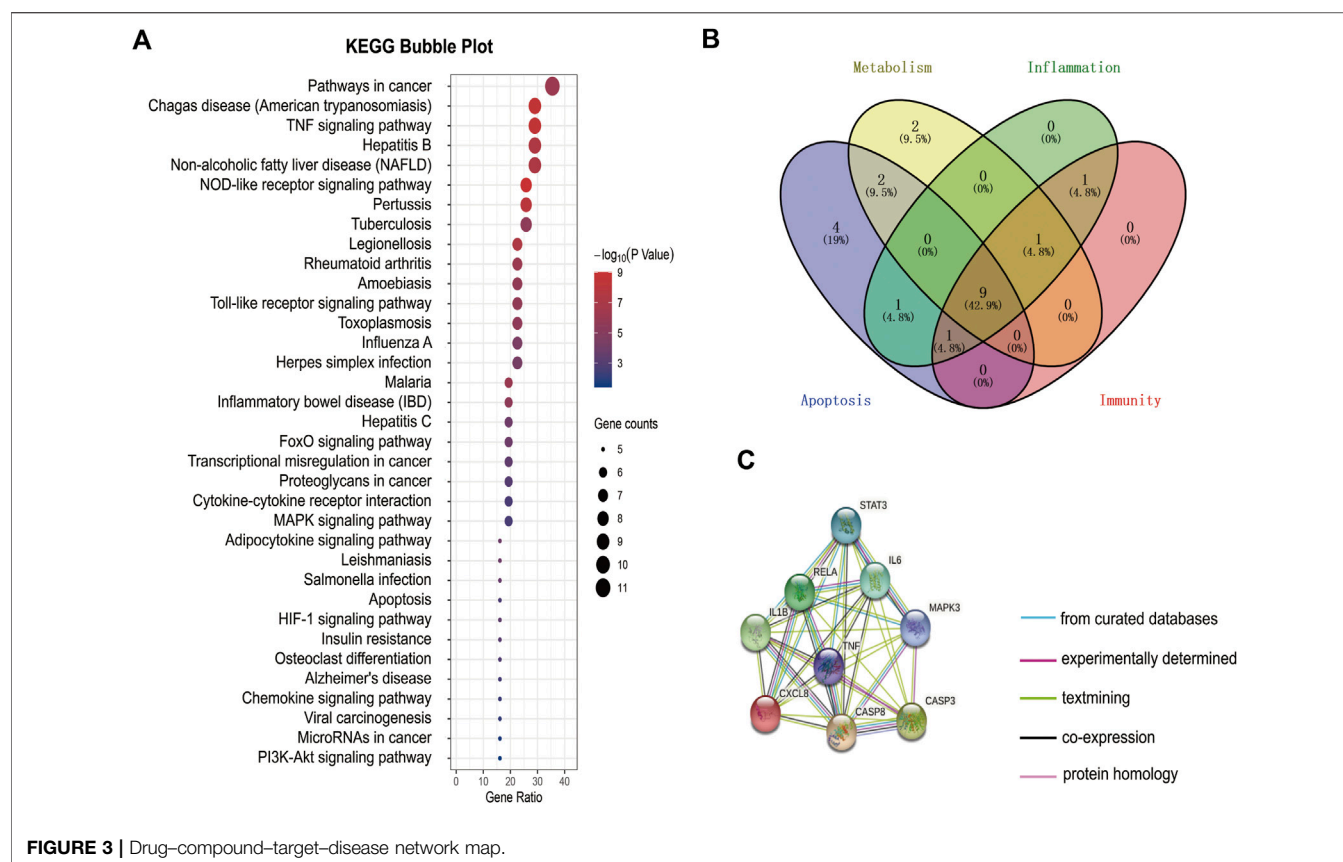

Cells were cultured onto a laser confocal cell culture dish (Thermo Fisher Scientific, NY, United States) in accordance with specific protocols. 24 h later, the cells were washed with PBS and fixed by 4% paraformaldehyde in PBS. Thereafter, 10% BSA contained within PBS was utilized to block the cells for 30 min, whereas the GSDMD and NLRP3 antibodies in 10% BSA were used to incubate the cells at  $4^{\circ}\text{C}$  overnight. Then, the cells were rinsed with PBS thrice and incubated with goat anti-rabbit antibodies (Invitrogen, Grand Island, NY, United States) for 1 h in the dark. The cells were washed consecutively thrice, and a confocal imaging system (LSM 780; Carl Zeiss, Jena, Germany) was employed to examine the dishes.

## RNA Extraction and Quantitative Real-Time PCR

Trizol (Life Technologies, United States) was employed to isolate total cellular and tissue RNA in accordance with specific

**FIGURE 3 |** Drug-compound-target-disease network map.

protocols. The content and purity of RNA were detected through a NanoDrop 2000 (Thermo Fisher Scientific, United States). To carry out mRNA quantification, we applied a reverse transcription kit (Vazyme, China) for the reverse transcription of total RNA according to specific instructions. Afterward, SYBR Green Master Mix (Vazyme, China) was utilized to perform qPCR, whereas a Roche Light Cycler system (Roche, Switzerland) was adopted for analysis, with GAPDH being an endogenous control. **Table 2** lists the primer sequences. Gene expression was normalized to the GAPDH level, which was presented in the manner of FC ( $2^{-\Delta\Delta CT}$ ). All results were repeated thrice.

## WB Analysis of the Cultured Human PTECs

Supernatants of cell culture were collected according to the previous description and then the lysis buffer supplemented with protease inhibitor cocktails (Sigma, St Louis, MO, United States) was used to lyse the rest cells. After collecting total proteins, we carried out WB analysis according to the previous description (Xiao et al., 2015). In the present work, the following primary antibodies (all were diluted at 1:1,000) were adopted, including rabbit pAb Glut9, rabbit pAb URAT1, rabbit pAb caspase-1, rabbit pAb caspase-3, rabbit pAb NLRP3, rabbit pAb IL-1 $\beta$ , rabbit pAb GSDMD, rabbit pAb Bax, rabbit pAb caspase-8, rabbit pAb cytochrome c, rabbit pAb Bcl-2, and rabbit pAb caspase-9.

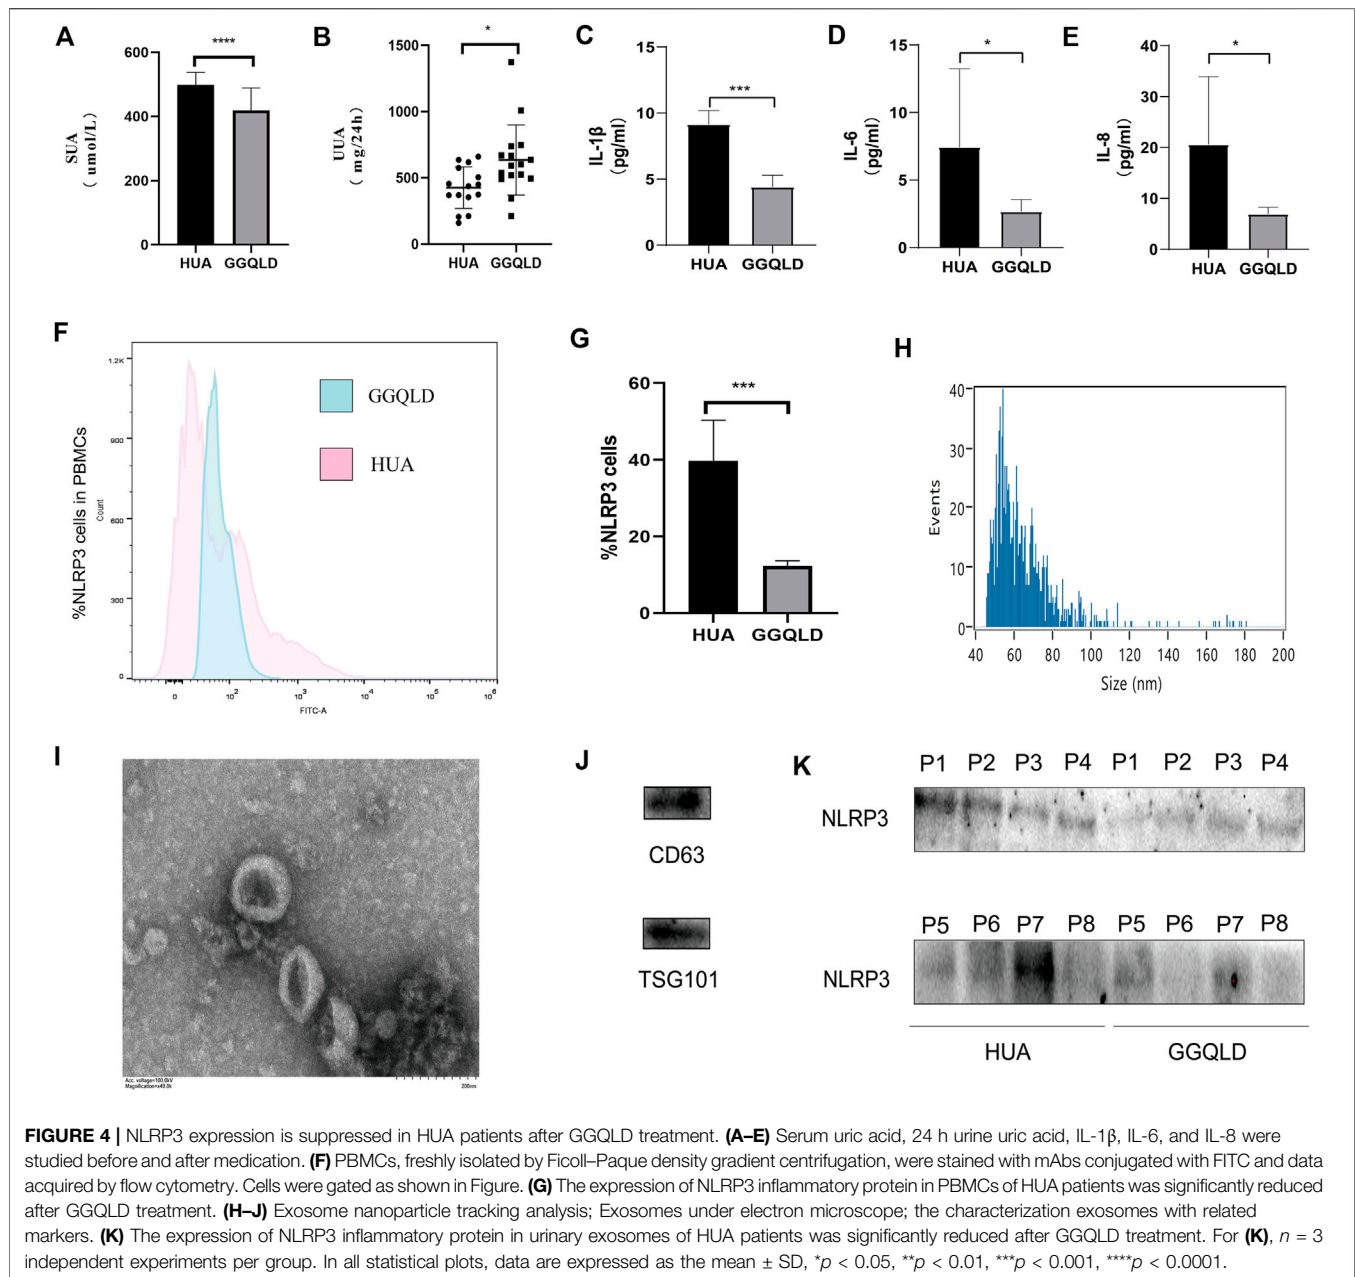

## Statistical Analysis

Data were presented in the manner of means  $\pm$  SD, except as otherwise noted. SPSS19.0 (SPSS, Inc., Chicago, IL, United States) was applied for all statistical analyses. For continuous variables, multivariate ANOVA was utilized to assess the differences between the groups.  $p < 0.05$  indicated that a difference was statistically significant. GraphPad Prism 5.0 was employed for drawing plots.

## RESULTS

### Acquisition of Potential Active Ingredients in GGQLD and Common Targets of HUA

A total of 907 ingredients were discovered in GGQLD through the TCMSP database, including 62, 123, 178, and 278 in Gegen, Huangqin, Huanglian, and Gancan, respectively. The thresholds of DL  $\geq 0.18$  and OB  $\geq 30\%$  were used to screen the active ingredients. Finally, 372 candidate active ingredients conformed to our preset screening thresholds. A total of 196 genes in HUA were screened from the database (DisGeNET). In TCM, a medication displays diverse pharmacological effects via various targets. Therefore, it is greatly significant to determine the TCM medication mechanisms in treating complicated diseases based on network analysis. Previously, we acquired a total of 196 targets

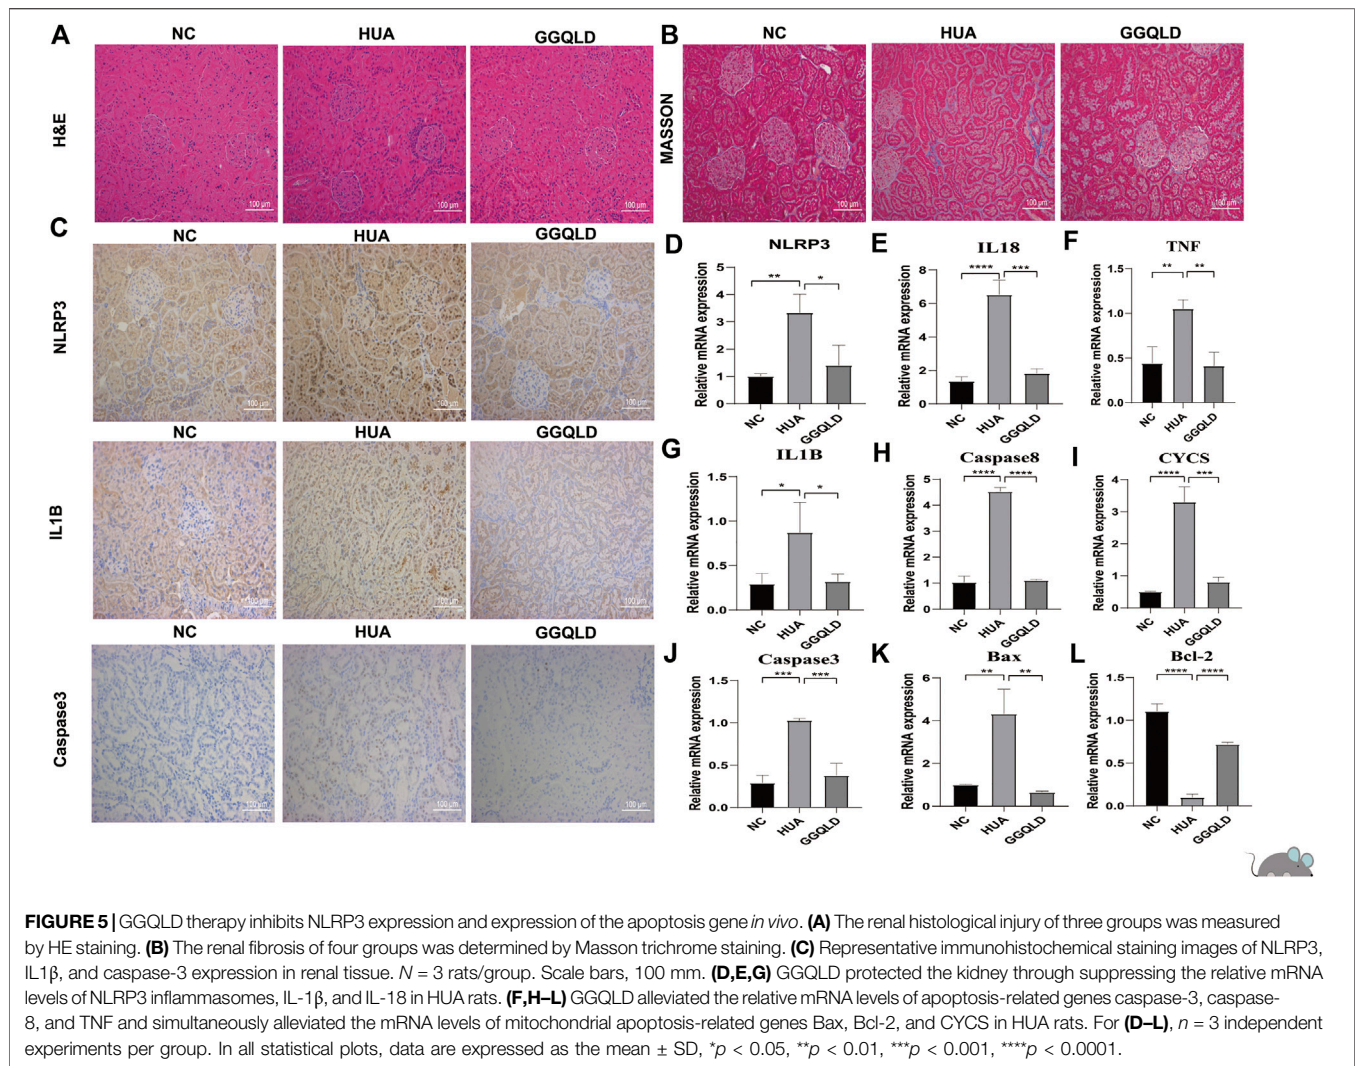

for HUA from the DisGeNET database. Then, targets were predicted by incorporating 372 active ingredients in the UniProt database. Consequently, 31 overlapped targets between GGQLD and HUA were obtained by VENN map (Figure 1A).

## Potential Therapeutic Mechanisms of GGQLD in HUA

We performed GO functional annotations of the 31 identified genes, suggesting their involvements in cell components (CCs), biological processes (BPs), and molecular functions (MFs). To be specific, these genes were mainly involved in various BPs, including inflammatory

response and negative regulation of the apoptotic process (Figures 1B–D). In addition, according to KEGG pathway analysis, the intersected genes were mainly associated with 40 pathways. Among them, 35 pathways with the most significant  $p$ -values are shown in Figure 2A including cancers, apoptosis, and inflammatory signaling pathways. In addition, we also constructed the active ingredient–target–disease network by adopting Cytoscape 3.8.0 software, obtaining the interactions among drugs, compounds, diseases, and targets. The results are shown in Figure 3. Obviously, 17 targets were related to the apoptosis pathways, 14 to the metabolism pathways, 13 to the inflammation pathways, 13 to the immunity pathways, and 14 to the signal transduction pathways. As illustrated by the VENN map, we acquired 8 intersected targets in the

5 pathways (Figure 2B). Moreover, the STRING platform was adopted to establish the protein–protein interaction (PPI) (Figure 2C).

## GGQLD Downregulated the Expression of NLRP3 in PBMCs and Urinary Exosomes in HUA Patients

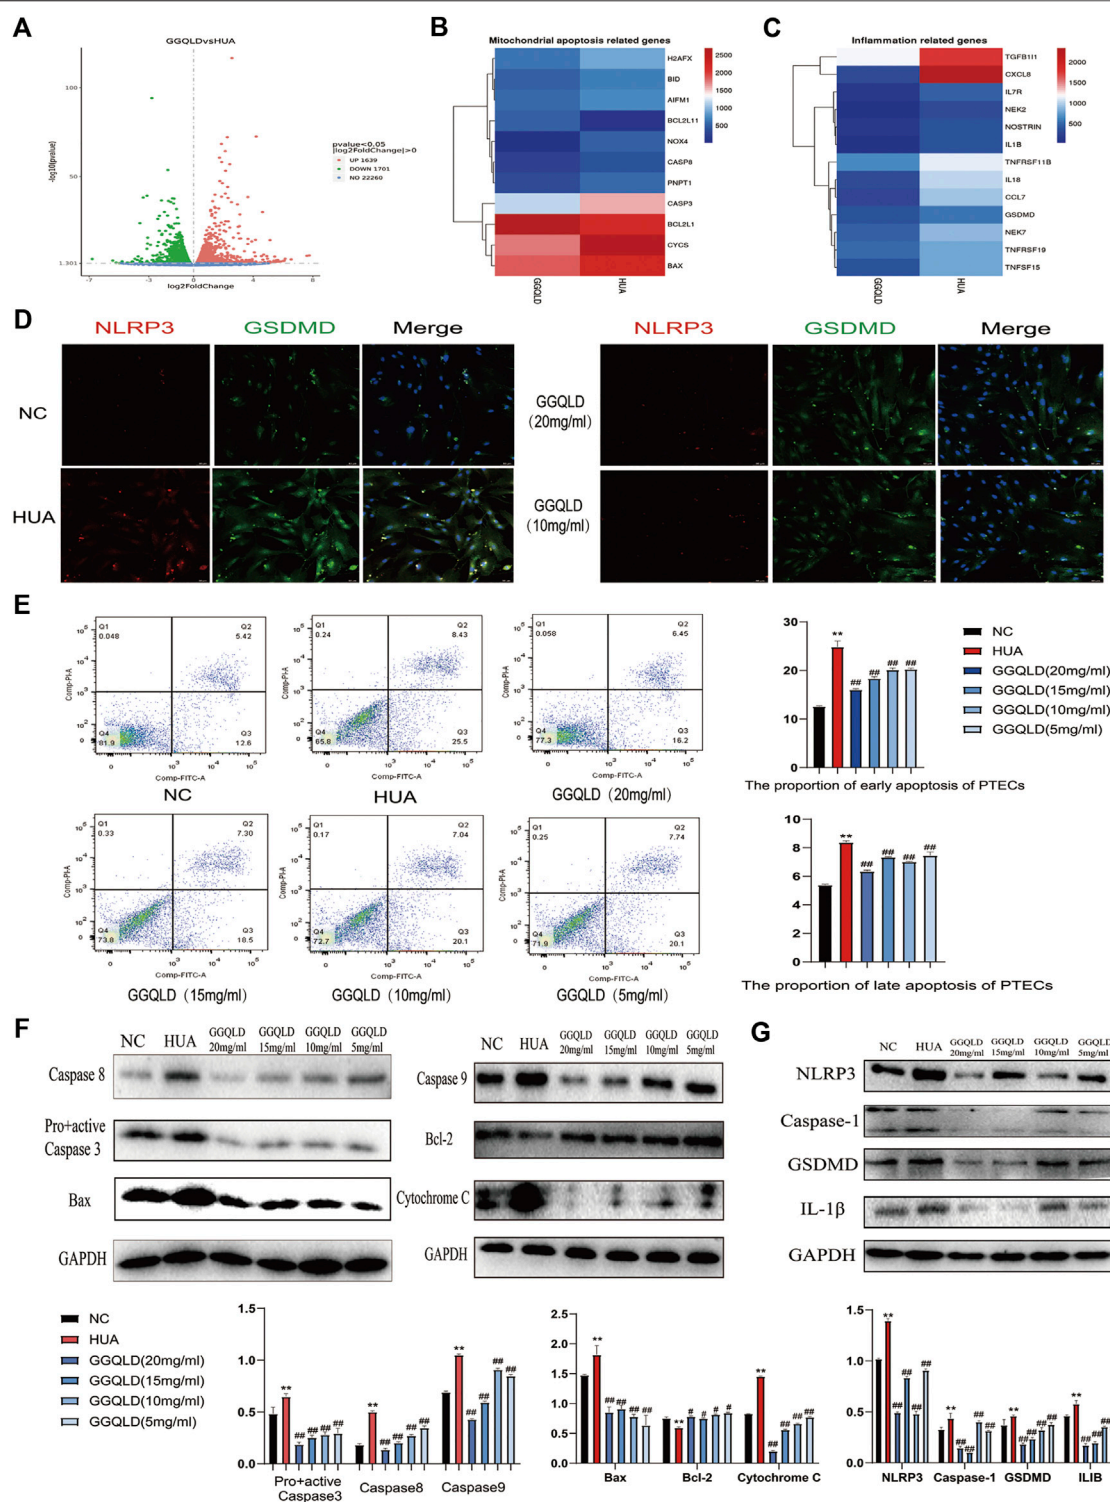

We found that the SUA and UUA levels (Figures 4A,B) in HUA patients were reduced after GGQLD treatment. Besides, the levels of IL-6, and IL-8 (Figures 4C–E) also significantly decreased in the GGQLD group. According to our previous study, soluble UA induced NLRP3 inflammasome production. To define the possible therapeutic approaches of HUA-induced renal tubular injury, the present study analyzed the expression of NLRP3 in PBMCs and that of urinary exosome protein in HUA patients before and after GGQLD treatment. By isolating PBMCs and extracting urinary exosomes from HUA patients before and after treatment, this study conducted flow cytometry and WB assays to analyze two groups

of PBMCs and urinary exosomes. As a result, GGQLD downregulated the expression of NLRP3 in HUA patients (Figure 4F,G,K).

## HPLC Profiles of GGQLD and Its Fractions

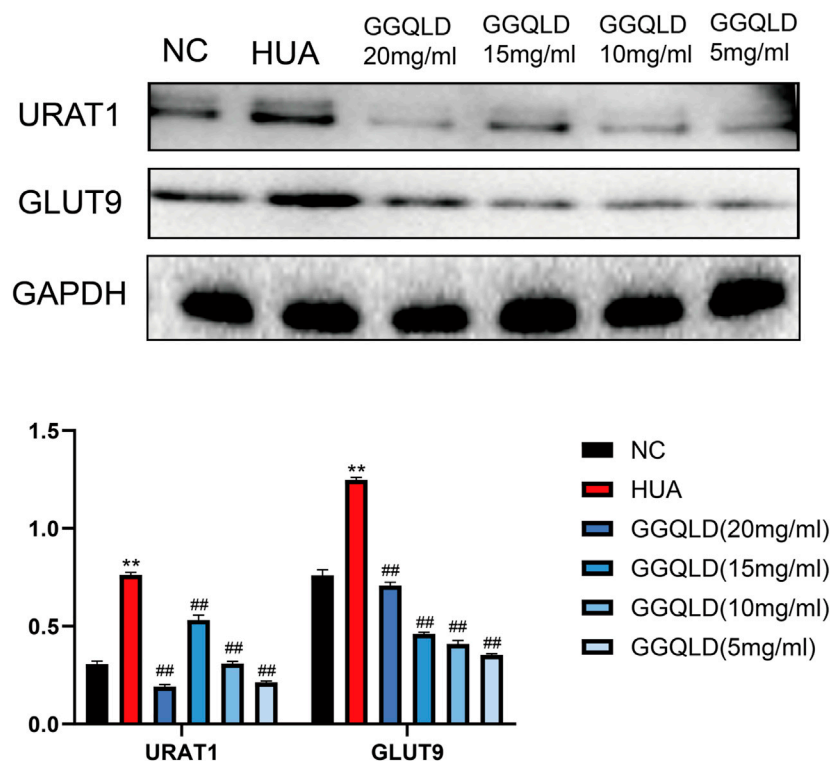

We obtained GGQLD extract through the purification of chromatographic grade methanol, since saponin and flavone were the major bioactive ingredients in GGQLD. Besides, HPLC analysis was performed to investigate the chemical features of GGQLD extract, with methanol being the eluent. To obtain the superb efficiency and favorable separation selectivity of HPLC analysis, we optimized the composition of the mobile phase (10 mmol/l acetonitrile–water contained within the ammonium formate solution). According to Supplementary Figure S1, the major bioactive ingredient puerarin was identified in Gegen, baicalin in Huangqin, berberine in Huanglian, and liquiritin in Gancao, which were later adopted to construct a combined standard approach. Accordingly, we detected four peaks of GQT extract from the HPLC chromatogram and adopted related chemical standards to quantify levels of puerarin, liquiritin, berberine, and baicalin (Peaks A–D), respectively. To be

**FIGURE 6 |** GGQLD inhibits mitochondrial apoptosis and inflammation in PTECs. **(A)** Gene expression profile was compared between cells in response to GGQLD treatment, and heat maps were generated based on expression of the significantly changed genes related to inflammatory response and the mitochondrial apoptosis process **(B,C)**. **(D)** GGQLD alleviating inflammasome-induced pyroptosis through inhibiting the NLRP3/GSDMD signal in UA-stimulated PTECs. **(E)** GGQLD alleviated early and late apoptosis. **(F,G)** GGQLD also reduced Bcl-2, Bax, cytochrome c, pro + active caspase-3, cleaved caspase-3, caspase-9, and caspase-8 expression in UA-stimulated PTECs. The levels of key proteins of the NLRP3 signaling cascade in PTECs by GGQLD treatment. For **(D–G)**,  $n = 3$  independent experiments per group. \* $p < 0.05$  vs. NC, \*\* $p < 0.01$  vs. NC, # $p < 0.05$  vs. HUA, ## $p < 0.01$  vs. HUA.

**FIGURE 7 |** GGQLD alleviated urate transporter expression in UA-stimulated PTECs. GGQLD significantly reduced URAT1 and GLUT9 expressions.  $n = 3$  independent experiments per group. \* $p < 0.05$  vs. NC, \*\* $p < 0.01$  vs. NC, # $p < 0.05$  vs. HUA, ## $p < 0.01$  vs. HUA.

specific, the contents of the above four active ingredients were 3.9, 0.3, 2.9, and 1.0 mg/ml in GGQLD extract, respectively (Table 3).

### GGQLD Alleviated HUA-Induced Renal Tubular Inflammation and Apoptosis *In Vivo*

Furthermore, the current work verified the protection of GGQLD against HUA in rat models. In brief, gastric OA at 750 mg/kg/day was given to male SD rats for eight consecutive weeks. Meanwhile, GGQLD at 10 ml/kg/day initiating on week 5 was given for four consecutive weeks. As a result, NLRP3 staining and mRNA expression increased in renal cortical tissues of OA rats (Figures 5C,D). GGQLD reduced the NLRP3 expression in OA-treated rats (Figures 5C,D). GGQLD significantly attenuated the mRNA expression and staining of IL-1 $\beta$  and caspase-3 in renal tissues of UA rats (Figures 5C,G,J). Additionally, it was found that GGQLD significantly alleviated the mRNA expression of TNF, caspase-3, caspase-8, Bax, Bcl-2, and CYCS in renal tissues of HUA rats (Figures 5F,H–L).

### GGQLD Inhibited Mitochondrial Apoptosis and Inflammation of PTECs

According to the CCK-8 results, different doses of GGQLD (20, 15, 10, and 5) were used to treat the UA-induced PTECs (Supplementary Figure S2). Based on our RNA-seq data, GGQLD was found to suppress BPs related to mitochondrial apoptosis and inflammatory response (Figures 6A–C).

Moreover, GGQLD significantly reduced the expression of NLRP3 and GSDMD compared with UA (Figure 6D). UA remarkably promoted apoptosis at the early and late stages (Figure 6E), while GGQLD had the opposite effect (Figure 6E). Besides, we also investigated the effect of GGQLD on the UA-induced expression of Bcl-2 and caspase gene family proteins in PTECs. Consequently, as further confirmed by WB assays, GGQLD significantly reduced the UA-induced NLRP3 expression (Figures 6F,G).

### GGQLD Down-Regulated the Expression of Urate Transporter in UA-Stimulated PTECs

UA is mainly regulated by urate transporters. To explore the effect of GGQLD on HUA, this study investigated its effects on URAT1 and GLUT9. As a result, GGQLD significantly downregulated the expression of URAT1 and GLUT9 (Figure 7) in comparison with the HUA group.

## DISCUSSION

In the present study, clinical data proved that GGQLD reduced the SUA levels and NLRP3 expression in PBMCs and urinary exosomes in asymptomatic HUA patients. In addition, it could also be demonstrated that GGQLD significantly suppressed NLRP3 inflammasome production within the renal cortical

**FIGURE 8 |** The mechanism of the protective effect of GGQLD in HUA-induced renal injury. The increased UA led to PTEC mitochondrial apoptosis and assembled NLRP3 inflammasomes and facilitated IL-1 $\beta$  maturation and thus inflamed the cells, which damaged the mitochondria and caused pyroptosis to lead to renal tubule damage. GGQLD protected cells from inhibiting the mitochondrial apoptotic pathways through caspase-9, caspase-8, and Bcl-2/Bax/caspase-3, thus alleviating inflammation via inhibition of NLRP3/caspase-1/IL-1 $\beta$ /GSDMD.

tissues in HUA rats and UA-stimulated PTECs. GGQLD significantly prevented the UA-induced renal inflammation, which caused apoptosis via the NLRP3 signaling pathway and the mitochondrial-dependent pathway. The HUA-induced renal injury was significantly alleviated by GGQLD *in vitro* and *in vivo*.

It is beneficial to inhibit receptors and inflammasomes to reduce renal fibrosis and inflammation. Knocking down Aim2 and NLRP3 can alleviate renal fibrosis, inflammation, and injury (Kopalli et al., 2016; Cao et al., 2021). In clinical settings, GGQLD has frequently been adopted for the treatment of diabetes and UC (Xu et al., 2011; Zhao et al., 2020). GGQLD has been suggested to suppress the inflammatory signal transduction pathway and promote the antioxidant effect, thus improving UC. Additionally, GGQLD promotes glucose metabolic disorders, protects pancreatic  $\beta$  cells, and elevates the insulin sensitivity index, thereby exerting an important role in treating diabetes

(Ahmed et al., 2017). On this basis, we performed bioinformatics analysis to identify potential therapeutic targets of GGQLD. Our results of the systemic pharmacological analysis proved that the treatment of GGQLD mainly involved the anti-inflammatory and antiapoptotic pathways. In our previous study, NLRP3 was found to be related to the pathogenesis of HUA. Therefore, we hypothesized that GGQLD targeted NLRP3 to exert its anti-inflammatory activity.

NLRP3 is one of the key elements during the activation of inflammation, which can interact with an apoptotic speck-like protein that contains a caspase recruitment domain (CARD) (ASC) through the pyrin domain (PYD). Later, ASC will recruit and activate pro-caspase-1 via CARD. The aforementioned interaction constitutes the NLRP3 inflammasome, which is a kind of great cytosolic protein complex (Csak et al., 2011; Wree et al., 2014; Shi et al., 2015; Abraham et al., 2016). Afterward, the

**TABLE 3 |** Contents of the four major compounds in GGQLD.

Sample name	Puerarin (mg/ml)	Liquiritin (mg/ml)	Baicalin (mg/ml)	Berberine (mg/ml)
Sample 1	3.971	0.310	2.970	1.047
Sample 2	3.967	0.312	2.983	1.051
Sample 3	3.969	0.306	2.967	1.048

activation of NLRP3 inflammasomes can activate caspase-1. First, caspase-1 cleaves gasdermin D (GSDMD), which can be activated for releasing the active N-terminal protein, and the latter can mediate pyroptosis (Derangère et al., 2014; Ding et al., 2016; Sborgi et al., 2016; Liu et al., 2017). Second, the activation of caspase-1 will recruit and activate the inflammatory molecules like IL-1 $\beta$ , while inducing inflammatory responses. Pyroptosis, also called cellular inflammatory necrosis, can promote the release of cellular contents to activate the inflammatory response (Shi et al., 2017; Wang et al., 2018). Evidence from previous studies shows that the NLRP3 inflammasome-induced GSDMD-dependent pyroptosis, accompanied by IL-1 $\beta$  processing, is responsible for renal tubular epithelial cell injury (Miao et al., 2019; Wang et al., 2019; Yasukawa and Koshiba, 2021). In our study, we first compared the difference of NLRP3 expression in PBMCs and urinary exosomes of HUA patients before and after treatment, finding that the expression of NLRP3 significantly decreased after treatment, providing that GGQLD exhibited significant anti-inflammation activity. We further validated and demonstrated that GGQLD significantly reduced the expression of NLRP3, caspase-1, GSDMD, and IL-1 $\beta$  in the UA-stimulated PTEC model *in vitro*, suggesting that GGQLD alleviated IL-1 $\beta$  processing and the subsequent amplification of inflammatory cascades. Some scholars have proved that GGQLD exerts an anti-inflammatory effect, and we confirmed that GGQLD showed anti-inflammatory effect by targeting NLRP3-induced GSDMD-dependent pyroptosis in the treatment of HUA.

The mitochondrion is an organelle with multiple functions, which is involved in a lot of biological processes, such as energy metabolism and cell suicide (Dagvadorj et al., 2021). It is currently proposed that mitochondrial damage accounts for an important determining factor for the activation of NLRP3 inflammasomes (Mohan et al., 2012). The NLRP3 stimuli-induced mitochondrial destruction contributes to exposing mitochondrial DNA (mtDNA) into cytoplasm and generating reactive oxygen species (ROS). The mtDNA in cytoplasm can colocalize with NLRP3, which can thus promote IL-1 $\beta$  release, whereas the oxidized mtDNA can serve as the stronger factor to induce IL-1 $\beta$  secretion. Till the present, mtDNA is only associated with the activation signal related to the responses of NLRP3 inflammasomes. According to the network pharmacology analysis, it is considered that GGQLD exhibited protective effects on uric acid-induced renal injury through the apoptotic pathway. Therefore, we speculated that GGQLD may protect HUA-induced renal injury through the antimitochondrial apoptosis pathway.

Proteins in the Bcl-2 family, which include the proapoptotic proteins (like Bad, Bal, and Bax) and the antiapoptotic proteins

(like Bcl-2, Mcl-1, and Bcl-xl), are responsible for regulating mitochondrial disruption (Degenhardt et al., 2002; Vucicevic et al., 2016; Peña-Blanco and García-Sáez, 2018). Among them, the proapoptotic proteins play the roles of the mitochondrial pathway promoters. After being stimulated, Bak and Bax will be transported in the mitochondrial membrane, which increases the permeability of the mitochondrial outer membrane, causing caspase cascade activation and cytochrome c release (Dairaku et al., 2004; Fang et al., 2012). In addition, the antiapoptotic proteins play the roles of suppressors through suppressing cytochrome c release (Mo et al., 2019). Bcl-2 is reported to directly reduce mitochondrial membrane permeability through binding to the mitochondrial outer membrane protein voltage-dependent anion channel 1 (VDAC1). Therefore, inducing Bax transport in mitochondria and inhibiting Bcl-2 transport in mitochondria can serve as two approaches for inducing the mitochondria-regulated apoptosis. In our study, we found that GGQLD significantly attenuated the miRNA expression of caspase-3, caspase-8, Bax, Bcl-2, and CYCS in renal tissue from HUA rats. We also examined the effect of GGQLD on the UA-induced expression of Bcl-2 and caspase gene family proteins in PTECs. It can be demonstrated that GGQLD can protect HUA-induced renal epithelial cells by inhibiting mitochondrial apoptosis.

In summary, GGQLD positively affects HUA by suppressing apoptosis and enhancing renal inflammation, which provides laboratory data supporting its clinical application. All the medicinal herbs in GGQLD have been utilized in TCM for thousands of years. Therefore, GGQLD is regarded to be safe and tolerable. GGQLD treatment reduces IL-1 $\beta$  production, NLRP3, caspase-1, and GSDMD expression depending on its concentration. In addition, GGQLD inhibits the apoptosis of PTECs, upregulates the expression of Bcl-2, and downregulates that of Bax, cytochrome c, and caspase-3/8/9. The present work suggests that GGQLD is the best treatment for HUA, which exerts its effects through suppressing apoptosis and renal inflammation. More studies are warranted to examine the systemic molecular mechanisms of GGQLD via the selection of diverse blockers and development of experimental technologies.

## DATA AVAILABILITY STATEMENT

The data presented in the study are deposited in the ENA repository, accession number is PRJEB43968.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by The Local Ethical Committee of Huadong Hospital Affiliated to Fudan University (No. 20190037). The patients/participants provided their written informed consent to participate in this study. The animal study was reviewed and approved by The Institutional Animal Care and Use Committee (License: SYXK(H)2016-0004).

## AUTHOR CONTRIBUTIONS

LF, M-QY, and JX conceived and designed the study. X-JW, Y-DQ, H-CG, and H-GL performed the experiments. P-QH and K-WG provided the samples. X-JW wrote the paper. IW, M-QY,

and JX reviewed and edited the manuscript. All authors read and approved the manuscript.

## FUNDING

This study was supported by a grant of the Shanghai Municipal Commission of Health and Family Planning Project Grant (No. 2018LQ003).

Fu-you formula (FY), a Traditional Chinese Medicine (TCM) formula composed of 12 herbs, as an in-hospital preparation, has been used to treat precocious puberty (PP) for decades. However, the lack of phytochemical characterization and mechanism of FY remains the main limitation for its spreading. In this study, we analyze the components and mechanisms of FY in PP, based on the integrated pharmacology. Investigated main constituents, targets, pathways of FY by using an integrative pharmacology, and recognized main constituents by HPLC-MS/MS. Then, observed the levels of Follicle-stimulating hormone (FSH), luteinizing hormone (LH), and estrogen (E<sub>2</sub>) in danazol-induced PP in Sprague-Dawley (SD) rats. Lastly, retrospective study analyzed the clinical data of 575 patients who were diagnosed PP, treated by the FY, and followed-up in our hospital from 2014–2020. The result that total of 116 important candidate targets were selected based on pharmacological analysis. Selected the top 10 values key targets such as the estrogen receptor alpha (ESR1) and insulin-like growth factor 1 (IGF1), were localized and the related gene functions were determined. Gene functions were associated with biological regulation, a cellular process, or signaling pathway, such as the Estrogen signaling pathway, MAPK signaling pathway and PI3K-Akt signaling pathway. By recognizing the five compounds related to the ESR1 and IGF1, which are Quercetin, kaempferol, Luteolin, Apigenin, and Emodin. The results of the molecular docking study further showed that the flavonoids had a strong binding affinity for ESR1 and IGF1 after docking into the crystal structure. The results showed that the FY could effectively reduce E<sub>2</sub>, LH, and FSH levels in SD rats. Furthermore, the results of the retrospective analysis of medical records showed that the FY could remarkably reduce E<sub>2</sub> levels in girls with PP.

**Keywords:** integrated pharmacology, precocious puberty, Chinese medicine, protein-protein interaction network, Fuyou formula

## INTRODUCTION

Precocious puberty (PP) is a common endocrine disorder among children. It occurs before the age of eight years in girls and before the age of 9 years in boys. In recent years, the annual incidence of this condition has been on the rise, and the incidence among girls is 5–10 times that among boys (Chinese Society of Pediatric Endocrinology and Metabolism (CSPERM), 2015). At present, early initiation of

the gonadal axis is believed to be the cause of PP. Therefore, modern medicine holds the view that the administration of a gonadotropin releasing hormone antagonist (GnRHa) in the treatment of PP is the most effective method. However, clinical results show that the long-term use of a GnRHa has inhibitory effects on growth and the thyroid in children. In addition, some children require simultaneous treatment with growth hormone or even thyroxine. Clinical studies on the FY as a treatment for girls with PP at our hospital have shown that it can control the early symptoms, and effectively reduce estrogen levels and bone age (Liu et al., 2009; Pan et al., 2019). At present, the literature comprises mostly clinical reports and observations of curative effects. However, in-depth research on the effective components, key targets, and mechanisms of action of the FY are still lacking. Integrative pharmacology could enhance our comprehension and facilitate the prediction of potential targets, pathways, and effects, which might provide clues for the design of subsequent research studies. In the present study, we used an integrative pharmacological approach to understand the systemic, organ-related, and molecular effects of the FY. The components and mechanisms of the FY in the treatment of PP were preliminarily analyzed and explored. The TCM integrated pharmacology platform was used and a TCM-component-network target-disease multi-level network was considered as the underlying framework.

## MATERIALS AND METHODS

### Materials and Reagents

Danazol was obtained from the A&D Technology Corporation (Beijing, China). Leuprorelin acetate microspheres for injection were purchased from Livzon (Zhuhai, China). FSH, LH, and E<sub>2</sub> ELISA kits were obtained from Cloud-Clone Corp (Wuhan, China). The TCM standards Quercetin (serial number: 100081–201610, purity: 99.90%), Luteolin (serial number: 111520–202006, purity: 94.40%), kaempferol (serial number: 110861–202013, purity: 93.20%) and Emodin (serial number: 110756–201913, purity: 96.0%) were purchased from the National Institutes for Food and Drug Control (Beijing, China). Apigenin (serial number: B20981–20 mg, purity: 98.00%) was purchased from the Shanghai Yuanye Bio-Technology Co., Ltd. (Shanghai, China).

### Plant Materials and Fu-you Formula Preparation

The FY was an in-hospital preparation (Approval number: Z20053679). It comprised a mixture of *Prunella vulgaris* L. (Xiakucao); *Carapax Trionycis* (Cubiejia); *Gentiana scabra* Bunge (Longdan); *Chrysanthemum morifolium* (Ramat.) Hemsl (Juhua); *Lycium chinense* Mill (Digupi); *Alisma plantago-aquatica* L (Zexie); *Scrophularia ningpoensis* Hemsl (Xuanshen); *Paeonia suffruticosa* Andrews (Mudanpi); *Rehmannia glutinosa* (Gaertn.) DC (Shengdi Huang); *Hordeum vulgare* L (Maiya); *Concha oetreae* (Muli); *Thallus laminariae* (Kunbu) (1.5:1.0:6.0:6.1:1.1:5.0:6.1:2.2:3:1). All herbs were purchased from the Beijing Bencao Fangyuan

Pharmaceutical Group Co. Ltd. and the FY was prepared by the Preparation Center of the Beijing Children's Hospital (Lot number: 20201202).

## Construction of the Compound-Target and Disease-Target Database

To identify the corresponding targets of the 12 active ingredients of the FY, several approaches combining chemometric methods, information integration, and data mining were implemented. First, all active compounds were submitted to the TCM-IP platform (<http://www.tcmip.cn/TCMIP/index.php/Home/Index/index.html>) Xu et al. (2019), as well as the TCMSP (<http://tcmispw.com/tcmisp.php>) Ru et al. (2014), and TCMID (<http://119.3.41.228:8000/tcmid/search/>) Huang et al. (2018) to mine compound-target interactions. The biological targets of the active ingredients were obtained from the STITCH (<http://stitch.embl.de/>) Szklarczyk et al. (2016); SwissTarget (<http://www.swisstargetprediction.ch/>) Gfeller et al. (2014); CTD (<http://tcmispw.com/index.php>) Yan et al. (2019); and SymMap (<https://www.symmap.org/>) Wu et al. (2019) databases. Known therapeutic targets for PP were obtained from the DrugBank (<http://www.drugbank.ca/>) Wishart et al. (2018); Online Mendelian Inheritance in Man (OMIM) (<http://www.omim.org>) Hamosh et al. (2005); and DisGeNET (<https://www.disgenet.org/home/>) Janet et al. (2020) databases.

## Protein-Protein Interaction Network Construction

The protein-protein interaction (PPI) data were imported from the STRING ([https://string-db.org/cgi/input.pl?sessionId=rEkaDRgfV0vC&input\\_page\\_show\\_search=on](https://string-db.org/cgi/input.pl?sessionId=rEkaDRgfV0vC&input_page_show_search=on)) PPI databases. An interactive network for the candidate drug targets and known PP-related targets of the FY was constructed based on their interaction data and was visualized using the Cytoscape software (Shannon et al., 2003). Interactions between the targets of the traditional Chinese medicine components of the FY and the targets related to PP were determined. Furthermore, the gene interaction network of the Chinese medicine components of the FY and PP was established. The degree centrality (DC) equal to two times the median value, was applied as the core for selection of the network nodes (hubs node). Thus, the median of node connectivity, closeness centrality, and betweenness centrality were the key values that determined the selection of nodes. Nodes that met three values simultaneously were selected as the candidate key targets of the FY in the treatment of PP.

## Gene Oncology Enrichment and Pathway Analysis

We performed gene ontology (GO) analysis of the non-repetitive putative targets of the FY using the database for Annotation, Visualization, and Integrated Discovery (DAVID) to gain insights into their involvement in two different categories namely, biological process and molecular function (Sherman and Lempicki, 2009). Tissue enrichment analysis was performed

using the FunRich software (<http://www.funrich.org>) (Pathan et al., 2015). We then performed Kyoto Encyclopedia of Genes and Genomes (KEGG) signaling pathway enrichment analysis of the candidate targets of the FY after topological analysis. A  $P$ -value  $< 0.05$  was considered significant, and the enriched GO terms were identified using the hypergeometric test. A bubble chart was plotted using the OmicShare tools, a free online platform for data analysis ([www.omicshare.com/tools](http://www.omicshare.com/tools)).

## Chemical Components Analysis

Characterization of main chemical components in FY was assayed by HPLC-MS/MS (AB SCIEX QTRAP 5500). Chromatographic separation was performed on a Hypersil Gold C18 column ( $150 \times 2.1$  mm,  $5 \mu\text{m}$ ) (Thermo Scientific), with column temperature set at  $40^\circ\text{C}$ . The mobile phase was solution A, 2 mM ammonium acetate in water containing 0.4% formic acid, and solution B, methanol. Gradient elution program was: 0–1.5 min, 60–10% A; 1.5–3.5 min, 10% A; 3.5–3.51 min, 10–60% A; 3.51–6.0 min, 60% A. The flow rate of mobile phase was 0.4 ml/min. The mass spectrometer was operated in negative ion mode with a needle potential of  $-4,500$  V; the source temperature was set at  $500^\circ\text{C}$ . Nitrogen was used as the sheath gas and auxiliary gas at pressures of 50 and 40 psi. Multiple reactions monitoring (MRM) mode was used to identify the five compounds by monitoring their transitions from the molecular ions to product ions. The proper amounts of standard substance were weighed and dissolved in methanol-water (1:1, v/v) to prepare standard solutions at  $1 \mu\text{g/ml}$ . Meanwhile,  $10 \mu\text{L}$  of FY was mixed with 1 ml of methanol-water (1:1, v/v) by vortexing for 10 min, then centrifuge for 15 min at 15,000 rpm. The supernatant fluid was used as sample solution. The chromatograms of standard solution and sample solution were used to compounds matching.

## In Silico Molecular Docking

*In silico* molecular docking studies of bio-active peptides or chemical drug molecules that exert their action by binding with specific receptors provides evidence on binding conformation, pattern and affinity. To identify the binding ability of active constituents with PP related targets, the crystal structures of ESR1 (PDB code: 6VIG) and IGF-1 (PDB code: 1IMX) were obtained from RCSB Protein Data Bank (<http://www.rcsb.org/>), and three main compounds structure of Quercetin, Apigenin and Luteolin were obtained from PubChem (<https://pubchem.ncbi.nlm.nih.gov/>) to establish molecular docking model with Discovery Studio 4.5. The CDOCKER module of Dock Ligands in Discovery Studio 4.5 was used to do the docking. The kinetic method was used to randomly search the small molecule conformation, and then the simulated annealing method was used to optimize each conformation in the receptor active site region, so as to make the docking results more accurate.

## Animals

At postnatal day (PND) 3, female Sprague-Dawley rats and their mothers were obtained from SPF Biotechnology Co., Ltd. (Beijing, license no: SYXK (Beijing) 2016–0038). The rats were housed in the laboratory animal room and maintained at  $24 \pm 2^\circ\text{C}$ , with  $42 \pm 5\%$  humidity on a 12-h light/dark cycle (lights

on from 07:30 to 19:30) in a specific-pathogen-free animal room. The animals were supplied food and water *ad libitum* and acclimated for three days before the start of the experiments. All animal experiments were performed in strict compliance with Chinese guidelines, including the standards for Laboratory Animals (GB14925–2001), and the Guideline on the Humane Treatment of Laboratory Animals (MOST 2006a). All animal procedures were approved by the Beijing Administration Office for Laboratory Animals.

## Animal Grouping and Drug Administration

The animals were randomly divided into four groups: the control group, model group, positive control (leuprorelin) group, and FY group. At PND 5, the rats in the three experimental groups were given a single subcutaneous injection of  $300 \mu\text{g}/25 \mu\text{L}$  danazol (ethylene glycol:ethanol = 1:1, v/v). The rats in the control group were given a subcutaneous injection of  $25 \mu\text{L}$  of glycol/ethanol (Morishita et al., 1993; Ju et al., 2019). The rats in the positive control (leuprorelin) group were subcutaneously injected with  $100 \mu\text{g/kg}$  leuprorelin. The rats in the FY group were given a solution formulated with dry ointment powder, by intragastric administration every day. The rats in the control and model groups were given the same amount of normal saline. The rats that exhibited vaginal opening were sacrificed at diestrus after a complete estrous cycle. The remaining rats were sacrificed at the same time point. All rats were anesthetized with an intraperitoneal injection of 2% pentobarbital sodium. Blood samples were collected from the abdominal aorta before sacrifice. Blood serum was separated by centrifugation ( $3,500$  rpm, 20 min,  $4^\circ\text{C}$ ) and preserved at  $-80^\circ\text{C}$  for further analysis of serum hormone levels.

Drug dosage: The FY dose was calculated according to the clinical dosage administered to 6-year-old girls. According to the following formula:

$$d_B = d_A d_A \times R_B / R_A \times (W_A / W_B)^{1/3}$$

with  $d_B$  representing the animal/human body weight dose,  $d_A$  representing the known human/animal body weight dose,  $W_A$  and  $W_B$  representing known human and animal weights, respectively, and  $R_A$  and  $R_B$  representing known human/animal body shape coefficients, respectively. Every two days, the animals were weight, and the dose was recalculated.

## Serum Hormone Level Detection

After anesthesia, blood was collected from the abdominal aorta, and the serum was centrifuged at  $4^\circ\text{C}$  and stored at  $-20^\circ\text{C}$  until further analysis. The serum concentrations of FSH, LH, and  $E_2$  were measured using ELISA kits, according to the manufacturers' instructions. The ELISA kits, which employ a competitive inhibition enzyme immunoassay technique, were purchased from Cloud-Clone Corp (Wuhan, China).

## Retrospective Analysis of Cases

Children with PP, treated with the FY at the outpatient department of our hospital from 2014 to 2020 were also evaluated. The inclusion criteria were as follows: 1) continuous

**TABLE 1 |** Composition of the FY.

Chinese name	Scientific name	Family	Lot No	Place of origin	Parts of plant used
Xia Ku Cao	<i>Prunella vulgaris</i> L.	Lamiaceae	20201010	Jiangsu, China	Dried erial parts
Cu Bie Jia	<i>Carapax Trionycis</i>	Trionyxsinensis Wiegmann	20201018	Hubei, China	Carapace
Long Dan	<i>Gentiana scabra</i> Bunge	Gentianaceae	20200927	Yunan, China	Dried roots and rhizomes
Ju Hua	<i>Chrysanthemum morifolium</i> (Ramat.) Hemsl	Compositae	20201027	Anhui, China	Capitulum
Di Gu Pi	<i>Lycium chinense</i> Mill	Solanaceae	20201105	Hebei, China	Dried root bark
Ze Xie	<i>Alisma plantago-aquatica</i> L.	Alismataceae	20201126	Fujian, China	Dried tuber
Xuan Shen	<i>Scrophularia ningpoensis</i> Hemsl	Scrophulariaceae	20201019	Zhejiang, China	Dried root tuber
Mu Dan Pi	<i>Paeonia suffruticosa</i> Andrews	Paeoniaceae	20201123	Anhui, China	Dried root bark
Sheng Di Huang	<i>Rehmannia glutinosa</i> (Gaertn.) DC	Plantaginaceae	20201104	Henan, China	Dried root tuber
Mai Ya	<i>Hordeum vulgare</i> L.	Triticum	20201030	Hebei, China	Dried ripe fruit
Mu Li	<i>Concha oestreae</i>	Ostrea	20200917	Guangdong, China	Shell
Kun Bu	<i>Thalluslaminariae</i>	Laminaria	20200922	Fujian, China	Dried lobes

**TABLE 2 |** Basic data on the components and targets of traditional Chinese medicines.

TCM	Number of components	Number of targets
<i>Prunella vulgaris</i> L.	39	10,189
<i>Carapax Trionycis</i>	16	374
<i>Gentiana scabra</i> Bunge	45	1289
<i>Chrysanthemum morifolium</i> (Ramat.) Hemsl	101	11,384
<i>Lycium chinense</i> Mill	22	1358

<i>Thalluslaminariae</i>	12	114

use of the FY for 1 year; and 2) evaluation of sex hormone levels every 6 months. The exclusion criteria were as follows: 1) the presence of other endocrine diseases; 2) the presence of ovarian cysts. This retrospective study was approved by the Medical Ethics Committee of Beijing Children's Hospital, Capital Medical University.

## Statistical Analysis

All results were presented as the mean  $\pm$  SD. Differences were analyzed using one-way ANOVA. The data were further analyzed and plotted using the SPSS 19.0 software (IBM SPSS Software, New York, United States). Differences were considered statistically significant at  $p < 0.05$ .

## RESULTS

### Formula Analysis of Fu-you Formula

*Prunella vulgaris* L. and *Carapax Trionycis* act on the liver and relieves congestion, nourishes yin and clears heat; *Gentiana scabra* Bunge, *Chrysanthemum morifolium* (Ramat.) Hemsl, *Lycium chinense* Mill, *Alisma plantago-aquatica* L, *Scrophularia ningpoensis* Hemsl, *Paeonia suffruticosa*

Andrews, *Rehmannia glutinosa* (Gaertn.) DC, which clear heat and removes dampness, nourishes yin, and cools the blood; *Hordeum vulgare* L, *Concha oestreae* and *Thalluslaminariae* act on the liver and relieves congestion, used as an adjuvant. All herbs combined act on the liver, clear congestion, nourish yin, and clear heat, can reduce the size of nodules in the breast, eliminate vaginal secretions, and dissipate scrofula, and reduce sputum production. The TCM composition are listed in **Table 1**.

## Chemical Composition and Prediction Target Analysis

Four hundred and thirteen chemical components were detected from 12 TCM in the FY. Furthermore, 37,468 predicted drug targets were obtained. The predicted target information and the characterization of each herb were derived from data on the TCM-component-targets, as shown in **Table 2**. Analysis of the common targets among the predicted targets, yielded a total of 4,741 predicted targets, among the 12 TCM. No common intersection targets were detected among the 12 TCM. 97 targets were detected between the two key herbs, which each had common targets with other herbs, as shown in **Table 3**.

TABLE 3 | Number of common targets.

TCM	<i>Prunella vulgaris</i> L.	<i>Carapax Trionycis</i>	<i>Gentiana scabra</i> Bunge	<i>Chrysanthemum morifolium</i> (Ramat.) Hemsl	<i>Lycium chinense</i> Mill	<i>Alisma plantago-aquatica</i> L	<i>Scrophularia ningpoensis</i> Hemsl	<i>Paeonia suffruticosa</i> Andrews	<i>Rehmannia glutinosa</i> (Gaertn.) DC	<i>Hordeum vulgare</i> L	<i>Concha oetreae</i>	<i>Thalluslaminae</i>
<i>Prunella vulgaris</i> L.	—	97	358	3975	417	262	168	3991	293	181	25	61
<i>Carapax Trionycis</i>	97	—	48	95	58	37	30	88	43	41	7	16

## Construction and Analysis of Compound-Target Network of Fu-you Formula

After removing redundant targets, 4,741 targets obtained from 12 herbs intersected with 166 disease targets to obtain 79 mapped-genes. We then explored the predicted therapeutic targets of the FY, using multiple online databases as previously described. A network of potential targets of the compounds in the FY was then constructed using the Cytoscape software, as shown in **Figure 1A**. Based on the 1,224 core nodes obtained, 116 key candidate targets for the treatment of PP girls were screened out, 75 were direct targets and 41 were predicted targets. The degree values were determined for the top 10 hub genes, two of the most important targets are ESR1 and IGF1. After further analysis, there were 96 chemical components acting on 10 hub genes in the formula, and 42 chemical components acting on ESR1 and IGF1, which the five components most widely distributed in medicinal materials were Luteolin, Quercetin, Apigenin, Kaempferol and Emodin. The interaction relationships between targets were determined and a network map of the hub targets for the treatment of PP in girls was constructed (**Figure 1B**).

## Gene Oncology and Kyoto Encyclopedia of Genes and Genomes Enrichment Analysis of Hub Targets for the Fu-you Formula in Precocious Puberty

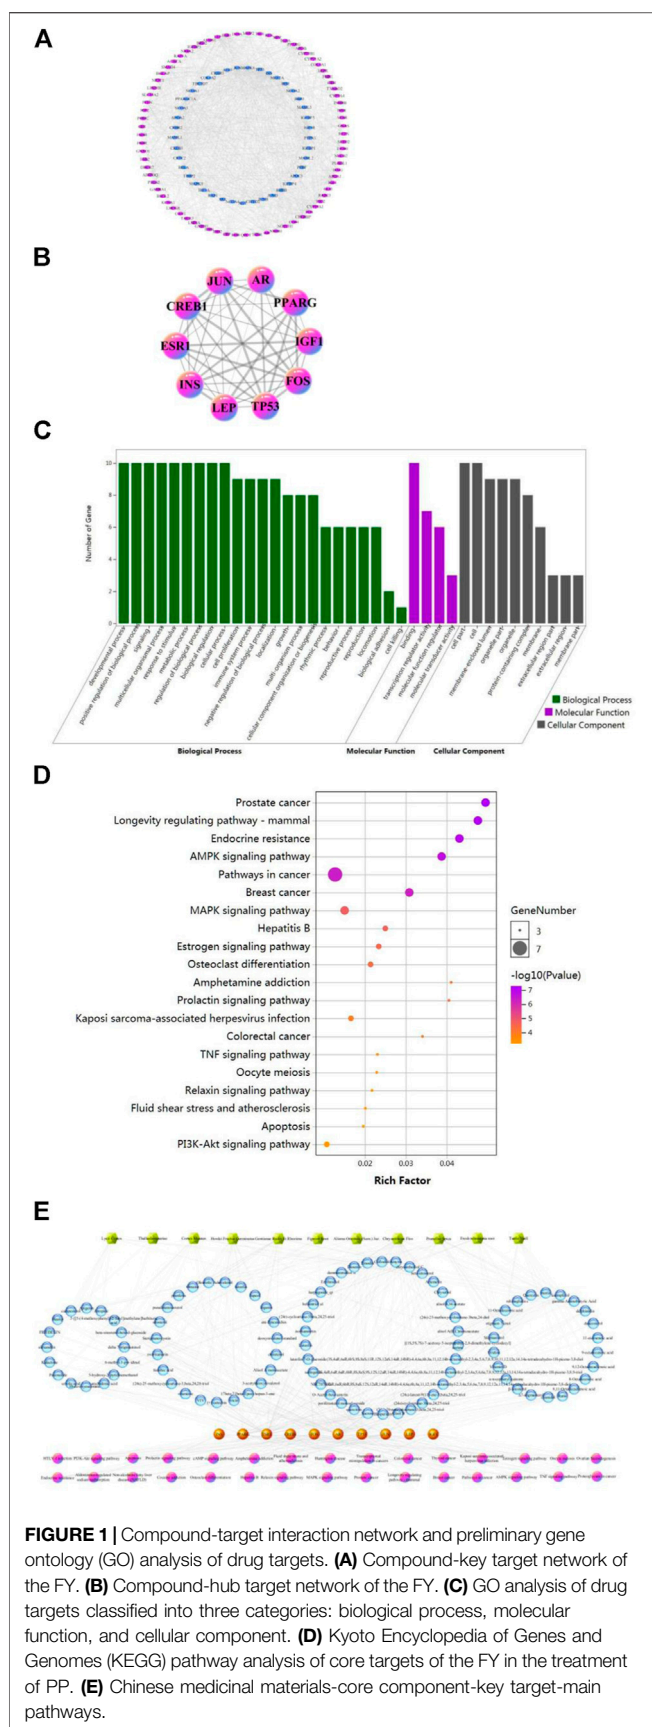

Based on the results of GO and KEGG pathway analyses, the enriched pathways were determined. A total of 2,462 hub genes were identified based on the GO analysis, which were associated with the target genes or proteins of cells (cellular component), molecular functions (function), or biological processes (in process). Gene function information is presented in **Figure 1C**. A total of 133 KEGG pathways were enriched, which were associated with key candidate targets. The top 20 pathways were sorted by *P*-value, as shown in **Figure 1D**.

## Construction and Analysis of the Multi-Layer Network Correlation Diagram of Traditional Chinese Medicine-Core Component-Hub Target-Main Pathways in the Treatment of PP With the Fu-you Formula

The KEGG pathways of the top 30 key candidate targets, based on their *P*-values were selected to construct the multi-level network association diagram of the “traditional Chinese medicine-core component-key target-main pathways” for the FY in the treatment of PP in girls (**Figure 1E**). The *P*-values were used to sort 30 KEGG pathways, which included 10 hub genes.

## Phytochemical Characterization of Fu-you Formula

To identify the main constituents of FY, we analyzed the FY using HPLC-MS/MS. Five compounds were recognized from FY as

**TABLE 4 |** MRM transitions for identify of the target compounds.

Analyte	Precursorion (m/z)	Production (m/z)	DP	EP	CE	CXP
Luteolin	284.8	132.8	-150	-2	-40	-40
Quercetin	300.9	150.8	-120	-2	-27	-40
Apigenin	269.0	116.8	-150	-2	-40	-40
Kaempferol	284.9	93.0	-180	-2	-40	-40
Emodin	268.9	224.8	-150	-2	-36	-40

shown in **Table 4**. The standard solution and the sample solution were analyzed by the HPLC-MS/MS method upper to identify the five constituents of FY. According to the chromatograms (**Figure 2**), the consistent chromatographic peaks of the five compounds could be recognized in standard solution and sample solution, including of Luteolin, Quercetin, Apigenin, Kaempferol and Emodin. Therefore, it is convincing that FY contains these five constituents.

## Molecular Docking

To further validate the potential targets possessing good affinity to the ingredients, molecular docking was performed for 3 high content ingredients with the 2 high relevance degree proteins. The docking results of the 3 flavonoids with the target proteins ESR1 and IGF1 are shown in **Table 5** and **Figure 3**. As shown in the results, all the active compounds have favorable binding energy ( $<0$  Kcal/mol) with their relative potential target proteins, and 3 flavonoids interact with ESR1 more stronger, which adds chips to the reliability of the virtual screening results.

## Serum Test Results

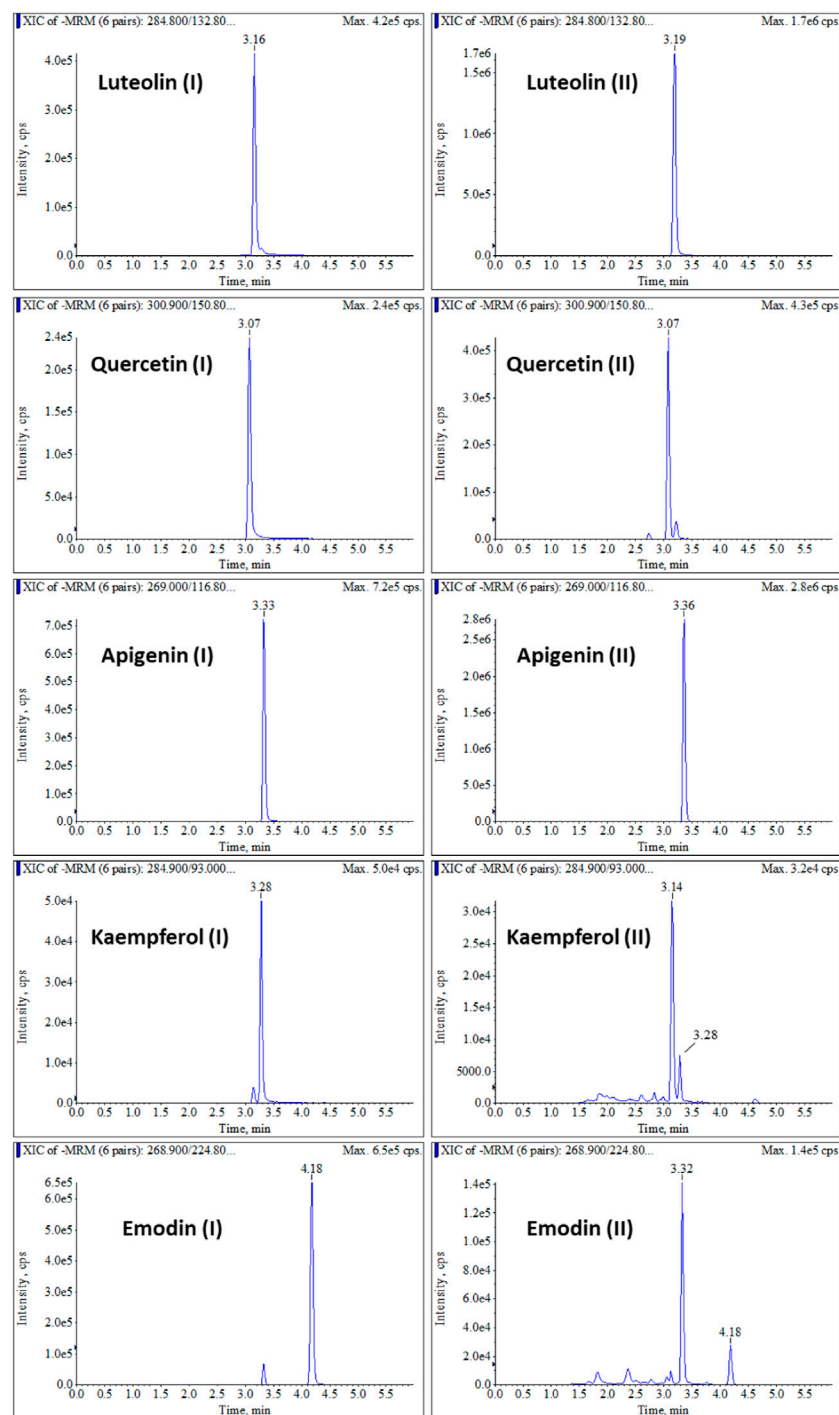

Compared with the normal control group,  $E_2$ , LH, and FSH levels in the model group were significantly increased ( $p < 0.01$ ), indicating that the model of PP was successfully established. After treatment with the FY, the  $E_2$  and LH levels in rats with PP were significantly reduced compared with the model group ( $p < 0.01$ ); and FSH levels were significantly reduced ( $p < 0.05$ ), compared with the model group. However, in the leuporelin group, only the LH levels showed a reduction ( $p < 0.05$ ) (**Figure 4A** and **Figure 4B**).

## Retrospective Analysis of Cases

Retrospective analysis showed that 575 children who met the inclusion criteria were included. It showed that  $E_2$ , LH, and FSH levels were significantly reduced after 12 months treatments ( $p < 0.01$ ). Significant differences were noted in  $E_2$  levels between groups ( $p < 0.01$ ). The FSH levels were significantly lower at 12 months after treatment compared with 6 months after treatment ( $p < 0.05$ ) (**Figures 4C,D**).

## DISCUSSION

The results of the analysis of the common targets of the FY revealed a total of 97 targets for *Prunella vulgaris* L. and *Carapax Trionycis*, which had common targets with other drugs. These

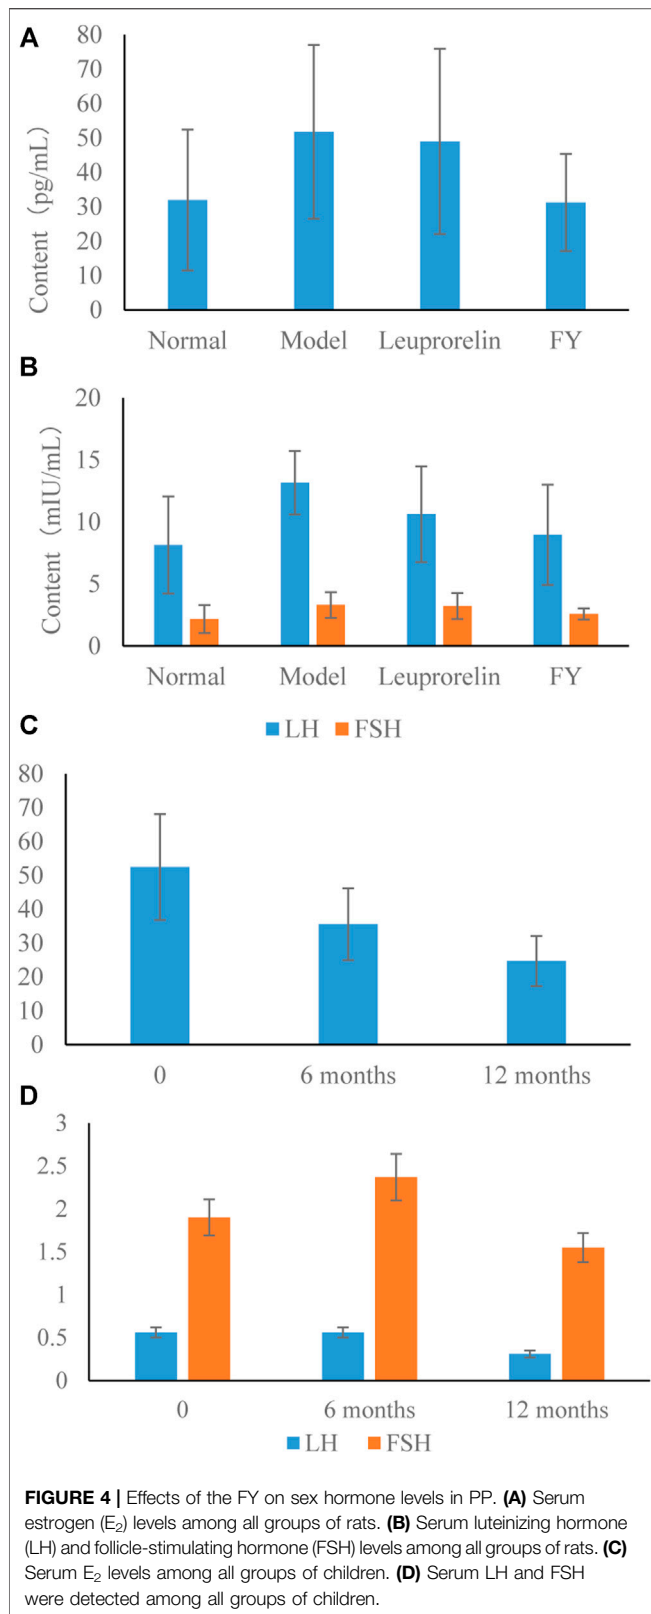

**FIGURE 2 |** Chromatograms of HPLC-MS/MS of FY. [(I) Standard solution; (II) Sample solution of FY; Retention time of Kaempferol and Emodin were 3.28 and 4.18 min, respectively].

findings suggest that these herbs had close synergistic effects with the other herbs. The following herbs: *Gentiana scabra* Bunge, *Chrysanthemum morifolium* (Ramat.) Hemsl., *Lycium chinense* Mill, *Alisma plantago-aquatica* L, *Scrophularia ningpoensis* Hemsl, *Paeonia suffruticosa* Andrews and *Rehmannia glutinosa*

(Gaertn.) DC had a total of 51 targets. These findings indicate that these 7 herbs in the prescription also had synergistic effects. Furthermore, no common targets were detected for *Hordeum vulgare* L, *Concha Etreae*, and *Thallus laminariae*, indicating that these 3 herbs are not key active ingredients in the formulation.

At present, GnRHa is recommended to treat CPP, but not incompleteness precocious puberty in the relevant guidelines.

The premature thelarche is the most common type of incomplete precocious puberty, 14–23% of which will develop to CPP (Zhu et al., 2008). So intervene as early as possible is the present clinical needs to solve the problem. Literature shows that Zhibai Dihuang Pill and Dabuyin Pill can treat precocious puberty (Liu and Wang, 2018; Wang and Zhao, 2019; Wang et al., 2020), but there is no indication for this in their instructions, so it belongs to off-label drug use.

The above-mentioned number of common targets of each herb is consistent with compatibility principles of the formulation. We identified main chemical constituents of FY using HPLC-MS/MS and confirmed that the main constituents related to the key targets in FY are Quercetin, kaempferol, Luteolin, Apigenin and Emodin. Analysis of the formulation reveals that the core components are mainly flavonoids, as well as kaempferol and quercetin, which are all phytoestrogens. Modern pharmacological studies have shown that phytoestrogens can make two-way adjustments, as they are similar to endogenous estrogen in structure and function. When the level of estrogen in the body is lower than the normal level, it can play an estrogen-like role, which can prevent and cure women's menopausal syndrome, prostate cancer, osteoporosis and cardiovascular diseases. On the other hand, when the level of estrogen in the body is higher than the normal level, such as breast hyperplasia, uterine fibroids and other diseases, it can produce estrogen antagonism and effectively weaken the response of target cells to estrogen (Chen et al., 2017; Cai and Zhanf, 2020).

Among the top 10 core targets selected, ESR1, IGF1 and other direct therapeutic targets are reportedly related to the onset and development of PP (Ye et al., 2011; Yang and Zhao, 2013; Wang et al., 2016), and are important targets in the treatment of PP. We further analyzed and clarified the core targets of biological function, gene function, and signal pathways. The results showed that the key components of the FY alone or combined were associated with transcription factor binding, transcription factor regulation, biological and cellular processes, such as GO or biological process-related gene/protein molecular function, and the estrogen signaling pathway, MAPK signaling pathway, and PI3K-Akt signaling pathways. These pathways mediate hormones that act on target tissues to achieve endocrine regulation. The  $E_2$  hormone binds with ESR1 to form a hormone-receptor complex that activates the estrogen signaling pathway. The MAPK signaling pathway and PI3K-Akt signaling pathway regulate the secretion of GnRH, LH, and FSH, as well as metabolic processes associated with bones. In addition, the growth hormone-insulin-like growth factor-1 (GH-IGF1) is the most important neuroendocrine factor associated with growth and development. Excessive IGF1 levels can inhibit GH secretion, and thereby inhibiting the growth of articular cartilage and epiphyseal cartilage, and retard growth in children (Su et al., 2017).

Treatment with GnRH analogues, such as Leuproline, which act by downregulating pituitary GnRH receptors (Carel et al., 2009), represent the standard of care for the treatment of CPP. The integrated pharmacological results suggest that the mechanism of the FY in the treatment of PP may include:

competitive binding of E<sub>2</sub> with ESR1 and reduction in serum IGF1 concentrations. At the same time, animal experiments showed that the FY could reduce E<sub>2</sub>, LH, and FSH levels in rats with PP. Retrospective analysis of the medical records also showed that the FY could control the early symptoms of PP, and effectively inhibit E<sub>2</sub> levels. The results of the animal experiments and retrospective analysis of medical records have confirmed the feasibility of studies of the mechanism of action of Chinese herbal compounds by integrative pharmacological methods.

In addition, the complex key targets of the FY and predictions based on the KEGG pathway analysis results show that the treatment may have effects on ovarian steroidogenesis, prostate and breast cancer, and other signaling pathways. These results are consistent with our previous clinical studies, which have shown that the effects of complex mixtures in girls with PP and ovarian cysts may be a more favorable intervention. Mixtures such as the FY may diminish ovarian cysts, regulate character development, improve liver function and qi stagnation, alleviate yin deficiencies and heat symptoms, reduce levels of E<sub>2</sub>, and retard bone aging and maturation. The present findings also provide a novel basis for the clinical application, and further research and development of the FY.

However, this study has some limitations that are worth mentioning. First, the reliability of the effects of FY against PP depends on database, so biological verification is necessary to evaluate the reliability of bioinformatics analysis *in vitro*, *in vivo* and *in silico*. Secondly, quantitative analysis of the synergistic effect of the main compounds should be investigated in the future.

## CONCLUSION

In conclusion, we combined methods of big data discovery with biological validation to study the mechanism of actions of the FY in PP at the systemic level. We used the TCM-IP database for the treatment of PP and considered various components and molecular mechanisms in the preliminary analysis. We determined that the FY acts through multiple component interactions with targets. The mixture also exerts its effects through multiple pathways involved in the regulation of PP, and may thus play a role in treatment of the condition. Whether

other pathways or mechanisms predicted in this network pharmacological approach also contribute to the beneficial effects of the FY requires further investigation.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding author.

## ETHICS STATEMENT

The animal study was reviewed and approved by the animal experimental design and protocols of this study was reviewed and approved by the Ethics Review Committee for Animal Experimentation of Beijing University of Chinese Medicine (BUCM-4-2017090116-3016).

## AUTHOR CONTRIBUTIONS

LZ and XW designed the experiments. CG and NS analyzed the data and wrote the manuscript. YH helped to conduct the animal experiments. MZ and GB provided technical support. QW, QD, and JL helped to construct the illustrations and revised the manuscript.

**Background:** Osteoarthritis (OA) is imposing substantial burdens on individuals and society with the aging population. Cortex *Daphnes* patch is widely used for symptomatic knee OA in China with a satisfying clinical efficacy; however, there is scant clinical evidence supporting its use. To evaluate its efficacy, we conducted a multicenter, non-inferiority, randomized, parallel-group study comparing Cortex *Daphnes* patch with topical nonsteroidal anti-inflammatory drugs in patients with knee OA (NCT02770950).

**Methods:** A total of 264 symptomatic knee OA patients were treated with Cortex *Daphnes* or indomethacin cataplasms applied to affected sites once daily for 2 weeks. The primary outcome was improvement in knee pain on walking as assessed using a visual analog scale (VAS). The non-inferiority margin based on the full analysis population was set as –5 mm on the pain VAS. The secondary outcomes were changes of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) total score, WOMAC scores for pain, function and stiffness, the 36-item Short Form Health Survey (SF-36), and global assessment of knees by the patients. Responder rates for pain VAS, WOMAC total score, and WOMAC pain were also included in the secondary outcomes.

**Results:** The Cortex *Daphnes* patch was non-inferior to indomethacin cataplasms for the primary outcome with a group difference (Cortex *Daphnes* patch–indomethacin cataplasm) of 2.1 mm (95% confidence interval: 2.1–6.4); similar results were found in the per-protocol population. For all other outcomes, no significant differences were found in the full analysis set or in the per-protocol analysis set, except the responder rates for WOMAC pain was higher in the Cortex *Daphnes* patch group than in the indomethacin cataplasm group (78.4 vs. 64.7%,  $p = 0.022$ ) in the per-protocol analysis set. Overall,

28.8% patients in the Cortex Daphnes patch group and 9.8% in the indomethacin cataplasm group reported treatment-related adverse events, the vast majority of which were mild-to-moderate skin irritation, resulting in only 3.8 and 0.8% of patients dropping out, respectively.

**Conclusion:** The Cortex Daphnes patch, which provides satisfactory analgesic efficacy and enhances the physical function of the knee, as well as improving quality of life, may be a promising alternative to knee OA.

**Keywords:** knee osteoarthritis, nonsteroidal anti-inflammatory drugs, Cortex Daphnes patch, pain, non-inferiority trial design

## INTRODUCTION

Osteoarthritis (OA) is a progressive disease of joints, common in middle and old age, that leads to joint capsule and ligament contracture, resulting in joint pain and functional impairment, as well as social and economic burdens (Dieppe and Lohmander, 2005; Hunter et al., 2014; Sharif et al., 2017). The joint pain, deformity, and motor dysfunction caused by OA can further increase the incidence of cardiovascular events and all-cause mortality (Xing et al., 2016; Liu et al., 2017). Knee OA is the most common type of OA; symptomatic knee OA is associated with considerable morbidity both in China and elsewhere (Cooper and Arden., 2011; Tang et al., 2016), with the result of an almost 90% increase in all-cause mortality (Liu et al., 2015). There is no specific treatment for osteoarthritis so far. Nonsteroidal anti-inflammatory drugs (NSAIDs) have been recognized as a good choice to manage symptomatic knee OA; however, oral NSAIDs are associated with higher risk of gastrointestinal, cardiovascular, and renal injury than placebo (Cepeda et al., 2006). Topical NSAIDs can avoid many of the adverse effects associated with systemic medications, can be considered as alternative therapy by patients with knee OA (Ringdahl and Pandit, 2011), but in fact, topical NSAIDs were less effective than oral NSAIDs (Lin et al., 2004). Therefore, it is of great significance to develop novel and more efficient therapeutic strategies for treatment of knee OA.

Traditional Chinese medicine has been accepted as a complementary therapy for knee OA, owing to its effects on relieving pain and improving functions of knee joint (Wang et al., 2020). Topical Chinese herbal preparation, as a representative form of traditional Chinese medicine, is commonly used in patients with symptomatic knee OA. Also known as Zushima (pronounced/zu-shi-ma:/), Cortex Daphnes is the processed stem and root barks of *Daphne giraldii* Nitsche., *Daphne tangutica* Maxim., and *Daphne retusa* Hemsl., all of which belong to the genus *Daphne* (Thymelaeaceae) (Pharmacopoeia of the People's Republic of China, 1977).

According to Chinese medicine theory, the function of Cortex Daphnes herb is to remove blood stasis and relieve pain, removing cold-wind and dredge collaterals. It is used to treat headache, stomach ache, bruises, limb numbness, joint pain, and others. Although Cortex Daphnes patch has been widely used to treat arthritis in China, there have been few clinical studies reporting its effect and safety. The first published clinical

study of Cortex Daphnes patch was in the 1980s, reporting the effects of pain relief in Chinese patients with soft tissue injury (Wang, 1986). Only one low-quality randomized controlled trial in patients with knee OA reported satisfactory clinical efficacy of Cortex Daphnes patch when combined with acupuncture (Wang and Zhan, 2014).

The aim of the present study is to evaluate whether Cortex Daphnes patch has the potential to be a valuable topical intervention for patients with knee OA. For this reason, we conducted a multicenter, non-inferiority, randomized controlled trial to compare the safety and efficacy of the Cortex Daphnes patch to indomethacin cataplasms for the treatment of knee OA.

## MATERIALS AND METHODS

### Plant Material, Handling, and Phytochemical Analysis

Cortex Daphnes is majorly derived from the field-grown root bark and stem bark of *Daphne giraldii* Nitsche., which were collected in the plateau region of Gansu Province, China, and processed as described in the standard of Chinese medicinal materials in Gansu Province (Gansu Medical Products Administration, 2009). The main processing methods include rinsing, drying, and cutting pharmaceutical materials. Cortex Daphnes patch is the inheritance and innovation of traditional techniques of the black plaster. The black plaster, as a representative form of topical Chinese herbal preparation, has been used in China for at least thousands of years. The processing and extraction of Cortex Daphnes patch mainly include the following steps: Cortex Daphnes decoction pieces are cut off and boiled twice with water. Then, the decoction is filtered, concentrated, and dried. Finally, the Cortex Daphnes dry powder is added to the traditional black plaster matrix that is refined and smeared in the center of the plaster cloth. Cortex Daphnes patch is made by adding water-extracted Cortex Daphnes dry powder instead of the traditional frying extraction method, so as to avoid extreme damage to the active ingredients. Cortex Daphnes patch in the current study was produced by Gansu Taikang Pharmaceutical Co., Ltd. (China, batch number: 20150679). Preparation and assay methods of Cortex Daphnes patch are based on the pharmaceutical standards of the Ministry of Health of the

People's Republic of China (Standard No. WS3-B-3456-98; Pharmacopoeia Committee of National Health, 1998). Its phytochemical content (daphnetin) in each patch, according to extraction and assay methods, was 600 µg dry weight. The chemical profiling of Cortex Daphnes patch was detected using LC/MS/MS method, and the details were provided in supplementary material.

## Study Design

This was a multicenter, randomized, active controlled trial with duration of 2 weeks to evaluate the efficacy and safety/tolerability of Cortex Daphnes patch in patients with symptomatic knee OA. The study was conducted at eight sites in China from May 2016 to December 2017.

Among those NSAIDs used for local treatment of OA, topical administration of indomethacin has been widely prescribed for pain in China. According to package instructions, the dose of indomethacin cataplasm was one patch for one site once daily for 24 h.

## Selection Criteria

Participants were all outpatient patients who visited doctors complaining of knee pain. Patients were aged 40–75 years who met the 1995 American College of Rheumatology combined clinical and radiographic criteria for knee OA (Hochberg et al., 1995) and had symptoms in both knees. The inclusion criteria were knee pain of no less than 20 mm on a 100-mm visual analog scale (VAS) when walking flat. Patients taking oral NSAIDs prior to the breakthrough period (one week before starting) were included. The exclusion criteria included swollen and hot knees at the time of recruitment and patients with other joint diseases, such as rheumatoid arthritis, ankylosing spondylitis, congestive heart failure and edema, and advanced renal disease. We also excluded patients who were allergic to any ingredient in Cortex Daphnes patch (Cortex Daphnes and substrates including lithargite, linseed oil, and red lead) and in indomethacin cataplasm, as well as those who had punctured knee skin or other skin diseases.

## Randomization and Masking

This was a multicenter and active-controlled design. Using the block randomization method, a random number table was generated by an independent third party, the Clinical Evaluation Center of China Academy of Chinese Medical Sciences, using SAS 9.4 software (SAS Institute, Cary, NC, United States). The randomized assignment sequence was placed in a sealed opaque envelope and was kept by the scientific research management department of the research unit and can be reproduced upon request. Eligible patients were randomized 1:1 to either Cortex Daphnes or indomethacin cataplasm topical treatment. Prior to recruitment, study investigators, site staff, and patients were blinded to the details of the allocation sequence. In order to avoid patient's preference for treatment method, we discussed all the interventions (the Cortex Daphnes patch and the indomethacin cataplasm) involved in this study with each

participant, and informed them that all the treatments may benefit them. Furthermore, we asked a staff member not to discuss the intervention with participants when dispensing the medicine. The therapeutic and side effects were evaluated by a trained staff member of each site who was blinded to group allocation.

## Outcome Measures

The study included a screening visit to determine eligibility, a baseline visit, and a 2-week visit. Patient-reported outcome measures were collected at baseline and at the 2-week visit. Unscheduled visits were also possible at any time during the study treatment if required.

The primary outcome was change in the patient's global assessment of pain intensity score from baseline to posttreatment. The Patient's Global Assessment of Pain Intensity score employed a 100-mm VAS pain scale evaluating knee pain when walking flat (0 for no pain and 100 for pain as bad as it could possibly be) (Cao et al., 2009). The secondary outcomes included changes in the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) total score, WOMAC scores for three subscales (pain, function, and stiffness), the 36-item Short Form Health Survey (SF-36), and the patient's global assessment of knees from baseline to posttreatment. Responder rates for pain VAS (at least a 30% improvement from baseline), WOMAC total score (at least a 30% improvement from baseline), and WOMAC pain (at least a 30% improvement from baseline) were also included in the secondary outcomes. The WOMAC is a 24-item disease-specific patient-reported outcome measure with five questions assessing pain (range 0–20), two assessing stiffness (range 0–8), and 17 assessing function (range 0–68) (Bellamy et al., 1988). The WOMAC total score ranges from 0 to 96, with higher scores indicating greater burden of knee OA (Bellamy et al., 1988). The SF-36 is a generic quality of life instrument with eight health domains. It consists of 36 questions and assesses eight dimensions: physical functioning, role physical, pain index, general health, vitality, social functioning, role emotional, and mental health index (Li et al., 2002). It also provides two summary measures of physical and mental components, physical component score and mental component score, ranging from 0 to 100, with higher scores indicating better health status (Li et al., 2002). The participants were all self-assessed using VAS score to document the overall symptom severity of their knees at the beginning of the study and after treatment.

Safety evaluations included monitoring of adverse events (AEs), treatment discontinuations, measurement of skin irritation, and the assessment of clinical laboratory investigations. Skin irritation intensity evaluation criteria were used to record adverse skin events, which were the most commonly expected side effects. According to these criteria, the degree of the irritation symptoms including erythema, edema, and pruritus, were divided into mild, moderate, and strong irritation and were assessed by a trained physician (Bureau of Drug Policy and Administration of the People's Republic of China, 1994). The specific laboratory assessments included complete blood counts and urinalyses, as well as

measurements of glutamic-pyruvic transaminase, glutamic-oxalacetic transaminase, creatinine, and blood urea nitrogen.

## Treatment

Patients whose eligibility was confirmed at the baseline visit were randomly assigned to treatment with one or the other intervention. During the treatment period, participants were instructed to apply the Cortex Daphnes patch or the indomethacin cataplasm (Nipro Patch CO. LTD. Japan, batch number: EM002) onto clean skin overlying the affected sites on both knees every night and keep it in place for 24 h. The standard operation procedure for the application of Cortex Daphnes patch has been established. As shown in **Figure 1**, instructions were offered to every participant in the Cortex Daphnes patch group to standardize the external use site, the administration time, and the method of placing and removing the patch to ensure the consistency of application.

No other treatments for knee OA were permitted during the treatment period: systemic and topical NSAIDs; opioid analgesics; acetaminophen; oral and intra-articular injection of corticosteroids; intra-articular knee injections (hyaluronic acid injection and local anesthetics); surgical or physiotherapeutic therapies; acupuncture; and aspirin. All AEs were recorded in detail and were monitored regularly until properly resolved or the condition was stable.

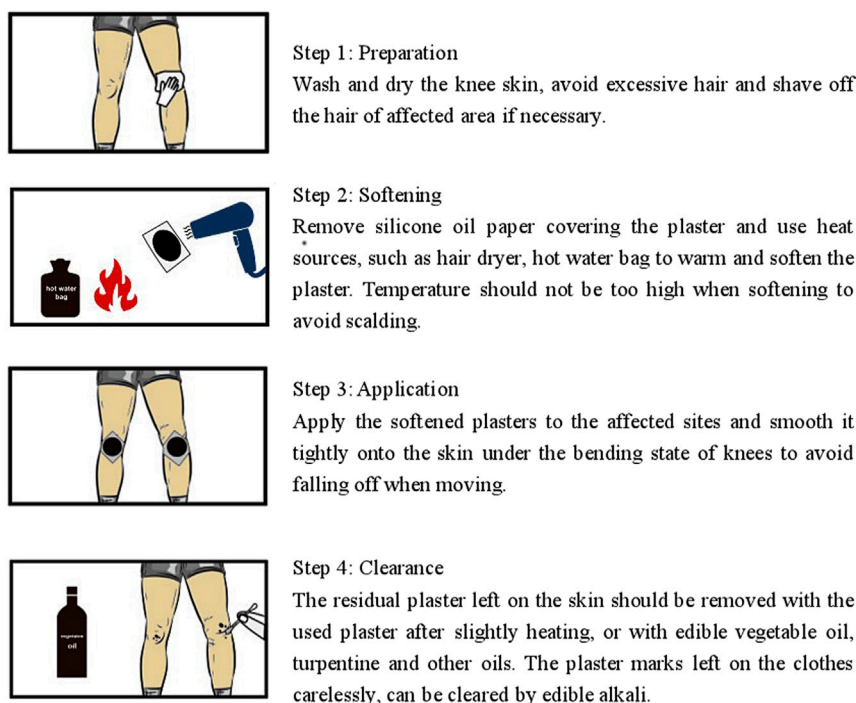

## Sample Size Calculation

The sample size was determined using the primary endpoint of the change of VAS pain score. The literature showed that the

effect for Cortex Daphnes patch with the same primary endpoint was 44.6 mm (SD: 33.4 mm) and it was 35.3 mm (SD: 30.4 mm) for indomethacin cataplasms at week 2 (Wang et al., 2016). Assuming a non-inferiority margin of -5 mm and that the ratio of the Cortex Daphnes patch group and the indomethacin cataplasm group was 1:1, using a two-sided test with a significance level ( $\alpha$ ) of 0.05 and a power ( $1-\beta$ ) of 0.90, the required sample size was estimated at 105 cases in each group. Allowing for a dropout of 20%, the Cortex Daphnes patch group and the indomethacin cataplasm group each required 132 patients, a total of 264 patients.

## Statistical Analysis of Data

Statistical analyses were performed using SAS version 9.4 (SAS Institute, Cary, NC, USA). The full analysis set (FAS) and per-protocol (PP) analysis set were analyzed. The FAS population included all participants who were randomized and underwent the assigned treatment. Non-inferiority of the primary endpoint (change of VAS pain score of Cortex Daphnes patch vs. indomethacin cataplasm) was determined if the lower limit of the 95% CI for the difference was not less than the cutoff value of -5 mm. The changes of primary and secondary endpoints at week 2 from baseline were analyzed using an analysis of covariance (ANCOVA) model with the treatment group and the study center as factors and the baseline score as a covariate. The point estimate, the least squares (LS) means, and the two-sided 95% CI based on the ANCOVA model were provided for the difference between treatment groups. The 30% responders were defined as patients who experienced a 30% reduction of WOMAC pain score,

Abbreviations: FAS = full analysis set; BMI = body mass index; pain VAS = pain visual analog scale; NRS = numerical rating scale for pain; OA = osteoarthritis. WOMAC = Western Ontario and McMaster Universities Osteoarthritis Index; SF-36 = Short Form-36 Health Status Questionnaire; PCS = physical component score; MCS = mental component score.

<sup>a</sup>Pain VAS is a measurement for body pain. Scores range from 0 to 100 mm, with higher score indicating greater pain.

<sup>b</sup>The NRS allows a person to describe the intensity of his/her pain, as a number ranging from 0 to 10. "0" indicates "no pain," "1 to 3" "mild pain," "4 to 6" "moderate pain," "7 to 9" "severe pain," and "10" "bad as it could be."

<sup>c</sup>The WOMAC is a 24-item disease-specific outcome measure and the higher score indicates greater burden of knee OA. Scores range from 0 to 96 with five questions assessing pain (range 0–20), two assessing stiffness (range 0–8), and 17 assessing function (range 0–68).

<sup>d</sup>SF-36 is a self-administered, 36-item questionnaire that assesses the physical and mental quality of life. Both of physical and mental component summaries can be combined ranging from 0 to 100, with higher scores indicating better health status.

WOMAC total score, and VAS score from baseline for each respective outcome. A p-value of <0.05 was considered statistically significant. All patients who received at least one dose of the study drug were included in the safety set (SS). Incidence of AEs, treatment-related AEs, and discontinuation rate due to AEs were compared between the two groups using the Pearson chi-square test and Fisher's exact model.

## RESULTS

### Baseline of Clinical Cohorts

All patients were Chinese. Among 292 patients with symptomatic knee OA who were initially screened, 264 eligible patients were enrolled and constituted the FAS population. There were no statistically significant differences between the groups with respect to demographic and baseline clinical characteristics (Table 1). There were 21 (15.9%) patients in the Cortex

Daphnes patch group and 13 (9.8%) patients in the indomethacin cataplasm group who did not complete the 2-week treatment, resulting in an overall dropout rate of 12.9% (Figure 2). Finally, 230 patients were included in the PP population for the efficacy analyses.

## Treatment Effects

### The Primary Outcome: Patient's Global Assessment of Pain Intensity

In the FAS population, the LS mean changes from baseline in the pain VAS score at week 2 was −25.4 mm in patients receiving the Cortex Daphnes patch and −23.3 mm in patients receiving indomethacin cataplasms. The treatment difference (Cortex Daphnes patch–indomethacin cataplasm) in the FAS population was 2.1 mm and the two-sided 95% CI for the treatment difference was −2.1–6.4 mm. In the PP population, the result was similar (treatment difference and two-sided 95% CI: 3.8 [−0.6 to 8.2] mm). The lower limit of the 95% CI was

–5 mm, which indicates that Cortex Daphnes patch was non-inferior to indomethacin cataplasm for the treatment of Chinese patients with knee OA.

## Secondary Outcomes

In the FAS population, there were no significant differences between groups with respect to any secondary endpoint after 2-week treatment (Table 2). The LS mean change from baseline in WOMAC total score was –13.9 in the Cortex Daphnes patch group and it was –12.6 in the indomethacin cataplasm group. WOMAC pain, stiffness, and function subscales were –3.1, –1.2, and –9.7 in the Cortex Daphnes patch group and –2.7, –1.1, and –8.9 in the indomethacin cataplasm group, respectively. The LS mean changes from

baseline in SF-36 physical component scores and mental component scores were 9.3 and 5.8 in the Cortex Daphnes patch group and 8.7 and 5.2 in the indomethacin cataplasm group, respectively. The LS mean change from baseline in patient's global assessment of disease activity was –24.6 in the Cortex Daphnes patch group and –23.2 in the indomethacin cataplasm group. In the PP population, the treatment differences between the groups for all secondary endpoints were similar (Table 3).

In the FAS population, no differences between groups were significant in terms of responder rates for pain VAS, WOMAC total score, and pain subscale ( $p > 0.05$ ) (Figure 3). In the PP population, no significant differences were found, except that the percentage of 30% responder WOMAC pain subscale was higher

**FIGURE 3 |** Responder rates for Pain VAS, WOMAC total, and pain score in FAS population posttreatment.

**FIGURE 4 |** Responder rates for Pain VAS, WOMAC total, and pain score in PP population.

in the Cortex Daphnes patch group than in the indomethacin cataplasm group (78.4 vs. 64.7%,  $p = 0.022$ ; **Figure 4**).

## Safety Profile

AEs are displayed in **Table 4**. AEs were documented 60 times during the study with a higher rate in the Cortex Daphnes patch group than in the indomethacin cataplasm group (29.5 vs. 19.5%,  $p = 0.008$ ). The majority of these 60 events (51, 85%) were skin irritation and all were treatment-related AEs reported by 38 patients in the Cortex Daphnes patch group and 13 patients in the indomethacin cataplasm group. Routine laboratory examinations indicated that no patients in either group developed abnormalities. Most of the skin irritation AEs were mild-to-moderate in intensity with only five patients in the Cortex Daphnes patch group and one patient in the indomethacin cataplasm group discontinuing treatment.

The severity for skin AEs of erythema, itching, and edema are summarized in **Table 5**. Most expected side effects were slight in severity and resolved within 7 days without any additional intervention. The occurrence and severity of skin irritation, including erythema, itching, and edema tended to be higher in

the Cortex Daphnes patch group than in the indomethacin cataplasm group. However, there were 38 patients in the Cortex Daphnes patch group reporting skin irritation symptoms. Among them, the knee skins of only 4 patients were allergic to the black plaster, while the other 34 patients reported that the knee skin around the plaster was allergic due to the mount material used in the Cortex Daphnes patch. Erythema and itching skin AEs resulting from black plaster were less likely to occur when using indomethacin cataplasms. There was one severe erythema and one itching skin AE in the Cortex Daphnes patch group due to black plaster, while no severe skin AEs occurred due to indomethacin cataplasms.

## DISCUSSION

Current international and Chinese guidelines support the use of topical NSAIDs as an early treatment option for symptomatic relief of the management of knee OA (Hochberg et al., 2012; McAlindon et al., 2014; Joint Surgery Group of Chinese Orthopedic Association, 2018). Despite extensive clinical applications, definitive evidence of the efficacy of the Cortex

Daphnes patch as an alternate option has yet to be provided. Against this background, the current multicenter, randomized clinical trial showed that the Cortex Daphnes patch was not inferior to indomethacin cataplasms with respect to efficacy, and its safety profile was also favorable, with no serious AEs being observed. These observations strongly support the existing evidence to the effect that Cortex Daphnes patch may be a potential alternative topical application for treatment of knee OA.

Our results suggest that the Cortex Daphnes patch can effectively relieve the symptoms of knee OA, in line with the findings of previous clinical studies. Cui et al. demonstrated that a 2-week regimen of Cortex Daphnes patch could relieve pain, swelling, and restricted movement in patients with knee synovitis when compared with infrared radiation therapy (Cui and Liu, 2017). A randomized controlled clinical trial with a short duration of about 2 weeks reported that, when combined with acupuncture, Cortex Daphnes patch was superior to glucosamine sulfate in terms of pain relief and joint function improvement in patients with knee OA (Wang and Zhan, 2014). Due to its warm property, Cortex Daphnes patch even reduced wrist joint pain, swelling, and stiffness in cold-type patients with rheumatoid arthritis (Wang et al., 2016), as well as alleviating lumbar pain and promoting functional status when combined with herb decoction in cold-type patients with chronic lumbar muscle strains (Wu et al., 2020). The key differences between the current and previous studies involve differences in use of the Cortex Daphnes patch as well as different target patient populations. In our study, we used a single Cortex Daphnes patch in patients suffering from knee OA; the previous studies used single Cortex Daphnes patches in patients with other chronic pain or arthritis diseases, and in the only study of knee OA study, the intervention was Cortex Daphnes patch combined with acupuncture. Using a higher quality of design and well-recognized outcome measures, the current study is the first clinical evidence to suggest the effectiveness of Cortex Daphnes patch for treatment of symptomatic knee OA.

Our findings show that Cortex Daphnes patch has a favorable anti-inflammatory analgesic effect. In recent years, daphnetin, coumarins,

lignins, flavonoids, diterpenes, and other chemical components have been isolated and identified from Cortex Daphnes. Daphnetin, the main phytochemical component of Cortex Daphnes, has provided dramatic improvement in percutaneous absorption results *in vivo* and *in vitro* experiments. Pharmacological activity experiments showed that prostaglandin E2 generation was inhibited by extract of Cortex Daphnes by inhibiting the expression of cyclooxygenase-2 (Yuan et al., 2009). An animal experiment showed that daphnetin significantly reduced the swelling of feet and the severity of arthritis in adjuvant-induced arthritis rat model (Gao et al., 2008). Daphnetin, a natural product, inhibits not only lipoxygenase and cyclooxygenase but also neutrophil-dependent superoxide anion generation (Fylaktakidou et al., 2004).

In recent years, more than 250 chemical constituents have been identified from the genus *Daphne*. The most important classes of compounds obtained from this genus include coumarins, flavonoids, lignans, terpenoids, and several other less common groups (Xu et al., 2011; Moshiaishvili et al., 2020). Coumarins are among the most common compounds in the *Daphne* genus and major toxic components. *Daphne* genus-related potential risks include hepatotoxicity, nephrotoxicity, burning in the pharynx, gastrointestinal discomfort (nausea, vomiting, burning of stomach, gastroenteritis, and diarrhea), internal bleeding, muscle spasms and paralysis, and skin irritation (redness, swelling, and blisters). In severe cases, circulatory arrest and coma may be observed (Goel et al., 2007; Xu et al., 2011; Moshiaishvili et al., 2020; Wink, 2009; Stefanachi et al., 2018). Therefore, we should pay more attention to the safety of the Cortex Daphnes patch. In the study, the safety profiles suggested a trend toward higher frequency and more severity of treatment-related adverse effects in the Cortex Daphnes patch group. Although skin irritation was the most frequently reported treatment-related adverse effect in both treatment groups, the material used in the Cortex Daphnes patch predisposes patients to increased risk of developing erythema and edema, as well as itching of the contact skin, especially after fixing the plasters for 24 h daily, for 2 weeks, on knee skin.

Fortunately, those skin side effects were mostly mild in severity, were transient, and did not require intervention. Moreover, the skin reactions may be alleviated after discontinuation of the Cortex Daphnes patches. These findings suggest a rest time for skin is needed when using the Cortex Daphnes patch, and the components containing the Cortex Daphnes patch should be changed to be milder and less irritating.

There are some limitations with respect to the design of this non-inferiority study. First, the completely different physical characteristics and smell between the Cortex Daphnes patch and the indomethacin cataplasm prevented double-dummy design from being applied. Nevertheless, considering that those two medicines and their topical simulators could not be used on the knee simultaneously, or even used separately on each knee, an enormous difference in efficacy might result in a substantial decline in compliance with the treatment plan. Therefore, to ensure the reliability of evaluation measurements, instead of using the double-dummy design, a staff member who dispensed the investigational medicine was trained not to discuss the intervention with participants, and the therapeutic effects and side effects were evaluated by another blinded trained staff member. Second, its long-term efficacy remains unclear due to a paucity of follow-up. Third, we did not pay attention on the average time for skin irritation after medication and relevant data need to be supplemented in the following Cortex Daphnes patch-related research.

## CONCLUSION

The Cortex Daphnes patch exerts favorable effects in decreasing knee pain and improving joint function for patients with knee OA, especially with mild-to-moderate knee OA, which were non-inferior to the therapeutic effects of a recognized treatment for knee OA. The clinical evidence presented here highlights the promising therapeutic efficacy of the Cortex Daphnes patch for the treatment of pain and symptoms associated with knee OA, particularly as part of a changing healthcare landscape that seeks to identify effective and safe plant medicines to treat chronic pain.

**Background:** Oral Chinese patent medicine (OCPM) combined with western medicine (WM) are believed to be effective for the therapy of chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) with sexual dysfunction (SD). These western medicines mainly involve antibiotics, phosphodiesterase type-5 inhibitor (PDE-5i),  $\alpha$ -blockers. But there is no randomized controlled trial (RCT) that directly compares the efficacy of different OCPM. Hence, we operated a network meta-analysis (NMA) to contrast the efficacy of different OCPM for CP/CPPS with SD.

**Methods:** Relevant studies were searched in PubMed, Cochrane Library, Web of Science, Embase, China National Knowledge Infrastructure (CNKI), Chinese Scientific Journal Database (VIP), and Wanfang database. All of the RCTs concentrated on the use of OCPM to cure CP/CPPS with SD from the inception of the databases to November 2020. We appraised the risk of bias under the Cochrane Handbook and CONSORT statement. The data were statistically analyzed *via* STATA 13.0 and WinBUGS 1.4.3 instrument.

**Results:** Altogether, 30 pieces of literature with 2,996 participants containing 11 oral Chinese patent medicine and 11 interventions were included in the NMA. In terms of The National Institutes of Health chronic prostatitis symptom index (NIH-CPSI), Qianlie Shutong Capsules (QLSTC) + WM had the most possible of being the optimal treatment. In the light of the International Index of Erectile Function (IIEF-5), Congrong Yishen Granules (CRYSG) + WM had the most possible of being the optimal treatment. Shugan Yiyang Capsules (SGYYC) + WM performed the highest likelihood efficacy under cluster rank graph combined NIH-CPSI and IIEF-5. Liuwei Dihuang Pills/Yougui capsules (LWDHP/YGC) + WM had highly possible to be the optimal treatment not only for the clinical effective rate of CP/CPPS but also for the clinical effective rate of SD. Considering four outcomes, QLSTC, CRYSG, SGYYC, LWDHP/YGC, Qianlie Beixi Capsules (QLBXC) plus WM were the best

therapy approach for CP/CPPS with SD, especially LWDHP/YGC + WM and QLBXC + WM.

**Conclusion:** Based on the NMA, QLSTC, CRYSG, SGYYC, LWDHP/YGC, QLBXC plus WM demonstrated the maximum probability of being the optimal therapies. Owing to the limitations of this research, these results should be confirmed by elaborate RCTs.

## INTRODUCTION

“Prostatitis is classified as acute bacterial prostatitis (category I), chronic bacterial prostatitis (category II), chronic prostatitis (CP)/chronic pelvic pain syndrome (CPPS, category III, inflammatory IIIA, noninflammatory IIIB) and asymptomatic inflammatory prostatitis (category IV), according to the National Institutes of Health (NIH) classification system for prostatitis” (Krieger et al., 1999). CP/CPPS, a very common urinary system disease, with small and complex symptoms, which seriously affect patient’s quality of life. Furthermore, “men with CP/CPPS had a high probability to suffer sexual dysfunction (SD) than those without, such as erectile dysfunction (ED), premature ejaculation (PE), decreased sexual desire, ejaculatory pain and so on” (Li and Kang, 2016). “A meta-analysis involving 11,189 men showed that the prevalence of sexual dysfunction in men with CP/CPPS was high (SD was 62%, ED was 29% and PE was 40%), even though overall SD demonstrated a slightly decreasing trend, ED prevalence rate had an increasing trend in recent years” (Li and Chen, 2016). “A questionnaire survey was conducted among 1786 men indicated that the prevalence rate of SD in Chinese men with CP/CPPS is high (SD was 49%, ED was 15% and PE was 26%) and related to age” (Liang et al., 2004). Sexual dysfunction (SD) in our studies mainly refer to self-reported erectile dysfunction (ED) or premature ejaculation (PE), or both.

The studies on CP/CPPS with SD mainly concentrated on “epidemiology” (Liang et al., 2010; Hao et al., 2011), “risk factors” (Zhang et al., 2015a; Ma et al., 2020), and “relationship” (Chung et al., 2012), researches focus on therapeutics are scarce. “The National Institutes of Health (NIH) reached the consensus about prioritization of treatments for chronic prostatitis, rank 1 is antimicrobials (e.g., antibiotics), rank 2 is  $\alpha$ -blockers (e.g., terazosin)” (Nickel et al., 1999). Lately, “ $\alpha$ -blockers, antibiotics, and combinations of these therapies appear to achieve the greatest improvement in clinical symptom scores compared with placebo” (Anothaisintawee et al., 2011; Qin et al., 2016). However, the effectiveness of  $\alpha$ -blockers and antibiotics has been controversial. Additionally, due to the long treatment time, we need to choose some drugs with fewer side effects and a longer course of treatment, so “Chinese patent medicine has become the best choice for us to treat chronic prostatitis with sexual dysfunction” (Zhong et al., 2013). “Oral Chinese patent medicine (OCPM) combined with western medicine (WM)

has the beneficial effects for CP/CPPS with SD” (Wang et al., 2012; Feng et al., 2013).

“Under traditional Chinese medicine (TCM) theories, CP means damp-heat and blood stasis syndromes” (Wang et al., 2016). Therefore, the top priority of treatment is to activate blood circulation and remove dampness. TCM combines syndrome differentiation with disease differentiation was more favorable to us to understand and treat CP. Syndrome differentiation is used to identify different types of a single disease to create a specific treatment plan. Hence, our research evaluated the clinical curative effect of OCPM combined with WM in patients who meet the standard therapy of CP/CPPS with SD: syntheses, individualization, and sequencing. Yet, there is no direct evidence showing the optimal OCPM for CP/CPPS with SD treatment. It is difficult to decide the superiority of treatment under a meta-analysis of pairwise comparisons. A network meta-analysis (NMA) combines existing evidence makes it possible to compare different treatment options at the same time. So, our research compared the curative effect of 11 OCPM combined with WM through NMA to reveal the optimal OCPM for CP/CPPS with SD and provide more perspectives for the choice of CP/CPPS with SD. The graphic workflow in our research is illustrated in **Figure 1**.

## METHODS

### Eligibility Criteria

The RCTs that were published in English or Chinese were included if they met the following standard: 1) “Participants met criteria for CP/CPPS categories IIIA or IIIB according to the National Institutes of Health classification” (Krieger et al., 1999); 2) Participants met criteria for SD categories “erectile dysfunction (ED)” (Rosen et al., 1999) or “premature ejaculation (PE)” (Screponi et al., 2001), or both; 3) The interventions of experiment group involve OCPM add WM, the interventions of control group consist of WM alone or another OCPM plus WM. Besides, “these OCPMs must be included in the Pharmacopoeia of the People’s Republic of China” (Lin et al., 2020) or the data query system of the National Medical Products Administration website <https://www.nmpa.gov.cn/>; 4) The full text could be found and had sufficient data for collection,

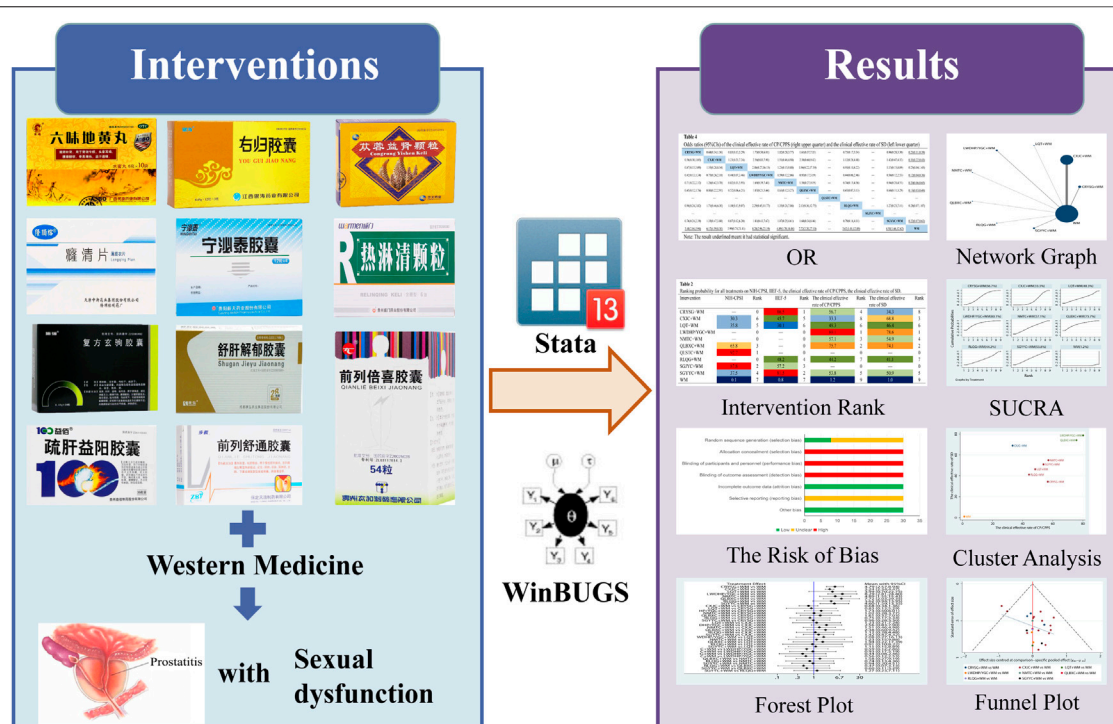

FIGURE 1 | Graphic workflow for the NMA.

including the number of patients, age of patients, duration of therapy; 5) The study contained any of the following outcomes: NIH-CPSI scores, IIEF-5 scores, the clinical effectiveness of CP/CPPS, the clinical effectiveness of SD. The following formula was utilized: the clinical effectiveness (%) = (quantity of recovered patients + quantity of improved patients)/total quantity  $\times 100\%$ . The clinical effective rate of SD = the clinical effective rate of ED + the clinical effective rate of PE. The clinical effective rate of CP/CPPS was primary according to the reduction of the NIH-CPSI score, the clinical effective rate of ED was based on the increase of the IIEF-5 score and the clinical effective rate of PE was on the basis of the increase of Chinese Index of Premature Ejaculation (CIPE-5) score. These scores could be divided into three grades: recovery, improvement, and inefficiency. For response to treatment, various definitions were used in the original studies; recovery was determined when the decrements of the NIH-CPSI score  $>50\%$ , recovery definition to reach the IIEF-5 score  $>21$ , recovery definition to reach the CIPE-5 score  $>17$ ; improvement was defined when the decreases of the NIH-CPSI score  $>25\%$ , improvement definition to reach the IIEF-5 score  $>15$ , improvement definition to meet 4-unit score increases in the CIPE-5 from baseline; the rest was inefficiency.

The following studies were excluded: studies involving patients who had 1) major psychological or somatic diseases; 2) the use of drugs that influence sexual function; 3) the use of antibiotics during the preceding 2 weeks; 4) missing or incorrect data; 5) experimental research, retrospective studies, conference abstracts, case reports, and reviews or meta-analyses.

## Data Sources and Retrieval Strategy

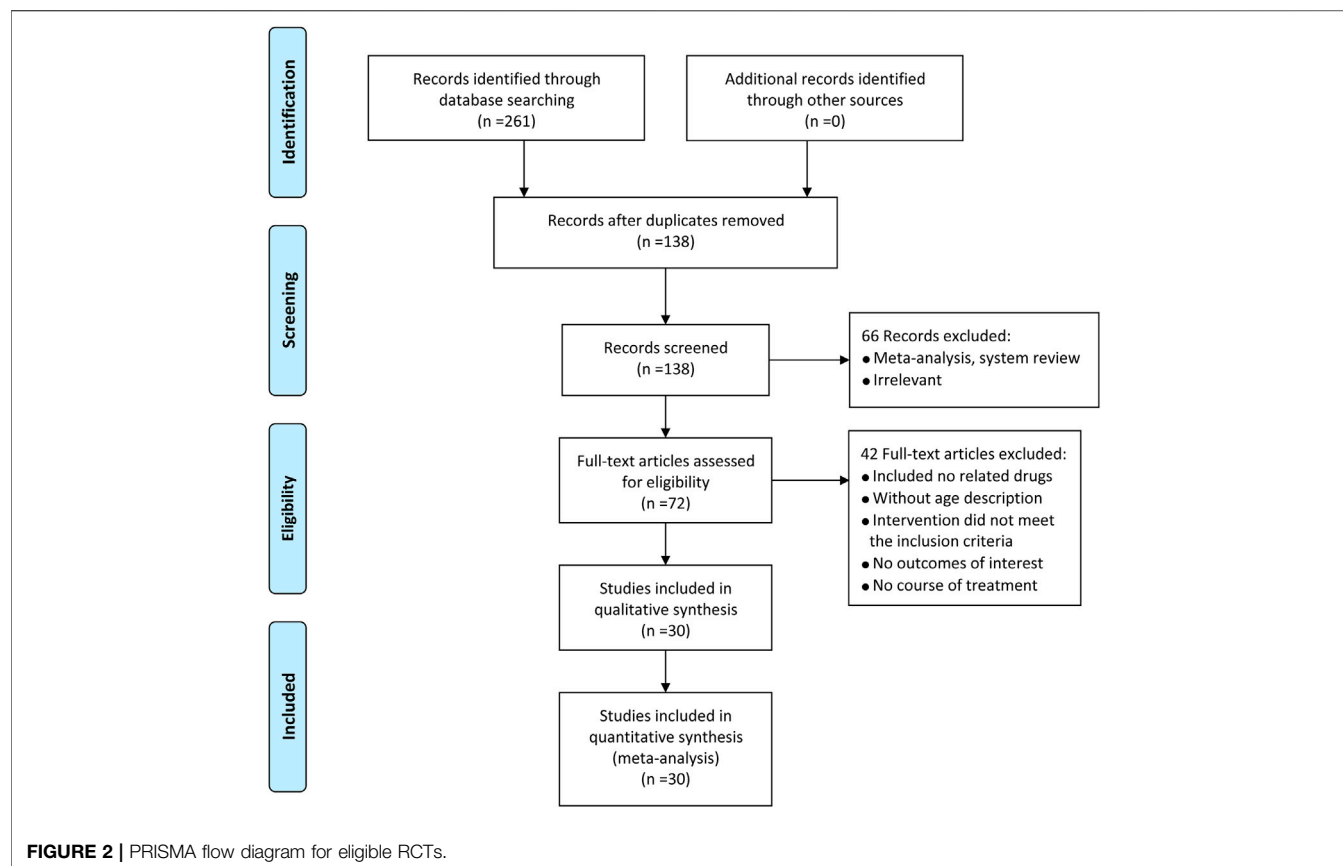

This research retrieves literature by employing the following databases from inception to November 2020: PubMed, Web of Science, Embase, Cochrane Library, CNKI, VIP, and Wanfang database. The free text words and medical subject headings (MeSH) were adopted. The restriction of language includes English and Chinese. Besides, we manually retrieved the reference of involved researches.

After overlaps were removed by EndNote X9, two researchers browsed the titles and abstracts of involved researches respectively. Besides, we also confirmed the potential articles. Any divergence could be solved through discussions or negotiations with a superior researcher.

## Data Extraction and Quality Evaluation

This information was extracted on the basis of the designed table: identity document (author's name and year), participant's characteristics (number of patients, age of patients, chronic prostatitis category, and sexual dysfunction category), methods of intervention, duration, outcomes, the random method.

Two authors evaluated the risk of bias. The intervention was systematically evaluated in randomized controlled trials and Cochrane Handbook. "The quality evaluation of the included RCTs focused on several key domains: selection bias (sequence generation and allocation concealment), performance bias (blinding of patients and personnel), detection bias (blinding of outcome assessors), attrition bias (incomplete outcome data), reporting bias (selective reporting), and other biases" (Higgins et al., 2011). Each of these options was evaluated as high, low or

unclear. When described a valid generation of random number, blinding, and results, they will be categorized as low-risk, otherwise, they will be high-risk. Once described an ambiguous information, they will be categorized as an unclear risk. Any divergence could be solved through discussions or negotiations with a superior researcher.

## Statistical Analysis

The article adopted a Bayesian frame structure employing WinBUGS 1.4.3 and Stata 13.0 instrument to compute the outcomes. As for statistical processes, Random and fixed effects model was adopted for continuous and dichotomous variables, respectively. Simulation iterations were commanded to 200,000, adaptation iterations were required to 10,000. Dichotomous variables or count data made use of odds ratios (ORs), continuous variables or measuring data chose mean difference (MD), as well as used their 95% confidence intervals (95% CIs). In addition, “the ranking probability of each treatment in different results was evaluated through the surface under the cumulative ranking area (SUCRA) value, a larger SUCRA value indicating a better treatment option” (Rücker and Schwarzer, 2015). Cluster analysis about variable results could be used to determine an optimal OCPM about therapy of CP/CPPS with SD under conducting a SUCRA. We didn’t implement the hypothesis of consistency because of non-close loops. Meanwhile, funnel graphs were plotted to identify the presence of publication bias.

The forest graph, the risk of bias graph, and network plot were also illustrated.

## RESULTS

### Study Characteristics of the Involved Researches

All of 261 pieces of literature from seven databases, 72 reserved by removing overlaps, reviews, unrelated researches, and research on animal. What’s more, 42 articles were removed on account of the following causes: no related drugs, without age description, the intervention did not meet the inclusion conditions, no results of interest, no course of treatment. Ultimately, 30 (Liu et al., 2009; Sa et al., 2009; Li et al., 2011; Guo, 2012; Li et al., 2012; Luo, 2012; Wang et al., 2012; Yang, 2012; Feng et al., 2013; Zheng and Li, 2013; Zhong et al., 2013; Chen et al., 2014; Zhang et al., 2014a; Zhang et al., 2014b; Chen et al., 2015; Lang and Xia, 2015; Zhang et al., 2015b; Liu and Chen, 2016; Liu et al., 2016a; Liu et al., 2016b; Su et al., 2016; Wu et al., 2017; Liu et al., 2018; Zhou, 2018; Li et al., 2019; Liu et al., 2019; Hong and Liu, 2020; Wang, 2020; Xia et al., 2020; Zhao, 2020) two-arm randomized controlled trials presented in China from 2009 to 2020 were covered in our study. The PRISMA flow diagram was depicted in **Figure 2**.

Thirty studies with 2,996 patients (1,507 cases in the experimental group, 1,489 cases in the control group)

①NIH-CPSI, ②IIEF-5, ③the clinical effective rate of CP/CPPS, ④the clinical effective rate of SD, ⑤SAS, ⑥CIPE-5, ⑦adverse reaction.

involving 11 oral Chinese patent medicine and 11 interventions (LWDHP/YGC was one intervention based on syndrome differentiation, LWDHP for kidney-yin deficiency, YGC for kidney-yang deficiency) with CP/CPPS with SD (include PE = 5, ED = 10, SD = 15) were included in this NMA. The age range of the participants was approximately 15 to 66, and the young and middle-aged crowd made up the majority. Ten comparisons were appraised: Compound Xuanju Capsules+WM vs. WM ( $n = 15$ ), Congrong Yishen Granules+WM vs. WM ( $n = 3$ ), Liuwei Dihuang Pills/Yougui capsules+WM vs. WM ( $n = 2$ ), Longqing Tablets+WM vs. WM ( $n = 1$ ), Ningmitai Capsules+WM vs. WM ( $n = 1$ ), Qianlie Beixi Capsules+WM vs. WM ( $n = 1$ ), Qianlie Shutong Capsules+WM vs. WM ( $n = 2$ ), Relinqing Granules+WM vs. WM ( $n = 1$ ), Shugan Jieyu Capsules+WM vs. WM ( $n = 2$ ) and Shugan Yiyang Capsules+WM vs. WM ( $n = 2$ ). Western medicine regimen contained antibiotics,  $\alpha$ -blockers, phosphodiesterase type-5

inhibitor (PDE-5i), an anti-inflammatory drug, pollen extract, etc. All the eligible Chinese patent medicine were taken orally, and the course of treatment ranged from 3 to 12 weeks, and most of the studies were 8 weeks. The detailed characteristics of included researches are demonstrated in **Table 1**, the patented formulations of involved literature are listed in **Supplementary Table S1** and the network plots about diverse results could be found in **Figure 3**.

Quality Assessment

Two authors appraised the risk of bias in contained researches respectively by utilizing the Cochrane Risk of Bias Tool proposed by the Cochrane Handbook 5.1. Items assessed were as follows: Low-risk items: 1) seven studies about selective bias (explained utilized table of random numbers) and one study in selection bias (stated adopted lottery method). 2) All studies in attrition bias (reported outcome data completely). 3) All studies in other biases

**TABLE 2 |** Mean difference (95% CIs) of NIH-CPSI (right upper quarter) and IIEF-5 (left lower quarter).

(stated a baseline of randomized controlled trials). High-risk events: 1) All studies about selection bias (did not adopt allocation concealment). 2) All studies in performance bias (did not utilize blinding of participants and personnel). 3) All researches in detection bias (did not report blinding of outcome assessment). Unclear risk items: 1) 22 studies in selection bias (did not state specific random method). 2) All studies in reporting bias (unclear selective reporting). A detailed description of the risk of bias evaluation is shown in **Figure 4**.

## Outcomes

### NIH-CPSI Score

All 15 pieces of research including six OCPM and seven interventions recorded the NIH-CPSI score. As the dominating results, the NIH-CPSI score was depicted in the right upper quarter of **Table 2** and **Figure 5A**, CXJC+WM, LQT+WM, QLBXC+WM, QLSTC+WM, SGJYC+WM, and SGYYC+WM were better than the WM regimen alone in terms of the NIH-CPSI score. These results were statistically

**FIGURE 5 |** Forest graphs of Meta-analysis **(A)** NIH-CPSI; **(B)** IIEF-5; **(C)** the clinical effective rate of CP/CPPS; **(D)** the clinical effective rate of SD.

significant, MD and 95% CIs were 2.88 (1.78, 3.98), 3.13 (0.77, 5.49), 5.30 (3.03, 7.57), 7.93 (6.14, 9.71), 7.47 (4.70, 10.24) and 3.23 (1.38, 5.08), respectively. Additionally, QLSTC+WM was more effective than LQT+WM (MD = -4.80, 95% CI = -7.76 to -1.84) and CXJC+WM (MD = -5.05, 95% CI = -7.14 to -2.95); SGJYC+WM was more effective than LQT+WM (MD = -4.34, 95% CI = -7.98 to -0.70) and CXJC+WM (MD = -4.59, 95% CI = -7.57 to -1.61). According to the calculated probabilities of **Figure 6A** and **Table 3**, QLSTC+WM (92.7%) was the optimal combination in decreasing NIH-CPSI score, SGJYC+WM (87.8%) was number two, and QLBXC+WM (65.8%) was the third.

## IIEF-5 Score

All 14 pieces of literature including six OCPM and seven interventions recorded the IIEF-5 score. As the other dominating outcomes, the IIEF-5 score was demonstrated in the left lower quarter of **Table 2** and **Figure 5B**, CRYSG+WM, CXJC+WM, RLQG+WM, SGJYC+WM, and SGYYC+WM were better than the WM regimen by itself according to the IIEF-5 score. These results were statistically significant, MD and 95% CIs were 6.33 (3.16, 9.50), 3.91 (2.63, 5.18), 3.94 (1.22, 6.66), 4.40 (2.16, 6.65), and 5.72 (3.70, 7.75), respectively. No statistical significance was proved in the rest of the treatments. Relying on the ranking probabilities of **Figure 6B**

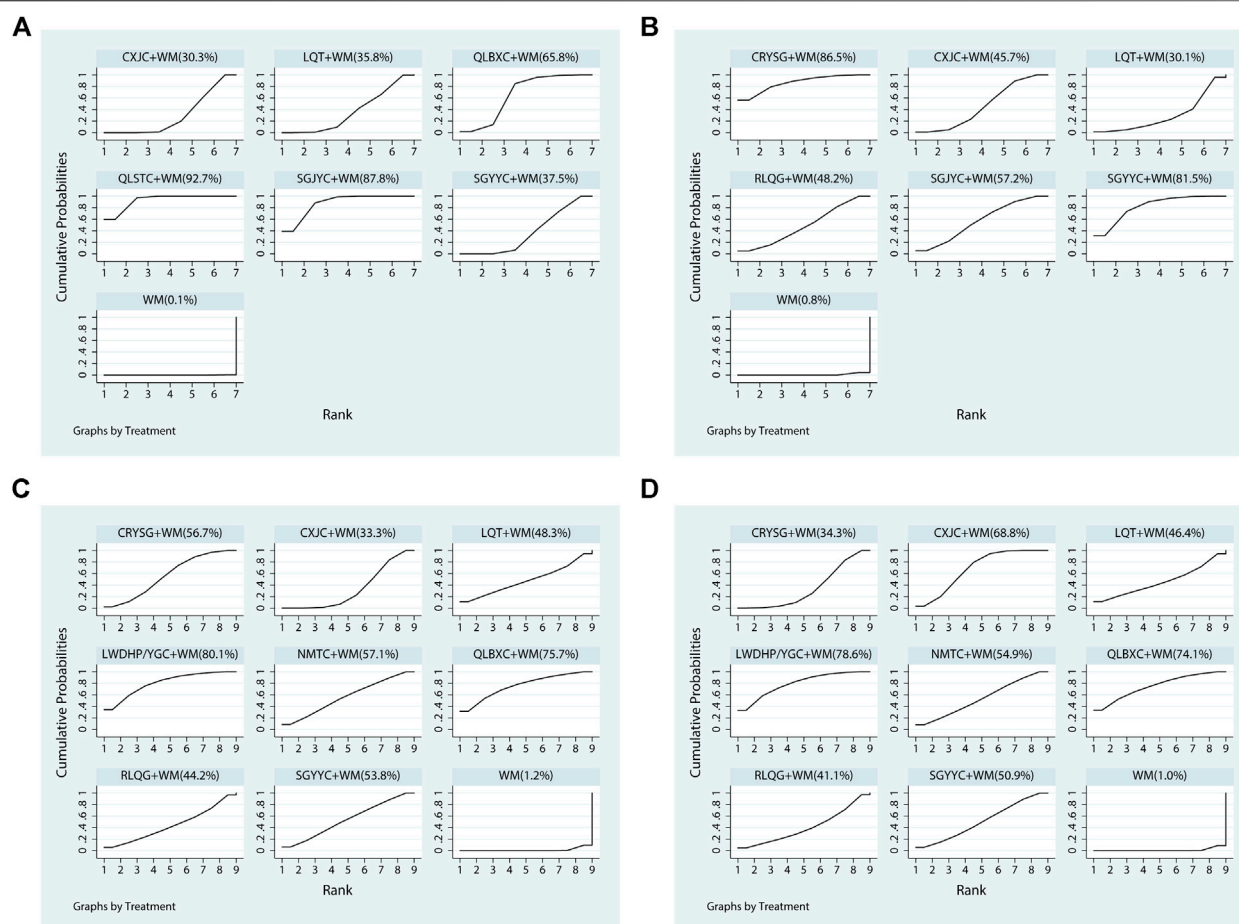

and **Table 3**, CRYSG+WM (86.5%) was the best combination in increasing the IIEF-5 score, followed by SGYYC+WM (81.5%) and SGJYC+WM (57.2%).

## The Clinical Effective Rate of CP/CPPS

All 24 pieces of research including nine OCPM and nine interventions recorded the clinical effective rate of CP/CPPS. It was considered to the main outcomes, was displayed in the right upper quarter of **Table 4** and **Figure 5C**, CRYSG+WM, CXJC+WM, LWDHP/YGC+WM, NMTC+WM, QLBXC+WM, and SGYYC+WM were better than the WM regimen alone according to the clinical effective rate of CP/CPPS. These results were statistically significant, ORs and 95% CIs were 0.21 (0.11, 0.39), 0.31 (0.22, 0.43), 0.12 (0.04, 0.36), 0.20 (0.06, 0.65), 0.13 (0.03, 0.49), and 0.22 (0.07, 0.63), respectively. Nevertheless, other interventions had no statistical difference. On the basis of the ranking probabilities of **Figure 6C** and **Table 3**, LWDHP/YGC+WM (80.1%) was the optimum combination in improving the clinical effective rate of CP/CPPS, QLBXC+WM (75.7%) was number two, and NMTC+WM (57.1%) was the third.

## The Clinical Effective Rate of SD

All 24 pieces of literature including nine OCPM and nine interventions recorded the clinical effective rate of SD. As the

**FIGURE 6 |** Plots of the surface under the cumulative ranking curves for all treatments **(A)** NIH-CPSI; **(B)** IIEF-5; **(C)** the clinical effective rate of CP/CPPS; **(D)** the clinical effective rate of SD.

The result underlined meant it had statistical significant.

12.62), respectively. No statistical significance was testified in the rest of the treatments. According to the ranking probabilities of **Figure 6D** and **Table 3**, LWDHP/YGC+WM (78.6%) was the first-rank combination in improving the clinical effective rate of SD, followed by QLBXC+WM (74.1%) and CXJC+WM (68.8%).

## SAS, CIPE-5, and Adverse Reaction

All five pieces of research including 2 OCPM and 3 interventions recorded the Self-rating anxiety scale (SAS), four studies involving three OCPM, and four interventions reported the Chinese Index of Premature Ejaculation (CIPE-5) and eight studies involving four OCPM and five interventions reported the adverse reaction. No statistical analysis was performed on these secondary outcomes on account of the scarcity of studies and inconsistent evaluation criteria.

## Cluster Analysis

The influences of interventions in two diverse results were synthetically contrasted by cluster analysis. Two sets of cluster analyses were conducted in our study, containing NIH-CPSI and IIEF-5, the clinical effective rate of CP/CPPS and the clinical effective rate of SD, respectively. The results are shown in **Figure 7**. Through synthetical analysis by means of cluster analysis, SGJYC+WM had the better efficacy in decreasing the NIH-CPSI score, SGYYC+WM had the better curative effect in increasing the IIEF-5 score. Nevertheless, there was no optimum combination associated with a preferable response in both aspects. On the other group of cluster analysis, LWDHP/

YGC+WM might possess the best efficacy in improving the clinical effective rate of CP/CPPS and SD, QLBXC+WM was in hot pursuit, their efficacy in the therapy of CP/CPPS with SD is worthy of attention.

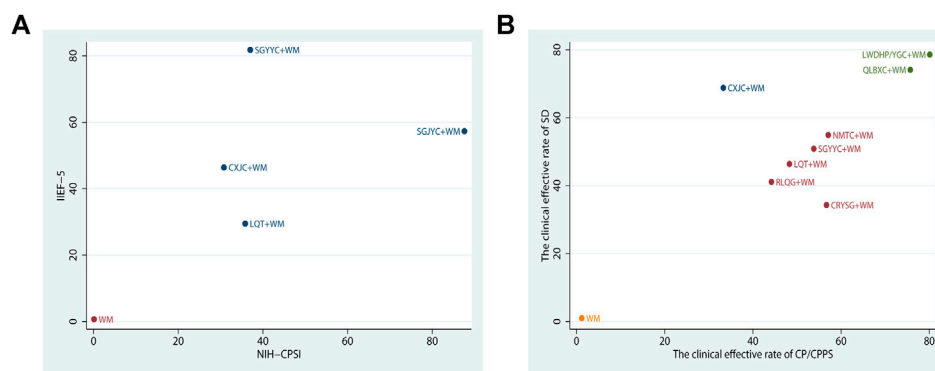

## Publication Bias

A funnel graph for four major outcomes was presented in **Figure 8** to evaluate publication bias. All of the funnel graphs were not completely symmetrical visually, and each of the adjusted auxiliary lines was not perpendicular to the centerline. Thus, there may be significant publication bias.

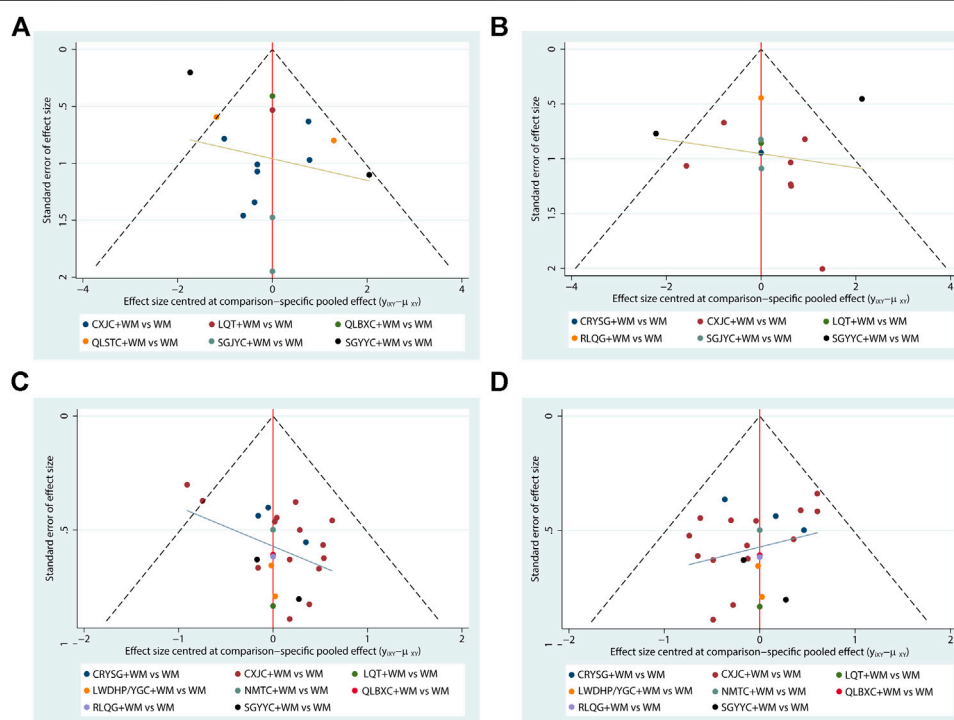

## DISCUSSION

### Summary of Main Findings

According to the information from 30 involved pieces of research with four primary outcomes, this article systematically appraised the efficacy of 11 commonly used OCPM (CRYSG, CXJC, LQT, LWDHP, NMTC, QLBXC, QLSTC, RLQG, SGJYC, SGYYC, and YGC) combined with WM in treating CP/CPPS with SD by taking advantage of network meta-analysis method. It's worth noting that LWDHP/YGC belonged to one intervention through adopting dialectical treatment, LWDHP for kidney-yin deficiency, YGC for kidney-yang deficiency. On the account of the result of NMA, most OCPM combined with WM presented better results than utilizing WM by itself in various outcomes, and these results between groups were statistical differences. On the

**FIGURE 7 |** Cluster analysis plots. Interventions located in the upper right corner indicate optimal combination therapy for two different outcomes.

**FIGURE 8 |** Funnel plots (A) NIH-CPSI; (B) IIEF-5; (C) the clinical effective rate of CP/CPPS; (D) the clinical effective rate of SD.

account of SUCRA results, QLSTC + WM had the maximum probability to be the best treatment in the NIH-CPSI. While in IIEF-5, CRYSG + WM intervention might be the best intervention. LWDHP/YGC had highly possible to be the optimal therapy in both the clinical effective rate of CP/CPPS and the clinical effective rate of SD. The clustered ranking according to NIH-CPSI compared with IIEF-5 showed there was no optimum combination better than any other combination. Fortunately, the clustered ranking based on the clinical effective rate of CP/CPPS compared with the clinical effective rate of SD showed LWDHP/YGC + WM had highly possible to be the best treatment on both sides. Considering four

outcomes, QLSTC, CRYSG, SGYYC, LWDHP/YGC, Qianlie Beixi Capsules (QLBXC) plus WM were the optimum treatment regimens for CP/CPPS with SD, especially LWDHP/YGC + WM and QLBXC + WM. Therefore, the efficacy of LWDHP/YGC + WM and QLBXC + WM in the therapy of CP/CPPS with SD was worthy of attention, but clinicians should also select appropriate methods on the basis of specific situations of clinical patients.

## Research Significance and Importance

This article utilizes a network meta-analysis approach to appraise the curative effect of OCPM for treating CP/CPPS with SD for the

first time. Meanwhile, our studies involved utilized treatment based on syndrome differentiation in Traditional Chinese Medicine (TCM) theories (e.g., LWDHP for kidney-yin deficiency, YGC for kidney-yang deficiency) and “obtained satisfactory curative effect” (Zhong et al., 2013; Zhou, 2018). In fact, “From the diagnosis of TCM, it included primarily type of syndrome, pathogen, position or name of a disease, such as wind-chill virus cold, wind-heat mycoplasma pneumonia” (Hou and Liu, 2013). Meanwhile, “Western medicine also developed a six-point clinical phenotyping of CP/CPPS to create a specific symptomatic treatment plan (UPOINT system), these clinical domains contained urinary symptoms, psychosocial dysfunction, organ-specific findings, infection, neurologic/systemic, and tenderness of muscles” (Shoskes and Nickel, 2013). “People have different opinions on whether to add SD into the UPOINT system” (Magri et al., 2010; Ersan et al., 2016). Basing on the above theory and method of integrated Chinese and Western medicine, we ranked the outcomes for the sake of offer evidence and recommendations for clinical medication. Furthermore, from the view of mechanisms, on the one hand, antibiotics could control infection and  $\alpha$ -blockers could relaxes smooth muscles in areas such as the prostate and bladder and improves lower urinary tract symptoms and pain except anxious emotion, on the other hand, traditional Chinese medicine theory believes that anxiety is related to liver stagnation, OCPM could regulate liver stagnation and improves deficiency of kidney and spleen to relieves anxious emotion, improves erectile function and inhibit premature ejaculation ultimately. So as to say, OCPM and WM complement each other, physiotherapy and psychotherapy are as important as pharmacotherapy in the therapy of CP/CPPS with SD, “multi-disciplinary treatment (MDT) schema is expected to be preferred treatment in future” (Cheng and Zhang, 2018; Yan et al., 2019).

## Limitations

Nevertheless, this research also possessed limitations. In the first place, among 30 literature, only eight literature that utilized the correct method of a random number, none of them adopted allocation concealment, applied the blind method (blind to participants and personnel), and reported blinding of outcome evaluation. The quality of the involved researches might not be high, which reduced the persuasiveness of research results. In the second place, limited by application area of OCPM, all researches were reported in China and published in a Chinese journal, lacking the resource in other languages, which is not beneficial to the international promotion of study outcomes. In the third place, most RCTs studied on OCPM + WM vs. WM, lacking direct study on comparisons between diverse OCPM combined with WM. Finally, this research didn't limit the phenotyping of CP/CPPS (include III = 26, IIIB = 4) and SD (include PE = 5, ED = 10, SD = 15). Therefore, we need to further analyze the efficacy of various OCPM on CP/CPPS with SD in the future.

## Prospects

Eventually, we propound the following recommendations: firstly, multicenter randomized double-blind tests should be

implemented in rigorous in the light of regulations when conducting RCTs. The method of a random number, allocation concealment, and blind method performance are committed steps that need to be attentive in the future study program. Secondly, it is important to perform more clinical researches compared to the effect of different OCPM to make up for the absence of study in this domain. Finally, because of recurrent frequently of CP/CPPS with SD, a subsequent program should be carried out to supervise the prognosis of participants.

## CONCLUSION

By means of this NMA, OCPM combined with WM offered significant benefits compared to WM by itself in the therapy of chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) with sexual dysfunction (SD). What's more, among the OCPM, LWDHP/YGC + WM and QLBXC + WM should be worthy of attention. But, on account of the limitations of this article, these conclusions were supposed to be certified *via* multicenter, high-quality, and larger-sample randomized controlled trials.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

## AUTHOR CONTRIBUTIONS

YZ, HM, and TN were involved in the design and conception of the network meta-analysis. YZ was responsible for the conduct of the network meta-analysis. YL and WZ took charge of the quality evaluation of the NMA. YZ and TN saw to the analysis of study information. YZ and HM took charge of the writing of the article. ZZ and XG saw to the revision of the article. All authors read and approved the final version of the manuscript.

Exploring the Mechanism of Zhibai  
Dihuang Decoction in the Treatment of  
Ureaplasma Urealyticum-Induced  
Orchitis Based on  
Integrated Pharmacology.  
Front. Pharmacol. 12:602543.  
doi: 10.3389/fphar.2021.602543

**Background:** Ureaplasma urealyticum (UU) infection is the most common cause of male infertility. Zhibai Dihuang Decoction (ZBDHD) can improve the rate of forwarding motility sperm, sperm deformity rate, seminal plasma zinc and refined berry sugar levels.

**Methods:** The potential targets of ZBDHD are obtained from The Encyclopedia of Traditional Chinese Medicine (ETCM). Orchitis-related targets were collected from the Genecards and OMIM databases. The Cytoscape and the Database for Annotation, Visualization and Integrated Discovery (DAVID) were utilized to construct and analyzed the networks. Finally, a rat model of orchitis caused by UU infection was used to detect related indicators of mitochondrial energy metabolism using TUNEL apoptosis detection technology, loss cytometry, Real-Time Quantitative Reverse Transcription PCR (qRT-PCR) and Western Blot.

**Results:** A total of 795 ZBDHD targets and 242 orchitis-related targets were obtained. The “ZBDHD- orchitis PPI network” was constructed and analyzed. ZBDHD can regulate signaling pathways and biological processes related to mitochondrial energy metabolism. The results of experimental studies have shown that ZBDHD maintains the integrity of sperm mitochondrial respiratory chain function by enhancing mitochondrial Na<sup>+</sup>-K<sup>+</sup>-ATPase and Ca<sup>2+</sup>-Mg<sup>2+</sup>-ATPase activities, promotes the synthesis of mitochondrial ATP, and improves sperm energy supply, thereby improving the motility, vitality and survival rate of sperm, and effectively improving the quality of semen in UU-infected rats ( $p < 0.05$ ).

**Conclusion:** This study discovered the multi-pathway mechanism of ZBDHD intervention in UU-induced orchitis through integrated pharmacological strategies, which provides a reference for further research on the mechanism of ZBDHD intervention in orchitis in the direction of mitochondrial energy metabolism.

**Keywords:** Zhibai Dihuang decoction, ureaplasma urealyticum, orchitis, integrated pharmacological, bioinformatics, Chinese medicine, herb medicine

## INTRODUCTION

With the development and progress of society, the influence of many factors such as psychology, environment, diet, bad living habits, etc., human reproductive function shows a downward trend year by year, and about one-sixth of couples suffer from infertility (Moridi et al., 2020). This has an adverse effect on family harmony and social stability. Therefore, infertility has become a serious public health problem. Among the many factors that cause infertility, males account for about 30–50% (Huang et al., 2016), among which low sperm motility and reduced sperm count are important reasons for male infertility (Huang et al., 2015). Reproductive system infection is one of the important causes of male infertility, and Ureaplasma urealyticum (UU) infection is the most common (Gdoura, et al., 2007; Lee et al., 2013). The pathogenesis and treatment of low sperm motility caused by UU infection are still problems facing the medical community. Due to the continuous increase of antibiotic resistance and the existence of the blood-testis barrier, the efficacy of antibiotics in the treatment of UU infectious infertility has been affected. Although it has a certain effect in killing UU, it is not effective in improving sperm motility (Zhu et al., 2012; Kokkayil and Dhawan, 2015; He et al., 2016). Therefore, an important topic in the field of male diseases is to reveal its pathogenesis in depth and to find efficient, stable and durable treatments (Wang, 2017). Traditional Chinese medicine (TCM) treatment is unique in that it emphasizes a holistic view, uses multiple channels for adjustment, and two-way balance adjustment. It is of great significance to use TCM to prevent and treat UU infectious infertility to enhance sperm “vitality” (Bin et al., 2016; Wang, 2017).

Zhibai Dihuang Decoction (ZBDHD) comes from “The Golden Mirror of Medicine”. Current research shows that: ZBDHD is a classic prescription for nourishing yin and nourishing kidneys, clearing heat and reducing fire, and it has significant clinical treatment effects on various diseases (such as urinary system, endocrine system, gynecology, andrology, pediatrics, skin diseases, and venereal diseases, etc.) (Gao et al., 2020; Wu et al., 2020). The pharmacological mechanisms involved in ZBDHD include lowering blood sugar, enhancing immunity, anti-oxidation, anti-fatigue, regulating neuroendocrine, anti-tumor, etc. (Liu et al., 2018a; Liu et al., 2018b; Gao et al., 2020; Wu et al., 2020). Our previous research also found that ZBDHD can improve the rate of forwarding motility sperm, sperm deformity rate, seminal plasma zinc and refined berry sugar levels (Sheng and He, 2019; Li et al., 2019). However, its specific mechanism is still unknown.

At present, integrated pharmacology, as a new discipline, is a discipline that studies the interaction of multi-component drugs with the body and its integration laws and principles of action (Zeng and Yang, 2017). It emphasizes multi-level and multi-link integrated research such as “whole and part,” “*in vivo* and *in vitro*,” “*in vivo* process and activity evaluation,” which is in line with the overall and systematic treatment of TCM (Yang et al., 2020; Zeng et al., 2020). Previously, we have explored the mechanism of multi-component Chinese herbal medicines in

infectious diseases, endocrine diseases and immune diseases by using integrated pharmacology (Zhang et al., 2020a; Zhang et al., 2020b). In this study, we would use the strategy of integrating pharmacology and multi-directional pharmacology to study the mechanism of ZBDHD intervention in UU-induced orchitis. The process of this research is shown in **Figure 1**.

## MATERIALS AND METHODS

### Potential Targets and Orchitis-Related Targets Collection

The potential targets of ZBDHD were collected from the Encyclopedia of Traditional Chinese Medicine (ETCM, <http://www.tcmip.cn/ETCM/index.php>) (Xu et al., 2018). ETCM is a database that include comprehensive and standardized information for the commonly used herbs and formulas of TCM, as well as their ingredients. The Orchitis-related targets were collected from Genecards (<http://www.genecards.org>) (Stelzer et al., 2018), and Online Mendelian Inheritance in Man (OMIM) (<http://omim.org/>) databases (Hamosh et al., 2015). The proteins were introduced into UniProt (<https://www.uniprot.org/>) to correct their official gene symbols. Finally, a total of 795 ZBDHD targets and 242 orchitis-related targets were obtained (Supplementary Tables S1, S2).

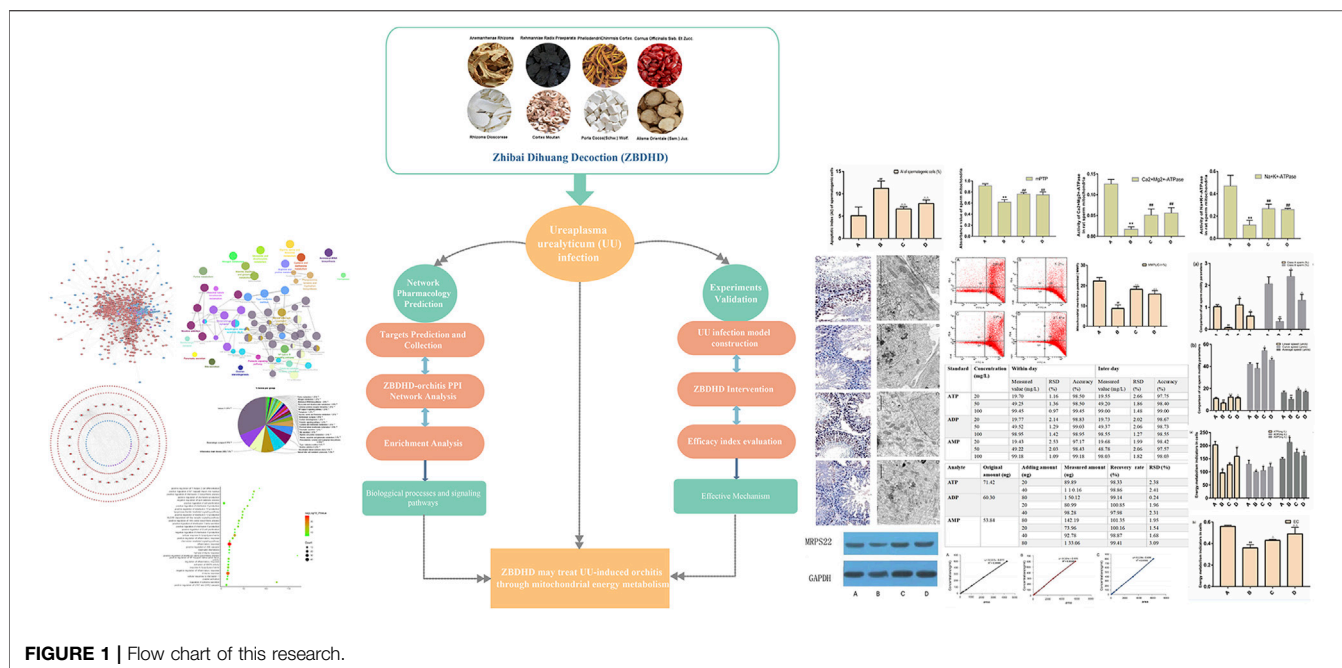

### Network Construct and Analysis Methods

The protein-protein interaction (PPI) information of ZBDHD targets and orchitis-related targets were collected from String 11.0 (<https://string-db.org>) Szklarczyk et al., 2015). The drug target-disease target PPI network (such as ZBDHD-orchitis PPI network) were constructed by Cytoscape 3.7.2 ([www.cytoscape.org/](http://www.cytoscape.org/)) (Bader and Hogue, 2003). The ZBDHD-orchitis PPI network was analyzed by the “Network Analyzer” and “MCODE” plug in of Cytoscape to obtain the degree of each node and clusters of this network. Finally, the Database for Annotation, Visualization and Integrated Discovery (DAVID) ver 6.8 (<https://david.ncifcrf.gov/>) and the “ClueGO”, plug-in of Cytoscape, were utilized to perform Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis and Gene Ontology (GO) enrichment analysis (Huang et al., 2009).

### Experimental Materials Instruments and Reagents

The UU standard strain and UU culture medium were provided by the Department of Microbiology, Nanhua University, and the reagents required for electron microscopy were provided by the Electron Microscopy Room of Xiangya Medical College, Central South University. Mitochondrial membrane potential (mitochondrial membrane potential, MMP) detection reagent JC-1, PCR kit, and reverse transcription kit were all purchased from Kilon Biotechnology (Shanghai) Co., Ltd. BCA protein quantification kit, mouse anti-rat MRPS22 monoclonal antibody, and HRP-labeled goat anti-mouse IgG were purchased from Biyuntian Biotechnology Co., Ltd. C 18 column Diamonsil, sum, 250 × 4.6 mm; ADP reference substance (SIGMA company A2754, content 95%), ATP reference substance

(SIGMA company A26209, the content is 99%), AMP reference substance (SIGMA company 01930, content is 99%). CytC ELISA kit (BOSTER Biological Technology co. Ltd.). Loganin reference substance (China Institute for the Control of Pharmaceutical and Biological Products, batch number 111640-201602). Tissue Mitochondrial Isolation Kit (Cat. No.: 050217171026, Biyuntian Biotechnology Company). Purified mPTP Colorimetric Detection Kit (Cat. No.: 6-4267-11, GENMED Technology Company).

Azithromycin tablets were purchased from CSPC Ouyi Pharmaceutical Company (Lot No.: 001120941), and were formulated with normal saline to make 25 mg/ml. ZBDHD is composed of *Rehmanniae Radix Praeparata*, *Cornus Officinalis* Sieb. Et Zucc., *Rhizoma Dioscoreae*, *Alisma Orientale* (Sam.) Juz., *Cortex Moutan*, *Poria Cocos* (Schw.) Wolf, *Anemarrhenae Rhizoma*, *Phellodendri Chinensis Cortex* with ratio 24:12:12:9:9:6:6. The medicinal materials are provided by the First Affiliated Hospital of Hunan University of Chinese Medicine. They are appraised by Chinese pharmacists and processed in strict accordance with traditional methods. The medicinal materials are decocted in distilled water. Finally, ZBDHD was concentrated to 1 g crude drug/ml, and stored in a refrigerator at 4°C for later use.

HT7700 transmission electron microscope (Hitachi Inc.), FACSaria flow cytometer (BD Inc.), electrophoresis (Bio-Rad), ABI-7300 Real-time detector (ABI Inc.). Other instruments are provided by the Central Laboratory of Hunan University of Chinese Medicine. High performance liquid chromatograph (HPLC) (Waters company, model Waters 1525); UV detector (U.S. Waters company, model Waters 2489).

## Experimental Animals

60 specific pathogen free (SPF) SD male rats were purchased from Hunan Slack Jingda Experimental Animal Company, 4–5 months

old, weight ( $208 \pm 15$ ) g, laboratory animal production license number: SCXK (Xiang) 2011-0003. The animals were kept in the Special Animal Room for Pathogenic Microorganisms of Hunan University of Chinese Medicine [Permit No.: SYXK (Xiang) 2009-0001]. All animal care and use procedures comply with the National Institutes of Health (NIH) guidelines for the care and use of experimental animals and have been approved by the Institutional Animal Ethics Committee of Hunan University of Chinese Medicine.

## ZBDHD Quality Control by HPLC

### Preparation of Sample Solution

Loganin solution: The loganin reference substance was added to 50% methanol to make a reference solution containing 50 µg per 1 ml.

ZBDHD solution: ZBDHD solution was prepared according to the aforementioned method.

### HPLC Condition

Shim-Pack CLCDS column (150 mm × 4.6 mm, 5 µm); acetonitrile: water (15:85) as mobile phase, flow rate 1.0 ml·min<sup>-1</sup>, detection wavelength 232 nm, column temperature at room temperature. Under these conditions, the loganin peak in the sample chromatogram reached baseline separation without interference (Figure 2).

## Experimental Methods

### Animal Modeling

First, UU titer titration was performed. The UU standard strain (freeze-dried product) was resuscitated, inoculated into liquid culture medium under aseptic conditions, cultured at 37°C for 16–24 h, and the logarithmic phase bacteria were taken. When the culture medium appears orange-red and clear bacterial liquid,

**FIGURE 2 |** The results of HPLC. (A): Loganin solution; (B): ZBDHD solution.

the multiple dilution was implemented. The color change unit of the bacterial liquid with a titer of  $10^6$  ccu/ml is used in the *in vitro* experiment. Then, the UU standard strain suspension was injected into the bladder to establish a UU infection animal model. The rats were fasted for 12 h before modeling. After the rats were anesthetized with 2% pentobarbital sodium (0.2 ml/100 g) and disinfected, the abdominal cavity was opened and the bladder was freed. The residual urine in the bladder was drained with a syringe, and 2 ml of normal saline or UU standard strain was injected into the bladder, and finally the abdominal cavity was sutured.

After the inoculation, the testicular puncture fluid was taken after routine feeding for 7 days and inoculated in UU culture medium at 37°C and 5% CO<sub>2</sub>. If the culture medium turns from yellow to red and is transparent and clear, 0.2 ml UU is transferred to solid medium after filtering through a microporous membrane. After culturing at 37°C and 5% CO<sub>2</sub> for 72 h, the colonies were observed under a low-power microscope to confirm whether there was UU growth in the testicular tissue.

### Animal Grouping and Intervention

Successfully modeled UU-infected rats were randomly divided into model group, ZBDHD group, and positive control group. At the same time, normal rats were used as normal group, with 15 rats in each group. Gavage was started on the 10th day after the successful model building, once daily. According to Sellami et al., 2014, (Guo et al., 2017) the dose of ZBDHD group is 1 g/(kg d) [i.e. ZBDHD 1 ml/(kgd)], the dose of positive control group is 0.105 g/(kg d) [i.e. azithromycin suspension 1 ml/(kgd)]. The normal group and the model group were given corresponding volume of normal saline by gavage. The testes of the rats were removed, the testis capsule and blood vessels were thoroughly stripped, and the testes were placed in a cell culture dish, and 3 ml PBS was added to completely soak the testes for later use.

### Detection of Spermatogenic Cell Apoptosis

The prepared rat testis tissue sections were tested for spermatogenic cell apoptosis according to the instructions of the TUNEL detection kit. The cells with brown particles in the nucleus were apoptotic cells. Twenty seminiferous tubules were randomly selected from each section, and the number of positive spermatogenic cells apoptosis in the total spermatogenic cells was counted, and the positive cell rate was calculated, which was the apoptotic index (AI).

### Preparation of Spermatogenic Cell Suspension and Sperm Motility Test

The testicular tissue was collected under aseptic conditions to prepare a spermatogenic cell suspension, which was placed in a 32°C, 5% CO<sub>2</sub> incubator for 5 min to diffuse for use. Sperm suspension was diluted with PBS solution in a ratio of 1:9, fully shaken. Color sperm dynamic detection system was used to measure sperm motility parameters.

### Detection of MMP and Mitochondrial Structure of Spermatogenic Cells

Alexa Fluor 488 and R-phycoerythrin are excited by the 488 nm light of the flow cytometer to detect the fluorescence signal at 520 nm and analyze the MMP of spermatogenic cells. A long strip specimen of the middle part of the left testis of the rat was taken out, and ultra-thin sections were made according to the requirements of electron microscopy. The ultra-thin sections were stained with uranyl acetate and lead nitrate, and then electron microscopy observations and photographs were performed to observe the mitochondrial structure of spermatogenic cells.

### Detection of MRPS22 mRNA in Spermatogenic Cells by Real-Time Quantitative Reverse Transcription PCR

The total RNA of the spermatogenic cell suspension was extracted and subjected to RTPCR detection. The data obtained in the experiment was analyzed by ABI's own RQ software, and the relative quantification of target gene expression was analyzed by the 2- $\Delta\Delta C_t$  method. Each sample was repeated 3 times in parallel, and the average was taken for analysis.

### Detection of MRPS22 Protein in Spermatogenic Cells by Western Blot

The spermatogenic cell suspension was lysed and homogenized, and the MRPS22 protein of spermatogenic cells was detected by Western blotting. Using  $\beta$ -actin as the internal reference, the Image-pro Plus processing software was used to analyze the image information and calculate the relative expression level.

### Quantitative Detection of ATP, ADP, AMP in Sperm Mitochondria

A random number table was used to select 5 rats in each group, and the contents of ATP, ADP, and AMP in sperm mitochondria were detected by HPLC, and proceeded in accordance with the

procedures of each kit. Energy charge (EC) value:  $EC = (ATP + 0.5 ADP) / (ATP + ADP + AMP)$ .

### Determination of Sperm CytC Content by ELISA

The content of CytC in rat testis tissue was tested according to the operation steps of the ELISA test kit.

### Mitochondrial Permeability Transition Pore Opening Detection

After the purified mitochondrial sample to be tested was prepared, 100  $\mu$ l of the mitochondrial sample (a total of 0.2 mg) was transferred to a 1.5 ml centrifuge tube, 10  $\mu$ l of staining solution (Reagent A) was added, and the mixture was evenly mixed. Then, it was incubated in a cell incubator at 37°C in the dark for 15 min, and then centrifuged in a miniature benchtop centrifuge at 4°C for 5 min at a speed of 16,000 g, and the supernatant was removed. Then the pre-heated preservation solution (Reagent C) at 37°C was added to mix the particles. Finally, 100  $\mu$ l of the above suspension was transferred to a black 96-well plate, and put into a fluorescence microplate reader for detection (Excitation wavelength 488 nm, emission wavelength 505 nm). If the relative fluorescence units (RFU) decreases, it indicates that mPTP is enhanced.

### Sperm Mitochondrial $Na^+-K^+-ATPase$ , $Ca^{2+}-Mg^{2+}-ATPase$ Detection

After the sperm suspension is prepared, the sperm mitochondria are separated by a differential fractionation method and placed in an ice tank for later use. The determination of  $Na^+-K^+-ATPase$  and  $Ca^{2+}-Mg^{2+}-ATPase$  activity is strictly in accordance with the instructions of the mitochondrial  $Na^+-K^+-ATPase$  and  $Ca^{2+}-Mg^{2+}-ATPase$  kit instructions.

### Statistical Analysis

SPSS 17.0 is used for statistical analysis, and the measurement data is expressed as  $\bar{x} \pm s$ . The independent sample t test was used to compare the difference in means between two groups. One-way ANOVA is used to compare the mean difference between multiple groups, and the LSD test is used for pairwise comparison between multiple groups. Pearson analysis was used to analyze the correlation between MRPS22 and MMP. All tests are two-sided tests, and  $p \leq 0.05$  is considered statistically significant.

## RESULTS

### ZBDHD-Orchitis PPI Network Analysis

#### ZBDHD-Orchitis PPI Network Construction

ZBDHD-orchitis PPI network consists of 946 nodes (726 ZBDHD target nodes, 194 orchitis target nodes and 26 ZBDHD-orchitis target nodes) and 18,098 edges (Figure 3). The targets are arranged in descending order according to their degree, the top 20 can be divided into 3 category: 1) ZBDHD target: GAPDH (294 edges), INS (290 edges), AKT1 (253 edges), MAPK3 (199 edges), SRC (166 edges), EGF (157 edges), CASP3 (153 edges); 2) Orchitis related targets: ALB (276 edges), CXCL8 (188 edges), IL10 (180 edges), STAT3 (167 edges), CAT (160

edges), IL2 (158 edges), IL4 (151 edges), HSP90AA1 (147 edges); 3) ZBDHD-orchitis target: IL6 (249 edges), TNF (227 edges), VEGFA (192 edges), IL1B (173 edges), TLR4 (168 edges).

### Biological Processes of ZBDHD-Orchitis PPI Network

The ZBDHD-orchitis PPI network was analyzed by MCODE and 27 clusters were obtained (Figure 4 and Table 1). The targets and genes of top 10 clusters were input into DAVID and ClueGO to perform GO enrichment analysis so as to obtain the biological processes of each cluster.

Cluster 1, 6 and 9 is related to inflammation and immune response. Cluster 2, 4 and 5 are associated with mitochondria and energy metabolism. Cluster 8 are associated with mitochondria and nutrient metabolism. Cluster 3 and 10 did not return any orchitis-related biological processes (Supplementary Table S3). The *p*-value, fold enrichment and count of biological processes in cluster 1 were shown in Figure 5 as an example.

### Pathway of ZBDHD-Orchitis PPI Network

The targets in ZBDHD-orchitis PPI network were input into DAVID and ClueGo to perform pathway enrichment analysis and a lot of human signaling pathways returned (Figure 6).

The pathway enrichment analysis showed that ZBDHD can regulate a lot of orchitis-related signaling pathways, such as Metabolic pathways, Neuroactive ligand-receptor interaction, Arginine biosynthesis, Alanine, aspartate and glutamate metabolism, Glutamatergic synapse, Biosynthesis of amino acids, Arginine and proline metabolism, cAMP signaling pathway, 2-Oxocarboxylic acid metabolism, Glycine, serine and threonine metabolism (Figure 7 and Supplementary Table S4). The *p*-value, fold enrichment and count of each signaling pathways were shown in Figure 8.

### Evaluation of Establishment of UU Infection Rat Model

Seven days after the rat bladder was inoculated with UU, the testicular puncture fluid changed from yellow to red and the culture medium was transparent and clear after cultured in the UU liquid culture medium. After the solid medium was filtered through a microporous filter membrane, fried egg-like colonies were observed under a low power microscope, confirming that the rat testis tissue had UU growth, and the model was successful.

### UU Infection Rate in Rats

After treatment, rats in each group were sacrificed, and the epididymal tissue fluid was cut and cultured for UU. The results showed that UU was not cultured in the normal group, the positive rate of UU in the model group was 93.3% (14/15), the positive rate of UU in the ZBDHD group was 33.3% (5/15), and the positive rate of UU in the positive control group was 26.7% (4/15). Compared with the normal group, the positive rate of UU in the model group was higher, and the difference between the two groups was statistically significant ( $p < 0.01$ ). Compared with the model group, the positive rates of UU in the ZBDHD group and the positive control group were reduced, and the difference was statistically significant ( $p < 0.05$ ).

## The Ultrastructure of Rat Spermatogenic Cell Mitochondria

In the normal group, the morphology and structure of spermatogenic cells at all levels were normal, and mitochondria could be observed in the cytoplasm with normal structure and abundant numbers and orderly arrangement. In the model group, spermatogenic cells at all levels showed obvious swelling and mitochondria with vacuolated ridges, and the membrane structure was unclear. In the positive control group, the arrangement, cell morphology and structure of spermatogenic cells were basically normal, and the size and number of mitochondria were basically normal; the mitochondria were slightly swollen but the mitochondrial cristae structure was still clear (Figure 12).

## Rat Spermatogenic Cell MMP

The results of flow cytometry showed that the MMP level of spermatogenic cells in the model group was significantly lower than that of the control group ( $p < 0.01$ ), and the MMP level of the ZBDHD group was significantly higher than that of the model group and the positive control group ( $p < 0.01$ ) (Figure 13).

## Expression of MRPS22 mRNA and Protein in Rat Spermatogenic Cells

### Expression of MRPS22 mRNA

The expression of MRPS22 mRNA was the lowest in the model group ( $p < 0.01$ ), and the expression of MRPS22 mRNA in ZBDHD was significantly higher than that of the positive control group ( $p < 0.01$ ) (Figure 14A).

### Expression of MRPS22 Protein

The MRPS22 protein of the model group was significantly lower than that of the control group, ZBDHD group and the positive control group ( $p < 0.01$ ). There was no significant difference between the MRPS22 protein of the ZBDHD group and the control group, but they were significantly higher than that of the positive control group ( $p < 0.01$ ) (Figure 14B and Figure 15).

## Effect of ZBDHD on the Energy Metabolism Index of Rat Sperm

### Methodological Quality Control

Under the aforementioned HPLC conditions, the precision, accuracy, stability, repeatability and recovery experiments were

**TABLE 1 |** Clusters of DGBXD known Target-AS PPI Network.

performed. The accuracy is controlled above 95%, the recovery rate is controlled above 95%, and the RSD is controlled within 4%, indicating that the instrument has good precision and reliable experimental methodology (Tables 2–4).

### Quantitative Analysis

Equal volumes of ATP, ADP, and AMP standard solutions are mixed and diluted into a series of working solutions for injection analysis. The standard curve is drawn (Supplementary Figure

**FIGURE 5 |** Bubble chart of biological processes in cluster 1 (X-axis stand for fold enrichment).

S1) with the concentration as the x-axis and the area under the peak area as the Y-axis:

- 1) ATP regression equation:  $y = 0.117x - 0.077$ , correlation coefficient  $R^2 = 0.9999$  (Supplementary Figure S1A);
- 2) ADP regression equation:  $y = 0.104x + 0.695$ , correlation coefficient  $R^2 = 0.998$  (Supplementary Figure S1B);
- 3) AMP regression equation:  $y = 0.128x - 0.606$ , correlation coefficient  $R^2 = 0.9998$  (Supplementary Figure S1C).

Compared with the normal group, the sperm ATP and EC values of the model group decreased, and the AMP value increased ( $p < 0.01$ ). Compared with the model group, the sperm ATP and EC values of the positive control group increased, while the AMP value decreased ( $p < 0.05$ ,  $p < 0.01$ ), while the AMP value of the ZBDHD group decreased ( $p < 0.05$ ) (Supplementary Figure S2).

### Effect of ZBDHD on CytC in UU Infection Model Rat Sperm

Compared with the normal group, the CytC content of the model group and the positive control group was significantly increased ( $p < 0.01$ ). Compared with the model group, the CytC content in

the ZBDHD group decreased ( $p < 0.05$ ). It shows that ZBDHD can inhibit sperm apoptosis and reduce the release of CytC from mitochondria in UU infection model rats (Supplementary Figure S3).

### Effect of ZBDHD on the Opening of Mitochondria mPTP in UU Infection Model Rat Sperm

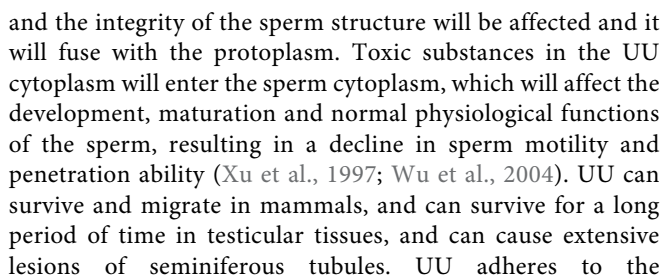

Compared with the sham operation group, the absorbance of sperm mitochondria in the model group decreased ( $p < 0.01$ ). Compared with the model group, the absorbance of sperm mitochondria of rats in each treatment group increased ( $p < 0.01$ ) (Supplementary Figure S4).

### Effect of ZBDHD on the Activities of $\text{Na}^+/\text{K}^+$ -ATPase and $\text{Ca}^{2+}/\text{Mg}^{2+}$ -ATPase in UU Infection Model Rat Sperm

Compared with the sham operation group, the sperm  $\text{Na}^+/\text{K}^+$ -ATPase and  $\text{Ca}^{2+}/\text{Mg}^{2+}$ -ATPase activities of the model group were reduced ( $p < 0.01$ ). Compared with the model group, the sperm  $\text{Na}^+/\text{K}^+$ -ATPase and  $\text{Ca}^{2+}/\text{Mg}^{2+}$ -ATPase activities of rats in each treatment group increased ( $p < 0.01$ ) (Supplementary Figure S5).

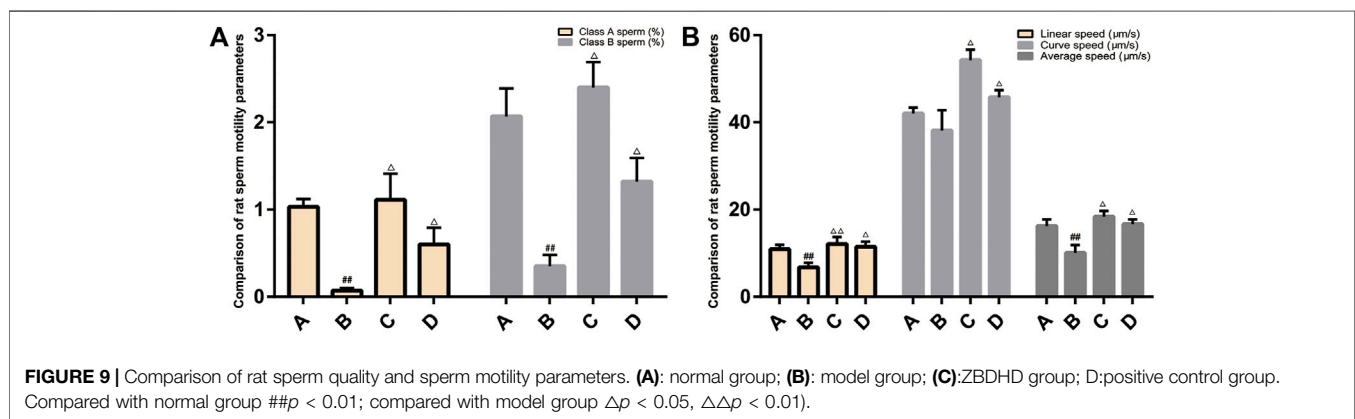

spermatogenic cells, which can cause the latter to fall off the seminiferous tubules (Zhang et al., 2011; Qian et al., 2016). At the same time, UU can lead to the formation of multinucleated giant cells and sperm cell nucleus, seminal convoluted tubule atrophy, interstitial edema and exudation and other pathological changes, leading to oligospermia, azoospermia, and affecting sperm maturation. Meanwhile, UU infection can severely damage the morphology and function of sperm, and also make the acrosome membrane

**FIGURE 10** | The AI of spermatogenic cells. (A): normal group; (B): model group; (C): ZBDHD group; (D):positive control group. Compared with normal group  $##p < 0.01$ ; compared with model group,  $\Delta\Delta p < 0.01$ .

and the plasma membrane unable to fuse normally, the acrosome and the nuclear membrane are separated, the double-layer structure is partially interrupted, and the structure of part of the sperm head is damaged, which increases the rate of sperm deformity (Yang et al., 2018). UU infection has an impact on sperm density, sperm motility and forward motility, which can lead to a decrease in semen quality (Zhou et al., 2018).

Mitochondria regulate the energy production and apoptosis of eukaryotic cells, and provide energy for sperm movement. Normal mitochondrial structure is the basis for spermatogenic cells to exert their respiratory function to produce energy, which is directly related to the motility of sperm (du Plessis et al., 2015). UU infection can affect the structure and function of sperm mitochondria in many ways. UU enzymes and toxins can damage the sperm mitochondrial membrane, thereby affecting the production of sperm motility energy (Burrello et al., 2009). UU infection reduces the mitochondrial membrane potential (MMP) of sperm cells and hinders mitochondrial function (La

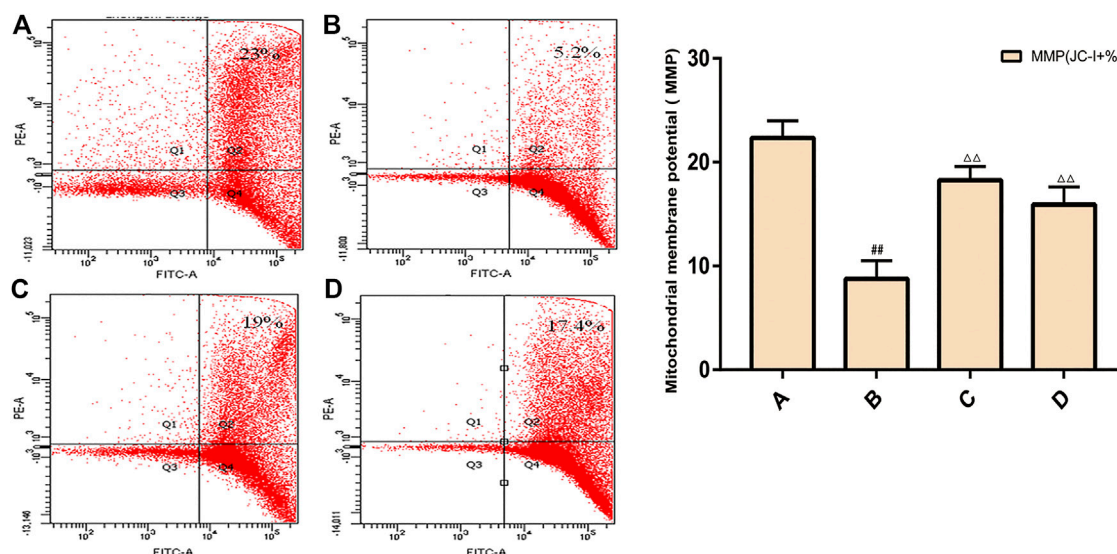

**FIGURE 11 |** The Apoptosis of rat spermatogenic cells [TUNEL  $\times 400$ . (A): normal group; (B): model group; (C): ZBDHD group; (D): positive control group].

**FIGURE 13 |** Rat spermatogenic cell MMP. (A): normal group; (B): model group; (C): ZBDHD group; (D): positive control group. Compared with normal group  $##p < 0.01$ ; compared with model group,  $\Delta\Delta p < 0.01$ .

Vignera et al., 2012). When the MMP of sperm cells decreases, the arrangement of mitochondria in the sperm tail will be disordered, the mitochondrial sheath will be missing, and the mitochondrial

morphology and position will also be abnormal (La Vignera et al., 2012). UU infection will increase the content of reduced coenzyme oxidase that transfers single electrons in the

reproductive system, and produce a series of reactive oxygen specie (ROS). ROS can promote the lipid peroxidation of unsaturated fatty acids on the inner and outer membranes of sperm mitochondria, resulting in sparse lipid arrangement of the membrane, reduced inner membrane ridges, and reduced ATP synthesis. MMP is negatively correlated with ROS content, so excessive production of reactive oxygen species in sperm is one of the important reasons for the decline of mitochondrial membrane potential (MMP). Sperm mitochondrial membrane may be damaged by reactive oxygen and insufficient energy supply and decreased vitality (La Vignera et al., 2012; Sellami et al.,

2014). Mitochondrial energy synthesis will be affected by abnormal mitochondrial structure, so sperm motility and fertilization ability decrease (Agarwal and Said, 2005). MMP reflects the tricarboxylic acid cycle that generates energy in the mitochondria. Its decrease means that the mitochondrial energy supply is impaired, and it is a sensitive indicator for evaluating mitochondrial function. Studies have shown that there is a positive correlation between MMP and sperm viability, motility and sperm fertilization rate (Brahem et al., 2012). According to classical theory, the mitochondrial sheath in the middle of the sperm, synthesized by oxidative phosphorylation, is the source of energy required by the flagella of the sperm tail during sperm movement (Gong et al., 2017).

The permeability and fluidity of mitochondrial membrane are the guarantee for maintaining the structure and function of mitochondria. Abnormal mitochondrial permeability transition (MPT) can cause mitochondrial dysfunction. MPT is achieved through two mechanisms: the opening of the mPTP and the activation of Bax and Bak proteins to increase the permeability of the mitochondrial outer membrane (Baines et al., 2007). The abnormal opening of mPTP would cause the decrease of mitochondrial membrane potential, cell energy metabolism level and cell activity (Shen et al., 2014). mPTP is a transmembrane multi-protein complex pore, mainly composed of adenine nucleotide translocase (ANT) in the inner membrane, voltage-dependent anion channel (VDAC)

**TABLE 2 |** Precision and accuracy (n = 6).

AMP	3 .36	2 .24

in the outer membrane, cyclosporin A receptor D (cyclophilin-D, CyP-D) in the mitochondrial matrix (Lam et al., 2015). mPTP is normally closed to maintain the integrity of the mitochondrial structure, which is a necessary condition for mitochondria to undergo oxidative stress, ATP synthesis, and achieve their physiological functions (Lam et al., 2015). The synthesis of ATP and the electron transfer in the respiratory chain are carried out in the mitochondria. ATP and ADP are effectively exchanged and transported between the mitochondria and the cytoplasm, so that the cell respiration and the coupling of the respiratory chain are maintained normal (Halestrap and Brenner, 2003). The transport of ATP and ADP depends on the ANT/VDAC transporter complex formed by the adenine nucleotide carrier ANT and VDAC. The former is located in the inner mitochondrial membrane and the latter is located in the outer mitochondrial membrane (Halestrap and Brenner, 2003; Veenman et al., 2007). As a transmembrane protein with abundant content in the outer mitochondrial membrane, VDAC is involved in many physiological and pathological mechanisms, including energy metabolism and cell apoptosis (Vyssokikh and Brdiczka, 2003). In a certain pathological state, the continuous opening of the mitochondrial outer membrane VDAC reduces the mitochondrial inner membrane potential, that is, energy production decreases, respiratory function decreases, cytochrome C leaks, cell energy metabolism level decreases, and cell activity decreases. The excessive opening of mPTP leads to a decrease in the ratio of ATP/ADP, mitochondrial respiratory function is inhibited, the  $H^+$  gradient inside and outside the mitochondria disappears, the respiratory chain is uncoupled, and energy production is interrupted (Neginskaya et al., 2019). When the stimulation was mild, the number of irreversible openings of mPTP was small or it is temporarily opened and then closed again, and the intracellular ATP

concentration did not decrease significantly, and apoptosis can only be induced by releasing CytC.

Our research shows that ZBDHD can improve sperm motility. After successful UU infection modeling, the proportion of sperm cells in the model group with decreased MMP was higher. After ZBDHD treatment, the proportion of sperm cells with decreased MMP in each group decreased. After successful UU infection modeling, the sperm ROS level of the model group was higher, which was significantly different from the normal group. After treatment with ZBDHD, the sperm ROS level of rats in each group decreased, which proved that ZBDHD can reduce the sperm ROS level of UU infection model rats and reduce the sperm ROS production of UU infection model rats. After successful modeling of UU infection, the content of CytC in sperm of the model group was higher, indicating that UU infection can increase sperm apoptosis and cause the release of CytC. After ZBDHD treatment, the content of CytC in sperm of rats decreased, suggesting that ZBDHD can inhibit sperm apoptosis and reduce the release of CytC from mitochondria in UU infection model rats.

In summary, the results of this study indicate that UU infection can lead to increased sperm MMP reduction ratio, ROS level and CytC content increase, and ZBDHD can reduce the production of sperm ROS, reduce the pathological damage of ROS to sperm membrane and function, and improve sperm MMP. This increases the energy synthesis of sperm mitochondria, reduces sperm apoptosis, and inhibits the release of CytC, so as to achieve the goal of anti-oxidation to increase sperm density, viability and vitality. This may be one of the mechanisms of ZBDHD in the treatment of male infertility caused by UU infection.

## CONCLUSION

This study discovered the multi-pathway mechanism of ZBDHD intervention in UU-induced orchitis through integrated pharmacological strategies, which provides a reference for further research on the mechanism of ZBDHD intervention in orchitis in the direction of mitochondrial energy metabolism. At the same time, it provides new research ideas for the research of classic famous TCM prescriptions.

**TABLE 4** | Recovery rate experiment results (n = 2).

Analyte	Original amount (ug)	Adding amount (ug)	Measured amount (ug)	Recovery rate (%)	RSD (%)

**Background:** Pneumonia is a prevalent and complicated disease among adults, elderly people in particular, and the debate on the optimal Chinese herbal injections (CHIs) is ongoing. Our objective is to investigate the comparative effectiveness of various CHIs strategies for elderly patients with pneumonia.

**Methods:** A comprehensive search strategy was executed to identify relevant randomized controlled trials (RCTs) by browsing through several databases from their inception to first, Feb 2020; All of the direct and indirect evidence included was rated by Network meta-analysis under a Bayesian framework.

**Results:** We ultimately identified 34 eligible randomized controlled trials that involved 3,111 elderly participants and investigated 4 CHIs combined with Western medicine (WM) (Xianping injection [XYP]+WM, Yanhuning injection [YHN]+WM, Tanreqing injection [TRQ]+WM, Reduning injection [RDN]+WM), contributing 34 direct comparisons between CHIs. Seen from the outcome of Clinical effective rate and time for defervescence, patients taking medicine added with CHIs [Clinical effective rate, XYP + WM (Odd ratio (OR): 0.74, 95% Credible intervals (CrIs): 0.55–0.98), YHN + WM (OR: 0.66, 95% CrI: 0.45–0.95), TRQ + WM (OR: 0.65, 95% CrI: 0.50–0.83), RDN + WM (OR: 0.60, 95% CrI: 0.40–0.89); Time for defervescence, YHN + WM (Mean difference (MD): –2.11, 95% CrI: –3.26 to –0.98), XYP + WM (MD: –2.06, 95% CrI: –3.08 to –1.09), RDN + WM (MD: –1.97, 95% CrI: –3.61 to –0.35), TRQ + WM (MD: –1.69, 95% CrI: –2.27 to –1.04)] showed statistically better effect compared with participants in the Control group (CG) who only took WM. Meanwhile, based on the time for disappearance of cough, 3 out of 4 CHIs [TRQ + WM (MD: –2.56, 95% CrI: –3.38 to –1.54), YHN + WM (MD: –2.36, 95% CrI: –3.86 to –1.00) and XYP + WM (MD: –2.21, 95% CrI: –3.72 to –1.10)] strategies indicated improvement of clinical symptoms. Only XYP + WM (MD: –1.78, 95% CrI: –3.29 to –0.27) and TRQ + WM (MD: –1.71, 95% CrI: –2.71 to –0.73) could significantly shorten the time for disappearance of pulmonary rales.

**Conclusion:** According to the statistical effect size (The surface under the cumulative ranking), we found that XYP + WM was presumably to be the preferable treatment for treating elderly patients with pneumonia compared with WM alone in terms of clinical effective rate. Our findings were based on very limited evidence and thus should be interpreted with caution. The application of the findings requires further research.

**Keywords:** elderly people, pneumonia, traditional medicine, chinese herbal injections, bayesian network meta-analysis

## Background

Pneumonia, a common disease with detrimental effect among adults worldwide, particularly elderly people, is posing substantial healthcare costs, and social burdens globally (GBD Diarrheal Diseases Collaborators, 2017). Study indicated that the number of old people aged over 80 hit the highest hospital admission rate record (16.4 cases/1,000 persons per year) for Community Acquired Pneumonia (CAP), a figure higher than that for common adults whose rate was 2.5 cases/1,000 people per year (Jain et al., 2015). To make matters worse, the global outbreak of coronavirus disease 2019, a relevant pneumonia, namely Severe Acute Respiratory Syndrome Coronavirus 2, is rapidly evolving and expanding on a global scale (Ronco et al., 2020). The ever-increasing cases of pneumonia imposes much stress on intensive care management and urges a systematical method to help policy-makers and clinicians in making the optimal decisions among numerous available therapies (Mandell et al., 2007). To further complicate the situation, despite the extensive use of drugs to treat the pneumonia patients, such as antiseptics, statins, as well as antibiotics, a first-tier preferred treatment was of huge benefit to patients' health but it also brought about a great risk of drug resistance and various adverse drug reactions (ADRs) (Labeau et al., 2011; Zampieri et al., 2015). The number of people who were diagnosed with pneumonia was going upwards rather than downwards, which directly exacerbated both the financial and resources burden on healthcare system (GBD 2016 Causes of Death Collaborators, 2017).

In the past decade, owing to the unsatisfactory response to current treatments, a considerable amount of research have focused on Chinese herbal medicine (CHM) to address a series of clinical symptoms of pneumonia patients (Zhou et al., 2000). As a potent, selective and promising formulation, Chinese herbal injection (CHI) was obtained via extracting and purifying the effective and active herbs compounds. The CHIs have gained more popularity in China due to their instant effects, few side effects and remarkable tonic function, and their efficacy was supported by previous studies not only on respiratory system, but also on many other systems (Zhao et al., 2013; Li et al., 2016). However, up to now, evidence that proves the efficacy of CHIs treating pneumonia has remained scarce among older adults. There is no study comparing the efficacy of CHIs in elderly adults with pneumonia. The necessity to bridge this gap via Network meta-analysis (NMA) is as follows: CHI combined with Western medicine (WM) was considered as a comprehensive therapy that is relatively effective and safe for treating pneumonia. However, the conventional meta-analysis can merely group various CHIs into a comprehensive CHI and analyze them separately while NMA can evaluate each CHI

individually and compare them simultaneously. Consequently, our study used Bayesian NMA method to ascertain exactly whether such CHIs are truly helpful in preventing pneumonia among elderly people and to rank the efficacy of them.

## METHOD

### Search Strategies

Based on the Pubmed, embase, Cochrane Central register of controlled trials, Wan Fang database, China National Knowledge Infrastructure database, Chinese Biomedical Literature database, Chinese Scientific Journal database, we adopted a comprehensive search strategy from their inception to first, Feb 2020 to identify the eligible randomized controlled trials (RCTs) which scrupulously evaluate the efficacy of CHIs among elderly people with pneumonias according to various proper diagnostic criteria.

Without any language restriction, the following Medical Subject Heading (MeSH) terms incorporating with keywords by using the framework of Boolean logical operators were adopted: "Pneumonias", "Pneumonitis", "Lung Inflammations", "Chinese herbal", "Chinese drugs", "Chinese plant extracts", "Traditional medicine", "Randomized controlled trials", additional text-terms as well. We additionally implemented a recursive manual-search to retrieve full-text studies from the bibliographies of obtained trails or the similar systematic reviews in order to check the potentially eligible studies we missed at first. Details of the search strategy was introduced in **Supplementary File S1**. At the same time, all the records were collected and processed in **Endnote X9** (Thompson ISI Research Soft, Philadelphia, PA) software.

### Inclusion and Exclusion Criteria

We defined the satisfactory randomized controlled trials based on the predetermined selection rules that met the following PICOS criterion:

**Population:** Pneumonitis was diagnosed by any proper clinical criteria, such as "Guidelines for diagnosis and treatment of community acquired pneumonia (Chinese revision)" (Academy RBoCM, 2006). Aged over 60 years old, without sex, race or region restriction.

**Intervention:** Based on the basis of literature and a pre-search we conducted before, patients with pneumonitis treated by numerous CHIs were conceptualized in four main CHIs, namely, Tanreqing injection (TRQ), Xiyanping injection (XYP), Yanhuning injection (YHN) and Reduning injection

(RDN) (Ye, 2016; Xia, 2017; Yao, 2017; Zhou, 2017), while the other CHIs failed to report the sufficient available data for our analysis. We excluded the studies in which either different CHIs are combined or the definition of CHI is vague.

**Comparison:** CHIs or the control group alone. Placebo and most of them were WM.

**Outcomes:** Primary outcome: The clinical effective rate [CER, CER = (Total sample size of patients–total sample size of patients ineffective)/total sample size of patients \* 100%]; Secondary outcomes: Clinical symptom disappearance time (cough disappearance, lung rale disappearance time).

**Study design:** We confined our study design to RCTs published without year and language restriction. Non-randomized controlled studies such as case-control studies, cohort studies, full-text but unpublished studies were all excluded.

Initially, two investigators respectively screened the collected studies by title and abstract. Duplications were removed primarily according to their titles and the first author's name. Through a full-text review, all the potentially relevant articles were further perused and assessed at length. Our study adheres to the Network Meta-analysis of the Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA-NMA) (See in **Supplementary File S2**) and the Cochrane Handbook for Systematic Reviews of Interventions (Higgins and Green, 2011; Hutton et al., 2015). All analyses were based on previous published studies and therefore no ethical approval and patients' consent were required.

## Data Extraction and Quality Assessment

Following the Cochrane consumers and Communication Review Group's data extraction template, two investigators independently implemented a data extraction form to collect the relevant data of the included studies such as Essential publication information (name of first author, year of publication), characteristic of participants (Total sample size, baseline age), and quality of the RCT. Any conflict or discrepancy regarding screening reached consensus after discussion, or was judged by an expert as a third author.

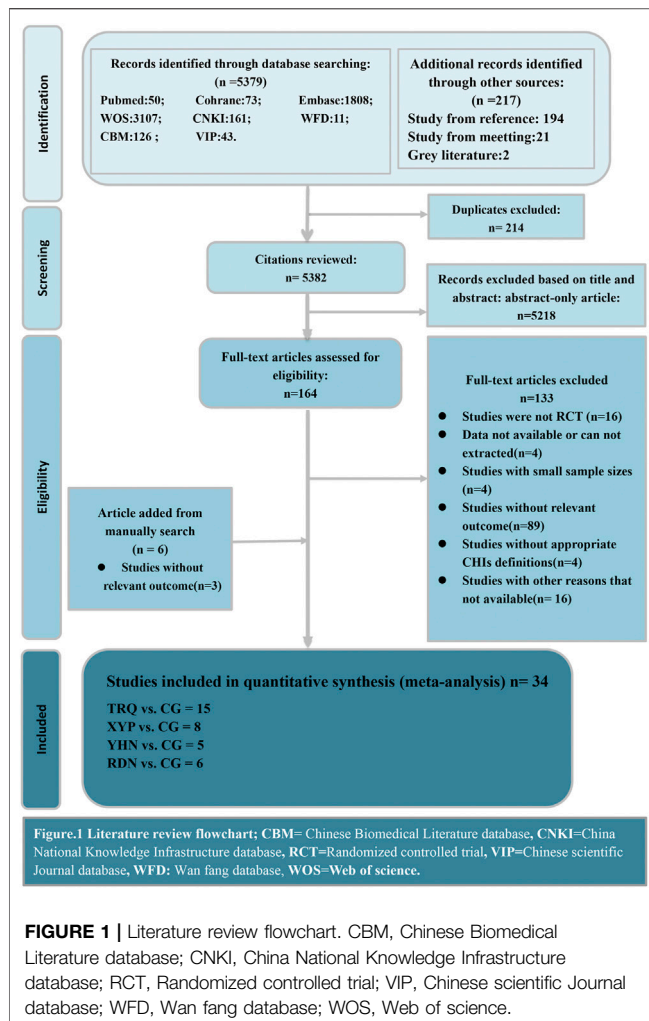

The Cochrane Risk of Bias tool (ROB) was utilized to assess the quality of each trial, which divided ROB into seven items, and all trials were rated as low, unclear or high bias level (HGGs, 2011). For the selection bias, studies would be accepted as low risk of bias if they had described the details of sequence generation and approach of allocation concealment. Otherwise, the studies would be regarded as high risk of bias. We judged the items Performance and Detection Bias based on whether the study was blind or not to the participants, personnel and outcome assessors. For the attrition bias, we rated studies as high-risk whose data was insufficient for contributing to the analysis especially the primary outcome. For judging other biases, if the study had an imprecise study design, or reported an obvious inconsistency compared with the previous studies, they would be rated as high risk of bias. We assessed selective biases by detecting whether the included studies reported the

raw data for analysis. All the 7 items were rated as “unclear risk” when the study did not mention the relevant items. We focused on the selection bias and attrition bias due to their specificity in the assessment of ROB. Any disagreement generated during the procession of assessment was resolved by team-discussion.

## Statistical Analyses

Our study first carried out a conventional pairwise meta-analysis to analyze the direct evidence by synthesizing the available data from the included studies.  $I^2$  statistics were set to judge the magnitude of heterogeneity with higher values indicating more heterogeneity (Higgins and Thompson, 2002). The sensitivity analysis was conducted to test if there was any heterogeneity existing and to explore its sources. A network geometry was constructed firstly to provide comparative evidence among treatments, with distinguishing treatments expressed by different nodes whose size corresponded to the sample of participants, and studies were connected by appropriate lines. Moreover, in order to assess whether other publication biases or small-study biases were generated in our study, we created comparison-adjusted funnel plots to detect whether the scatter distributed to the vertical axis is asymmetric in the funnel plot (X-axis is sample size, Y-axis is effect) (Seagroatt and Stratton, 1998). The above analyses were conducted by using STATA/SE version 15.0 (Stata, corp, College Station, TX).

The Transitivity Assumption was applied to the appraisal of the robustness and reliability of the NMA by comparing the clinical similarity (e.g., patients, sample size and origin) and the methodological characteristics (e.g., random method, outcome and bias) among the studies involved (Caldwell et al., 2005). For outcomes presented as the numerical variable and the categorical variable, we generated a pooled Mean difference (MD) (Hedge's  $g$ ) and Odd ratio (OR) following 95% Credible intervals (CrIs) as a conservative estimate to summarize the treatment and effects respectively. Based on the maximum likelihood and Bayesian estimation, the approach of Markov-chain Monte Carlo with prior non-informative distributions were performed in our NMA (Salanti et al., 2008; Mavridis and Salanti, 2013). We set up three parallel chains running in our model simultaneously by means of Gibbs sampling and different initial values during the beginning period, through stimulation to obtain their target distributions (Valkenhoef and Kuiper, 2016). Each chain was put into 100,000 interactions and the first 20,000 were discarded to minimize the bias which may be produced at the initial stage. The Brooks-Gelman-Rubin diagnostic statistics were used to spot the convergence of model by checking the density plot and tract plot (Brooks and Gelman, 1998). The surface under the cumulative ranking (SUCRA), a concisely hierarchical curve, was produced to rank the possible efficacy of each treatment and it was found that higher SUCRA values denoted greater efficacy (Dias et al., 2012). Finally, the inconsistency of our NMA was examined by the split-node method and the  $p$ -value was obtained to indicate whether a

**FIGURE 1 |** Literature review flowchart. CBM, Chinese Biomedical Literature database; CNKI, China National Knowledge Infrastructure database; RCT, Randomized controlled trial; VIP, Chinese scientific Journal database; WFD, Wan fang database; WOS, Web of science.

significant inconsistency existed (Valkenhoef et al., 2016). All Bayesian analyses were done in R Version 3.32 (X64) with package “Gemtc” and WinBUGS Version 1.4.3 (MRC Biostatistics Unit, Cambridge, United Kingdom) (Coreteam, 2014), and details of code were shown in **Supplementary File S3**.

## RESULTS

### Study Selection

We obtained 5,596 records initially and reviewed 164 potentially relevant studies in full-text after screening the titles and abstracts. Overall, 214 nonduplicate citations were identified, and we retrieved 6 relevant articles by hand-search in case of omitting the eligible research we probably left out in the electronic database. 34 RCTs eventually met our pre-established criteria after a rigorous full-text review, which consisted of 4 CHIs treatments. The details of literature screen were depicted in **Figure 1**. All the investigators involved reached a unanimous approval for the selection and the assessment of the studies.

### Study Characteristics and Risk of Bias Quality Assessment

**Supplementary Table S1** revealed the detailed demographic characteristics of 34 included studies. All the 34 parallel randomized controlled trials took place in China from 2008 to 2019. In total, 682 participants were randomly assigned to TRQ + WM group, 425 to XYP + WM, 213 to YHN + WM and 247 to RDN + WM whereas 1,544 were categorized into the CG (All the CG were conducted with WM only). Our NMA comprised 1,030 males participants and 2081 female participants, all of whom were qualified in terms of age according to the definition offered by World Health Organization (WHO) (WHO, 2017) that elderly people are those aged at least 60. The mean of all participants ranged from 60 to 85. Most trials (22/34, 64.71%) recruited participants with CAP, but few of them (4/34, 11.76%) considering the patients with Hospital Acquired Pneumonia (HAP). The citations of the included studies are introduced in detail in **Supplementary File S4**.

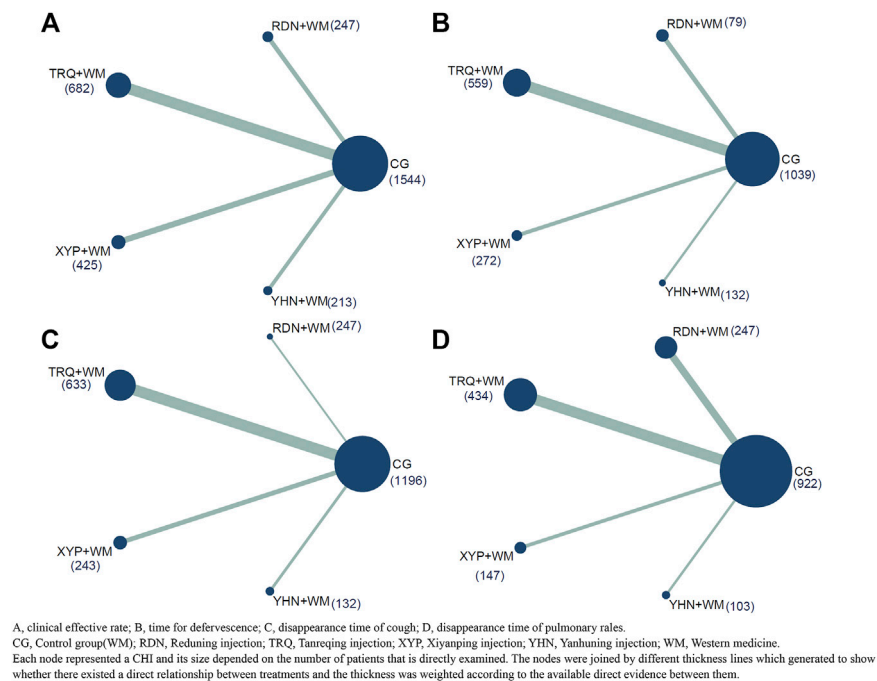

The overwhelming majority of the trials rendered a low risk of bias in “Random sequence generation” and all trials reflected a low risk of bias in Incomplete Outcome Data with sufficient original data. Notably, two studies were judged to be high-risk bias of “selective reporting” because their data for our analysis were calculated by transforming the original data manually (Li, 2010; Zhou, 2019). Due to their less rigorous study design, three studies (Huang, 2014; Zhang, 2014; Tian, 2016) were rated as high-risk bias in “other bias” items, among which the first two (Zhang, 2014; Tian, 2016) had less precise definition on pneumonia with one (Tian, 2016) not further reporting the calculation procedures for its relevant outcomes, and the third (Huang, 2014) had a bad representativeness of cases compared with other included studies since it recruited all the participants with pneumonia for a long-term period from 2000 to 2013. The remaining two items (“Allocation Concealment”, “Blinding of Participants and Personnel”) were generally ranked as unclear-to-moderate risk of bias. Full details regarding risk of bias for each RCT were shown in **Supplementary Figure S1** and summarized in **Supplementary Figure S2**, respectively. Funnel plots throughout the included studies based on the four endpoints showed a relatively symmetric distribution (**Supplementary Figure S3**).

### Network Meta-analysis

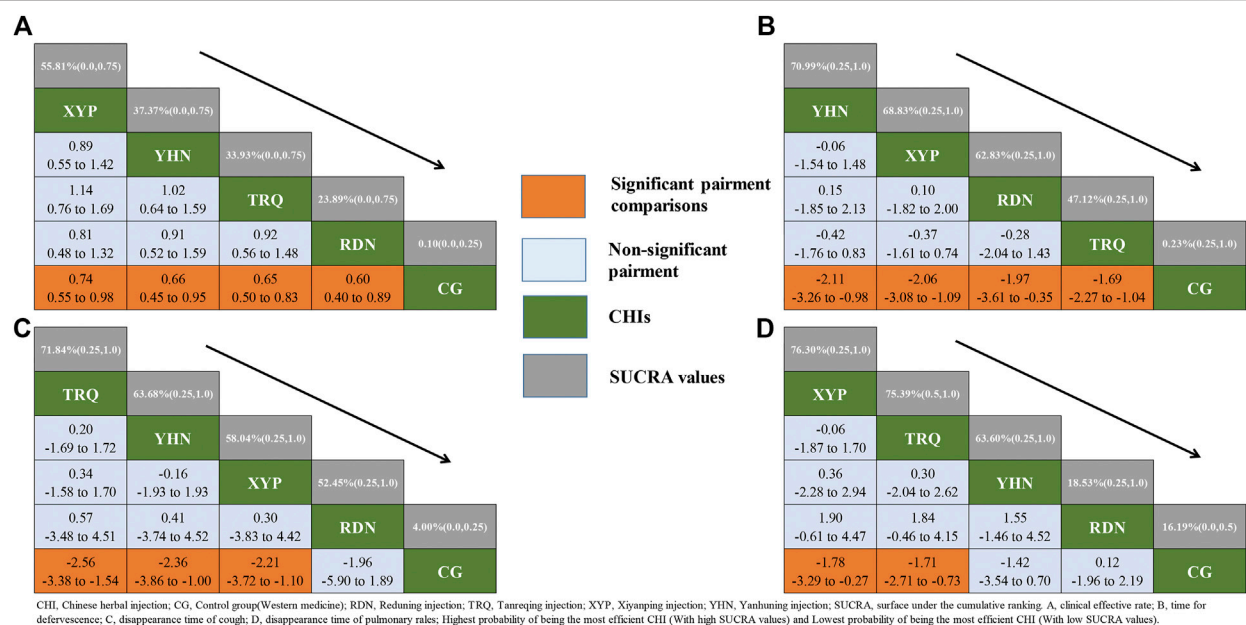

**Figure 2** presented all the primary evidence between each CHI, and all the CHIs had at least one comparison with CG while all of CHIs lacked a closed loop between them. According to the network geometries of clinical effective rate, CG (1,544) obtained the largest sample size (SS) compared with other three CHIs whereas YHN + WM (213) got a relative lower SS throughout the entire network.

### Primary Outcome Clinical Effective Rate

In terms of the outcome of CER, all four CHIs had significant benefits to patients with pneumonia compared with CG. XYP + WM (OR: 0.74, 95%CrI: 0.55–0.98), YHN + WM (OR: 0.66, 95%

**FIGURE 2 |** Network plot of all the trials based on the outcomes. **(A)** Clinical effective rate; **(B)** time for defervescence; **(C)** disappearance time of cough; **(D)** disappearance time of pulmonary rales. CG, Control group; RDN, Reduning injection; TRQ, Tanreqing injection; XYP, Xiyanping injection; YHN, Yanhuning injection; WM, Western medicine. Each node represented a CHI and its size depended on the number of patients that is directly examined. The nodes were joined by different thickness lines which generated to show whether there existed a direct relationship between treatments and the thickness was weighted according to the available direct evidence between them.

**FIGURE 3 |** Relative effect sizes of efficacy at post-treatment according to network meta-analysis. CHI, Chinese herbal injection; CG, Control group (Western medicine); RDN, Reduning injection; TRQ, Tanreqing injection; XYP, Xiyanping injection; YHN, Yanhuning injection; SUCRA, surface under the cumulative ranking. **(A)** Clinical effective rate; **(B)** time for defervescence; **(C)** disappearance time of cough; **(D)** disappearance time of pulmonary rales; Highest probability of being the most efficient CHI(With high SUCRA values) and Lowest probability of being the most efficient CHI(With low SUCRA values).

CrI: 0.45–0.95), TRQ + WM(OR: 0.65, 95%CrI: 0.50–0.83), RDN + WM(OR: 0.60, 95%CrI: 0.40–0.89) (See in **Supplementary Table S2**). However, no significant difference was observed in any comparison among CHIs(See in **Figure 3**). Based on the SUCRA values, XYP + WM(SUCRA = 55.81%) took the lead in the effect on pneumonia patients in terms of CER compared with other three CHIs, closely followed by two equally remarkable CHIs, namely, YHN + WM(SUCRA = 37.37%) and TRQ + WM(SUCRA = 33.93%) while RDN + WM(SUCRA = 23.89%) lagged behind (See in **Figure 3** and **Supplementary Figure S4**).

## Secondary Outcomes

### The Time for Clinical Symptoms to Disappear

With regarding to the time for defervescence, all CHIs, similar to the above outcome, produced a significant efficacy compared with CG. YHN + WM(MD: -2.11, 95%CrI: -3.26 to -0.98), XYP + WM(MD: -2.06, 95%CrI: -3.08 to -1.09), RDN + WM(MD: -1.97, 95%CrI: -3.61 to -0.35), TRQ + WM(MD: -1.69, 95%CrI: -2.27 to -1.04) (See in **Supplementary Table S2**).

For cough disappearance, only TRQ + WM(MD: -2.56, 95%CrI: -3.38 to -1.54), YHN + WM(MD: -2.36, 95%CrI: -3.86 to -1.00) and XYP + WM(MD: -2.21, 95%CrI: -3.72 to -1.10) were associated with a significant improvement among patients. However, the results didn't show statistical difference between RDN + WM (MD: -1.96, 95%CrI: -5.89 to 1.89) injection and other groups (See in **Supplementary Table S2**).

As for the time for disappearance of pulmonary rales, only XYP + WM(MD: -1.78, 95%CrI: -3.29 to -0.27) and TRQ + WM(MD: -1.71, 95%CrI: -2.71 to -0.73) had desirable performance in accelerating the disappearance of pulmonary rales (See in **Supplementary Table S2**).

Based on the SUCRA values, it seemed that among these CHIs injections, YHN + WM(SUCRA = 70.99%), TRQ + WM(SUCRA = 71.84%) and XYP + WM (SUCRA = 76.30%) became the optimal CHI compared to CG for the outcome of time for defervescence, cough disappearance and pulmonary rales disappearance, respectively. Conversely, TRQ + WM(SUCRA = 47.12%), RDN + WM(SUCRA = 52.45%) and RDN + WM(SUCRA = 18.53%) were most likely to be the least efficacious for defervescence, cough disappearance and pulmonary rales disappearance, respectively (See in **Figure 3** and **Supplementary Figure S4**). According to the four endpoints, forest plot was conducted in order to display the efficacy of each CHI for improving the clinical symptoms among patients (**Supplementary Table S2**). Relative effect sizes of treatments efficacy according to all outcomes were shown in **Figure 3**.

## DISCUSSION

This NMA has adopted a consecutive Bayesian model which involves 34 parallel randomized controlled trials to appraise 4 CHIs with four outcomes by comparing their effect among elderly patients with pneumonia. Considering the primary outcome, XYP + WM seemed to be most promising CHI in helping the elderly with pneumonia to improve their clinical symptoms

whereas YHN + WM and TRQ + WM are suboptimal and can be regarded as complementary therapies.

Pneumonia represents a progressive and prevalent clinical condition due to its relatively high morbidity and mortality, and high incidence was found among elderly adults due to their higher susceptibility (Thomas et al., 2012). As the first-line preferred therapy which is widely used for respiratory disease, antibiotic is a double-edged sword, because though improving the clinical symptom of patients, it, as the same time, causes some adverse effects (AEs) (Mandell et al., 2007). Due to the fault of current treatment and much attention being concentrated on the efficacy of CHIs, our study was attempted to achieve relatively objective evidence in the hope of seeking the optimal CHI among elderly people in order to offer an evidence-base mirror.

From the perspective of Traditional Chinese Medicine (TCM), pneumonia belongs to the category of asthma and cough, and its clinical symptoms such as cough, expectoration, fever and asthma should be treated; Other symptoms caused by exogenous pathogens invading the lung should be focused on the way of allaying fever and soothing the lung (Feng, 2014). Modern pharmacology shows that CHIs have multiple effects on antipyretic and analgesic, antiviral and antibacterial symptoms (Li et al., 2017), such as XYP injection. As a derivative of andrographolid with the characteristics of antipyretic and anti-inflammatory, it holds the most likelihood to be the optimal CHI injection among 4 CHIs, which enhances the immunity of the body. Moreover, XYP can improve the smooth muscle spasm, relax the smooth muscle, control the symptoms of cough and resolve phlegm by reducing the recreation of serous fluid (Zhang, 2011; L, 2017). TRQ classifies Chinese herbal into five categories: Scutellaria, Bear(bile) powder, Cornu gorais, honeysuckle and forsythia, with the efficacy of heat-clearing and detoxicating. It also has a positive effect on fever, cough and sore throat triggered by pulmonary disease (Huang, 2018). Patients with pneumonia would ameliorate their symptom by the usage of YHN injection or RDN injection, which was corroborated by numerous studies. But the two aforementioned CHIs got a relatively poor ranking in our study, possibly due to that they two mainly played a role in inhibiting respiratory viruses and blocking bacterial growth among patients with viral pneumonia rather than with the ability of anti-inflammatory, antipyretic and immunoregulatory effects among CAP patients (Gao et al., 2011; Nie, 2018). Although conclusions drawn by numerous studies showed consistency with our study that most such CHIs were preferable in the clinical treatment for patients with pneumonia when compared with CG (Sun, 2019; Wang, 2018). But there is no significant difference detected in any comparison between CHIs due to the absence of the indirect evidence among them. XYP + WM seem to be the most effective CHI for the outcome of clinical effective rate and the disappearance time of pulmonary rales while based on the results of time for defervescence and the disappearance time of cough that YHN + WM and TRQ + WM got the highest possibility become the most effective for improving these clinical symptoms, respectively. In spite of the evidence regarding the effectiveness of YHN + WM on reducing the fever is limited,

some relatively convincing evidence can account for it that YHN + WM is an effective extract of *Andrographis paniculate* which was recommended by Chinese medicine as one of the most effective herbal with the function of clearing away heat and toxic material (Tian, 2011). Compared with other CHIs, the main function of TRQ is diluting the sputum which makes the sputum thinner and easier to cough up and further improves the patients' breath, so that the clinical symptoms of cough can disappear in a short time (Ye, 2016). One previous study has compared the effect of various CHIs on CAP for all age groups and our study only shared similar analysis methods with it. Focusing on elderly people and all the types of pneumonia, our study arrived at a conclusion that XYP + WM might be the best CHI for improving elderly people with pneumonia, which was inconsistent with the results of the previous study that YHN + WM was the best CHI for treating pneumonia (Huang et al., 2019). The difference of research subjects may account for the different conclusions between our study and the former one since our study was more specifically targeted at elderly patients rather than patients of all ages. As we mentioned before, although YHN had rapid onset of action, as well as good bioavailability widely used in clinical, but it had a greater incidence of toxicities or AEs (Nie, 2018). One study indicated that YHN injection had the highest incidence of AEs among numerous CHIs (Xiong et al., 2016), and the Food and Drug Administration of China also indicated the usage of YHN was accompanied with substantial AEs especially the systemic damage (China Tfdao, n.d.). The above findings would diminish metabolizing capacity and excretory functions in the elderly patients since metabolism and excretion are significant parameters to evaluate the transformation and delivery of drugs in the body (Gao, 2017; Gao et al., 2017). As a result, it was more likely to lead to accumulation of drugs in elderly bodies and increased their risk of AEs compared with ordinary adults, and thus decreased the effectiveness of TCM for elderly people in terms of population (Gao, 2017). We may hypothesize that elderly population was probably sensitive and fragile to be affected by the acceptability of TCM especially the drug toxicology of TCMs. Therefore, the XYP + WM is the most effective based on the result of our study while the previous study focus on ordinary adults is in favor of YHN + WM.

## Strength and Limitations

Instead of performing a traditional meta-analysis, our study lies in the fact that we structured a Bayesian framework to evaluate the effectiveness of current CHIs simultaneously for pneumonia patients among elderly population based on several endpoints. Moreover, we enriched the way of search strategy in order that more potentially eligible trials would be found for the establishment of the literature basis of our NMA.

The limitations across our study also should not be ignored. First, we have not registered our study either in Cochrane central or PROSPERO, which may indirectly influence the generalization of our results. Due to the fact that the topic of

our study is CHI, all trials were simply conducted in China and our NMA therefore might not apply to cases in other countries. We have not collected and analyzed the data regarding AEs, because only two studies mentioned the AEs (One study conducted with XYP + WM found a patient getting a rash during the therapy duration while the other study reported several patients with bloating, nausea, vomiting and facial flushing after taking YHN + WM) and we could not estimate it without sufficient data (Yuan, 2010; Wang, 2014). Quality of several studies would possibly weaken the reliability and robustness of our results. Only two studies mentioned the blind method (Zhang, 2010; Guo, 2019a), and two studies were rated as low risk of bias in selection bias (Li, 2018; Guo, 2019b). Moreover, there were three trials with a high risk of bias with regard to other biases (Huang, 2014; Zhang, 2014; Tian, 2016).

## CONCLUSION

In summary, based on the clinical effective rate, our NMA suggested that XYP + WM probably was the better CHI choice among numerous CHIs for elderly patients with pneumonia when compared to WM. Meanwhile, it worth mentioning that this finding should be interpreted with caution due to the limited evidence. Besides, the present study put emphasis on the need of future guidelines to optimize their management and further similar high-quality trials should be carried out to confirm our results.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding authors.

## AUTHOR CONTRIBUTIONS

YY conducted the database search, screened and extracted data for the meta-analysis, prepared extracted data for the procedures, and had primary responsibility in writing this article. QZ and ZS performed statistical analysis and interpretation of data. JL, ZL, LX, PL and XL contributed to the discussion and editing. CH and JL critically revised the draft manuscript. All authors read and approved the final manuscript.

Traditional Chinese medicine (TCM) has been used successfully to treat rheumatoid arthritis (RA). Qingre Huoxue treatment (Qingre Huoxue decoction (QRHDX)/Qingre Huoxue external preparation (QRHXEP)) is a therapeutic scheme of TCM for RA. To date, there have been few studies comparing the efficacy and safety of QRHDX and conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) for the treatment of active RA. This was investigated in a multicenter, double-blind, randomized controlled trial involving 468 Chinese patients with active RA [disease activity score (DAS)-28 > 3.2] treated with QRHDX/QRHXEP (TCM group), methotrexate plus hydroxychloroquine [Western medicine (WM) group], or both [integrative medicine (IM) group]. Patients were followed up for 24 weeks. The primary outcome measure was the change in DAS-28 from baseline to 24 weeks. The secondary outcome measures were treatment response rate according to American College of Rheumatology 20, 50, and 70% improvement criteria (ACR-20/50/70) and the rate of treatment-related adverse events (TRAEs). The trial was registered at ClinicalTrials.gov (NCT02551575). DAS-28 decreased in all three groups after treatment ( $p < 0.0001$ ); the score was lowest in the TCM group ( $p < 0.05$ ), while no difference was observed between

the WM and IM groups ( $p > 0.05$ ). At week 24, ACR-20 response was 73.04% with TCM, 80.17% with WM, and 73.95% with IM (based on the full analysis set [FAS],  $p > 0.05$ ); ACR-50 responses were 40.87, 47.93, and 51.26%, respectively, (FAS,  $p > 0.05$ ); and ACR-70 responses were 20.87, 22.31, and 25.21%, respectively, (FAS,  $p > 0.05$ ). Thus, treatment efficacy was similar across groups based on ACR criteria. On the other hand, the rate of TRAEs was significantly lower in the TCM group compared to the other groups ( $p < 0.05$ ). Thus, QRHDX/QRHXEP was effective in alleviating the symptoms of active RA—albeit to a lesser degree than csDMARDs—with fewer side effects. Importantly, combination with QRHDX enhanced the efficacy of csDMARDs. These results provide evidence that QRHDX can be used as an adjunct to csDMARDs for the management of RA, especially in patients who experience TRAEs with standard drugs.

Clinical Trial Registration: ClinicalTrials.gov, identifier NCTNCT025515.

**Keywords:** qingre huoxue decoction, damp-heat-stasis syndrome, active rheumatoid arthritis, comprehensive treatment., randomized controlled trial

## INTRODUCTION

Rheumatoid arthritis (RA) is the most common autoimmune inflammatory arthritis in adults. RA has significant negative impacts on the ability of patients to perform daily activities—including work and home tasks—and health-related quality of life, and increases the risk of mortality (Singh et al., 2016). The incidence of RA is about 1% globally (van der Woude and van der Helm-van Mil, 2018) and 0.28–0.40% in China (Chinese Rheumatology Association, 2018), with no fewer than five million people in China living with the disease. In traditional Chinese medicine (TCM), clinical manifestations of active RA such as joint swelling and tenderness, morning stiffness, and local skin redness constitute a “damp-heat-stasis syndrome” that is similar to the active period of RA [i.e., disease activity score (DAS)-28  $> 3.2$ ]. TCM has been used successfully to treat RA. Specifically, Qingre Huoxue decoction (QRHDX) may prevent bone destruction by modulating inflammation, and short-term application of a cream prepared from *Tripterygium wilfordii*—the source of a QRHXEP component—was shown to be an effective and safe adjunctive treatment (Jiang et al., 2012; China Association of Chinese Medicine, 2017; Jiao et al., 2019). Oral Chinese medicines were found to relieve joint symptoms with minimal adverse reactions in combination with topical formulations for improved disease control (Xing et al., 2020).

The goals of RA treatment are to achieve disease remission or low disease activity and ultimately control the disease, reduce the disability rate, and improve patients' quality of life (Smolen et al., 2020). Conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) are the first-line treatment for RA in China and elsewhere (Singh et al., 2016; Chinese Rheumatology Association, 2018; Lau et al., 2019; Smolen et al., 2020). Methotrexate (MTX) is the anchor drug (Pincus et al., 2003) while hydroxychloroquine (HCQ) is mainly used in combination treatment regimens (95%) (Zhang et al., 2013); the utilization rates of these drugs are 55.9 and 30.4%, respectively, (Jin et al., 2017). However, MTX and HCQ have adverse effects such as gastrointestinal discomfort (e.g., nausea and diarrhea) (Giraud et al., 2020), hepatitis, interstitial pneumonitis,

cytopenias, and retinopathy (Abbasi et al., 2019); as such, the vast majority of RA patients in China are willing to receive TCM treatment (Lu et al., 2019).

Qingre Huoxue treatment (QRHDX plus QRHXEP) is a therapeutic scheme of TCM for RA that have been routinely used in clinical practice for at least 40 years at Guang'anmen Hospital, China Academy of Chinese Medical Sciences. However, there have been few blinded trials systematically comparing the efficacy and safety of Qingre Huoxue treatment and csDMARDs in RA treatment. Thus, the aim of this investigation was to evaluate the effects of Qingre Huoxue treatment vs. MTX plus HCQ in patients with active RA.

## MATERIALS AND METHODS

### Trial Design

This multicenter, double-blind, randomized controlled clinical trial has been registered at ClinicalTrials.gov (NCTNCT02551575). The study was conducted in accordance with the principles outlined in the Declaration of Helsinki, Good Clinical Practice Guidelines of the International Conference on Harmonization, and local regulatory requirements. This study followed CONSORT. The protocol was approved by the ethics committee at Guang'anmen Hospital, China Academy of Chinese Medical Sciences (no. 2013EC122). A study period of 24 weeks was selected based on pilot clinical trials.

### Participants

Men and women aged 18–65 years were considered for enrollment if they met the American College of Rheumatology (ACR) criteria for RA (Arnett et al., 1988; Lu and Jiao, 1996; Aletaha et al., 2010) as well as TCM criteria for the diagnosis of RA “damp-heat-stasis syndrome” (Zheng, 2002) (**Supplementary Material**). The trial was conducted at 16 hospitals. An independent committee monitored the trial for safety and scientific integrity. The inclusion criteria were as follows: 1) DAS-28 score  $> 3.2$ ; 2) patients were taking csDMARDs for at least 3 months at a

stable dose, and continued the same treatment for the duration of the present study; and 3) patients voluntarily participated in the study and signed an informed consent form. Exclusion criteria were as follows: 1) patients with skin burst or allergies; 2) patients with cancer or other malignant diseases such as cardiovascular, hematopoietic, liver, or kidney disease or psychopathy; 3) patients with active or chronic infection, including HIV, hepatitis C virus, hepatitis B virus, or tuberculosis; 4) treatment with *Tripterygii*, glucocorticoid, or biologic DMARDs in the prior 3 months; 5) previous treatment with MTX or HCQ; and 6) patients with retinopathy. Patients who met the following criteria were not allowed to continue receiving the therapy as part of the study, but were followed up until the end of the trial: 1) patients who experienced intolerable adverse events (AEs), complications, or physiologic changes, and had discontinued the study drug for more than 14 days; 2) patients who demonstrated poor compliance (the number and course of medication were not between 80 and 120%); 3) patients who were unwilling to continue participating in the study or were lost to follow-up; and 4) patients who used a nonprescribed range of combined medications that could affect the efficacy and safety assessments.

## Treatment

Eligible patients obtained sequence numbers from the trial coordinator and were allocated to 1 of the 3 following groups by computer-generated sequence randomization: 1) TCM group (TCM plus MTX and HCQ placebos); 2) Western medicine (WM) group (12.5 mg MTX once weekly plus 200 mg HCQ twice daily combined with TCM placebo); and 3) integrative medicine (IM) group (TCM combined with 12.5 mg MTX once weekly plus 200 mg HCQ twice daily). MTX and HCQ tablets were obtained from Shanghai Xinyi Pharmaceutical Co. (Shanghai, China) and Shanghai Zhongxi Pharmaceutical Co. (Shanghai, China), respectively, and were taken orally. TCM Qingre Huoxue treatment for RA “damp-heat-stasis syndrome” with QRHDX and QRHXEP optimized by the Guang’anmen Hospital China Academy of Chinese Medical Sciences were used in this study. QRHDX was processed into granules that were packaged in a tin foil bag by Sichuan New Green Pharmaceutical Technology Development Co. (Chengdu, China). QRHXEP was processed into a gel formulation and packaged in a plastic tube at Guang’anmen Hospital China Academy of Chinese Medical Sciences (batch no. 15011303). QRHDX was taken twice daily—at breakfast and 0.5 h after dinner—for 24 weeks (1 bag boiled in water for each dose). QRHXEP was applied topically once daily 1 h after dinner for 12 weeks [20 g (1 stick) daily in weeks 1–4 and 10 g (half a stick) daily in weeks 5–12] to the skin surface of affected joints, while avoiding the face and temporomandibular joint.

QRHDX has 12 components including animal drug wugong (*Centipede* [4 g]) and the botanical drugs species or TCM plant preparations tufuling (*Smilax glabra* Roxb [30 g]), yinhua (*Lonicera japonica* Thunb [30 g]), huangqi (*Astragalus mongholicus* [30 g]), chaocangzhu (bran-fried *Atractylodes chinensis* [15 g]), huangbo (*Phellodendron amurense* [9 g]),

chishao (*Paeonia lactiflora* [15 g]), bixie (*Dioscoreae hypoglaucae rhizoma* [15 g]), danshen (*Salvia miltiorrhiza* [15 g]), ezhu (*Curcuma zedoaria* [9 g]), qingfengteng (*Sinomenium acutum* (Thunb.) [15 g]), and fengfang (*Nidus vespa* [5 g]). The granules were packaged as 10-g bags, with each bag containing 96 g of crude product. QRHXEP is composed of six botanical drugs including leigongteng (*T. wilfordii* [120 g]), chuanxiong (*Ligusticum wallichii* [60 g]), baizhi (*Angelica dahurica* [60 g]), dahuang (*Rheum officinale* [30 g]), ruxiang (*Boswellia carterii* [30 g]), and bohe (*Fructus forsythiae* [30 g]), as well as the resin moyao (*Myrrh* [30 g]) and mineral mangxiao (*Mirabilite* [120 g]). *T. wilfordii*, *R. officinale*, and *A. dahurica* were refluxed in a volume of 75% ethanol eight times the combined weight of the three components for 1 h. The extracts were combined and filtered, and the ethanol was separated from the filtrate and set aside with the residue stored in another container. *L. wallichii*, *B. carterii*, and myrrh were added to a volume of water 6 times the combined weight of the three components and the volatile oils were extracted for 8 h, and the liquid was filtered and set aside. The residues of *L. wallichii*, *B. carterii*, and *Myrrh* were combined with those of *T. wilfordii*, *R. officinale*, and *A. dahurica*; *Mirabilite* was added along with a 6 × volume of water. The mixture was decocted for 1 h and filtered; the filtrate was combined with the extract liquids that had been set aside, concentrated to a relative density of 1.055–1.075 (75°C), and filtered through a 100-mesh sieve and set aside. *F. forsythiae* was steam-distilled and frozen, and partially decapitated to obtain 0.3 ml peppermint oil. The volatile oils extracted from *L. wallichii*, *B. carterii*, and *Myrrh* were combined with the peppermint oil and ethyl benzoate and dissolved in ethanol. Carboxymethyl cellulose sodium and glycerol were added with stirring. Water was then added to the concentrated extract liquid up to a weight of 1,000 g with continuous stirring until a gel was obtained. The names of the TCM ingredients in Chinese and English are listed in **Supplementary Material**.

QRHDX placebo granules were composed of lactose, starch, edible colorant, and bitter taste agents packaged in a tin foil bag identical to the one containing QRHDX granules and had the same color, texture, taste, and smell as the actual medicine. The QRHXEP placebo gel was prepared from viscous agent with cane sugar color added so that it had the same color, texture, and smell as the actual QRHXEP gel. The MTX and HCQ placebo tablets were composed of lactose, starch, carboxymethyl starch sodium, and magnesium stearate and had the same color, texture, taste, and smell as the actual drugs.

The quality of the TCM granules and gel was evaluated according to the 2005 Chinese pharmacopoeia (Chinese Pharmacopoeia Commission, 2005). Before the start of the trial, the TCM granules and gel were tested for heavy metals, microbial contamination, and residual pesticides, and were determined to meet the safety standards in China. Laboratory personnel were blinded to the identity of the TCM granules and gel. QRHDX and QRHXEP and their placebos were prepared by the same manufacturer. The medicines were distributed to the 16 study sites from the same source.

## Measurements

The patients were observed for 24 weeks. The primary outcome measure was the change in DAS-28 from baseline to week 24, and the secondary outcome measures were ACR-20, ACR-50, and ACR-70 (ACR criteria for 20, 50, and 70% improvement, respectively), which were evaluated at week 24. DAS-28 was based on erythrocyte sedimentation rate (ESR), 28 tender and swollen joint counts (TJC and SJC, respectively), general health (GH; patient assessment of disease activity according to a 100-mm visual analogue scale with 0 = best and 100 = worst), and levels of acute phase reactant (ESR [mm/h]), and was calculated as  $0.56 \times \sqrt{(TJC28)} + 0.28 \times \sqrt{(SJC28)} + 0.014 \times GH + 0.70 \times \ln(ESR)$  (Wells et al., 2009). The ACR-20/50/70 response was defined as  $\geq 20\%/50\%/70\%$  improvement in both the TJC and SJC and  $\geq 20\%/50\%/70\%$  improvement in three of the five other core measures (resting pain, patient's global assessment, physician's global assessment, Health Assessment Questionnaire [HAQ] score, and ESR/C-reactive protein ratio) (Felson et al., 1995). Physical function was assessed at baseline and at week 24 with the HAQ (Bruce and Fries, 2005). Safety was assessed based on routine blood and urine tests, liver (alanine aminotransferase and aspartate aminotransferase) and renal (blood urea nitrogen and creatinine) function, electrocardiogram, and treatment-related (TR)AEs at week 24.

## Sample Size

The sample size was determined by the primary outcome. Assume that the ratio of the three groups is 1:1:1, using a two-sided test with a significance level ( $\alpha$ ) of 0.05 and a power ( $1-\beta$ ) of 0.90, and the required sample size is estimated by SAS 9.4 software for 129 cases in each group. Allowing for a dropout of about 20%, and the TCM group, WM group and the IM group each required 156 cases, a total of 468 cases.

## Statistical Analysis

Intention-to-treat (ITT) approach was performed using in all of analyses. Continuous data was presented as mean (SD), and categorical data was presented as numbers and/or percentages. A one-way ANOVA or Kruskal–Wallis rank test combined with the t or Wilcoxon rank test for post hoc testing was used in analyzing the continuous data. The chi-square or Fisher exact test was used in analyzing the categorical data. The Kruskal–Wallis test combined with the Wilcoxon rank test for post hoc testing was used in analyzing the ordinal data. A one-way ANOVA or Kruskal–Wallis rank test combined with the t or Wilcoxon rank test for post hoc testing was used in analyzing difference value (change before and after the treatment) among three groups. For this three-arm clinical study (groups TCM, WM, and IM), we care about whether there are differences in the efficacy of the three groups. Therefore, after completing the difference test for the three groups, it is necessary to further conduct multiple comparisons between the three groups. In order to avoid false positive results, it is necessary to adjust the test level in the multiple comparison. The Bonferroni method is one of the classic methods for the test level adjustment. The processing method is as follows: the accepted test level is divided by the times of multiple comparisons, and then used as the adjusted test level for

multiple comparisons. In this paper, it is necessary to complete the pairwise comparison between the three groups, TCM-WM, TCM-IM, and WM-IM, the test level is adjusted to 0.0167 (0.05/3). That is, the analysis method for two independent samples is used to test the differences between the TCM-WM, TCM-IM, and WM-IM groups. At this time, only when  $p < 0.0167$ , the difference is considered to be statistically significant. This method can effectively control the generation of false positive results. Statistical analyses were performed using SAS v9.4 software (SAS Institute, Cary, NC, United States).

## RESULTS

### Phytochemical Analysis

Preparation and assay methods of QRHDX and QRHXEP are based on the Pharmaceutical standards of the Ministry of Health of the People's Republic of China (Pharmacopoeia of the people's Republic of China [2010]). The chemical profiling of QRHDX and QRHXEP was detected using LC/MS/MS method, and the details were provided in **Supplementary Material**.

### Study Participants

Subjects were recruited at 16 medical research centers nationwide (**Supplementary Material**) from November 2013 to November 2015; the 24-week clinical observation period for all patients was completed in May 2016. A total of 522 patients were screened and 468 were enrolled (156 per group); treatment was discontinued for 109 patients (TCM group,  $n = 40$ ; WM group,  $n = 33$ ; IM group,  $n = 36$ ) and 8 cases were excluded (TCM group,  $n = 3$ ; WM group,  $n = 2$ ; IM group  $n = 3$ ) (**Figure 1**). There were no significant differences in baseline characteristics between the three groups (**Table 1**).

### Primary Outcome Measure (Disease Activity Score-28)

There was no significant difference in DAS-28—the primary outcome measure—among the three groups at baseline (**Tables 2, 3**). At week 24, DAS-28 was decreased in all three groups compared to the baseline score ( $p < 0.0001$ ). The rank order of DAS-28 at week 24 was  $IM < WM < TCM$  ( $p < 0.05$ ) (**Tables 4, 5**); the score was decreased to  $4.20 \pm 1.56$  in the TCM group,  $3.58 \pm 1.28$  in the WM group, and  $3.39 \pm 1.27$  in the IM group (all  $p < 0.0001$  vs. baseline). The difference value of DAS-28 (i.e., change in score from baseline to week 24) was greater in the IM ( $2.10 \pm 1.12$ ) and WM ( $2.24 \pm 1.40$ ) groups than in the TCM group ( $1.60 \pm 1.17$ ) ( $p < 0.05$ ), while no difference was observed between the former two groups ( $p > 0.05$ ) (**Figure 2**).

### Secondary Outcome Measures

#### American College of Rheumatology-20/50/70

There was no significant difference in ACR-20, ACR-50, and ACR-70 between the three groups at 24 weeks ( $p > 0.05$ ) based on the full analysis set (FAS) (**Tables 6, 7**). ACR-20 and ACR-70 responses at 12 weeks were lower in the TCM group than in the WM and IM groups ( $p < 0.05$ ). There was no significant

**FIGURE 1 |** Flowchart of patient selection and treatment group allocation.

difference in ACR-50 between the WM and IM groups at 12 weeks ( $p > 0.05$ ). At 24 weeks, there were no differences in ACR responses among the TCM, WM, and IM groups (ACR-20: 73.04, 80.17, and 73.95%, respectively,  $p = 0.3764$ ; ACR-50: 40.87, 47.93, and 51.26%, respectively,  $p = 0.2674$ ; ACR-70: 20.87, 22.31, and 25.21%, respectively,  $p = 0.7218$ ).

Based on the per protocol set (PPS), ACR-20 response at 12 weeks was significantly lower in the TCM group than in the WM and IM groups ( $p < 0.05$ ) (Tables 8, 9). There was no significant difference in ACR-50 and ACR-70 between the latter two groups at 12 weeks ( $p > 0.05$ ). Similarly, at 24 weeks there were

no differences in ACR responses among the TCM, WM, and IM groups (ACR-20: 73.45, 80.00, and 74.36%, respectively,  $p = 0.4431$ ; ACR-50: 40.71, 48.33, and 51.28%, respectively,  $p = 0.2540$ ; ACR-70: 20.35, 22.50, and 24.79%, respectively,  $p = 0.7237$ ).

### Safety

No patients died during the study period. More patients in the WM group ( $n = 12$ ) discontinued treatment because of TRAEs than in the IM ( $n = 3$ ) and TCM ( $n = 2$ ) groups ( $p < 0.05$ ) (Tables 10, 11). Fewer patients in the TCM group reported gastrointestinal discomfort ( $n = 4$ ) compared to the WM group ( $n = 18$ ) and

IM group ( $n = 16$ ) ( $p < 0.05$ ). Nausea occurred in one patient treated with TCM compared to eight patients in the WM group and 10 in IM the group ( $p < 0.05$ ). Bacteriuria was also reported at a lower rate in patients treated with TCM ( $n = 8$  vs. 20 with WM and 19 with IM) ( $p < 0.05$ ). There was no significant difference in the frequency of other TRAEs among the groups. The overall rate of TRAEs was lower in the TCM group than in the other two groups ( $p < 0.05$ ).

## DISCUSSION

The pathogenesis of RA is unknown. The aims of currently recommended treatments are mainly to reduce inflammation, suppress disease activity and delay progression, and prevent bone deformity. RA is classified as “Bi syndrome” in TCM, which refers to a group of diseases involving joint and muscle pain such as RA,

osteoarthritis, soft tissue damage, etc. The philosophy of TCM is to maintain overall health and intervene at early stages of disease to prevent progression. However, there is no professional term of “active RA” in TCM. Joint swelling and pain caused by inflammation in RA is considered to be related to dampness, heat, and stasis, which are similar to the active (inflammatory)

period of RA (Liu and Jiang, 2020). Therefore, we take the internationally recognized disease activity evaluation standard DAS-28 > 3.2 as the objective identification of RA “damp-heat-stasis syndrome”.

The results of this study demonstrate that TCM treatment is both effective and safe for the treatment of active RA compared to

csDMARDs. DAS-28 at 24 weeks was lower in patients treated with QRHDX alone than in those treated with MTX plus HCQ; thus, Qingre Huoxue treatment did not have the expected therapeutic advantage over standard RA treatments. However, it is worth noting that the score was lower in the IM group than in the WM group at the end of the treatment period, suggesting that QRHDX can enhance the efficacy of csDMARDs. It was previously reported that QRHDX is suitable for the treatment of “damp-heat-stasis” as it delayed disease activity by reducing inflammation and potentially conferred bone protection (Jiang et al., 2012). In line with the comprehensive treatment approaches used in TCM, patients received QRHDX and QRHXEP during the active period of RA. QRHXEP should not be ignored in efficacy assessments; however, as a topical formulation, its effects begin to decline after about 4 weeks and last only 12 weeks; thus, by the end of the 24-week study period, QRHDX was likely responsible for the observed therapeutic effects of TCM.

In order to standardize the evaluation of “damp-heat-stasis syndrome”, we used DAS-28 > 3.2 to define the active period of RA. DAS-28 (Prevoo et al., 1995), which is based on a count of 28 swollen and tender joints and ranges from 0 to 9.4, can be used to objectively evaluate a patient’s response to treatment (Fransen and van Riel, 2009). The European League Against Rheumatism response criteria combine the DAS-28 score at the time of evaluation with the change in DAS-28 score between two time points, which is a more useful measure of treatment response (van Gestel et al., 1998). Combining DAS-28 score and ACR-20/50/70 can provide more information on the therapeutic benefit of TCM for the treatment of RA beyond its effect on joints (He et al., 2007; He et al., 2008; He et al., 2014).

This is the first registered randomized controlled trial investigating the efficacy and safety of TCM Qingre Huoxue treatment compared to csDMARDs in active RA. Given the large sample size and the involvement of numerous medical centers, the results are representative of the Chinese population. We found that the TCM Qingre Huoxue treatment improved DAS-28 from baseline

to week 24, whether it was administered alone or in combination with MTX and HCQ. In the FAS, ACR-20 was 73.04%, ACR-50 was 40.87%, and ACR-70 was 20.87% with TCM Qingre Huoxue treatment at 24 weeks; the TCM efficacy at the end of the study was only slightly lower than that observed in the WM and IM groups. In this study, we found that Qingre Huoxue treatment can improve DAS-28 score and ACR-20/50/70 by improving joint tenderness, joint swelling, ESR and CRP. According to other studies (He et al., 2007; He et al., 2014), ACR-20 and ACR-50 responses with WM treatment were higher at 24 weeks than in the TCM group. Whether a therapeutic advantage of TCM over MTX and HCQ will be revealed with a longer follow-up period remains to be determined. At 24 weeks, ACR-20/50/70 was similar in patients treated with QRHDX alone to in those treated with MTX plus HCQ. In clinical practice, we often use QRHDX as a prescription for RA patients from active stage to remission stage, whether a longer follow-up might show further benefit for QRHDX treatment can only be answered with such a longer study.

In our study, subjects in the WM group received a combination the csDMARDs MTX and HCQ (Singh et al., 2016). In China, most rheumatologists choose to use two kinds of csDMARDs combined with drugs in the treatment of active RA patients, and MTX alone is only used for RA patients with mild condition. The combination of MTX and HCQ is the most commonly used prescription. Therefore, MTX + HCQ is more representative in China. With this treatment, DAS-28 score in the FAS decreased and ACR-20/50/70 responses were 80.17, 47.93, and 22.31%, respectively, at 24 weeks, which is in line with results obtained in other studies (O’Dell et al., 2002; Hua et al., 2020; Zhang et al., 2020). In one study, an ACR-20 of 71.4% was reported after 24 weeks with MTX treatment alone, which was lower than the response achieved with the combination of MTX and HCQ (Westhovens et al., 2021). In our study, there were no differences in ACR-20/50/70 among the three groups at 24 weeks.

The TCM group had the lowest rate of TRAEs. Patients in the WM group were more likely to discontinue treatment due to TRAEs,

and reported significantly higher rates of gastrointestinal discomfort (e.g., nausea) and bacteriuria along with the IM group compared to patients treated with TCM. These data suggest that TCM is more suitable for RA patients with poor gastrointestinal function or urinary tract bacterial infection, especially as the use of TCM did not increase the risk of infections (Table 10).

## CONCLUSION

The results of this study provide evidence that Qingre Huoxue treatment (QRHDX plus QRHXEP) is effective for the treatment of patients with active RA, with a better safety profile than MTX and HCQ. While the efficacy of QRHDX alone was lower than that of the two csDMARDs, combining QRHDX with MTX and HCQ yielded the greatest improvement in disease activity. The efficacy of QRHDX alone was similar to that of MTX + HCQ in achieving ACR-20/50/70. Thus, QRHDX is a useful adjunct that should be considered as a viable option in the management of RA.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by the ethics committee at Guang'anmen Hospital, China Academy of Chinese Medical Sciences. The patients/participants provided their written informed consent to participate in this study.

Wang Bi tablet (WBT) is used to treat rheumatoid arthritis (RA) in China. We employed integrative pharmacology, including rapid analysis of chemical composition, pharmacological experiment, and network pharmacology analysis, to elucidate the active components and mechanism underlying the effect of WBT against RA. The chemical fingerprint of WBT was revealed by UPLC-QTOF-MS/MS, and the chemical composition was identified. The anti-inflammatory effect of WBT was evaluated in TNF- $\alpha$ -stimulated RAW264.7 cells by ELISA and transcriptome sequencing. Network pharmacology analysis, functional enrichment analysis, and network visualization were performed. A total of 293 chemical constituents were preliminarily identified or tentatively characterized in WBT extract, and they effectively inhibited inflammatory response in TNF- $\alpha$ -stimulated RAW264.7 cells. Forty-eight key active constituents were identified based on high-frequency binding to hub targets and their corresponding targets number. Next, 135 corresponding hub genes, which may be the putative targets of WBT in treating RA, were selected. Functionally, the putative targets were significantly associated with the inflammatory immune response regulation module, energy metabolism regulation module, and cell function regulation module, corresponding to the traditional efficacy of WBT. In summary, this study revealed, for the first time using integrative pharmacology, that WBT may attenuate RA through the inflammation-immune regulation system.

## INTRODUCTION

Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by synovial hyperplasia, inflammatory cell infiltration, pannus formation, and destruction of articular cartilage and bone matrix, and this disease develops symmetrically and destructively, eventually leading to articular deformity and loss of function (Smolen et al., 2016; Burmester and Pope, 2017; McInnes and Schett, 2017; Aletaha and Smolen, 2018). RA has a worldwide prevalence of approximately 0.5–1%, affects women 2–3 times more often than men, and occurs in adolescents, adults, and the elderly, with a high

incidence in people aged 40–60 years (Saraux et al., 2006; Myasoedova et al., 2010). Globally, the overall age-standardized prevalence and incidence rates of RA have been increasing since 1990 (Safiri et al., 2019). Between 2005–2014, the overall incidence of RA was stable compared with that in the previous decade, possibly owing to the changing prevalence of lifestyle factors, such as smoking and obesity (Myasoedova et al., 2020). As RA is a chronic, progressive disease, patients with RA have serious comorbid conditions, such as infection (Au et al., 2011), osteoporosis (Jin et al., 2018), cardiovascular disease (England et al., 2018), respiratory disease (Chatzidionisyou and Catrina, 2016), and cancer (Askling, 2007). Early diagnosis and treatment could slow down the progression of arthritic damage in 90% of RA patients, thereby preventing irreversible disability (Goekoop-Ruiterman et al., 2005). However, only a few patients can achieve long-term remission without long-term medical treatment (Matcham et al., 2014). At present, the western drugs for RA can be divided into five generations according to the development time and principles: nonsteroidal anti-inflammatory drugs, glucocorticoids, disease-modifying antirheumatic drugs, early biological agents mainly composed of TNF- $\alpha$  inhibitors, and new biological agents directly targeting T cells. In recent years, the development of effective biologics and small-molecule kinase inhibitors has markedly improved both the management and long-term prognosis of RA. However, these treatments are mainly used to relieve symptoms, and they cause adverse side effects including vomiting, rash, leukopenia, and liver and kidney damage. Therefore, it is urgent to find a safe and effective treatment strategy to improve both the management and long-term prognosis of RA.

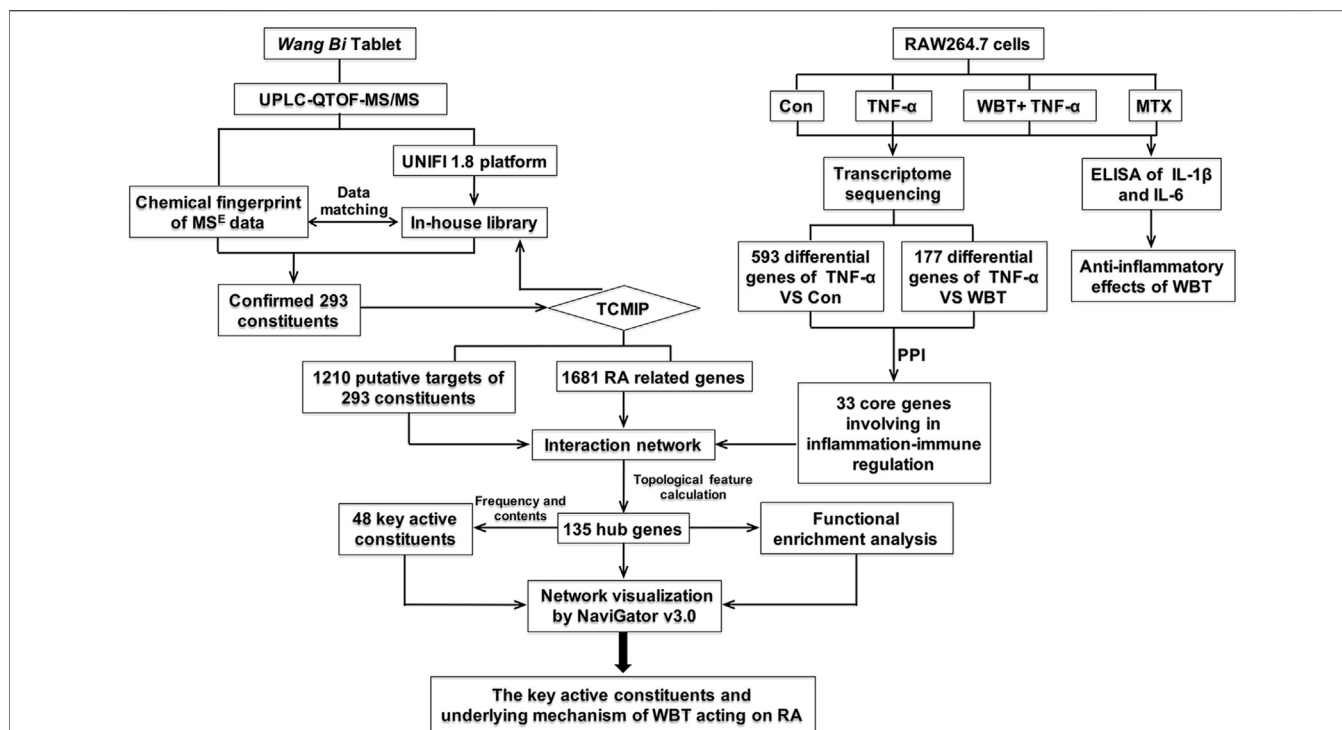

Traditional Chinese medicine (TCM) is a medical and pharmaceutical system with unique theories and techniques that reflect the Chinese nations understanding of life, health, and disease. Wang Bi was first proposed by Mr. Shude Jiao in 1981 in China, mainly refers to RA and other diseases with joint deformation and bone damage, such as ankylosing spondylitis, tuberculous arthritis, and Kashin-Beck disease (Jiao and Wang, 2009). Owing to its minor side effects and reasonable treatment expenditure, TCM has become a significant strategy for treating chronic, complex, and geriatric diseases, such as RA, diabetes, emphysema, and chronic nephritis. Herbal TCMs, such as Danggui Sini decoction (Cheng et al., 2017), Guizhi Fuzi decoction (Peng et al., 2013), Huangqi Guizhi Wuwu decoction (Wang et al., 2010), and Wang Bi tablet (WBT) (Yang et al., 2009; Kang et al., 2011; Wu and Shen, 2011; Liu et al., 2012), have a long history of use in the treatment of RA. WBT is a Chinese patent medicine produced exclusively by Liaoning Haohushi Pharmaceutical (Group) Co., Ltd., and it has been recorded in the Pharmacopeia of the People's Republic of China from the 2010 edition. WBT is composed of 17 herbal medicines, including *Rehmannia glutinosa* (Gaertn.) DC (Sheng Dihuang, SDH) 15.4g, processed *R. glutinosa* (Shu Dihuang, SD) 15.4g, *Dipsacus asper* Wall. ex DC (Xu Duan, XD) 11.5g, *Aconitum carmichaelii* Debeaux (Fu Zi, FZ) 11.5g, *Angelica pubescens* Maxim (Du Huo, DH) 7.7g, *Drynaria fortunei* (Kunze ex Mett.) J. Sm (Gu Suibu, GSB) 11.5 g, *Cinnamomum cassia* (L.).

J. Presl (Gui Zhi, GZ) 7.7g, *Epimedium brevicornu* Maxim (Yin Yanghuo, YYH) 11.5g, *Saposhnikovia divaricata* (Turcz.) Schischk (Fang Feng, FF) 7.7g, *Clematis chinensis* Osbeck (Wei Lingxian, WLX) 11.5 g, *Gleditsia sinensis* Lam (Zao Jiaoci, ZJC) 7.7g, *Paeonia lactiflora* Pall (Bai Shao, BS) 9.2 g, *Cibotium barometz* (L.) J. Sm (Gou Ji, GJ) 11.5g, *Anemarrhena asphodeloides* Bunge (Zhi Mu, ZM) 11.5 g, *Lycopodium japonicum* Thunb (Shen Jincao, SJC) 7.7g, *Carthamus tinctorius* L. (Hong Hua, HH) 7.7g, and goat or sheep bones 15.4g.

Accumulating evidence from clinical practices has proved the efficacy of WBT against RA (Yang et al., 2009; Wu and Shen, 2011) and its ability to enhance the therapeutic efficacy of western medicines, such as methotrexate (Li, 2013; Zhang, 2016; Fan, 2019), in the treatment of RA. Until now, WBT research has been focused on the clinical practice. Thus, at present, basic research on WBT is still lacking in China. There is only one report on analysis of the chemical composition of WBT, in which 138 compounds were characterized by UPLC-Q-TOF-MS (Wang et al., 2019). Research on the pharmacological mechanism of WBT is limited to the NF- $\kappa$ B and JAK-STAT3 signaling pathways (Guan et al., 2018; Shen et al., 2019) as well as the balance between Th1 and Th2 cells (Wang et al., 2020). As a consequence, the pharmacological mechanism of WBT is largely unclear.

Integrative pharmacology, first proposed in 2014 (Xu and Yang 2014), is an interdisciplinary science that comprehensively explores the interactions between multiple constituents of TCM and the body at multiple levels, such as molecules, cells, tissues, organs, and animals (Wang et al., 2018). Integrative Pharmacology-based Network Computational Research Platform of Traditional Chinese Medicine (TCMIP v2.0, <http://www.tcmip.cn/>), which is composed of five databases (Xu et al., 2019) and seven functional modules (Xu et al., 2017), could assist the identification of chemical constituents and the elucidation of the molecular mechanisms of TCM (Mao et al., 2019; Feng et al., 2020; Ma et al., 2020). In the Database of TCM ingredients, we have introduced a characteristic parameter, namely “quantitative estimate of drug-likeness” (QED) to evaluate the druggability of our herbal components. QED includes ADME, water solubility, plasma protein binding rate, blood brain barrier permeability, inhibition of hepatic drug enzymes, hepatotoxicity, and intestinal absorption rate (Bickerton et al., 2012; Doak et al., 2014; Doak et al., 2016).

Therefore, we aimed to systematically analyze the chemical compositions of WBT and explore its molecular mechanisms against RA through the following scheme, as shown in **Figure 1**: 1) analyzing the chemical components of WBT via UPLC-QTOF-MS/MS and identifying the main chemical components by using the UNIFI 1.8 software; 2) evaluating the anti-inflammatory activity of WBT in TNF- $\alpha$ -stimulated RAW264.7 cells via transcriptome sequencing; 3) predicting the putative targets of the identified chemical components of WBT and collecting the putative targets of RA using TCMIP; 4) constructing a network of “Anti-inflammatory Core Genes-Putative Targets-RA genes” to identify the hub genes; 5) selecting key active constituents according to the binding frequency between hub targets and WBT components, and 6) conducting a functional enrichment analysis to investigate whether the molecular mechanisms of

**FIGURE 1** | The scheme of the present study based on the “integrative pharmacology strategy” to elucidate the main active components and mechanism of WBT in treating RA.

WBT against RA is mediated via regulation of its candidate targets. The findings of this study would advance our understanding of the pharmacological mechanism of WBT against RA.

## MATERIALS AND METHODS

### Chemicals and Reagents

HPLC-grade methanol and acetonitrile were purchased from Fisher Scientific Co. (Loughborough, United Kingdom). HPLC-grade formic acid was purchased from Sigma-Aldrich (St. Louis, MO, United States of America). Distilled water was purchased from Watsons Water Co., Ltd. (Shenzhen, China). SDH, SD, XD, FZ, DH, GSB, GZ, YYH, FF, WLX, ZJC, BS, GJ, ZM, SJC, HH, and goat or sheep bones were purchased from Shanghai Traditional Chinese Medicine Co., Ltd. (Shanghai, China). The herbal medicines were identified by Mrs. Xirong He, a research assistant at the China Academy of Chinese Medical Sciences (Beijing), and the voucher specimens were deposited at the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences.

Recombinant human TNF- $\alpha$  (catalog #300-01A) was purchased from PeproTech, Inc (Rocky Hill, NJ, United States of America). An MTT assay kit (ab211091) as well as IL-1 $\beta$  (ab46052) and IL-6 (ab178013) ELISA kits were purchased from Abcam (Burlingame, CA, United States). Dulbecco's modified eagle medium (DMEM) (LOT26019006), 0.25% trypsin

(LOT10519010), penicillin streptomycin solution (LOT30002341), and phosphate buffer saline (PBS) (LOT18919010) were purchased from Corning, Inc (NY, United States). Fetal bovine serum (LOT10099-141) was purchased from Gibco BRL Co. (Boise, Idaho, United States). Methotrexate was purchased from Sigma-Aldrich (St. Louis, MO, United States of America).

### Preparation of Herbal Extracts

WBT preparation was conducted in complete compliance with that recorded in the Chinese Pharmacopeia (P985-986, 2015 edition). The procedure was as follows. Briefly, SDH 15.4 g, SD 15.4 g, GSB 11.5 g, GJ 11.5 g, and goat or sheep bones 15.4 g were decocted twice in eight and six volumes of water for 1.5 h. The decoctions were filtered and then combined to obtain extract S1. The remaining 12 herbal medicines were decocted as before to obtain extract S2. Next, S2 was evaporated under reduced pressure to the weight of the original herbal medicines in a rotary evaporator and then mixed with three volumes of EtOH. The mixture was allowed to stand for 16.0 h, and then the EtOH in the supernatant was recovered under reduced pressure to obtain extract S3. S1 and S3 were combined and concentrated under reduced pressure to obtain a thick paste (S4) with a relative density of 1.27–1.30 (50°C). BS 46 g and ZM 57.5 g were ground into powder and then filtered through a 100-mesh sieve. The fine powder was mixed thoroughly with S4 before freeze drying, and the

lyophilized powder was screened through a 40-mesh sieve. Six batches of herbal medicines were extracted in parallel.

The fine lyophilized powder of WBT was ultrasonically extracted using 20 volumes of 70% MeOH for 0.5 h before centrifugation at  $12,000 \times g$  for 10 min in an Eppendorf 5415D centrifuge (Eppendorf Co., Hamburger, Germany). After the supernatant was filtered through a  $0.22 \mu\text{m}$  filter (Pall Corporation, Beijing, China),  $2 \mu\text{l}$  aliquots were transferred to the UPLC-QTOF-MS/MS system for analysis. The quality control (QC) samples of WBT were prepared by mixing the six batches of herbal medicines.

## Instrumentation and UPLC-QTOF-MS/MS Conditions

The UPLC separation was performed using a Waters Acquity UPLC HSS T3 column ( $100 \text{ mm} \times 2.1 \text{ mm}$ , i. d.  $1.8 \mu\text{m}$ ) on a Waters Acquity UPLC I-Class system (Waters Corp., Milford, United States of America). The column was maintained at  $40^\circ\text{C}$ . The mobile phases consisted of eluent A (0.1% formic acid in deionized water, v/v) and eluent B (0.1% formic acid in acetonitrile, v/v), and the linear gradient program was as follows: 0–1 min, 1% B; 1–10 min, 1–20% B; 10–20 min, 20–40% B; 20–25 min, 40–50% B; 25–28 min, 50–100% B; 28–33 min, 100% B; 33–33.1 min, 1% B; 33.1–35 min, 1% B. The flow rate was  $0.5 \text{ ml/min}$ , and the injection volume was  $2 \mu\text{l}$ .

The MS experiment was performed on a Waters Xevo G2-S Q-TOF Mass System (Manchester, United Kingdom) equipped with electrospray ionization (ESI). The data acquisition modes were MS<sup>E</sup> centroid for all samples and the extra continuum mode for QC samples in both the ESI<sup>+</sup> and ESI<sup>−</sup> ionization modes. The operating parameters were set as follows: mass range, 50–1,500 Da; source temperature,  $100^\circ\text{C}$ ; desolvation temperature,  $400^\circ\text{C}$ ; desolvation gas flow,  $800 \text{ L/h}$ ; sampling cone,  $40 \text{ V}$ ; capillary voltage,  $2.5 \text{ kV}$  for ESI<sup>−</sup>,  $0.5 \text{ kV}$  for ESI<sup>+</sup>. At low CE scan, the auto MS collision energy was  $6 \text{ eV}$ . At high CE scan, the collision energy was  $15\text{--}45 \text{ eV}$  ramp for ESI<sup>+</sup> and ESI<sup>−</sup>.

Leucine enkephalin was selected as the lock-mass at a concentration of  $200 \text{ pg/ml}$  in acetonitrile (0.1% formic acid):  $\text{H}_2\text{O}$  (0.1% formic acid) (50:50, v/v) for the positive ion mode ( $[\text{M} + \text{H}]^+ = 556.2771$ ) and negative ion mode ( $[\text{M} - \text{H}]^- = 554.2615$ ) via a lock spray interface.

## Cell Culture

RAW264.7 murine macrophage-like cells were obtained from Cell Resource Center, IBMS, CAMS/PUMC (Beijing, China) and cultured in DMEM supplemented with 10% heat-inactivated fetal bovine serum and antibiotics ( $100 \text{ U/ml}$  penicillin and  $100 \text{ U/ml}$  streptomycin) at  $37^\circ\text{C}$  in a biochemical incubator (LRH-150, Shanghai, China) with humidified atmosphere containing 95%  $\text{O}_2$  and 5%  $\text{CO}_2$ .

## MTT Assay

The cytotoxicity of WBT was analyzed via MTT assay. RAW264.7 cells ( $1 \times 10^5$  cells/well) were plated in 96-well plates ( $p = 6$ ) and incubated for 24 h. After washing with PBS, WBT (12.8, 25.6, 128,

640, 3200,  $1.6 \times 10^4$ ,  $8.0 \times 10^4$ ,  $4.0 \times 10^5$ ,  $2.0 \times 10^6$ ,  $1.0 \times 10^7 \text{ ng/ml}$ ) or PBS was added to the cells, which were then incubated for another 24 h. Cell viability was evaluated using an MTT assay kit (#ab211091; Abcam) according to the manufacturer's protocol, and the absorbance was detected by a PerkinElmer EnVision multimode plate reader (2104, Wellesley, MA).

## Drug Treatment

RAW264.7 cells were seeded on 96-well plates ( $p = 6$ ) at a density of  $1 \times 10^5$  cells per well and incubated for 24 h. Next, the medium was discarded, and the cells were washed with PBS. The cells were subsequently incubated with PBS, TNF- $\alpha$  ( $20 \text{ ng/ml}$ ), TNF- $\alpha$  ( $20 \text{ ng/ml}$ ) + WBT (0.001, 0.01, 0.1, 1.0, or  $10 \mu\text{g/ml}$ ), or TNF- $\alpha$  ( $20 \text{ ng/ml}$ ) + methotrexate (MTX,  $0.2 \mu\text{g/ml}$ ) for another 24 h. Finally, the supernatant was collected for measurement of IL-1 $\beta$  and IL-6 using ELISA kits according to the manufacturer's instructions.

## RNA Extraction and Quality Control

Total RNA was isolated using a RNeasy mini kit (Qiagen, Germany) according to the manufacturer's protocol. RNA integrity was evaluated using an Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, United States of America). The quantity of total RNA in the samples was measured using a Qubit<sup>®</sup> 3.0 Fluorometer (Thermo Fisher Scientific, United States of America) and NanoDrop One (Wilmington, DE, United States of America).

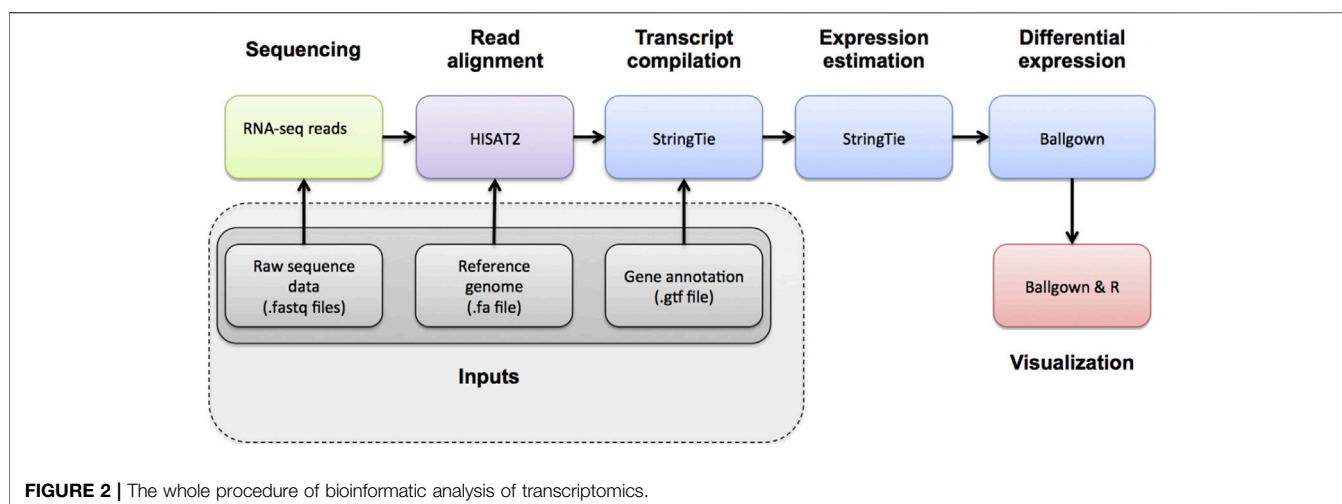

## mRNA-Seq

Paired-end libraries were synthesized using a TruSeq<sup>™</sup> RNA Sample Preparation Kit (Illumina, United States of America) following the TruSeq<sup>™</sup> RNA Sample Preparation Guide. Briefly, poly A-containing mRNA molecules were purified using poly T oligo-attached magnetic beads. Following purification, the mRNA was fragmented into small pieces using divalent cations at  $94^\circ\text{C}$  for 8 min. The cleaved RNA fragments were copied into first-strand cDNA using reverse transcriptase and random primers. This was followed by second-strand cDNA synthesis using DNA Polymerase I and RNase H. These cDNA fragments then went through an end-repair process, the addition of a single 'A' base, and then ligation of the adapters. The products were then purified and amplified via PCR to create the final cDNA library. Purified libraries were quantified using a Qubit<sup>®</sup> 2.0 Fluorometer (Life Technologies, United States of America) and validated using an Agilent 2100 Bioanalyzer (Agilent Technologies) to confirm the insert size and calculate the mole concentration. Clusters were generated by cBot with the library diluted to  $10 \text{ pM}$  and then sequenced on an Illumina NovaSeq 6000 (Illumina, United States of America). The sequencing work was performed by Beijing Zhimei Yinuo Biotechnology Co., Ltd. (Beijing, China). The sequencing data has been uploaded to GEO website with Series record GSE165272.

## Bioinformatic Analysis

Bioinformatic analysis was also undertaken by Zhimei Yinuo Biotechnology Co., Ltd. The whole procedure is shown in Figure 2.

## Prediction the Putative Targets of the Chemical Constituents of WBT

The TCM target prediction and function analysis module (TTFM) of TCMIP was employed to predict the putative targets of the compounds preliminarily identified in WBT. The prediction accuracy was set at 0.80 (moderate to high similarity) to select constitute-putative target pairs, and these genes were saved in the customer center. Simultaneously, the QED value was set at 0.49, and constituents with QED <0.49 will be filtered out.

## Collection of RA-Related Genes From TCMIP

The disease name “rheumatoid arthritis” and symptom nouns, such as “joint swelling”, “morning stiffness”, and “arthralgia” were selected to search in TCMIP in order to obtain RA-related genes among those saved in the personal user center.

## Network Visualization and Functional Enrichment Analysis

NaviGator v3.0 was employed to establish a network, and the Database for Annotation, Visualization and Integrated Discovery (DAVID) v6.8 (<https://david.ncifcrf.gov>) was used to elucidate the biological functions of the core efficacy gene set.

## Data Analysis

The UPLC-QTOF-MS/MS system was controlled by the Masslynx 4.1 software (Waters Corp.). The MS<sup>E</sup> continuum data were processed by UNIFI 1.8 (Waters Corp.). The processes included data acquisition, data mining, library searching, and report generation. The chemical information of the 16 herbal medicines (except for goat or sheep bones) was collected in a list consisting of molecular name/formulae/weights and chemical structures (mol. format) from the literature and the Encyclopedia of Traditional Chinese Medicine (<http://www.nrc.ac.cn:9090/ETCM/>) (Xu et al., 2019). The list, as a customized

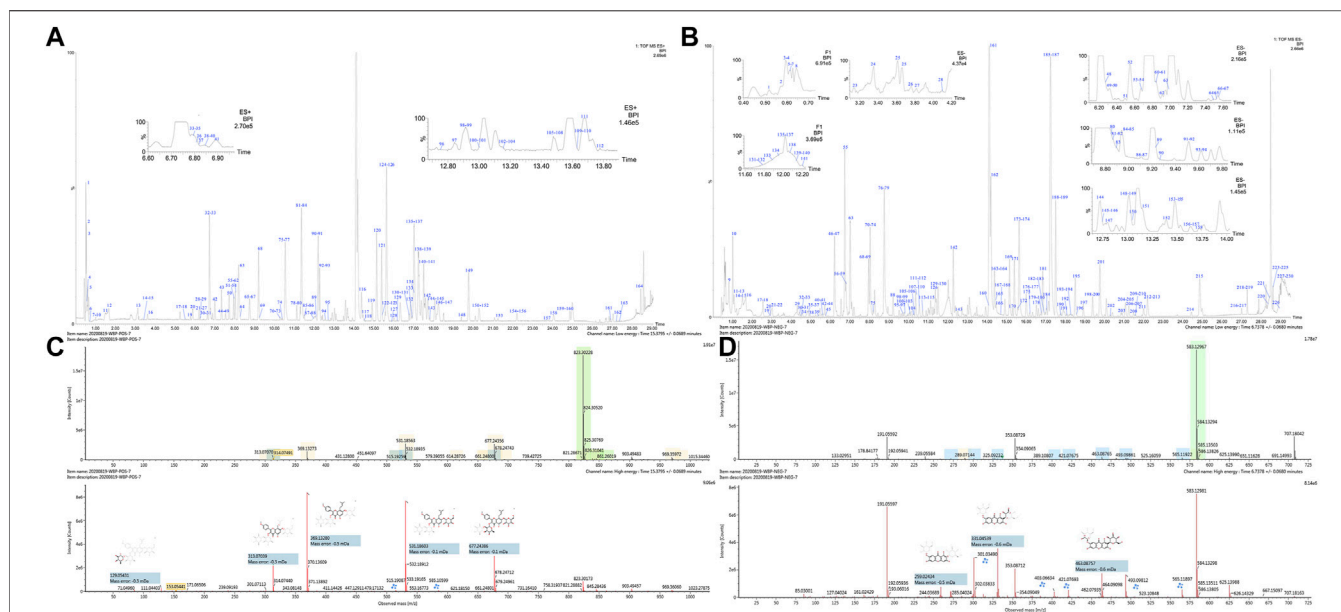

library that could facilitate chemical identification, is shown in **Supplementary Excel S1** [M+H]<sup>+</sup>, [M+K]<sup>+</sup>, [M+Na]<sup>+</sup>, [2M+H]<sup>+</sup>, and [M-e]<sup>+</sup> were selected as additive ions in the positive ion mode. [M+COOH]<sup>-</sup>, [M-H]<sup>-</sup>, and [2M-H]<sup>-</sup> were selected in the negative ion mode. The allowable maximum error range was 5 mDa/10 ppm, and the matched constituents were given the predicted fragments from the structure. The functional module of the mass fragment could facilitate the chemical identification of unmatched constituents based on the isotopic abundance, elemental composition, and i-FIT score.

## RESULTS

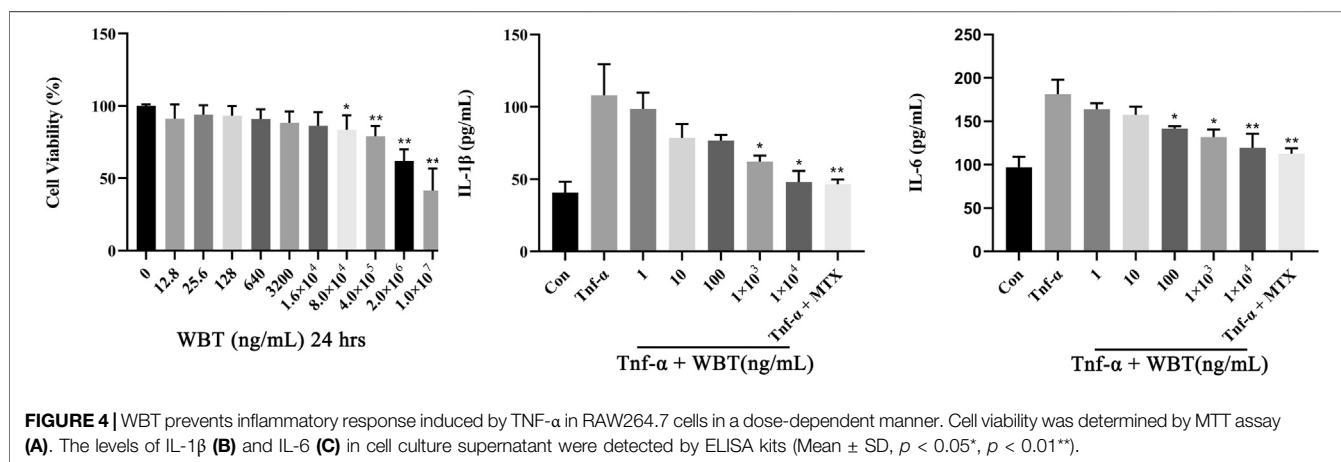

### Characterization and Identification of Chemical Constituents in WBT

A total of 293 compounds were identified or tentatively characterized in both the positive (165) and negative (229) ion modes, including flavonoids, alkaloids, glycosides, coumarins, saponins, phenolic acid, and iridoids. The base peak intensity (BPI) chromatograms of WBT in two ion modes are depicted in **Figures 3A,B**. Among the 293 constituents characterized, 45 were identified in SDH or SD, 28 in XD, 23 in FZ, 23 in DH, 15 in GSB, 14 in GZ, 36 in YYH, 22 in FF, 7 in WLX, 8 in ZJC, 28 in BS, 8 in GJ, 26 in ZM, 16 in SJC, and 31 in HH. Detailed information of the 293 compounds is listed in **Supplementary Excels S2, S3**, including RT, M/Z, error, response, adducts, formula, name, fragments, category, and origin.

The BPI chromatograms of the water extract of WBT corresponding to the positive and negative ion modes are shown in **Figures 3A,B**. The mass spectra of two compounds are shown below. The ion at RT = 15.37 and [M + H]<sup>+</sup> = 823.3022 was primarily identified as baohuoside VI (C<sub>39</sub>H<sub>50</sub>O<sub>19</sub>) in ESI<sup>+</sup> after matching with data from the customized database (**Supplementary Excel S4**) of UNIFI. The main fragments were m/z 677.2438 [M + H-rha]<sup>+</sup>, 531.1860 [M + H-2rha]<sup>+</sup>, 369.1328 [M + H-Glc-2rha]<sup>+</sup>, and 313.0703 [M + H-Glc-2rha-C<sub>4</sub>H<sub>7</sub>]<sup>+</sup>, which were consistent with those in literature (Yu et al., 2016). In the same way, the ion at RT = 17.27 and [M-H]<sup>-</sup> = 927.4931 was primarily identified as akebiasaponin D (C<sub>47</sub>H<sub>76</sub>O<sub>18</sub>) in ESI<sup>-</sup>. The main fragments were

**FIGURE 3 |** BPI chromatograms of WBT extracts (A) ESI<sup>+</sup>; (B) ESI<sup>-</sup>, and spectrum information of baohuoside VI (C) and akebiasaponin D (D) automatically provided by UNIFIT<sup>TM</sup>.

**FIGURE 4 |** WBT prevents inflammatory response induced by TNF- $\alpha$  in RAW264.7 cells in a dose-dependent manner. Cell viability was determined by MTT assay (A). The levels of IL-1 $\beta$  (B) and IL-6 (C) in cell culture supernatant were detected by ELISA kits (Mean  $\pm$  SD,  $p < 0.05$ \*,  $p < 0.01$ \*\*).

$m/z$  603.3904 [M-H-2Glc]<sup>-</sup>, 323.0984 [M-H-Glc-C<sub>4</sub>H<sub>8</sub>O<sub>4</sub>]<sup>-</sup>, and 179.0563 [M-H-Glc-C<sub>3</sub>H<sub>6</sub>O<sub>3</sub>]<sup>-</sup>, which were consistent with those in literature (Yang et al., 2016). The mass spectra and structures of the two compounds are displayed in Figures 3C,D.

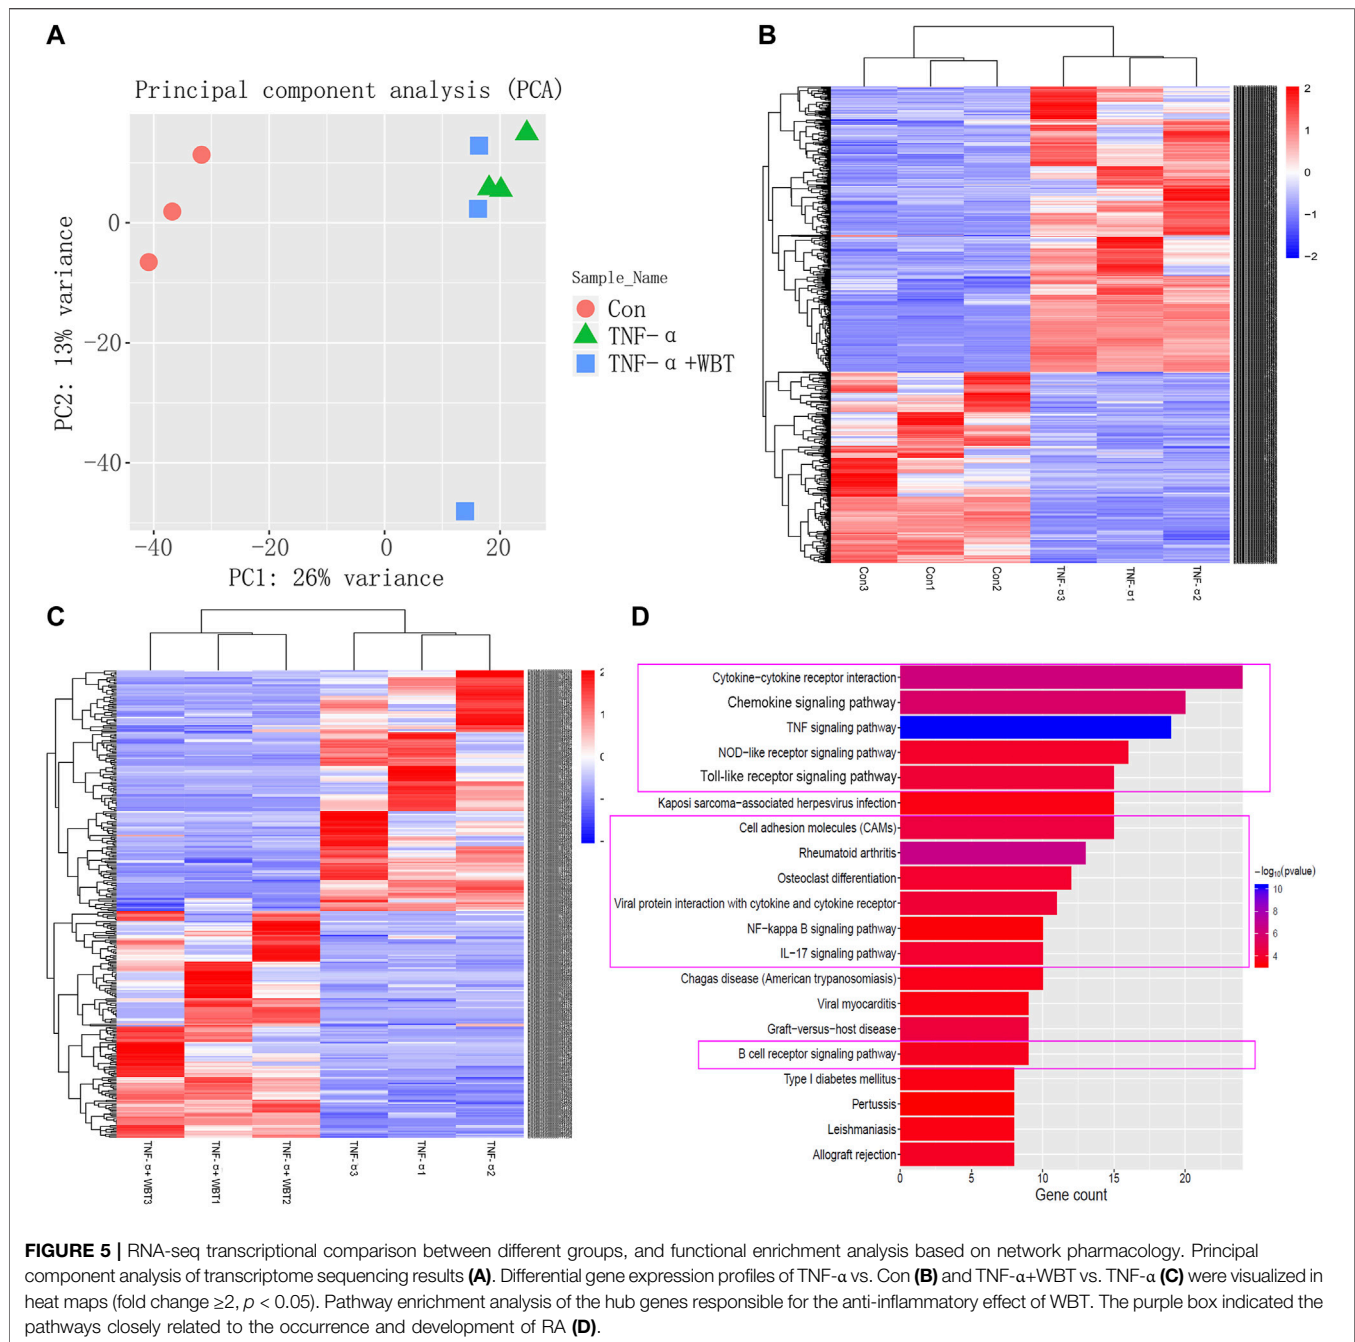

### WBT Reduces the Release of IL-1 $\beta$ and IL-6 in TNF- $\alpha$ Stimulated RAW264.7 Cells

The MTT assay showed that WBT exerted no significant cytotoxicity to RAW264.7 cells even at a concentration as high as  $1.6 \times 10^4$  ng/ml (Figure 4A). Therefore, WBT concentrations ranging from 0.001 to 10  $\mu$ g/ml were selected for the examination of the anti-inflammatory activity of WBT in TNF- $\alpha$ -stimulated RAW264.7 cells. In RAW264.7 cells stimulated with TNF- $\alpha$  (20 ng/ml) for 24 h, IL-1 $\beta$  and IL-6 levels in the culture

medium were significantly increased ( $p < 0.01$ ) compared with that in the control group. MTX, as a positive drug, exhibited an excellent effect against inflammatory responses, suggesting a good pharmacodynamic evaluation system. In RAW264.7 cells co-cultured with TNF- $\alpha$  and WBT at 0.1, 1, and 10  $\mu$ g/ml, IL-1 $\beta$  and IL-6 levels were significantly reduced ( $p < 0.01$ ) in a dose-dependent manner. WBT at a low dose (0.001, 0.01  $\mu$ g/ml) did not exhibit any anti-inflammatory effects (Figures 4B,C).

### RNA-Seq Transcriptional Comparison Between Different Groups and Functional Enrichment Analysis of Core Genes

To elucidate the mechanism by which WBT altered the transcriptomic profile of RAW264.7 cells simulated by TNF- $\alpha$ ,

RNA-seq experiments were performed. The control, TNF- $\alpha$ , and TNF- $\alpha$  + WBT (1.0  $\mu\text{g/ml}$ ) groups were selected as the biological samples according to the level of inflammatory factors. To ensure the accuracy of the analysis, we set three biological replicates for RNA-seq, a fold change of more than 2, and a  $p$  value of less than 0.05. Principal component analysis showed good separation between different groups and good consistency in the same group (Figure 5A). After treatment, 593 and 177 genes were differentially regulated between TNF- $\alpha$  vs. Con and between TNF- $\alpha$ +WBT vs. TNF- $\alpha$ , respectively (Supplementary Excel S5, S6). Between TNF- $\alpha$  vs. Con, 376 genes were upregulated,

and 217 genes were downregulated; these genes were regarded as “Inflammatory Immune Dysregulation Genes.” Between TNF- $\alpha$ +WBT vs. TNF- $\alpha$ , 92 genes were upregulated, and 85 genes were downregulated; these genes were regarded as “Anti-inflammatory Effect Genes.” Heat maps were generated to visualize the gene expression patterns in the three groups (Figures 5B,C). Interestingly, 45 genes that were differentially expressed between TNF- $\alpha$  vs. Con were significantly counter-regulated by WBT; thus, these genes may be the potential gene set responsible for the efficacy of WBT in reducing inflammatory responses. The 593 and 177 different genes were imported into

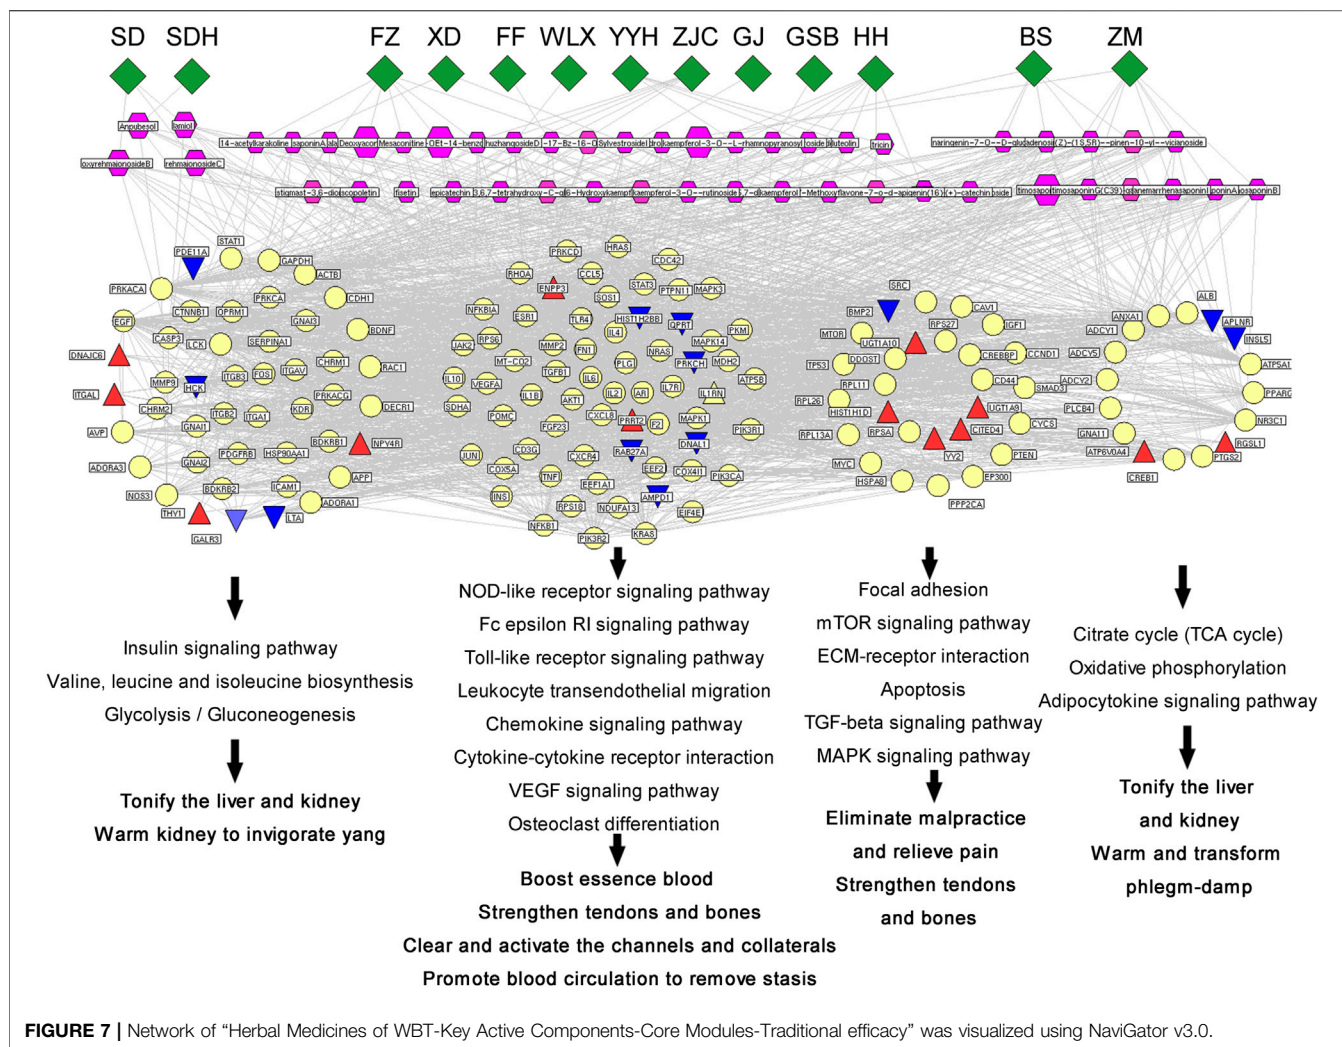

the STRING database for construction of a PPI network including 264 nodes and 599 edges (**Supplementary Excel S7**). Thirty-three core nodes of the network were obtained by calculating the topological feature values, including degree, betweenness, and closeness. Generally, the node with a degree value of two-fold the median as well as betweenness and closeness values of one-fold the median is selected as the hub node. The 33 hub nodes included ABL1, ACTG2, ALDH1A7, B2M, C3, CCL2, CCL20, CCL5, CCL9, CES2C, CSF1, CXCL1, CXCL10, CXCR3, EPHA3, EPHA5, H2-K1, HVCN1, IRF7, JUN, MF12, MMP3, MMP9, NMUR1, OLFM4, PLXNB3, RAB27A, RHBDF2, SEMA3G, THY1, TLR2, TRF, and VCAM1. Based on functional enrichment analysis, these 33 genes were mainly involved in the inflammation-immune regulation module, and the purple box indicates that the pathway information was closely related to the occurrence and development of RA (**Figure 5D**), such as cytokine-cytokine receptor interaction, chemokine signaling pathway, TNF signaling pathway,

NOD-like receptor signaling pathway, and Toll-like receptor signaling pathway.

### Underlying Mechanism and Key Active Components of WBT in Treating RA

By using the TTFM of TCMIP, we predicted a total of 1,210 putative targets based on the chemical structures of the 293 identified compounds (**Supplementary Excel S8**). Moreover, a total of 1681 RA-related genes were collected from the Disease-related Gene Database of TCMIP, as shown in **Supplementary Excel S9**. To illustrate the underlying mechanisms of WBT against RA, an interaction network of “Anti-inflammatory Hub Genes-Putative Targets- Disease Genes” was constructed using the TCM Association Network Mining Module of TCMIP. The interaction network included 2,251 nodes and 53,254 edges, with a network density of 0.011. A total of 566 core nodes of the network were obtained by calculating the topological feature values. In addition, a PPI network of the 566 core nodes was

constructed, which included 566 nodes and 23,558 edges and had a network density of 0.074, which was significantly higher than that of the initial network (density 0.011) and in accordance with network centrality of hub nodes. Finally, 135 hub nodes were obtained by calculating the topological feature values, of which 81 were putative targets of WBT corresponding to 225 chemical constituents.

To explore the biological function of these 135 hub genes, DAVID v6.8 was employed for KEGG analysis. As shown in **Figure 6**, the pathway information could be divided into five function modules: 1) the synovial inflammation-immune imbalance regulation module. It was the most significant functional module that included NOD-like receptor signaling pathway, B cell receptor signaling pathway, T cell receptor signaling pathway, Fc epsilon RI signaling pathway, Toll-like receptor signaling pathway, primary immunodeficiency, leukocyte transendothelial migration, chemokine signaling pathway, complement and coagulation cascades, natural killer cell-mediated cytotoxicity, regulation of actin cytoskeleton, Fc gamma R-mediated phagocytosis, and cytokine-cytokine receptor interaction; 2) energy metabolism regulation module,

including citrate cycle (TCA cycle), oxidative phosphorylation, adipocytokine signaling pathway, neurotrophin signaling pathway, insulin signaling pathway, valine, leucine and isoleucine biosynthesis, glycolysis/gluconeogenesis, and pyrimidine metabolism; 3) cell function regulation module, including focal adhesion, mTOR signaling pathway, ECM-receptor interaction, apoptosis, TGF-beta signaling pathway, and MAPK signaling pathway; 4) synovial pannus formation module, including VEGF signaling pathway and vascular smooth muscle contraction; 5) bone destruction regulation module, including osteoclast differentiation.

The constituents that showed high-frequency binding to hub targets and had high content were selected as the key constituents (the target frequency and content were higher than the corresponding medians). A total of 48 key active constituents were selected, which corresponded to 13 herbal medicines. The detailed information is shown in **Supplementary Excel S10**. A multidimensional association network of "Herbal Medicines of WBT-Key Active Components-Core Targets-Functional Modules-Traditional efficacy" was visualized using NaviGator v3.0, as shown in **Figure 7**. Among the hub targets, 13 red

triangles and 13 blue triangles represented the genes upregulated or downregulated, respectively, by WBT in the transcriptome data. These hub targets involved in different pathways were divided into four functional models corresponding to different traditional efficacies. The insulin signaling pathway; valine, leucine, and isoleucine biosynthesis; and glycolysis/gluconeogenesis were related to the tonifying of the liver and kidney as well as warming of the kidney to invigorate *yang*. The focal adhesion mTOR signaling pathway, ECM-receptor interaction apoptosis, TGF- $\beta$  signaling pathway, and MAPK signaling pathway were consistent with the elimination of malpractice, relief of pain, and strengthening of tendons and bones. The TCA cycle, oxidative phosphorylation, and adipocytokine signaling pathway were related to tonifying of the liver and kidney as well as warming and transforming of phlegm-damp. The other pathways were consistent with the boosting of blood essence, strengthening of tendons and bones, clearing and activation of the channels and collaterals, and promotion of blood circulation to remove stasis.

## DISCUSSION

In the present study, we analyzed the chemical compositions of WBT and explore its molecular mechanisms against RA using integrative pharmacology. This is the first study to explore the active constituents and underlying mechanism of WBT in treating RA using integrative pharmacology, including rapid analysis of chemical composition, transcriptome sequencing, and network pharmacology analysis. In this study, the BPI chromatogram of WBT extracts was obtained by UPLC-QTOF-MS/MS, and 293 chemical compounds were preliminarily identified or tentatively characterized by matching the MS<sup>E</sup> raw data to in-house library data using the UNIFI 1.8 software. WBT at 0.1, 1.0, and 10  $\mu$ g/ml significantly reduced IL-1 $\beta$  and IL-6 levels in RAW264.7 cells stimulated by TNF- $\alpha$ . Moreover, 593 and 177 differential genes were screened between TNF- $\alpha$  vs. Con and between TNF- $\alpha$ +WBT vs. TNF- $\alpha$  based on transcriptome sequencing analysis. An interaction network of “Inflammatory Immune Dysregulation Genes” and “Anti-inflammatory Effect Genes” was constructed, and the hub nodes, as calculated by the topological feature values, were mainly involved in the inflammation-immune regulation module, which is closely related to the occurrence and development of RA. To explore the underlying mechanism of WBT against RA and identify its key pharmaceutically active substances, a multidimensional association network of Real-World Medicines of WBT-Key Active Components-Core Targets-Functional Modules-RA Pathology” was visualized using NaviGator v3.0. A total of 48 key active constituents were obtained based on their high-frequency binding to hub targets and contents in WBT, and 135 hub corresponding genes were selected, which may be the putative targets of WBT in treating RA. Functionally, the 135 putative targets were significantly associated with the inflammatory immune response regulation module, energy metabolism

regulation module, and cell function regulation module, corresponding to their traditional efficacy.

WBT is composed of 17 herbal medicines that fit the compatibility principle of Monarch, Minister, Assistant, and Guide. We herein discuss the mechanism of WBT in treating RA according to this principle, as the 48 key active constituents were mainly involved in 13 herbal medicines: SDH and SD are Monarch drugs; YYH, XD, GJ, FZ, DH, FF, WLX, ZC, HH, and BS are Minister drugs; and ZM and BS are Assistant and Guide drugs. The other three herbal medicines and one animal drug may exert therapeutic effects through other pathways or systems than the inflammation-immune regulation system. 21 of the 48 key active constituents belong to flavonoids, 7 alkaloid, 7 steroidal saponin, 3 monoterpenoid, 3 iridoid, 2 coumarins, 1 ribonucleoside, 1 sterol, and 1 tannin. According to our experience, flavonoids may have greater potential against RA. RAW 264.7 cell which we all know is one of the media for RA testing. Inflammation is an important pathological process of RA, so we selected TNF- $\alpha$  as inflammatory inducer.

Interestingly, the enrichment pathways are consistent with the traditional efficacy of the corresponding herbal medicines (Figure 7.). For example, 20 hub genes corresponding to 5 chemical constituents of SDH and DH, are correlated with the regulation of glucose and lipid metabolism and blood circulation, which are consistent with the traditional effect of SDH and SD in “tonifying the liver and kidney, benefiting essence and blood”. 32 hub genes corresponding to 9 chemical constituents of FZ, FF and WLX, are mainly involved in signal transduction and inflammatory response of the nervous system, which are consistent with the traditional effect of the three herbs in “clearing and activating the channels and collaterals”. 24 hub genes corresponding to 8 chemical constituents of YYH, XD, GSB and GJ, are correlated with various regulation pathways and energy metabolism in the body, such as the citrate cycle; oxidative phosphorylation; adipocytokine signaling pathway; neurotrophin signaling pathway; insulin signaling pathway, which consistent with the “warming the kidney and strengthening *yang*” efficacy of Minister drugs. 44 hub genes corresponding to 19 chemical constituents of ZC and BS, are mainly involved in inflammatory immune regulation pathways, signal transduction, and neuroinflammatory response, which are related to the effects of warm channels and freeing of vessels, invigorating blood circulation and dispersing stasis. 48 hub genes corresponding to 14 chemical constituents of ZM and BS, were mainly involved in the regulatory pathways of nutrients and energy metabolism, blood circulation regulation pathway, which were related to the overall regulation of physical fitness and the enhancement of the effects of other drugs.

In the transcriptome sequencing experiment, we found that IL-13Ra2, Tnfrsf3, Tnfrsf14, and Tnfrsf9 were upregulated in TNF- $\alpha$ -stimulated RAW264.7 cells, which was related with the development of inflammation (Wilson et al., 2011). The expression of Il1rn was upregulated in WBT + TNF- $\alpha$ -stimulated RAW264.7 cells, suggesting WBT could ameliorate inflammatory conditions stimulated by TNF- $\alpha$

(Matsuki et al., 2005; Hada et al., 2020). These findings were consistent with ELISA results about IL-1 $\beta$  and IL-6. Moreover, IL-1 $\beta$  and IL-6 were involved in 4 prediction pathways, including cytokine-cytokine receptor interaction, TNF signaling pathway, NOD-like receptor signaling pathway, and Toll-like receptor signaling pathway.

There were two putative genes among the hub targets of WBT, which were also the drug effect genes identified by sequencing, namely hematopoietic cell kinase (HCK) and bone morphogenetic protein 2 (BMP2). The expression level of HCK was significantly downregulated, whereas that of BMP2 was remarkably upregulated after the treatment of RAW264.8 cells with WBT. HCK, a member of the Src family of non-receptor tyrosine kinases, is primarily expressed in myeloid cells and B lymphocytes. Moreover, HCK participates in the regulation of immune function by binding to the FC terminal of immunoglobulin (Ernst et al., 2002). HCK is highly expressed in macrophages, and its expression is further augmented during macrophage activation. HCK has been reported to be involved in various inflammatory reactions (English et al., 1993). The results of transcriptome sequencing showed that after inflammation was induced by TNF- $\alpha$ , cellular immunity was enhanced, and the expression level of was significantly increased. After WBT intervention, however, HCK expression level was effectively inhibited. BMP2, a member of the transforming growth factor- $\beta$  (TGF- $\beta$ ) superfamily (Koseki et al., 2002), plays an important role in the recruitment and differentiation of undifferentiated mesenchymal cells and osteoblasts (Lyons et al., 1995; Deng et al., 2008). In the early stage of bone formation, BMP2 not only induced undifferentiated stromal cells to accumulate into bone-forming centers and differentiate into osteogenic cells but also reversed the differentiation of fibroblasts, myoblasts, and bone marrow basal cells into osteoblasts. For osteoblasts, BMP2 maintains its unique cell phenotype, induces an increase in osteoblast markers, and promotes extracellular matrix calcification. In the late stage of bone formation, BMP2, as an osteoclast differentiation factor, directly or indirectly stimulates osteoclast differentiation together with other osteoclast differentiation supporting factors, and participates in bone reconstruction. It has been reported that the expression of BMP-2 decreases upon bone and cartilage destruction in the pathogenesis of RA (Sun et al., 2019). After intervention with anchoring agents or other cytokine inhibitors, the expression of BMP-2 increased significantly as the of the disease progressed, which was consistent with the transcriptome sequencing results of WBT in this study.

Although the current study reveals these important findings, there are still several potential limitations. Firstly, it is difficult to determine whether the correlation between herbs and their corresponding targets is direct or indirect. Secondly, it is difficult to confirm whether the interaction between herbs and their corresponding targets is positive or negative. Therefore, further experiments are needed to verify the results of this preliminary study.

## CONCLUSION

In summary, the 48 key active constituents contained in WBT may attenuate the major pathological changes in RA through their 135 candidate targets, which were involved the inflammation-immune regulation system, energy metabolism regulation module, and cell function regulation module. TCMIP v2.0 undoubtedly accelerates the process of chemical composition identification and network analysis, and transcriptome sequencing increases the accuracy of network prediction. This research strategy provides an efficient way to analyze chemical constituents and explore the pharmacological mechanism of TCM.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE165272>

## AUTHOR CONTRIBUTIONS

PW performed the experimental design and drafted the manuscript. YJ and HC performed the analysis of chemical constituents. JX and HC performed the analysis of network pharmacology. QG performed the cell experiment. XD, TZ, JZ, and CS helped to identify the chemical constituents. All authors read and approved the final manuscript.

## FUNDING

This work was supported by grants from the National Key Research and Development Program of China (2017YFC1702104), National Natural Science Foundation of China (81774201), National Key Research and Development Program of China (2017YFC1702303), and the National Natural Science Foundation of China (81830111). The funding agencies had no role in the study design, the collection, analysis, or interpretation of data, the writing of the report, or the decision to submit the article for publication.

## ACKNOWLEDGMENTS

Thank Liaoning Haohushi Pharmaceutical (Group) Co., Ltd. for providing WBT samples.

Protection against hypoxia injury is an important therapeutic strategy for treating hypertensive nephropathy. In this study, the effects of Qian Yang Yu Yin granule (QYYY) on spontaneously hypertensive rats fed with high salt diet and HEK293T cells exposed to hypoxia were investigated. After eight weeks' treatment of QYYY, blood pressure, serum creatinine, serum cystatin C, blood urea nitrogen, urinary  $\beta$ 2-microglobulin, urinary N-acetyl- $\beta$ -glucosaminidase, and urinary microalbumin were assessed. The changes of hypoxia-inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ), pyruvate kinase M2 (PKM2), glucose transport 1 (GLUT1), lactate dehydrogenase A (LDH-A), connective tissue growth factor (CTGF), transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1), ATP, lactate, pyruvate, and pathology were also assessed *in vivo*. HEK293T cells pre-treated with QYYY and/or HIF-1 $\alpha$  over expressing cells were cultured in a three gas hypoxic incubator chamber (5% CO<sub>2</sub>, 1% O<sub>2</sub>, 94% N<sub>2</sub>) for 12 h and then the expressions of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, CTGF, TGF- $\beta$ 1, ATP, lactate, and pyruvate were detected. Our results showed that QYYY promoted the indicators of renal inflammation and fibrosis mediated by HIF-1 $\alpha$ /PKM2 positive feedback loop *in vivo* and *vitro*. Our findings indicated that QYYY treated hypertensive nephropathy by regulating metabolic reprogramming mediated by HIF-1 $\alpha$ /PKM2 positive feedback loop.

**Keywords:** hypertensive nephropathy, metabolic reprogramming, HIF-1 $\alpha$ , PKM2, Qian Yang Yu Yin granule

## INTRODUCTION

Hypertension is a commonly observed cardiovascular disease and kidney damage is one of the major complications found in patients with hypertension. Hypertension is one of the important causes of chronic kidney disease. Statistics from the American Nephrology Association in 2009 showed that about 28% of patients with end-stage kidney disease were induced by hypertension (Mahmoodi et al., 2012). Traditional Chinese medicine (TCM) has its unique curative effects in the treatment of hypertensive renal damage, but the mechanism of TCM in the treatment of hypertensive renal damage is insufficient (Guo et al., 2019). Under the guidance of the theory of "blood stasis and heat" in TCM, Qian Yang Yu Yin granule (QYYY) was created and applied as hospital preparation and has been widely used in clinical practice for more than 20 years in Jiangsu Province Hospital of Chinese

Medicine. It is safe and effective in treating hypertensive kidney injury. Previous studies of our project group showed that QYYY had antioxidant, anti-inflammatory and anti fibrosis effects (Chen et al., 2013; Wang et al., 2014; Yan D et al., 2014; Ding et al., 2015; Yan et al., 2018; Liu et al., 2019; Zhang et al., 2020).

Metabolic reprogramming refers to the change of cell metabolic mode. In normal cells, when oxygen is sufficient, cells primarily obtain energy through the process of oxidative phosphorylation. However, under hypoxia, cells obtain energy through glycolysis, pentose phosphate and other pathways. This switch of cell energy acquisition mode has been termed as metabolic reprogramming (Vander et al., 2009; Krisher and Prather, 2012). Kidney is an organ that requires high-energy consumption. Therefore, the normal and optimal energy metabolism system serves as an important biochemical basis to maintain the specific structure and physiological functions of the kidney. A number of previous studies have reported that alteration in renal cell metabolism from oxidative phosphorylation to glycolysis is the main feature of cell activation during renal fibrosis and inhibition of renal cell glycolysis can significantly reduce renal fibrosis (Ding et al., 2017). Moreover, gene and protein analyses have showed that the expression of glycolytic enzyme was significantly up-regulated in renal interstitial fibroblasts treated with unilateral ureteral obstruction (UUO) or transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1). In nephropathy caused by UUO or renal interstitial fibroblasts treated with TGF- $\beta$ 1, the aerobic glycolysis flux was increased with glucose uptake and lactate production and it was reported to be positively correlated with the fibrosis process. Glycolysis inhibitors can be used as a potential anti fibrosis strategy.

Protection against hypoxia injury is an important therapeutic strategy for treating hypertensive nephropathy (Watson et al., 2019). Hypoxia inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ) is a special protein distributed in mammalian cells. Knockout or inhibition of HIF-1 $\alpha$  effectively improved hypertensive renal injury (Huang et al., 2019). In renal injury model, HIF-1 $\alpha$  mediated gene expression in renal medulla such as glucose transporter 1 (GLUT1), pyruvate kinase M2 (PKM2), connective tissue growth factor (CTGF), TGF- $\beta$ 1, and other related genes were increased. A related study showed that long-term over-expression of HIF-1 $\alpha$  was a pathogenic factor leading to chronic kidney injury and stimulating the expression of HIF-1 $\alpha$  in cells induced renal injury, hypertension and disease progression (Armutcu et al., 2019). Moreover, a related study found that the level of serum HIF-1 $\alpha$  may reflect the degree of damage of chronic glomerulonephritis and actively participate in the occurrence and development of chronic glomerulonephritis (Dallatu et al., 2014). It has been reported that an increase of HIF-1 $\alpha$  level could participate in the formation of proteinuria, promote metabolic reprogramming and renal fibrosis, and thereby aggravate the progressive deterioration of renal function. Our previous study found that HIF-1 $\alpha$  was highly expressed in hypertensive renal injury model (Wu, 2020). Therefore, we speculated that HIF-1 $\alpha$  is a key target of metabolic reprogramming of renal cell in hypertensive renal injury model.

A large number of studies have confirmed that HIF-1 $\alpha$  is closely related to PKM2 (Luo et al., 2011). For instance, Hasan D found that the antisense chain of the first intron of PKM gene contained hypoxia response element (HRE), and proved that HIF-1 $\alpha$  significantly promoted the expression of PKM2, which also formed a positive feedback mechanism at the gene level and played a key role in cell metabolic reprogramming (Hasan et al., 2018). In another study, Chai Xin Xin used shikonin, a specific inhibitor of PKM2, to down-regulate the expression of PKM2. They found that the down-regulation of PKM2 in breast cancer cells caused the down-regulation of HIF-1 $\alpha$  (Chai et al., 2019). Therefore, we speculated that HIF-1 $\alpha$ /PKM2 positive feedback is the key pathway of metabolic reprogramming of renal cell in hypertension.

## MATERIALS AND METHODS

### Preparation of Qian Yang Yu Yin

QYYY (Batch No. Z20100007) was obtained from Jiangsu Province of Chinese Medicine. It is made up of *Cyathula officinalis* K. C. Kuan [Amaranthaceae; cyathulae radix], *Scrophularia ningpoensis* Hemsl [Scrophulariaceae; scrophulariae radix], *Bidens pilosa* L. [Asteraceae; *Bidens bipinnata* L.], *Cornus officinalis* Siebold and Zucc [Cornaceae; corni fructus], *Alisma plantago-aquatica* subsp. orientale (Sam.) Sam. [Alismataceae; alismatis rhizoma] and *Reynoutria multiflora* (Thunb.) Moldenke [Polygonaceae; polygoni multiflori radix] (Rivera et al., 2014). Detailed information on the components of QYYY is listed in **Table 1**. The preparing process of QYYY was as below: six ingredients were mixed together. Then the mixture was decocted with 12 times of the amount of water twice, for 1 h each time. The supernatant obtained by high-speed centrifugation was concentrated to a relative density of 1.2 g/ml at 60°C. After stevioside was added to a concentration of 1% (weight/volume), the concentrated supernatant was mixed with dextrin and granulated in a fluidized bed granulator. The obtained particles were dried at 60°C for 1 h and then stored at 4°C (Ding et al., 2015). High performance liquid chromatogram (HPLC) was established to determine the active components in QYYY and 2,3,5,4'-tetrahydroxystilbene-2-O- $\beta$ -D-glucopyranoside (2,3,5,4'-TDG), morroniside, harpagide, ecdysterone, and hyperin were detected. The quality evaluation of QYYY is shown in **Table 2** (Zhang et al., 2020).

### Animals and Treatment

50 spontaneously hypertensive rats (SHR), 10 Wistar-Kyoto rats (WKY), 8 weeks old, male, weighing 200  $\pm$  30 g, were purchased from Beijing Weitong Lihua Experimental Animal Technology Co., Ltd. After four weeks of adaptive feeding, the rats were weighed and administrated. SHR were randomly divided into five groups: model group, QYYY (low, medium and high dose) group and valsartan group. Wistar-Kyoto rats (WKY) of the same age were used as the control group. WKY were fed with normal salt diet (0.4% NaCl) while SHR were fed with high salt diet (4% NaCl) for 8 weeks to establish hypertensive nephropathy model.

**TABLE 1 |** The components of Qian Yang Yu Yin.

Components	Chinese name	Family	Amount used (g)
<i>Cyathula officinalis</i> K. C. Kuan	Chuan Niu Xi	Amaranthaceae	170
<i>Scrophularia ningpoensis</i> Hemsl	Xuan Shen	Scrophulariaceae	180
<i>Bidens pilosa</i> L.	Gui Zhen Cao	Asteraceae	110
<i>Cornus officinalis</i> Siebold and Zucc	Shan Zhu Yu	Cornaceae	108
<i>Alisma plantago-aquatica</i> subsp. orientale (Sam.) Sam	Ze Xie	Alismataceae	180
<i>Reynoutria multiflora</i> (Thunb.) moldenke	He Shou Wu	Polygonaceae	180

**TABLE 2 |** Quality evaluation of Qian Yang Yu Yin.

and then be treated with QYYY or valsartan for another 8 weeks. QYYY group: QYYY granule (low dose 3.2 g/kg/d, medium dose 6.4 g/kg/d, high dose 12.8 g/kg/d) was given by gavage; valsartan group: valsartan (17 mg/kg/d) was given by gavage. This dose was 10 folds of clinic dosage according to the pharmacology experimental methodology of TCM which had obvious curative effect based on the results of the previous studies (Wang, 2020). After 8 weeks' treatment of QYYY or valsartan, serum creatinine (S-Cr), serum cystatin C (CysC), blood urea nitrogen (BUN), urinary  $\beta$ 2-microglobulin ( $\beta$ 2-MG), urinary N-acetyl- $\beta$ -glucosaminidase (NAG), and urinary microalbumin (mALB) were assessed. The changes of HIF-1 $\alpha$ , GLUT1, CTGF, IL-6, TGF- $\beta$ 1, ATP, lactate, pyruvate, and pathology were also assessed *in vivo*. The Experimental Animal Ethics Committee of Affiliated Hospital of Nanjing University of Chinese Medicine approved all animal experiments.

## Cell Culture

HEK293T cell was purchased from Cell Bank of the Chinese Academy of Sciences (Shanghai, China) and cultured with Dulbecco's modified Eagle's medium (DMEM; Gibco, United States of America) containing 10% fetal bovine serum (FBS; Gibco, United States of America) in a humidified 5% CO<sub>2</sub> atmosphere at 37°C.

## Preparation of Qian Yang Yu Yin-Containing Serum

Thirty 8 week-old Sprague Dawley rats (SD), male, weighing 200  $\pm$  30 g, were purchased from Beijing Weitong Lihua Experimental Animal Technology Co., Ltd. After four weeks of adaptive feeding, the rats were weighed and administrated. SD were randomly divided into five groups: blank group ( $n$  = 10), positive control group ( $n$  = 5) and QYYY group ( $n$  = 15). Blank group: pure water was given with 1 ml/100 g by gavage; positive

control group: valsartan was given according to 17 mg/kg/d; QYYY group: QYYY granule was given by gavage according to 12.8 g/kg/d. Each group was given drug intervention for seven consecutive days. Thereafter, the rats were anesthetized and their blood was drawn from abdominal aorta. 5–8 ml blood was collected from each rat and kept in the blood collection tube at room temperature for 2 h. After centrifugation at 3,000 rpm for 10 min, the upper serum was aspirated, and the serum of the same group was mixed, filtered with 0.22  $\mu$ M filter, placed into 1.5 ml sterile centrifuge tube and stored at -20°C.

## Hypoxia Treatment

We determined the optimal anoxia time according to the expression of HIF-1 $\alpha$ . HEK 293T cells were placed in a hypoxia cultivator containing a gaseous mixture of 5% CO<sub>2</sub>, 1% O<sub>2</sub>, and 94% N<sub>2</sub> at 37°C for durations of 0, 6, 12, 24, and 36 h respectively. Subsequently, the proteins from HEK 293T cells were extracted with RIPA lysis buffer (Beyotime, China) and subjected to western blot analysis to analyze HIF-1 $\alpha$  expression. We considered the time with the highest HIF-1 $\alpha$  expression as our optimal anoxic exposure time. In our study, we found that HIF-1 $\alpha$  expression peaked at 12 h of hypoxia, so we performed our experiments at 12 h of hypoxia in this study. Hypoxia was induced using a three-gas hypoxia incubator chamber (5% CO<sub>2</sub>, 1% O<sub>2</sub>, and 94% N<sub>2</sub>). For drug intervention, cultured HEK 293T cells were pre-treated with QYYY for 1 h before hypoxia. Cells were randomly divided into following groups: Model group (Hypoxia + 10% blank serum); QYYY group (Hypoxia + 5% QYYY-containing serum + 5% blank serum) and valsartan group (Hypoxia + 10% Valsartan-containing serum). The control group was maintained in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C till end of study.

## MTT Assay

The proliferation abilities of HEK 293T cells for 0, 6, 12, 24, and 36 h in the anoxic incubator were assessed by MTT assay. HEK293T cells were cultured in 96-well plates with 10% FBS in a three-gas hypoxia incubator chamber (5% CO<sub>2</sub>, 1% O<sub>2</sub>, and 94% N<sub>2</sub>) for 0, 6, 12, 24, and 36 h, respectively. Then 20  $\mu$ l MTT was added and then cultured for another 4 h. Finally, 150  $\mu$ l DMSO was added. Plates were shaken for 10 min at room temperature. We used microplate reader to measure absorbance at 570 nm.

## Western Blot

The protein was extracted by RIPA lysis buffer (Beyotime Biotechnology, Shanghai, China) mixed with

phenylmethanesulfonyl fluoride (PMSF). The quantity of proteins was measured using the BCA assay (Beyotime Biotechnology, Shanghai, China). 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis were used to separate different molecular weight proteins. Gels were then transferred onto PVDF membranes. Nonfat milk was used of for 1 h then and the membranes were incubated with the primary antibody against HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, IL-6, and GAPDH at 4°C overnight. Peroxidase-conjugated second antibody were used for 1 h on the shaking table at room temperature. Protein bands were detected by ChemiDoc XRS imaging system (Bio-Rad, United States of America) after using ECL reagents.

### Real-Time Quantitative PCR Analysis

The total RNA was extracted by using Trizol (Ambion, United States). The High Capacity cDNA Reverse Transcription Kit (Vazyme, Nanjing, China) was used to conduct the reverse transcription. SYBR Green chemistry (Vazyme, Nanjing, China) on a 7,500 fast RT-PCR system was used to perform amplified reaction. The primers (Invitrogen Co, Shanghai, China) were listed in **Supplementary Table S1**. The ratio of the mRNA expression of the target gene vs that of  $\beta$ -actin was defined as  $2^{-\Delta\Delta C_t}$ .

### Lentiviral Transduction to Establish Stable Cell Lines

HIF-1 $\alpha$ -overexpression, PKM2-overexpression, HIF-1 $\alpha$ -knockdown, and PKM2-knockdown lentiviruses were generated by Genechem Co., Ltd (Shanghai, China). Thereafter, over-expression and silencing lentiviral vectors of HIF-1 $\alpha$  were transfected into 293T cells when multiplicity of infection was 10. Green fluorescent protein was then expressed in all the lentiviral vectors. We also collected other lentiviral vectors without carrying HIF-1 $\alpha$  or PKM2 for excluding the influence of lentivirus itself on transfection. The stable cell lines were selected by using 2  $\mu$ g/ml puromycin (VWR, America) in medium. The levels of HIF-1 $\alpha$  and PKM2 were detected by using qPCR and western blotting.

### Kits for ATP, Lactate and Pyruvate

Levels of ATP, lactate and pyruvate were measured using the assay kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China) according to the instruction of manufacturer.

### HE Staining

The kidney tissues were fixed with 4% paraformaldehyde for 24 h, dehydrated gradiently in turn, and embedded in the paraffin wax blocks. The blocks were labelled based on the different treatment groups. The wax block was thereafter sliced, dewaxed and washed. Hematoxylin staining and eosin staining were used in a sequence.

### Masson Staining

The kidney tissues were fixed and sectioned as described above under HE staining. Weigert's iron hematoxylin staining was used to stain the nucleus, and ponceau S was used thereafter for

5–10 min. After rinsing with distilled water, they were treated with molybdophosphoric acid for 3–5 min. The samples were then stained using Aniline blue again for 5 min and treated with 1% glacial acetic acid for 1 min. The slides were then dried, mounted. The samples were finally observed by microscope and the images were analyzed.

### Immunofluorescence Staining

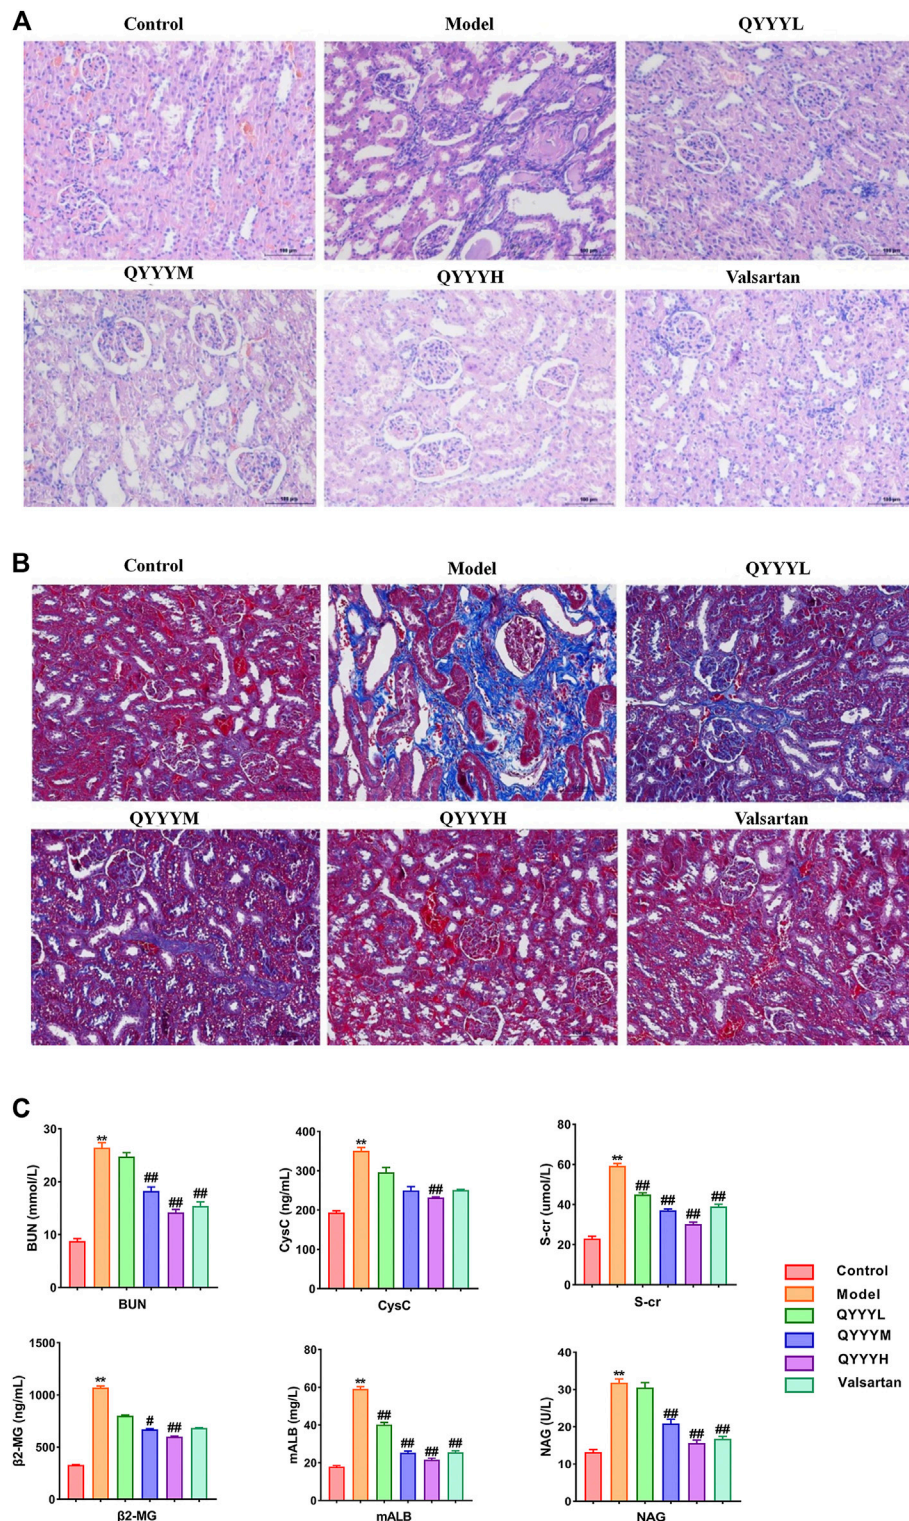

For immunocytochemistry, cells were seeded on poly-D-lysine precoated cell climbing films (Shanghai wohong Biotechnology Co., Ltd) in 12-well culture plate. The medium was removed and the cells were washed with PBS three times for 5 min each and then fixed with 4% paraformaldehyde for 15 min at room temperature. After washing with PBS three times for 5 min each, the fixed cells were blocked by using 0.3% Triton X-100/PBS for 1 h. Cells were incubated with the primary antibody, HIF-1 $\alpha$  (Proteintech: 20960-1-AP), PKM2 (Proteintech: 60268-1-Ig), GLUT-1 (Proteintech: 66290-1-Ig), LDH-A (Proteintech: 19987-1-AP) diluted in 1% BSA in PBS overnight at 4°C. After washing three times with PBS, cells were incubated for 1.5 h with CoraLite488-conjugated Affinipure Goat Anti-Rabbit IgG (H + L) (Proteintech: SA00013-2) or CoraLite594-conjugated Goat Anti-Mouse IgG (H + L) (Proteintech: SA00013-3) secondary antibodies. The unbound secondary antibody was removed with three washes of PBS for 5 min each. Next, the samples were counterstained with DAPI (Beyotime Biotechnology). Samples were visualized on fluorescence microscopes (Nikon, Japan). The intensity was quantified using ImageJ software.

### Immunohistochemistry

The rat kidney tissues were fixed and processed as described above for HE staining. The tissue sections were then placed in EDTA antigen repair buffer (pH = 9.0) for 15 min. After cooling, the slides were placed in PBS (pH = 7.4). The slides were shaken and washed for three times on the shaking table for 5 min each time. The slides were then placed in 3% hydrogen peroxide solution and incubated for 25 min at room temperature in the dark. The slides were shaken and washed for three times as before. The tissues were incubated with the primary antibody overnight at 4°C in a wet box. After washing three times with PBS, the tissues were incubated with secondary antibodies for 50 min at room temperature. The secondary antibody was removed by washing three times with PBS for 5 min each. After the slides have dried, DAB solution was added to observe the color, and then stained with hematoxylin for 3 min. Thereafter, dehydration was carried out, and the slides were observed under microscope, and the images were collected and analyzed. The optical density of immunohistochemical images was analyzed by ImageJ software.

### Bioinformatics Analysis and Network Pharmacology of Qian Yang Yu Yin

All of the compound data of the six botanical drugs contained in QYYY were retrieved from TCMSP and Chemistry database, and their corresponding ADME indices, including oral bioavailability (OB) and drug likeness (DL), were collected. The screening

**FIGURE 1** | QYYY promoted pathology, fibrosis and renal function *in vivo*. SHR were randomly divided into five groups: Model group, QYYYL (low dose 3.2 g/kg/d), QYYYM (middle dose 6.4 g/kg/d), QYYYH (high dose 12.8 g/kg/d) group and valsartan group (17 mg/kg/d). WKY of the same age were used as the control group. WKY were fed with normal salt diet (0.4% NaCl) while SHR were fed with high salt diet (4% NaCl) for 8 weeks to establish hypertensive nephropathy model and then be treated with QYYY or valsartan for another 8 weeks. **(A)** Effects of QYYY on renal histomorphology in rats. **(B)** Effects of QYYY on masson staining method for staining renal fibrosis. **(C)** Effects of QYYY on renal function in SHR. \* $p < 0.05$  and \*\* $p < 0.01$  as compared with the control group. # $p < 0.05$  and ## $p < 0.01$  as compared with the model group.

conditions were  $OB \geq 30\%$  and  $DL \geq 0.18$ . The putative target proteins of these active compounds were searched through TCMSP. The putative target proteins names were converted into gene names through UniProt database. With the help of Cytoscape 3.7.0 software, a network was constructed to connect the candidate compounds of QYYY with the putative targets. All of the hypertensive nephropathy-associated genes were obtained from the OMIM and GeneCards databases. The acquired genes were overlapped with the putative target proteins from QYYY. Upload the intersection target genes to the STRING platform to perform KEGG enrichment analysis and structure protein-protein interaction network.

## Statistical Analysis

SPSS 20 software was used to statistical analysis. The differences were considered statistically significant when  $p < 0.05$ .

## RESULTS

### Qian Yang Yu Yin Promoted Blood Pressure, Pathology, Fibrosis, Renal Functions *In Vivo*

Firstly, we successfully established the model by 12-week-old SHR which were fed with high salt diet (4% NaCl) for 8 weeks. We observed the effects of QYYY on BP, pathology, fibrosis and renal function *in vivo* to identify the effects of QYYY on hypertensive nephropathy. Effects of QYYY on renal histomorphology in rats were shown in **Figure 1A**. In model group, the arrangement of renal tubules was observed to be loose and the volume of epithelial cells was relatively smaller. In QYYYH and valsartan group, the atrophy of glomeruli was not obvious and the vacuoles in renal small cysts were improved (**Figure 1A**). After observing the effects of QYYY on masson staining method for staining renal fibrosis, it was found QYYY and valsartan effectively improved the renal fibrosis (**Figure 1B**). The effects of QYYY on indicators of BP and renal function including S-Cr, CysC, BUN,  $\beta$ 2-MG, NAG, and mALB in rats were shown in **Supplementary Tables S2 and S3; Figure 1C**. The results showed that QYYY significantly decreased the levels of S-cr, CysC, BUN, mALB, NAG, and  $\beta$ 2-MG in SHR. These data suggest that QYYY can treat hypertensive nephropathy effectively.

### Network Pharmacology Prediction of the Potential Active Compounds in Qian Yang Yu Yin and Corresponding Pathways Related to Hypertensive Nephropathy

After identifying that QYYY can effectively treat hypertensive nephropathy, we performed a network pharmacology investigation of QYYY to determine its candidate active compounds and the corresponding pathways underlying the progression of hypertensive nephropathy. Firstly, a library for active compounds of the six botanical drugs in QYYY was constructed based on online databases and literature mining.

Only compounds with favorable pharmacokinetic parameters of oral bioavailability ( $OB \geq 30\%$ ) and drug-likeness ( $DL \geq 0.18$ ) were included (**Figure 2A**) and their chemical information are listed (**Supplementary Table S4**). Secondly, we screened 181 putative target proteins from the 46 active compounds in QYYY and 30 candidate compounds were identified. To elucidate the multiple interactions of these target proteins, we constructed a Drug-Compound-Target (D-C-T) network (**Figure 2B**). To further identify the effects of QYYY on hypertensive nephropathy, 2,456 hypertensive nephropathy-associated genes were extracted from databases and 120 of these genes were overlapped with putative target proteins of QYYY (**Figure 2C**). KEGG analysis of the 120 gene targets (**Figure 2D**) showed that pathways involved in HIF-1 signaling pathway. PPI network (**Figure 2E**) was established to understand the possible regulatory mechanism and its relationship.

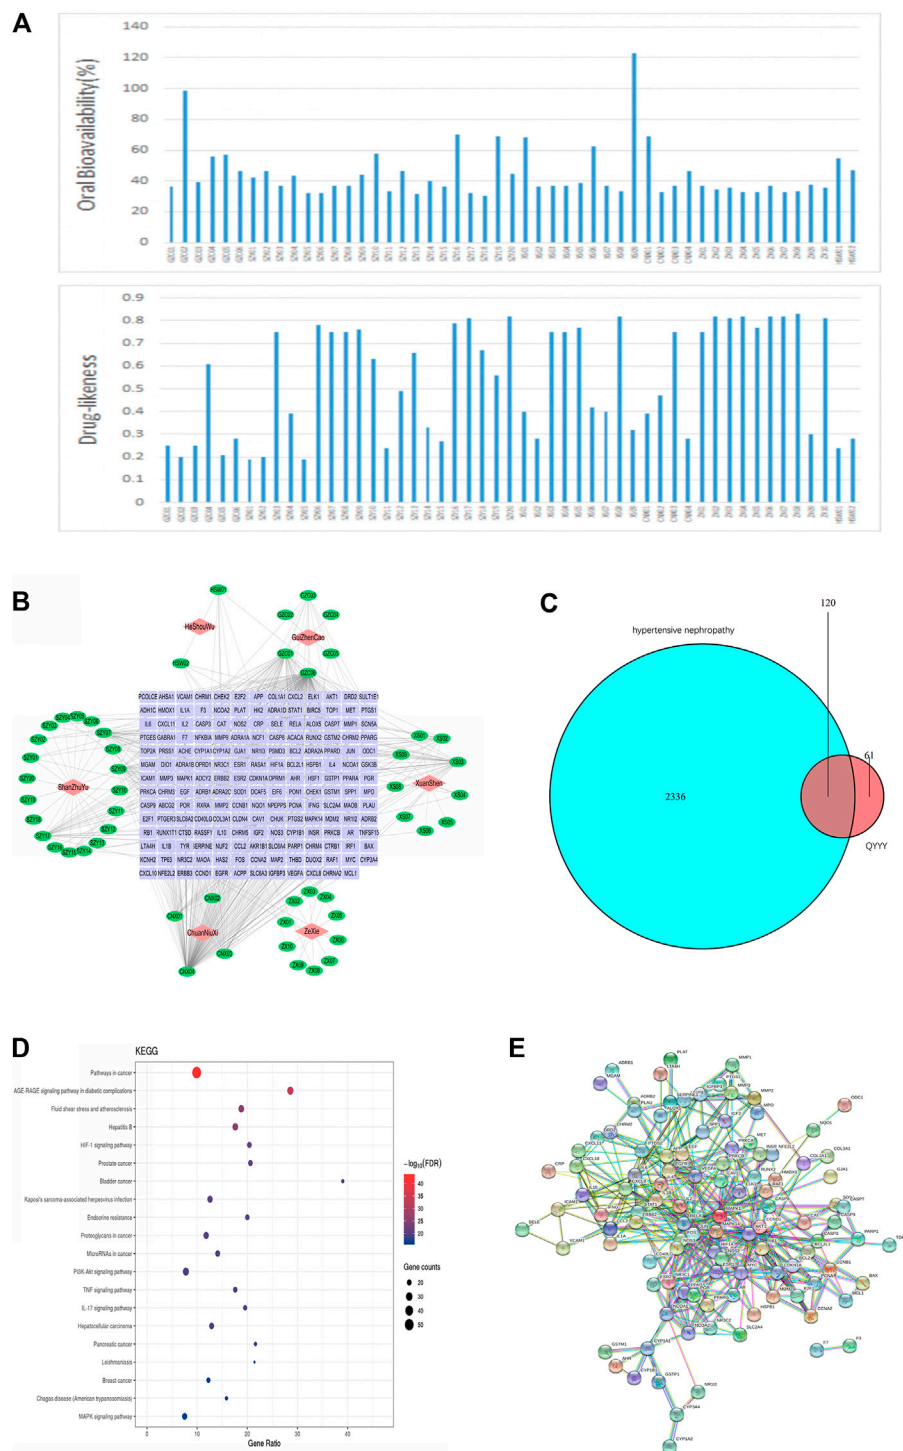

### Qian Yang Yu Yin Promoted HIF-1 $\alpha$ , PMK2, Metabolic Markers, Renal Inflammation and Fibrosis *In Vivo*

According to the results of the above network pharmacology prediction and some related studies. We speculated that QYYY can improve HIF-1 $\alpha$ , PKM2 and related metabolism, inflammation, and fibrosis indexes. Therefore, we observed the effects of QYYY on HIF-1 $\alpha$ , PMK2, metabolic markers, renal inflammation, and fibrosis *in vivo*. Western blot results indicated that QYYY significantly decreased the expression of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, and IL-6 in SHR (**Figure 3A**). The nucleoprotein expression of HIF-1 $\alpha$ , PKM2 were significantly increased and cytoplasmic protein of HIF-1 $\alpha$ , PKM2 were significantly decreased in model group. It triggered the nuclear translocation and increased the transcriptional activity of HIF-1 $\alpha$  and PKM2 in model group. QYYY significantly increased the cytoplasmic level of HIF-1 $\alpha$  compared to model group and blocked HIF-1 $\alpha$  nuclear accumulation significantly (**Figure 3F**). The results by using kits for ATP, lactate and pyruvate indicated that QYYY significantly increased the production of ATP and decreased the production of pyruvate and lactate in SHR (**Figure 3B**). QPCR results showed that QYYY significantly decreased the expression of HIF-1 $\alpha$ , PKM2, CTGF, TGF- $\beta$ 1, and TNF- $\alpha$  in SHR (**Figure 3C**). Immunohistochemistry showed that QYYY significantly decreased the expression of HIF-1 $\alpha$  and PKM2 in SHR (**Figures 3D,E**). These data suggest that QYYY can improve metabolic markers, renal inflammation and fibrosis *in vivo* to treat hypertensive nephropathy.

### Qian Yang Yu Yin Promoted HIF-1 $\alpha$ , PMK2, Metabolic Markers, Renal Inflammation and Fibrosis *In Vitro*

To further determine the effects of QYYY on HIF-1 $\alpha$ , PMK2, metabolic markers, renal inflammation, and fibrosis in hypertensive nephropathy. We also observed the curative effect *in vitro*. Hypoxia can stimulate the proliferation of mesangial and epithelial cells, thereby modulating the

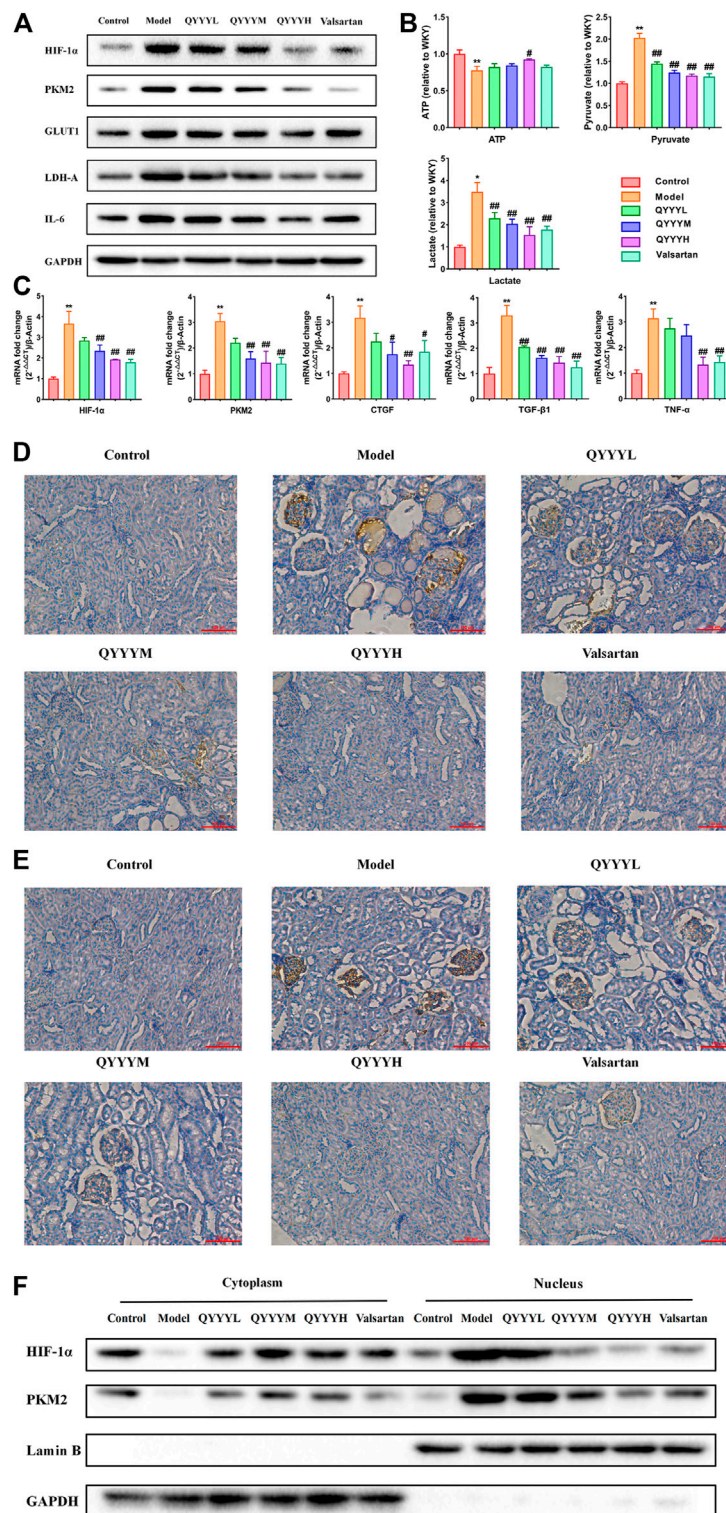

**FIGURE 2 |** Network pharmacology prediction of the potential active compounds in QYYY and corresponding pathways related to hypertensive nephropathy. **(A)** Active compounds in QYYY with oral bioavailability (OB)  $\geq 30\%$  and drug-likeness (DL)  $\geq 0.18$ . **(B)** Drug-Compound-Target Network: the nodes represent drug (red diamond), candidate compounds (green ellipse), and the targets proteins (purple rectangle). **(C)** Venn diagram of 2,456 hypertension nephropathy-associated genes and 181 putative target proteins screened from candidate compounds of QYYY. **(D)** KEGG analysis of the 120 gene targets. **(E)** PPI network of the 120 gene targets.

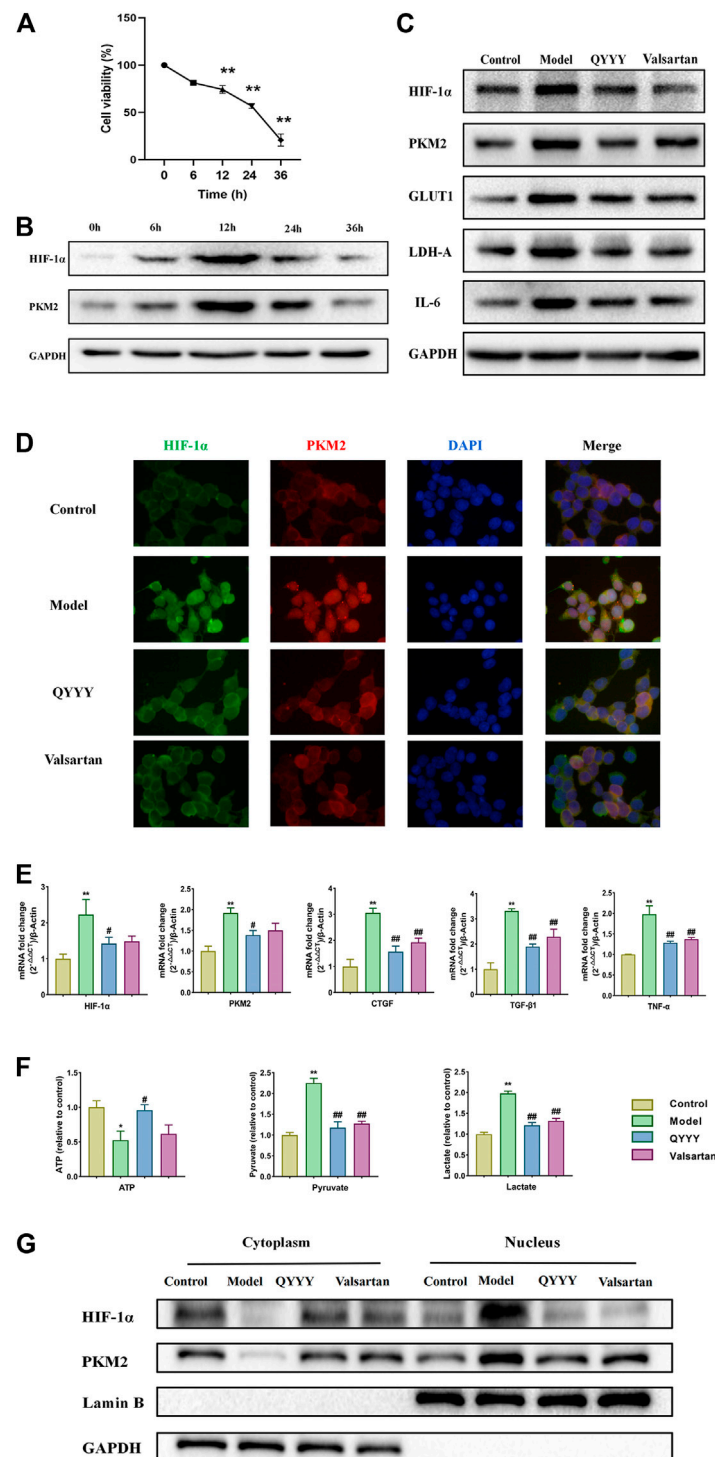

glomerular hemodynamics and leading to glomerular sclerosis and stimulation of tubular epithelial cells and renal interstitial fibroblasts to synthesize a large number of extracellular matrix

components and reduce their degradation. HEK293T cells, human renal epithelial cells, was chosen to be the model of renal damage of the hypertension in the current study. The

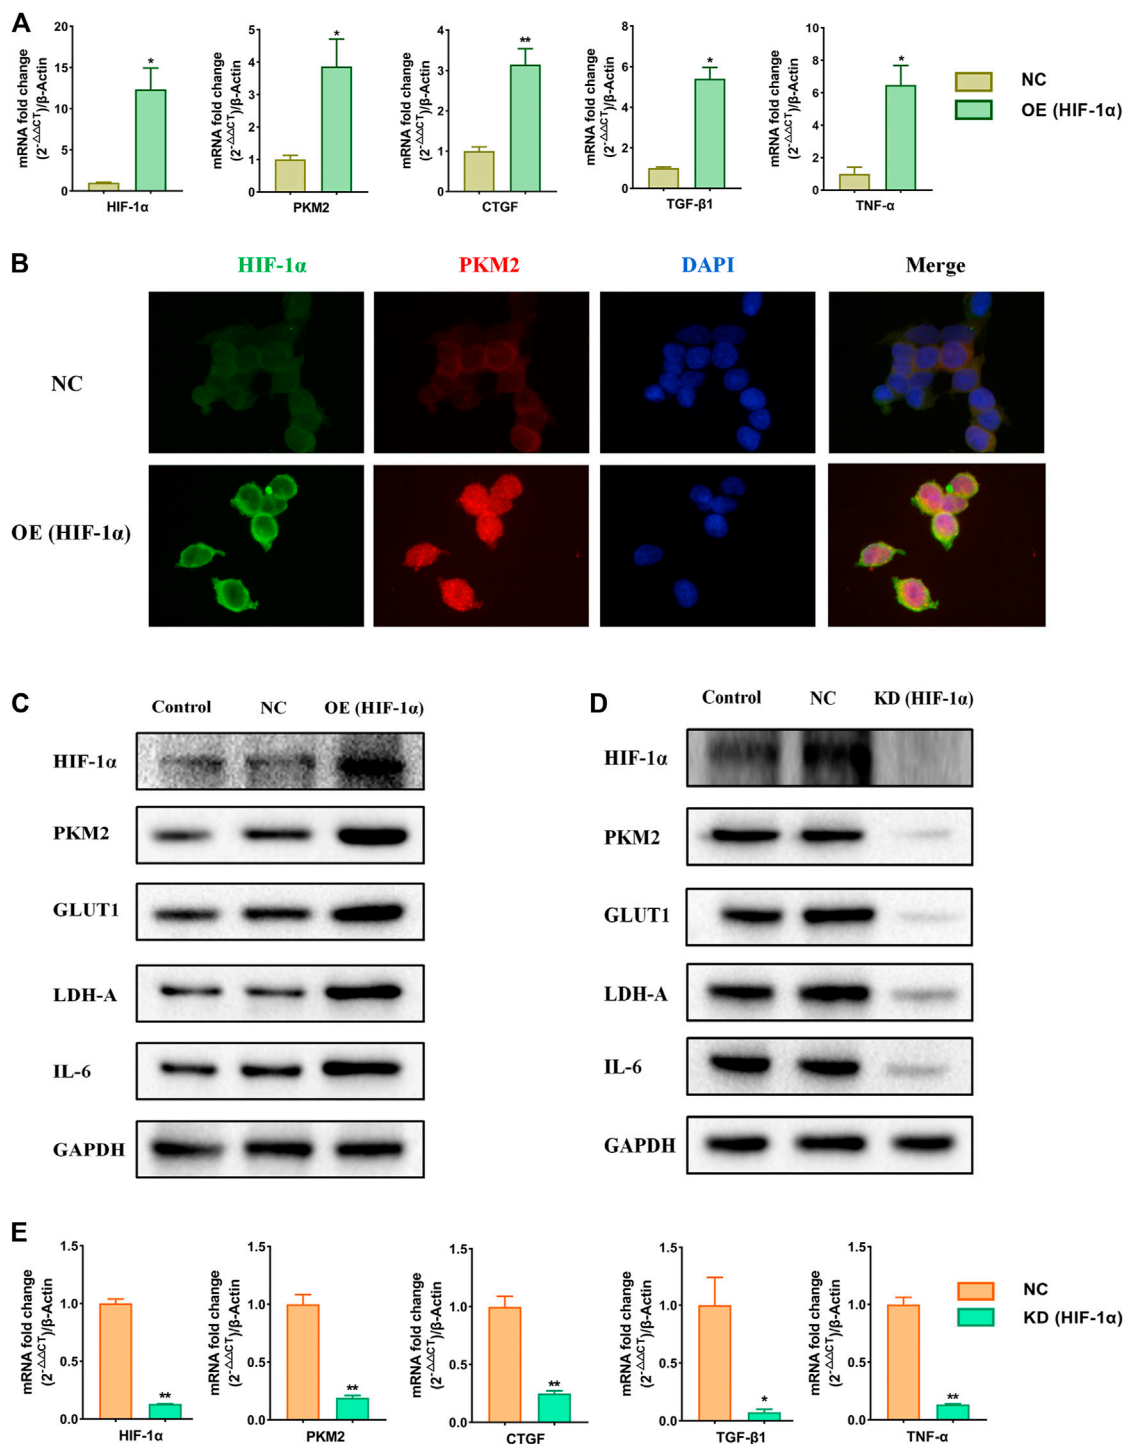

**FIGURE 3** | QYYY promoted HIF-1α, PKM2, metabolic markers, renal inflammation and fibrosis *in vivo*. **(A)** Effects of QYYY on protein expression of HIF-1α, PKM2, GLUT1, LDH-A, and IL-6 in SHR were examined using western blotting. **(B)** Effects of QYYY on changes of ATP, pyruvate and lactate using kits. **(C)** Effects of QYYY on mRNA levels of HIF-1α, PKM2, CTGF, TGF-β1 and TNF-α in SHR were examined using qPCR. **(D)** Effects of QYYY on protein level of HIF-1α in SHR were examined by immunohistochemistry. **(E)** Effects of QYYY on protein level of PKM2 in SHR were examined by immunohistochemistry. **(F)** Effects of QYYY on nuclear and cytoplasmic protein expression of HIF-1α, PKM2 in SHR were examined using western blotting. \* $p < 0.05$  and \*\* $p < 0.01$  as compared with the control group. # $p < 0.05$  and ## $p < 0.01$  as compared with the model group.

Cells were divided into following groups: Model group (Hypoxia + 10% blank serum); QYYY group (Hypoxia + 5% QYYY-containing serum + 5% blank serum) and valsartan group (Hypoxia + 10% Valsartan-containing serum). The control group was maintained in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C till end of study. **(A)** Effects of anoxia time on the cell viability of HEK293T were examined by using MTT. **(B)** Effects of anoxia time on the protein expression of HIF-1α and PKM2 of hypoxic HEK293T cells were examined by using western blotting. **(C)** Effects of QYYY on protein expression of HIF-1α, PKM2, GLUT1, LDH-A, and IL-6 in hypoxic HEK293T cells were examined by using western blotting. **(D)** Effects of QYYY on immunofluorescence staining of HIF-1α and PKM2 in hypoxic HEK293T cells. **(E)** Effects of QYYY on mRNA levels of HIF-1α, PKM2, CTGF, TGF-β1, and TNF-α in hypoxic HEK293T cells were examined by using qPCR. **(F)** Effects of QYYY on changes of ATP, pyruvate and lactate using kits. **(G)** Effects of QYYY on nuclear and cytoplasmic protein expression of HIF-1α and PKM2 in hypoxic HEK293T cells were examined by using western blotting. \**p* < 0.05 and \*\**p* < 0.01 as compared with the control group. #*p* < 0.05 and ##*p* < 0.01 as compared with the model group.

**FIGURE 5 |** Effects of over-expression and knockdown of HIF-1α on relative markers in HEK293T cells. Cells were divided into following groups: control, negative control (NC), HIF-1α-overexpression group (OE) and HIF-1α-knockdown group (KD). **(A)** Effects of over-expression of HIF-1α on mRNA levels of HIF-1α, PKM2, CTGF, TGF-β1, and TNF-α were examined by using qPCR. **(B)** Effects of over-expression of HIF-1α on immunofluorescence staining of HIF-1α and PKM2. **(C)** Effects of over-expression of HIF-1α on proteins of HIF-1α, PKM2, GLUT1, LDH-A, and IL-6 in HEK293T cells were examined by using western blotting. **(D)** Effects of knockdown of HIF-1α on proteins of HIF-1α, PKM2, GLUT1, LDH-A, and IL-6 in HEK293T cells were examined by using western blotting. **(E)** Effects of knockdown of HIF-1α on mRNA levels of HIF-1α, PKM2, CTGF, TGF-β1, and TNF-α in HEK293T cells were examined by using qPCR. \* $p < 0.05$  and \*\* $p < 0.01$ .

effects of different anoxia time on the viability of HEK293T cells were detected via MTT assay. We found there was no significant change in HEK293T cell viability at 6 h, but the cell viability was significantly decreased when treated for 12, 24, and 36 h (**Figure 4A**). We investigated the effect of anoxia time on HEK293T cells, which were exposed to the incremental durations of anoxia time of 0, 6, 12, 24, 36 h. The results showed that HIF-1 $\alpha$  and PKM2 reached its peak level at 12 h of anoxia which suggested a steady anoxic condition (**Figure 4B**). Hence, we selected 12 h as an optimal anoxia time-point in the following study. QPCR and western blot results indicated that QYYY significantly decreased the expression of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, CTGF, TGF- $\beta$ 1, TNF- $\alpha$ , and IL-6 in hypoxic HEK293T cells (**Figures 4C,E**). The nucleoprotein expression of HIF-1 $\alpha$ , PKM2 were significantly increased and cytoplasmic protein of HIF-1 $\alpha$ , PKM2 were significantly decreased in model group. Hypoxia also triggered the nuclear translocation and increased the transcriptional activity of HIF-1 $\alpha$  and PKM2 *in vitro*. The cytoplasmic level of HIF-1 $\alpha$  were significantly increased compared to model group and HIF-1 $\alpha$  nuclear accumulation was significantly blocked by using QYYY (**Figures 4D,G**). The results by using kits for ATP, lactate and pyruvate indicated that QYYY significantly increased the production of ATP and decreased the production of pyruvate and lactate *in vitro* (**Figure 4F**). These data suggest that QYYY can also improve HIF-1 $\alpha$ , PKM2, metabolic markers, renal inflammation and fibrosis *in vitro*.

### Effects of Over-Expression and Knockdown of HIF-1 $\alpha$ on Relative Markers in HEK293T Cells

To further study the role of HIF-1 $\alpha$  in the metabolic reprogramming, HIF-1 $\alpha$ -overexpression and HIF-1 $\alpha$ -knockdown lentiviruses were constructed (**Supplementary Figure S1**). We analyzed the changes of the expression of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, CTGF, TGF- $\beta$ 1, TNF- $\alpha$ , and IL-6 when HIF-1 $\alpha$  was over expressed or knockdowned respectively. The results showed that the expressions of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, CTGF, TGF- $\beta$ 1, TNF- $\alpha$ , and IL-6 were increased significantly following the HIF-1 $\alpha$  over-expression (**Figures 5A–C**). Over-expression of HIF-1 $\alpha$  triggered the nuclear translocation and increased the transcriptional activity of PKM2 (**Figure 5B**). After knockdowning HIF-1 $\alpha$ , the expression of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, CTGF, TGF- $\beta$ 1, TNF- $\alpha$ , and IL-6 was significantly decreased (**Figures 5D,E**). The results suggest that HIF-1 $\alpha$  is the up-stream in the metabolic reprogramming and plays a very important role in hypertensive nephropathy.

### Effects of Over-Expression and Knockdown of PKM2 on Relative Markers in HEK293T Cells

A large number of studies have confirmed that HIF-1 $\alpha$  is closely related to PKM2 and there is a strong mutual influence between them. Therefore, we speculated that HIF-1 $\alpha$ /PKM2 positive

feedback is the key pathway of metabolic reprogramming of renal cell in hypertension (Luo et al., 2011). As is shown above, the results showed that the expressions of PKM2 was increased significantly following the HIF-1 $\alpha$  over-expression. After knockdowning HIF-1 $\alpha$ , the expression of PKM2 was significantly decreased. To further study the influence of PKM2 on HIF-1 $\alpha$  and the role of PKM2 in the metabolic reprogramming, PKM2-overexpression and PKM2-knockdown lentiviruses were constructed (**Supplementary Figure S2**). We analyzed the changes of the expression of HIF-1 $\alpha$ , PKM2, ATP, pyruvate and lactate when PKM2 was over expressed or knockdowned respectively. The results showed that the expressions of HIF-1 $\alpha$ , PKM2, pyruvate and lactate were increased and ATP was decreased significantly following the PKM2 over-expression (**Figures 6A–D**). Over-expression of PKM2 triggered the nuclear translocation and increased the transcriptional activity of HIF-1 $\alpha$  (**Figure 6C**). After knockdowning PKM2, the expressions of HIF-1 $\alpha$ , PKM2, pyruvate, and lactate were significantly decreased and ATP was significantly increased (**Figures 6E–G**). The results suggest that the relationship of HIF-1 $\alpha$  and PKM2 was positive feedback.

### Rescue Assays Certify HIF-1 $\alpha$ as a Target of Qian Yang Yu Yin in Hypertensive Nephropathy

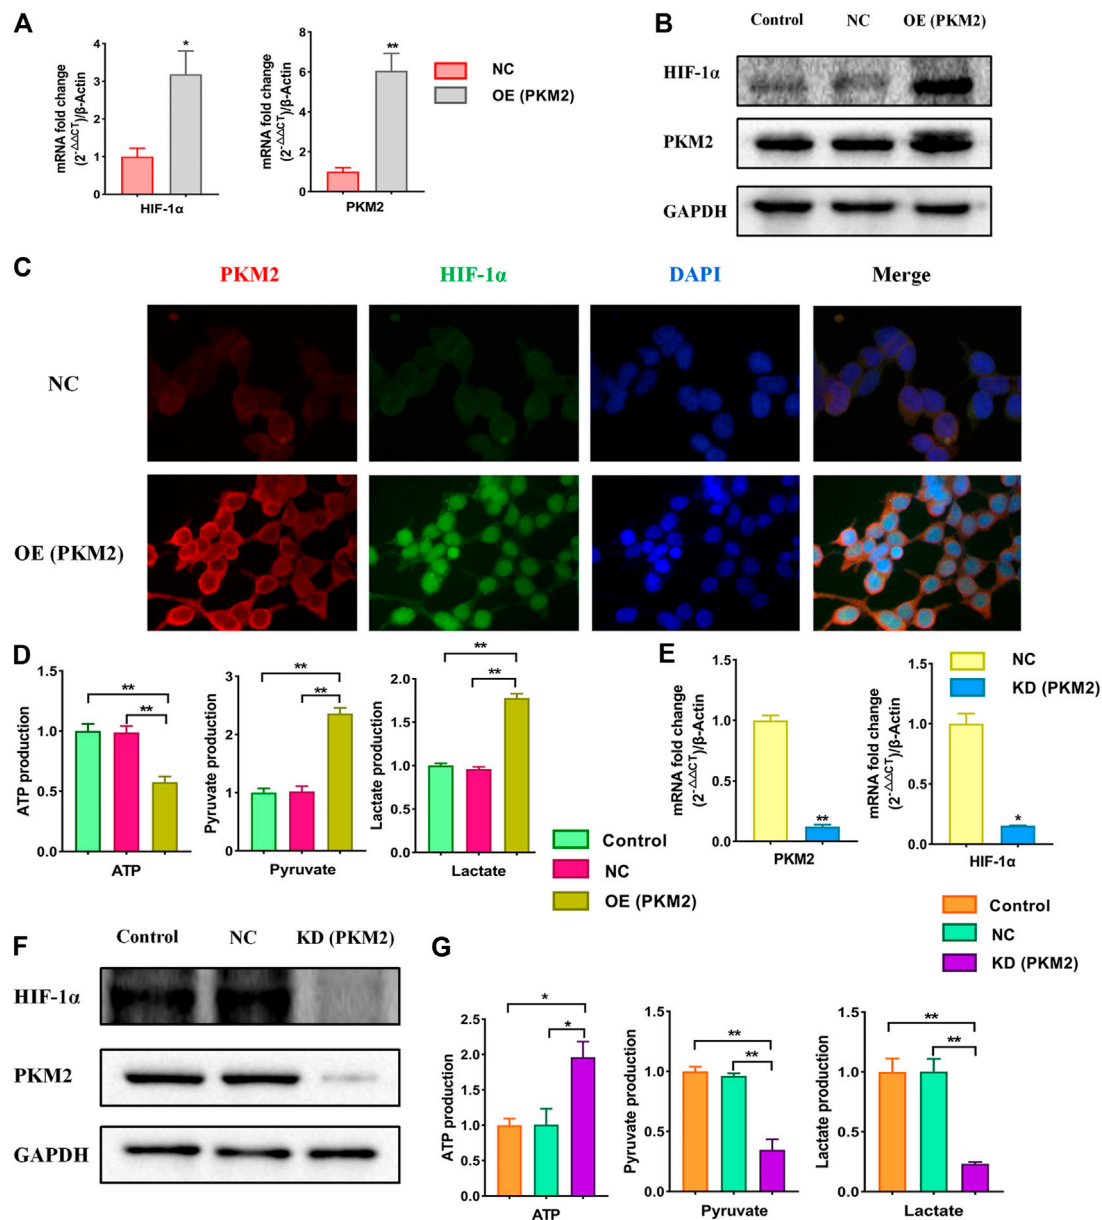

As is shown above, the relationship of HIF-1 $\alpha$  and PKM2 was positive feedback. To further verify that HIF-1 $\alpha$  was a target of QYYY in hypertensive nephropathy and study the role of HIF-1 $\alpha$  and PKM2 in the metabolic reprogramming, we observed the effect of QYYY on HIF-1 $\alpha$  and its downstream PKM2, GLUT1, LDH-A, and IL-6 in hypoxic HEK 293T cells in which HIF-1 $\alpha$  was over expressed and found that over-expression of HIF-1 $\alpha$  partially abolished the effects of QYYY on hypertensive nephropathy. The results showed that the protein expressions of HIF-1 $\alpha$ , PKM2, GLUT1, LDH-A, IL-6, and levels of pyruvate and lactate in Hypoxia + QYYY were significantly lower than those in HIF-1 $\alpha$ -OE + Hypoxia + QYYY. The level of ATP in Hypoxia + QYYY were significantly higher than those in HIF-1 $\alpha$ -OE + Hypoxia + QYYY (**Figure 7**). These data suggest that HIF-1 $\alpha$  is a target of QYYY and HIF-1 $\alpha$ /PKM2 positive feedback plays an important role in improving renal injury of hypertension by regulating metabolic reprogramming.

## DISCUSSION

Our experimental data demonstrated that QYYY improved renal injury of hypertension by regulating metabolic reprogramming mediated by HIF-1 $\alpha$ /PKM2 positive feedback *in vivo* and *in vitro*.

In TCM, hypertension mostly belongs to “vertigo” and “headache” category. Based on clinical and epidemiological studies of TCM, QYYY has been reported to exert the effect of tonifying the liver and kidney, promoting blood circulation and dredging collaterals. It has been awarded the national invention patent (Patent No: ZL 201010205024.2) and the Preparation Certificate of Jiangsu food and drug administration. Clinical

research showed that QYYY significantly improved the early renal damage of hypertension. QYYY contains six Chinese medical botanical drugs. HPLC was established to determine the active components in QYYY and 2,3,5,4-TDG, morroniside, harpgide, ecdysterone, and hyperin were detected (Zhang et al., 2020). In recent years, a number of previous studies have reported that 2,3,5,4-TDG can protect the kidney by reducing the expression of TGF-β1 mRNA (Li et al., 2010; Stanton, 2011).

2,3,5,4-TDG is also closely related to HIF-1 and a related study (Yang and Liu, 2016) has found that it can significantly reduce the production of HIF-1, thus delaying the progression of the disease. Morroniside also has been reported to be useful in protecting the kidney (Liu et al., 2018; Jin et al., 2019). Moreover, disorder of glucose metabolism is still a difficult problem in medical field. Ecdysterone can significantly enhance glucose metabolism, improve the excretion of urinary albumin, inhibit the

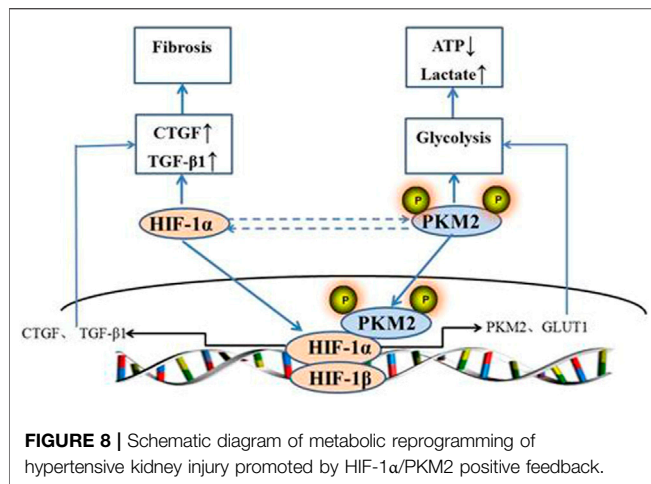

**FIGURE 7 |** Rescue assays certify HIF-1 $\alpha$  as a target of QYYY in hypertensive nephropathy. Over-expression of HIF-1 $\alpha$  partially abolished the effects of QYYY on hypertensive nephropathy. \* $p < 0.05$  and \*\* $p < 0.01$ .

expression of CTGF and collagen IV, and has the potential effect of improving renal fibrosis. It acts as a potential fibrosis antagonist for the renal proximal tubule cells. It might also act through suppressing post-receptor signaling of TGF- $\beta$ 1 and restoring the tubule epithelial character (Zou et al., 2010; Hung et al., 2012; Chen et al., 2017). Hyperin can inhibit renal fibrosis in the rats effectively. It can reduce  $\alpha$ -smooth muscle actin and fibronectin and improve the renal fibrosis (Yan et al., 2014). Therefore, we assume that improvement of metabolic disorder and anti-fibrosis of these compounds may be involved in the inhibitory effect of QYYY on treating renal injury of hypertension. Firstly, we successfully established the model by 12-week-old SHR which were fed with high salt diet (4% NaCl) for 8 weeks and we found QYYY improved BP, pathology, fibrosis, and renal function *in vivo*. In the present study, QYYYL (low dose 3.2 g/kg/d), QYYYM (middle dose 6.4 g/kg/d) and QYYYH (high dose 12.8 g/kg/d) were used and we found that the curative effects were statistically significant when administered in low dosage *in vivo*. In recent years, more and more authoritative studies have emphasized that the metabolic rate of rodents is higher and the results may be meaningless when the starting dose of rodents is too high. The evaluation of doses that are much higher than what can be achieved in humans may have no translational value from a therapeutic point of view. The importance of reasonable initial dosage for experiment was highlighted by relevant authoritative experts (Zou et al., 2012; White and Kearney, 2014; Nair and Jacob, 2016; Heinrich et al., 2020), therefore it is very necessary for us to use a lower starting dose in future experiments. From the existing experimental results, it was identified QYYY had good effects on hypertensive nephropathy. As a TCM, the components present in QYYY are complex and there are many related targets in QYYY, so it is difficult to decipher the mechanism of actions of

QYYY as a whole. In recent years, the advent of network pharmacology has provided a novel method to identify the various active components of TCM, predict its related targets, and decipher its molecular mechanisms, which could be helpful to understand the different complex interactions between the biological systems, drugs and complex diseases from the perspective of network (Li and Zhang, 2013; Boezio et al., 2017; Guo et al., 2019; Zhang et al., 2019; Zhang et al., 2019; Luo et al., 2020). So we then performed a network pharmacology investigation of QYYY to determine its candidate active compounds and the corresponding pathways underlying the progression of hypertensive nephropathy. And the results showed that HIF-1 signaling pathway is a key pathway of QYYY. Moreover, our previous study also found that QYYY improved the early renal damage of hypertension by inhibiting inflammatory reaction and reducing the expression of HIF-1 $\alpha$ , some inflammatory factors and fibrosis indexes (Ding et al., 2015; Yan et al., 2018; Wu, 2020). Many literatures also have shown the strong mutual influence between HIF-1 $\alpha$  and PKM2 and positive feedback of HIF-1 $\alpha$  and PKM2. HIF-1 $\alpha$ /PKM2 positive feedback may be involved in the regulation of hypertensive renal damage by enhancing cell glycolysis (Zhu et al., 2012; Prigione et al., 2014; Wang et al., 2014; Zhu et al., 2014; Luo et al., 2015). Therefore, we speculated that QYYY may affect hypertensive nephropathy via metabolic reprogramming mediated by HIF-1 $\alpha$ /PKM2 positive feedback. As expected, our results showed QYYY significantly improved the metabolic indexes, inflammatory fibrosis factors related to HIF-1 $\alpha$ /PKM2 positive feedback *in vitro* and *in vivo*.

Metabolic reprogramming refers to the change of cell metabolism, which has been extensively studied and an in-depth understanding of this process has been achieved in tumor biology and other fields (Biswas, 2015; Georgoudaki et al., 2016; Li and Zhang, 2016; Schito

and Semenza, 2016; Vaupel et al., 2019; Jin et al., 2020). However, it is still in its infancy in the field of research related to the kidney diseases, some evidences have shown that metabolic reprogramming plays an important role in the development of kidney diseases. As a result, novel studies elucidating the possible role of metabolic reprogramming in hypertensive nephropathy is of great significance for the treatment of renal damage of hypertension. Kidney is a high-energy consuming organ and optimal energy metabolism system is the biochemical basis for maintaining the specific structure and physiological function of kidney. During the early stage of chronic kidney disease, the glomerulus is generally characterized by high filtration and high perfusion. The glomerulus needs more energy. Fibroblasts are often activated and can proliferate rapidly in the renal interstitium. The local area of glomerular hypertrophy represents an anoxic state. In addition, when the glomerulus is in a state of hyperfiltration, the proton pump, which plays the role of renal tubular reabsorption, can also effectively reabsorb a large number of different ions in the urine and thereby increase the consumption of ATP in kidney. Under pathological conditions, the normal oxidative phosphorylation of glucose cannot provide sufficient energy or carbon groups to enable cell proliferation, so the ratio of glycolysis pathway increases. Although the increased ratio of glycolysis pathway can provide sufficient energy and necessary materials for maintaining cell proliferation and division, a few studies have reported that glycolysis pathway can increase renal fibrosis. Additionally, Some studies have also verified the potential relationship between glycolysis and renal fibrosis both *in vivo* and *in vitro*. These reports used mice with UUO as the model of renal fibrosis and found that with an increase of the degree of renal fibrosis, the levels of glucose metabolism related enzymes in the renal tissue increased synchronously. Additionally, the findings *in vitro* experiments have suggested that TGF- $\beta$ 1 could potentially induce renal fibroblast fibrosis and metabolic reprogramming thus increasing glycolysis pathway (Yin et al., 2018). It has been suggested that metabolic reprogramming occurs in the process of renal fibrosis and the enhancement of glycolysis can increase renal fibrosis. Therefore, inhibition of renal glycolysis may function as a new target for the treatment of chronic kidney disease. For instance, Hui Peng found

that the renal injury and fibrosis could be significantly improved by improving renal energy metabolism (Peng et al., 2017). PKM2 is a key rate-limiting enzyme involved in the process of glycolysis, which could directly regulate the occurrence of glycolysis and has been reported to be closely related to embryonic development, tissue fibrosis, tumor, and glucose metabolism (Luo et al., 2011). Our data suggested that the total protein expression of PKM2 *in vivo* and *in vitro* was upregulated and nuclear translocation of PKM2 was enhanced, thereby affecting glycolysis, decreasing ATP, increasing pyruvic acid and lactic acid and aggravated inflammation and fibrosis. QYYY effectively improved hypertensive renal damage through metabolic reprogramming. Glycolysis inhibitors can be used as a potential anti fibrosis strategy. Thus, the process of metabolic reprogramming has a significant potential in the study of hypertensive renal damage.

HIF is a special protein discovered by Semenza in 1992 (Semenza, 1999). HIF-1 $\alpha$  is ubiquitously found in the mammalian cells and plays a role in multiple signaling pathways (Liu et al., 2020). In recent years, the role of HIF-1 $\alpha$  in hypertensive renal damage has attracted more and more attention. Many factors present in the disease microenvironment, such as hypoxia, reactive oxygen species, nitric oxide, and some metabolites can increase the protein level of HIF-1 $\alpha$  and thus enhance cellular aerobic glycolysis, which is a significant feature of renal injury (Gerald et al., 2004; Hsu and Sabatini, 2008; Semenza, 2013; Briggs et al., 2016; Oh et al., 2016; Magistroni and Boletta, 2017). The activation of HIF-1 $\alpha$  signaling pathway may be involved in the regulation of hypertensive renal damage by enhancing cell glycolysis. A large number of studies have confirmed that HIF-1 $\alpha$  is closely related to PKM2. A few studies have suggested that HIF-1 $\alpha$  can potentially regulate reprogramming through early translocation of glycolysis and up regulation of PKM2. For instance, Luo W upregulated the expression of PKM2 through viral transfection and found that the fluorescence level of HIF-1 $\alpha$  was significantly enhanced but the transcriptional activity of HIF-1 $\alpha$  was significantly reduced by knockout of PKM2. Proline hydroxylase 3 can hydroxylate the proline at position 403 and 408 of PKM2, which can facilitate the binding of PKM2 with HIF-1 $\alpha$ , and thereby promote the binding of HIF-1 $\alpha$  with HRE, thus regulating the transcription of downstream genes such as lactate dehydrogenase and glucose transporter. The relationship between HIF and PKM is positive feedback (Prigione et al., 2014). Our data identified the role of HIF-1 $\alpha$  and PKM2 in the metabolic reprogramming in hypertensive renal damage. QYYY played an important role in the treatment of hypertensive renal damage by regulating metabolic reprogramming mediated by HIF-1 $\alpha$ /PKM2 positive feedback loop and HIF-1 $\alpha$  is a key target in the treatment of renal damage of hypertension by QYYY. We found that QYYY inhibited total protein expression of HIF-1 $\alpha$  as well as PKM2 and caused a significant increase in the accumulation of nuclear protein of HIF-1 $\alpha$  and PKM2, thereby improving their downstream target genes by regulating metabolic reprogramming such as aerobic glycolysis induced by HIF-1 $\alpha$  and PKM2 and inhibited inflammation and fibrosis of kidney tissue. And the schematic diagram of metabolic reprogramming of hypertensive kidney injury promoted by HIF-1 $\alpha$ /PKM2 positive feedback is shown in Figure 8.

## CONCLUSIONS

The present study demonstrated the effects of QYYY on the progress of hypertensive nephropathy and we investigated the underlying mechanisms involved in HIF-1 $\alpha$ /PKM2 positive feedback. Our present findings clearly indicated that QYYY inhibited the positive feedback of HIF-1 $\alpha$  and PKM2, reduced the nuclear accumulation of HIF-1 $\alpha$  and PKM2, regulated metabolic reprogramming, and then suppressed renal inflammatory fibrosis and improved hypertensive renal injury. In total, our study provides the basis for the treatment of hypertensive renal injury with TCM by regulating metabolic reprogramming mediated by HIF-1 $\alpha$ /PKM2 positive feedback.

**Background:** Icariin, a traditional Chinese medicine, plays a protective role in the treatment of exercise fatigue. Zinc, a trace element, plays an important role in the reproductive system. Therefore, we aimed to synthesize an Icariin-Zinc complex (by chemical means) and verify its protective effect on exercise fatigue and the reproductive system using animal experiments.

**Methods:** The icariin-zinc complex was prepared by the reaction of icariin carbonyl and zinc ions (molar ratio 1:3). The molecular formula and structural formula of the complex were identified and tested. Fifty-six rats selected by swimming training were randomly divided into six groups: static control, exercise control, icariin, gluconate zinc (G-Zn group), icariin glucose zinc and icariin-zinc exercise (low, high dose/L-E group, H-E group) groups. These groups respectively received the following doses: 1 ml/100 g, daily gavage with NS (for the first two groups), 45 mg/kg icariin, 110 mg/kg Gluconate Zinc, Icariin glucose zinc (45 mg/kg Icariin and 110 mg/kg Gluconate Zinc), 60 mg/kg icariin zinc and 180 mg/kg icariin zinc. After 3 weeks of gavage, we conducted 6 weeks of exhaustive swimming training. Test indices such as exhaustive swimming time of rats and body weight were evaluated after the last training exercise. The seminal vesicles, testes, and prostate gland were weighed, and their indices were calculated. The levels of testosterone (in the plasma) and glycogen (in the liver and muscle homogenates) were also evaluated using ELISA.

**Results:** Compared with the static control group, the exhaustive swimming time of the rats in each group was prolonged. Compared with the other groups, the exhaustive swimming time of the L-E and H-E groups was significantly longer ( $p < 0.01$ ); the Icariin-Zinc complex significantly increased the exhaustive swimming time of the rats. Compared with the static control group, the plasma testosterone content of the L-E and H-E groups increased significantly ( $p < 0.05$ ). Compared with the exercise control group and G-Zn group, the

**Abbreviations:** ICA: icariin; ICP-OES: inductively coupled plasma-optic emission spectrometer; NS: normal saline; ELISA: enzyme linked immunosorbent assay; H&E: hematoxylin & eosin; SD: standard deviation; SPF: specific pathogen free; ROS: reactive oxygen species.

plasma testosterone content of the H-E group also increased significantly ( $p < 0.01$ ). The Icariin-Zinc complex significantly increased the serum levels of testosterone in rats. Compared with the control group, the muscle glycogen reserves of each group decreased, indicating that the muscle glycogen reserves of the rats decreased after swimming. Compared with other groups, the Icariin-Zinc complex can reduce the level of glycogen in the muscles, indicating that it can increase the utilization efficiency of glycogen in muscles. Compared with the static control and exercise control groups, the testicular weight of rats in the administration groups increased slightly. The Icariin-Zinc complex increased the testicular weight, indicating that the function of the reproductive system was improved to some extent.

**Conclusion:** Icariin-Zinc can significantly prolong the exhaustive swimming time, improve exercise ability, and increase the plasma testosterone level (which is beneficial for improving the reproductive ability of male rats). Moreover, the beneficial effect of Icariin-Zinc on the glycogen content, testis index, and other reproductive system glands is dose-dependent.

## BACKGROUND

Fatigue is a complex physiological and pathological that seriously affects human health. Epimedium is a perennial herb belonging to the family Berberidaceae. It has been used for thousands of years to promote male potency. Traditional Chinese medicines are believed to help in tonifying the kidneys and invigorating the Yang, and they have been used to treat impotence, premature ejaculation, lumbago and leg pain, neurasthenia, forgetfulness, and other diseases. Icariin (ICA) is the main active component extracted from *Herba Epimedii* (herbal medicine made from dried aerial parts of *Epimedium*). ICA has many functions such as neuroprotection, antitumoral activity, antioxidative activities, immunomodulation, and promotion of reproductive functions (especially in male mice). It has become a research hotspot at home and abroad (Liu et al., 2004; Tan et al., 2016).

Many *in vivo* studies have shown the beneficial effect of ICA on reproductive functions (Kang et al., 2012; Chen et al., 2014). ICA increases the epididymal sperm count and testosterone level in male rats (Chen et al., 2014). Mechanistically, the improved sexual function of male mice mediated by ICA might be associated with the hypothalamic-pituitary-gonadal axis and the PI3K/AKT/eNOS/NO signaling pathway (Ding et al., 2017). In addition, ICA could protect human sperm from being damaged by  $\text{FeSO}_4/\text{H}_2\text{O}_2$  (Zhan et al., 2014). It can maintain the “Raman fingerprint” of human sperm, suggesting that ICA may serve as a tonifying and replenishing agent of herbal origin that enhances reproductive functions. These show that ICA can promote the function of human and animal reproductive systems and provide a basis for animal experiments.

Zinc is a component of more than 300 types of metal enzymes in the human body (Hennigar and Kelleher, 2012). Zinc is reported to be an essential element for the normal function of the male reproductive system and sperm. It plays an important role in the production, storage, secretion, and function of male

sex hormones (Chu et al., 2016). Studies have shown that there is a relationship between sexual dysfunction and physical fatigue (Young et al., 2017; Fairbanks et al., 2017).

Based on the protective effect of Icariin and Zinc on the reproductive system, we hypothesized that an Icariin-Zinc combination might have a synergistic protective effect on the reproductive system and exercise fatigue.

## METHODS

### Experimental Animals and Drugs

All procedures were performed in accordance with the NIH guidelines for the Care and Use of Laboratory Animals (NIH Publications No. 80–23, revised 1996), and the research protocol was approved by the Ethics Committee of Tianjin University of Traditional Chinese Medicine (TCM-LAEC2019069). Sixty-six Wistar male rats weighing 200–220 g were obtained from the Academy of Military Medical Science in Beijing and housed in special cages in a specific-pathogen-free (SPF) environment, allowing free movement and *ad libitum* access to food and drink. Icariin (purity  $\geq 98\%$ , Lot No. 181209, Shanghai Mochi Biotechnology Co., Ltd.), zinc chloride (GR, lot No. G1820107, Shanghai Alading Biochemical Technology Co., Ltd.), zinc reagent (AR, H08F9S54539, Shanghai Yuanye Biotechnology Co., Ltd.), distilled water, anhydrous ethanol (Shandong Lierkang Medical Technology Co., Ltd.), 75% ethanol (Shandong Lierkang Medical Technology Co., Ltd.), and 0.9% sodium chloride (NS, batch number 19012523, China Otsuka Pharmaceutical Co., Ltd.) were the main chemicals used in the experiment.

### Experimental Instruments

The main instruments used in the experiment were a constant temperature magnetic stirrer (78HW-1, Hangzhou instrument and

**TABLE 1 |** ICP-OES Instrument Operating Conditions.

Working Parameters	Setting Conditions	Working Parameters	Setting Conditions
Power	1200 W	Reading stability delay	10 s

Reading time	10 s		

motor company), a rotary vaporizer (re-2000e, Gongyi Yuhua Instrument Co., Ltd.), a circulating water multi-purpose vacuum pump (SHB-3, Gongyi Yuhua Instrument Co., Ltd.), an electronic analysis balance (BS210s, Beijing Saiduolis Balance Co., Ltd.), mobile phone timer (COR-AL10, honor), swimming sink (L×W×H=100 × 50 × 60 cm), and a water pump (Jiabao “AP1500” type).

## Preparation and Detection of the Icariin-Zinc Complex

### Preparation and Extraction of Icariin-Zinc

Three thousand milligrams of icariin and 1200 mg of zinc chloride were mixed (presumably the molar ratio of icariin to zinc chloride is 2:1 or 1:1 in theory). To make icariin fully react, 1: 2.5 mixture ratio was selected and dissolved in 500 ml (volume fraction is 45%) of ethanol solution, and a constant temperature magnetic stirrer was used (the parameters were set at 400 rpm, 70°C [range 60–80°C] oil bath) to stir the mixture for at least 24 h. The reacting solution was then placed in a water bath at 45°C. The final icariin-zinc product was obtained by centrifugation and was repeatedly washed with pure water to remove unreacted icariin.

### Preparation of the Zinc Reagent Solution

Zinc reagent (0.1 mg) was weighed and dissolved in 125 ml anhydrous ethanol. After it had completely dissolved, it was stored in a brown bottle.

### Identification of Compounds (Colorimetry)

The reaction between the zinc reagent solution and zinc ion was used for identification. The reactant (that is, final icariin-zinc product) was completely dissolved in anhydrous ethanol after the last washing. Adding the zinc reagent solution to it turned the color of the mixture blue; meanwhile, adding the zinc reagent solution to the last washing solution did not change its color to blue. As such, it could be concluded that the reactant was the icariin-zinc complex and that there was no zinc chloride residue in the reactant.

## Molecular Formula and Structural Formula of the Icariin-Zinc Complex

### Sample Pretreatment

A 0.05-g sample of the compound was placed in a microwave digestion tank made up of polytetrafluorethylene. The sample was soaked for 2 h in mixture of 6 ml of nitric acid and 1 ml of hydrogen peroxide. Subsequently, it was digested for 20 min at 190°C. Acid removal, constant volume to 100 ml. This needs to be determined. ICP-OES on-line measurement: A VISTA-MPX inductively coupled

plasma spectrometer (Varian Company, United States), referred to as ICP-OES was used to determine the formula (see **Table 1**).

The measured wavelength was 213 nm. The average of three results were taken.

The Zn<sup>2+</sup> content was 4.6%. Combining the structural formula and molecular weight of icariin, we found that icariin and Zn are 2-coordinated (that is, two carbonyls (C=O) and one Zn<sup>2+</sup> coordinate). The molecular formula is (C<sub>33</sub>H<sub>40</sub>O<sub>15</sub>)<sub>2</sub>Zn<sup>2+</sup>, with a relative molecular weight of 1417 (**Figure 1**).

## Experimental Groups

After 3 days of adaptive feeding and 3 days of swimming training (the rats were trained 20 min/d), the rats were randomly divided into 7 groups with 8 rats in each group. Each group received a basic feeding and distilled water, and was fed freely every day. Each group was treated with different doses of 1 ml/100 g by gavage for 3 weeks (see **Table 2**, Experimental grouping and intervention).

## Anti-Fatigue Experimental Method (Surhio et al., 2017)

The control group did not undergo any training. In the other groups, a swimming trough of 100 × 50 × 60 cm was used as the swimming training device for the rats, and the water depth was set at 50 cm. The water temperature was 31 ± 2°C, and a water pump was installed at the bottom of the water tank to cause the water to flow (the aim was to prevent rats from floating on the water surface). Swimming training to exhaustion was performed every week for a total of 6 weeks. The parameters were changed every week. The first week, the rats exercised without weight, the second week with 2% weight, the third week with 4% weight, and the fourth to the sixth week with 5% weight. Each time, the swimming training was performed to exhaustion. The last time, all groups performed exhaustion swimming training without weight, and the time of swimming before exhaustion was measured. The time from the beginning of swimming to exhaustion which is a measure of the exhaustion exercise ability, was used as an index of anti-exercise fatigue ability. The standard used to determine exhaustion was the inability of the rats to show up on the water surface 10 seconds after sinking.

## Test Indices and Methods of Measurement (Xi et al., 2018)

Each group was weighed 24 h after the last training. Blood samples were taken from the inner canthi of the rats and

**FIGURE 1** | Chemical Synthesis Route of the Icariin-Zinc complex.

**TABLE 2** | Experimental grouping and intervention.

Grouping	Intervention measures
Control group	Normal saline
Exercise group	Normal saline
Icariin group	45 mg/kg Icariin
G-Zn group	110 mg/kg Gluconate Zinc
Icariin glucose zinc	45 mg/kg Icariin, 110 mg/kg Gluconate Zinc
Low dose Icariin zinc exercise group (L-E group)	60 mg/kg Icariin zinc
High dose Icariin zinc exercise group (H-E group)	180 mg/kg Icariin zinc

sodium citrate solution added to prevent coagulation. The samples were incubated in a 37°C water bath for 30 min, centrifuged at 3000 R/min for 10 min, and plasma was separated. The plasma testosterone levels were measured.

All rats were administered with an overdose of 2,2,2-tribromoethanol (640 mg/kg, intraperitoneal injection) for anesthesia. The seminal vesicles, testes, prostate, liver, and the deep quadriceps femoris muscles (without the fascia) were removed. These organs were washed in precooled normal saline to remove the blood stains, dried with filter paper, and stored in a refrigerator at -20°C. The seminal vesicle, testis, and prostate glands were weighed, and their indices (the ratio of seminal vesicle gland, testis, and prostate gland weights to body weight) were calculated.

To prepare the liver and muscle tissue homogenate, appropriate amounts of tissues (0.2–1 g) and precooled normal saline (NS) were added into a beaker in a tissue mass (g) to liquid volume (ml) homogenate medium proportion of 1/9. The tissue was then quickly cut into pieces (the above operations were carried out in an iced water bath). The supernatant was separated and extracted by centrifugation at 4°C, 3000 rpm for 15 min and then refrigerated at 4°C or frozen at -20°C for standard. The supernatant was used to measure the

glycogen content of the liver or muscle homogenate. The remaining mice were killed (anesthetized and euthanized in a CO<sub>2</sub> chamber).

## RESULTS

### Observation of the Feeding and Swimming Behavior

The rats in each group were fed for 6 weeks. At the third week, the rats in each group were more excited, the amount of activity in the cages increased, the fighting phenomenon appeared, the number of squeaks increased, their voices became louder, and they struggled more strongly when grasped and during weighing. The amount of food and drinking water given to the icariin-zinc group and the exercise control group was slightly more than that in the static control group. The swimming abilities of the rats in each group were observed, and the rats in the icariin-zinc group were found to be more active, to jump out of the water and squeak more frequently, and their relative swimming distances were longer.

### Effect of Icariin-Zinc on Body Weight of Rats

Before the beginning of the experiment, the average body weight of the rats in each group was approximately 250 g. After continuous feeding for 3 weeks, the average body weight of rats increased steadily to approximately 320 g, and there was no significant difference in body weight between the three groups. After 6 weeks of weight-bearing swimming training, the body weight was taken before the last exhaustive swimming. The average body weight of the static control group had increased by about 4% meanwhile that of the exercise control group had reduced. After the administration of the different concentrations of icariin-zinc, the average body weight of rats in the L-E and H-E groups decreased compared with the exercise control group (Figure 2).

## The Effect of Icariin-Zinc on Anti-Fatigue in Rats

Compared with the static control, the exhaustive swimming time of rats in each group was prolonged. After administration of the icariin-zinc, the exhaustive swimming times of the L-E and H-E groups were significantly prolonged ( $p < 0.01$ ), just as that of the ICA group (Figure 3). It is suggested that icariin-zinc has the same function as ICA in improving the exercise ability of rats. The swimming abilities of rats in each group were observed, and the rats in the icariin-zinc group were more active, jumped out of the water more frequently during swimming, had a longer relative swimming distance, and had a more prolonged exhaustive swimming time. These showed that the physical functional reserves of the rats were better and their exercise ability was enhanced.

## The Effect of Exercise and Icariin-Zinc on Glycogen Storage in the Liver and Muscle of Rats

The content of liver glycogen was the same in all the groups but for the H-E group there was an increasing trend (Figure 4). Compared

with the control group, the muscle glycogen reserves of each group decreased after swimming (Figure 5). A comparative evaluation showed that icariin-zinc had no significant effect on liver glycogen and muscle glycogen storage in rats.

There was no significant difference between the testicular weights of the different groups when compared with the control (Figure 6). Hematoxylin and eosin (HE) staining showed normal morphologies of Leydig and Sertoli cells, continuous and complete membrane of the seminiferous tubules, and a regular arrangement of germ cells. These findings suggest that icariin-zinc does not affect testes histopathology (Figure 7).

## The Effect of Icariin-Zinc on the Testicular Weight and Index of Rats

Compared with the static control group and exercise control group, the testicular index of rats in the treatment group increased slightly (Figure 8). Testicular index = testis/weight  $\times$

1000. Testicular index measurement helps to eliminate the influence of animal weight, and can be used to evaluate the function of the rat's reproductive system. The results showed that after intragastric administration of ICA, G-Zn, icariin glucose, zinc, and icariin-zinc, the testicular index increased, indicating that icariin-zinc could improve reproductive function in male rats.

### The Effect of Exercise and Icariin-Zinc on the Weights of the Seminal Vesicle and Prostate Gland in Rats

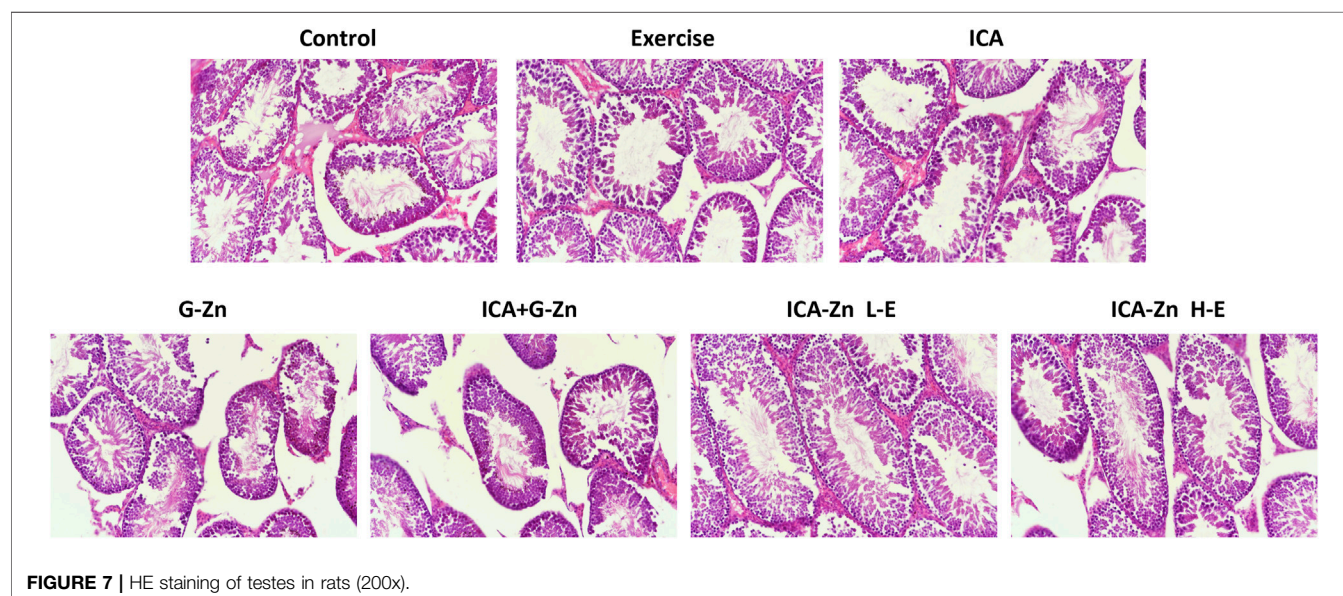

Compared with the exercise control group, the average weight of the seminal vesicles of rats in the L-E group increased

significantly, indicating that the sperm reserve of the rats in the L-E group was larger. This phenomenon was not observed in the H-E group (Figure 9). However, icariin-zinc had no significant effect on prostate weight in rats (Figure 10).

### The Effect of Exercise and Icariin-Zinc on the Plasma Testosterone Level in Rats

The concentration of testosterone in the plasma of rats was measured by ELISA, and the standard curve was obtained with good correlation ( $r = 0.9985$ ) (Figure 11). Compared with the static control group, the plasma testosterone content of the L-E and H-E groups increased significantly ( $p < 0.05$ ). Compared with the exercise control group and G-Zn group, the plasma testosterone content of the H-E group also increased significantly ( $p < 0.01$ ). The above experimental results show that icariin-zinc can significantly

improve the plasma testosterone level in rats, largely than icariin alone and zinc agents such as zinc gluconate (Figure 12).

## DISCUSSION

Icariin is the main extract and active component of the herbaceous plant epimedium which among others, plays a role in tonifying the kidney, strengthening the yang, and slowing down aging. Longh et al. (2018) found that icariin improved erectile function of SHR (Long et al., 2018). Zinc is a part of the structural composition of many proteins. It helps in the recovery of the nervous system. Zinc also plays an important biological role in male reproductive physiology and endocrine system (Santos and Teixeira, 2019). In this study, icariin and zinc were combined

to produce a synergistic effect. Icariin-zinc was prepared by chemical synthesis. It was formed by the combination of two molecules of icariin with one molecule of divalent zinc ion through ionic and coordination bonds (Figure 13). The hydroxyl group provides an electron pair and forms a coordination bond with zinc, giving the compound a good chemical stability. After chemical synthesis, the structure of each particle is the same, uniform, and easy to absorb. Physical mixing has different rules, and makes it difficult to achieve a uniform mixing proportion thus impacting the experimental data. Through the study of its effects on body weight, exercise exhaustive time, testicular and seminal vesicle weight, and glycogen storage, we were able to put into evidence preliminary improvements in anti-fatigue and sexual function in rats.

Body weight is an important indicator of the skeletal, muscular, and functional states, and overall development of the body. A change in body weight can reflect the adaptation of the body to sports training and the degree of its influence on the body. It is one of the most important indicators of animal growth and nutritional

state. Our results showed that there was no significant difference between the body weights of the rats in the different groups during the first three weeks. It was considered that the normal development of the body weight had occurred. At the end of the 6th week, the body weight of rats in the L-E and H-E groups decreased, which was due to the increase in excitability and activity. In the process of feeding, the rats in the icariin-zinc group began to show hyperactivities (increased activity, fighting, and frequent squeaking) compared with the exercise control group and the static control group during the third week. This indicates that icariin-zinc can improve the excitability and exercise ability of male rats. The rats' body weight change, and daily amounts of food and water consumed were similar in both the icariin-zinc and exercise control groups. The change in body weight was slightly higher in the control group. This was because the compound promotes the development of the body, increases the basal metabolic rate, appetite, and amount of exercise.

Exercise fatigue is the physiological decline in working ability, activity ability, and range of activity after a strenuous exercise (Narkhede et al., 2016; Górski et al., 2017). The recovery time of exercise fatigue is relatively long and this has an impact on human life and work. Exercise exhaustive time is an important sign reflecting the body's exercise ability. It can be used as an index to measure the anti-exercise fatigue ability of animals.

The exhaustion training resulted in the maintenance of the rats in both the icariin-zinc and exercise control groups in a state of exercise fatigue, and so, the exercise function could not be effectively recovered. Theoretically, in a short period of time, the exhaustion time would be shorter than that of the control group. The results of the anti-fatigue experiment showed that the exhaustive swimming time of rats in the exercise control group was shortened as expected. However, after the administration of icariin-zinc, the exhaustive swimming time of the L-E group was prolonged. Considering the hyperexcited state of the H-E group, the rats in the exercise control group

struggled more violently during the exhaustion swimming training, jumped out of the water more frequently incurring great energy losses, and failed to rest for a long period of time. Because they could not store enough energy for exhaustive training, the both H-E and L-E groups exhaustive times were not prolonged. Our results showed that the concentration of the icariin-zinc was very important, and high concentrations would cause high excitability, which was not conducive for physical recovery. Low concentration can enhance the anti-exercise fatigue abilities, a consequence of the improvement of the exercise level in skeletal muscles.

Glycogen is a form of energy storage in organisms. Glycogen in the skeletal muscle is an important form of energy storage. In long-term aerobic exercise, muscle glycogen consumption often occurs and is related to the inability to maintain muscle contractility (Britto et al., 2018). In long-term and high-intensity sports, the storage of muscle glycogen before exercise determines the time of exhaustion, which directly affects endurance training and competition. The importance of glycogen in exercise ability is reflected in endurance exercise. During exercise, glycogen decomposition is accelerated, and glucose is released into blood by the liver to maintain blood glucose balance. Our results showed that after swimming, the glycogen reserves in the liver and muscle of rats in the exercise control group decreased to the lowest level. However, the glycogen reserves increased in each group after the administration of different concentrations of icariin-zinc, especially in the H-E group.

These results indicate that icariin-zinc can promote glycogen synthesis in rats undergoing training. The possible mechanism is that icariin-zinc can enhance the oxidation and absorption of glucose, thus promoting the synthesis of muscle glycogen and liver glycogen.

The testis is a male internal reproductive organ and plays a role in the development of male secondary sexual characteristics and physiological function. The seminal vesicle is an important accessory gland of men, and is involved in the process of semen accumulation and release. Seminal vesicle secretion accounts for about 50–80% of the volume of semen, and thus closely influences the quality and quantity of sperm (Zhao et al., 2019). Our results showed that the testicular weights and indices of the L-E and H-E groups were increased. This could be because icariin-zinc promotes testicular development and spermatogenesis. We found that, compared with other administration groups, the weight of the seminal vesicle of rats in the L-E group increased significantly. This was probably due to the increase in seminal vesicle secretion caused by Icariin-Zinc.

Testosterone is one of the main components of androgen. It promotes spermatogenesis, stimulates the growth and development of reproductive organs, maintains normal sexual desire, and promote protein synthesis. From this experiment, we found that icariin-zinc can significantly improve the plasma testosterone level of rats, and this effect is significantly better than when icariin and zinc agents, such as zinc gluconate, are administered separately. It is suggested that ICA can promote the secretion of testosterone. ICA is a flavonoid that can protect the synthesis of testosterone in mouse Leydig cells (by the effects of 2-ethylhexyl phthalate). It protects mouse testes from the damage induced by DEHP by blocking ROS and promoting the secretion of testosterone (Sun et al., 2019). It can be concluded that icariin-

zinc may promote testosterone secretion by protecting rat testicular cells from damage.

To sum up, sports fatigue and men's health problems are of great concern, and they often affect each other. Male sexual dysfunction can cause other functional abnormalities in the body and thus, influence mental and physical health. Hence, it is a problem that requires an urgent solution. Therefore, it will be of great significance if a fast and effective drug that improves anti-fatigue and sexual abilities was found. Based on the behavior of animals in this study, and the analyses of specific experimental data, we believe that the combination of icariin and zinc ion can improve the motor and anti-fatigue abilities of male rats (through the improvement of the functions of skeletal muscles and joint). In addition, it can promote the index and function of the glands of the reproductive system (especially increase in testicular and seminal vesicle weights, increase the glycogen reserve in rats, and improve exercise ability). The mechanisms of action may be related to zinc induced oxidative stress mechanism, or improvement of sexual function by the regulation of the hypothalamic pituitary gonadal axis and the PI3K/Akt/eNOS/NO signal pathway by ICA (Ding et al., 2018). In the future, these mechanisms will be further studied in terms of enhancing testicular function, including steroid production, sperm count, sperm motility, and spermatogenesis in male rats. Therefore, the preparation and application of icariin-zinc provides a new idea to explore for increasing anti-fatigue ability, enhancing exercise ability, and solving male reproductive health problems.

## CONCLUSION

In this experiment, icariin-zinc was successfully prepared, and the reaction rate was positively related to the reaction temperature, reactant concentration, and reaction time. An appropriate amount of icariin-zinc compounds can promote development in male rats, improve their excitability, promote their recovery from the fatigue state, and enhance their anti-fatigue ability.

Icariin-zinc can significantly prolong the exhaustive swimming time, improve the exercise ability, and increase the content of testosterone in the plasma of male rats. However, there was no significant effect on glycogen content, testicular index, and other reproductive glands (such as the prostate gland and seminal vesicle). Moreover, icariin-zinc was better than zinc gluconate in

prolonging exhaustive swimming time, and increasing plasma testosterone content. Compared with icariin, the effect of high-dose zinc is more significant. It is suggested that in the application of the icariin-zinc complex, the dosage should be strictly controlled to obtain the best drug effect without affecting the reproductive system organs.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Ethics Committee of Tianjin University of Traditional Chinese Medicine (TCM-LAEC2019069).

## AUTHOR CONTRIBUTIONS

JZ, DM designed the research associated with the project, QJ, LX performed the acquisition and analysis in the experiment. MS and CZ, AF performed acquisition, analysis and interpretation of data. HY interpreted the data. CC, DL drafted the work and revised it. All authors have read and approved the submitted version of manuscript. And all authors have agreed their contributions in the manuscript.

Placebos for Clinical Research in  
Traditional Chinese Medicine:  
Assessing Organoleptic Properties of  
Three Dosage Forms (Oral Liquid,  
Capsule and Granule).  
Front. Pharmacol. 12:673729.  
doi: 10.3389/fphar.2021.673729

**Background:** The successful application of randomized, double-blind placebo-controlled studies requires maximum blinding. Organoleptic properties of the placebo should be similar to the drug, making it difficult to distinguish between the two. The uniqueness of traditional Chinese medicine (TCM) preparations makes it challenging to prepare placebo. Evaluation of the TCM placebo simulation effect can determine whether the preparation of placebo can be genuinely blind in clinical trials. There is still a lack of well-established methods to evaluate TCM placebos. Hence, this study aimed to explore the evaluation methodology of TCM placebo simulation.

**Methods:** An independent evaluation method and three comparative evaluation methods were proposed, and three dosage forms (oral liquid, capsule, and granule) were tested. The independent evaluation, in which each person was given an experimental drug or a placebo, gave an overall assessment of organoleptic properties in a blind state. We comparatively evaluated the similarity in organoleptic properties between the experimental drug and placebo. According to different distribution methods, we divided comparative evaluation methods into three. In method 1, the evaluator was given the experimental drug and placebo and was told that there must be a placebo among them. In method 2, each evaluator was randomly assigned to the combination group or two investigational drugs group. In method 3, the evaluator was assigned to a set of three coded samples, numbered by random three-digit numbers, each different, two of which were identical, and the two samples were equally frequent.

**Results:** In the independent evaluation, there was no difference between TCM placebo and experimental drugs in a blind state at the level of  $p = 0.05$ . Even though the comparative evaluation methods enabled identification of potential differences between the two samples, methods 2 and 3 were better than method 1 in eliminating psychological factors. Also, in method 3, the completely random method combined with the blind

method eliminated the subjectivity and objectivity bias and improved the experiment's credibility compared with the previous two methods.

**Conclusion:** Regardless of the methods that could evaluate the placebo's simulated effect in actual clinical trials, we suggest that independent evaluation and comparative evaluation (method 3) should be combined to reflect better whether the placebo is truly blind.

**Keywords:** traditional Chinese medicine, placebo, simulation effect, evaluation, organoleptic properties

## INTRODUCTION

Masking of participants and researchers has long been used in randomized clinical trials (RCTs) to eliminate the potential impacts of nondrug effects, including the natural course of the disease; the evaluator and researchers; and subjective factors in treatment, diagnosis, and clinical assessment (Jamshidian et al., 2014; Dube et al., 2007). In the past 40 years, at least 17,000 RCTs have been conducted in China to assess the efficacy and safety of traditional Chinese medicine (TCM), including Chinese herbal medicine, acupuncture, massage, moxibustion, Qigong, and other therapies, most of which are related to Chinese herbal medicine (Wang et al., 2007). Regardless of the increasing number of TCM studies, their reliability has been challenged because of the lack of rigorous evidence (Wang et al., 2007; Teschke et al., 2015; Liu et al., 2015). Inadequate randomization, insufficient sample sizes, and the lack of proper blinding make the research results vulnerable to the selection, reporting, and assessor bias.

A more recent review of TCM uncovered that many studies often lacked true blindness (Teschke et al., 2015). To meet the requirements for blinding, it is necessary to prepare a convincing TCM placebo, and these must be similar to the investigational drug in terms of visual attributes, dosage form features, and smell/taste attributes. Compared with western medicine placebo drugs, the unique odor, taste, and color of TCM preparations make it challenging to prepare placebo. At present, there are two forms of placebo preparation: no pharmacodynamic components and low-dose pharmacodynamic components. The placebo prepared by the simple excipient method placebo does not contain pharmacodynamic components. Generally, it uses flavorants (edible additives), colorants (edible pigments), and volatiles (agents to simulate a placebo) (Lu et al., 2018). The other is to use the drug with excipients in a low proportion. It is feasible to dilute the drug substance by 10 or 20 times, use it as a placebo, or use materials with certain pharmacological activities unrelated to the investigational drug's effect to prepare the placebo (Nakaya et al., 2003). To explore whether the organoleptic properties of the placebo are exactly the same as those of experimental drugs, it is imperative to evaluate the TCM placebo's simulation effect. Nevertheless, there is a lack of recognized evaluation methods and standards for TCM placebos (Wang et al., 2014).

At present, there are mainly two clinical evaluation methods: artificial and objective evaluation. For artificial evaluation, some researchers have proposed a placebo quality checklist (Brinkhaus et al., 2008), but this has never been appropriately validated. Some Chinese researchers have proposed to allow healthcare

professionals, pharmaceutical companies, and patients to score placebos, and the results should be used to determine whether the placebo simulation is successful (Tang et al., 2009; Wang et al., 2011; Jin et al., 2014a; Song et al., 2014; Yang, 2014; Sun et al., 2019; Yan and Zhang, 2020). For objective evaluation, some researchers have begun to use intelligent sensory analysis to evaluate placebo quality, including visual sensors, electronic tongue sensors, and other technologies. These are used to assess placebo consistency with the investigational drug in organoleptic properties, and they can transform subjective evaluation reports into objective data to standardize evaluations (Luo, 2012; Jin et al., 2014b; Liu et al., 2014; Fan, 2018).

Manual placebo evaluation can maximize the simulation of the patient judgment of drugs in the real clinical environment. Here, we proposed four methods for evaluating the simulated effect of placebo in TCM, including an independent evaluation method and three comparative evaluation methods. In the independent evaluation, only one of the two drugs, including experimental drug and placebo, was given to the evaluator. In contrast, in the comparative evaluation, the evaluator was given multiple boxes of drugs, including various possibilities. To fully explore whether the four evaluation methods identified and evaluated the simulation effect of TCM preparations stably, we took three commonly used TCM preparations (oral liquid, granule, and capsule) as an example to conduct the simulation effect evaluation test. We provided our insights and considerations for evaluating the manufacture and simulated effects of TCM placebos.

## MATERIALS AND METHODS

### Evaluation of Different Dosage Forms of Traditional Chinese Medicine Placebo

This study was intended to evaluate three different dosage forms of TCM placebo used in clinical studies and the following were in each: 1) Fufang Ejiao Syrup (FFEJJ) oral solution (batch number: Z37021371); this product is a brown to dark brown liquid, sweet in taste, and comes in 20 ml vials. The ingredients and contents in placebo FFEJJ oral solution (20 ml) are listed in **Table 1**. Shandong Dong-e E-Jiao Co., Ltd., produced both the investigational drug and placebo. 2) Zhizhu Kuanzhong (ZZKZ) capsules (batch number: Z20020003); this product is light grayish brown, slightly bitter, salty and comes in 0.43 g/grains. The ingredients and contents in placebo ZZKZ capsules (0.43 g) are listed in **Table 2**. The investigational drug and

**TABLE 1 |** Ingredients and their contents of FFEJ placebo in each placebo bottle (20 ml).

Ingredients	Content	Role(s)
Gelatina nigra syrup	0.9 ml	Equivalent to 5% of the original formula
Caramel pigment	0.8 g	Pharmaceutical excipient/food additive
Stevioside	0.025 g	Pharmaceutic adjuvant

placebo were produced by Langzhi Group Shuangren Pharmaceutical Co., Ltd., 3) Billing Weitong (BLWT) granules (batch number: Z19990069); this product is brown to tan granules with a bitter taste and comes in 5 g/bags. Ingredients and content contained in each placebo sachet (5 g) of BLWT granules are listed in **Table 3**. Both the investigational drug and placebo were prepared by Yangtze River Pharmaceutical Group Jiangsu Pharmaceutical Co., Ltd.

## Evaluation Methods of Placebo Simulation Effect of Traditional Chinese Medicine

The placebo should be completely consistent with the tested TCM in terms of appearance, color, odor, taste, packaging, usage, and dosage, so it was necessary to evaluate whether the placebo successfully mimicked the investigational drug by independent assessment and comparative effectiveness evaluation. Independent evaluation was required to determine if the actual medication was simulated. The evaluator determined whether a sample in the investigational drug or placebo was an investigational drug under a blinded state; for comparative effect evaluation, they evaluated the similarity of the investigational drug and placebo at different levels such as appearance texture, color, odor, and taste.

### Independent Evaluation

Three dosage forms of FFEJ oral solution, ZZKZ capsules, BLWT granules, and their placebos were evaluated. The investigational

drug or placebo was randomly distributed to 20 evaluators ( $n = 10$  each). The evaluators were randomly selected from the target evaluator for which the drug was acting. The evaluator made an overall assessment of the possibility that the sample was the investigational drug under a blinded state. There were two evaluation options: probably an investigational drug or probably a placebo. After unblinding, judgment accuracy was compared between the placebo and the investigational drug groups to determine whether there was a difference between them.

For the qualification criteria of the placebo simulation effect, the methods listed in **Table 4** were adopted. Twenty evaluators (10 each for placebo and investigational drug) were used to calculate the difference in the proportion of the investigational drug and placebo judged as the investigational drug in the blinded state ( $p < 0.05$ ). Assuming that the numbers of the evaluators who judged investigational drug as the investigational drug were 5, 6, 7, 8, 9, and 10, the cut-off value of the number of the evaluators who judged the placebo as the investigational drug varied from 0 to 5, indicating a significant difference at the 0.05 level. That is, when the number of evaluators was 20, and 5 evaluators judged the investigational drug as the investigational drug, the number of the evaluators who judged placebo as the investigational drug was at least 1, indicating there was no difference in the proportion of the evaluators who judged the placebo and investigational drug as the investigational drug in the blinded state at the 0.05 level. When all evaluators judged the investigational drug as the investigational drug, the number of the evaluators who judged the placebo as the investigational drug was at least 6, which means there was no difference in the proportion of evaluators who judged the placebo and the investigational drug as the investigational drug in the blinded state at the 0.05 level.

Comparably, if the number of evaluators was increased to 20 each for placebo and the investigational drug, with an assumption that the numbers of patients judged the investigational drug as the investigational drug were 10, 12, 14, 16, 18, and 20, and there was a difference in the proportion of the evaluators who judged both

Ingredients	Proportion	Role(s)
Microcrystalline cellulose	1	Filler (no pharmacological activity)
Starch	2	Filler (no pharmacological activity)
Magnesium stearate	0.5%	Lubricant (no pharmacological activity)
Food-grade pigment solution	--	Food additive

**TABLE 3 |** Ingredients and their contents of BLWT placebo in each placebo pack (5 g).

Ingredients	Content (g)	Proportion (%)	Role(s)
Dextrin	3.19	63.8	Pharmaceutic adjuvant
Sucrose	1.0	20.0	Pharmaceutic adjuvant
BLWT fine powder	0.375	7.5	Equivalent to 7.5% of the original formula
Povidone K30	0.25	5.0	Pharmaceutic adjuvant
Caramel	0.125	2.5	Pharmaceutical excipient/food additive
Low-substituted hydroxypropylcellulose	0.06	1.2	Pharmaceutic adjuvant

**TABLE 4 |** Cut-off values of the difference in the number of evaluators who judged the investigational drug and placebo as the investigational drug at the 0.05 level.

	No. of evaluators = 20 (50/50 received investigational drug and placebo)		No. of evaluators = 40 (50/50 received investigational drug and placebo)	
	Investigational drug	Placebo	Investigational drug	Placebo
Investigational drug	10	0	20	0
Placebo	5	5	15	5
Investigational drug	9	1	18	2
Placebo	3	7	11	9
Investigational drug	8	2	16	4
Placebo	2	8	9	11
Investigational drug	7	3	14	6
Placebo	1	9	6	14
Investigational drug	6	4	12	8
Placebo	0	10	4	16
Investigational drug	5	5	10	10
Placebo	0	10	3	17

the investigational drug and placebo as the investigational drug in the blinded state ( $p < 0.05$ ), the cut-off value of the number of evaluators who judged the placebo as the investigational drug varied from 3 to 15, suggesting a significant difference at the level of 0.05. That is, when 10 evaluators judged the investigational drug as the investigational drug, the number of evaluators who identified the placebo as the investigational drug was at least 4, which suggested there was no significant difference at the 0.05 level. When all evaluators judged the investigational drug as the investigational drug and the number of evaluators who thought the placebo was the investigational drug was at least 16, it was considered that there was no difference in the proportion of the evaluators who judged the investigational drug in the blinded state at the 0.05 level.

## Comparative Evaluation

### Method 1

All 20 evaluators were distributed an investigational drug and a placebo and the evaluators were told that one of them was a placebo, but they did not know which one was a placebo. Also, they were allowed to open the drug package. The evaluators scored the sensory similarities in terms of drug appearance, odor, taste, and characteristics. The judgment criteria were as follows: complete consistency corresponded to a score of 10.0 points, comparative consistency was 7.5 points, uncertainty scored 5.0 points, a large difference corresponded to 2.5 points, and complete inconsistency was 0 points. If the single evaluation content was  $< 5$  points, it was considered that there were certain differences between the two samples.

### Method 2

The evaluators were randomly distributed into two groups, and there were two scenarios in each: 1) both samples were the investigational drug; and 2) one sample was the investigational drug and the other was the placebo. The patients had an equal chance of obtaining either sample in both scenarios. There were a total of 20 evaluators. Each assessed the placebo/investigational drug or the investigational drug/investigational drug simultaneously, and they were allowed to open the packaging. The evaluators considered the similarities between the

placebo and investigational drug in terms of packaging, label, strength, drug form, color, odor and taste; they were instructed to determine if the placebo was similar to the investigational drug and whether the placebo could be identified. The judgment criteria were as follows: complete consistency corresponded to a score of 10.0 points, comparative consistency was 7.5 points, uncertainty scored 5.0 points, a large difference corresponded to 2.5 points, and complete inconsistency was 0 points. The 0.05 level was used to determine whether there was a difference in scores between the two groups.

### Method 3

A three-point test method was used to evaluate the slight differences between the two samples. Evaluation steps: the evaluator was provided with a group of three samples that were coded with a random three-digit number that was different each time. Two of the samples had the same numbers. The evaluators were required to pick out the sample different from the other two, with an equal occurrence rate of the three samples: BAA, ABB, ABA, BAB, AAB, and BBA. The statistical null hypothesis was that it is impossible to distinguish between these two samples based on their characteristic strength. In this case, the probability of correctly identifying an individual sample was  $p = 0.33$ . The alternative hypothesis was that these two samples could be distinguished based on their characteristic strength. The probability of correctly identifying a control sample, in this case, was  $p > 0.33$ . Finally, the number of correct responses and the total number of evaluators was statistically analyzed. When the number of correct responses was greater than or equal to the corresponding value at a certain level of the table tested by the three-point test method, the null hypothesis was rejected, and the alternative hypothesis was accepted at the significant level. A total of 36 samples were included, and the cut-off value for a difference between the two samples was 18 at the 0.05 level.

## RESULTS

### Independent Evaluation

In the independent evaluation of three dosage forms of TCM placebos, there were no significant differences across the groups

**TABLE 5 |** Basic information of patients independently evaluating FFEJJ placebo.

		Placebo ( <i>n</i> = 10)	Investigational drug ( <i>n</i> = 10)

	No	10	10

about the evaluator gender or age, or the time to make a judgment on whether the dispensed drug was the investigational drug or placebo. Three evaluators had taken FFEJJ before the study (all in the placebo group), and four evaluators had taken ZZKZ before evaluation (two in the placebo group). See **Tables 5–7** for specific information.

With regard to the evaluation of the FFEJJ oral placebo simulation effect, when the compound was actually the placebo, three of 10 evaluators judged it as the investigational drug, and when it was actually the investigational drug, seven of 10 evaluators judged both of them as investigational drugs.

Next, we evaluated the placebo simulation effect of ZZKZ capsules. When the compound was actually the placebo, eight of 10 evaluators judged it as the investigational drug; when it was actually the investigational drug, five of 10 evaluators judged it as the investigational drug.

Finally, we evaluated the placebo simulation effect of BLWT granules. When granules were the placebo and investigation drug, respectively, four and seven of 10 evaluators chose it as the investigational drug.

If the cut-off value of the evaluators who judged the investigational drug and placebo as the investigational drug was different at the 0.05 level, it was considered that there was no significant difference between the three different TCM preparations placebos, and the study was appropriately blinded (**Tables 4, 8**).

## Comparative Evaluation

### Method 1

A total of 20 evaluators participated in the placebo evaluation of ZZKZ capsule (10 male and 10 female, age range 27–69 years, mean 44.8 ± 12.2 years). Four evaluators had taken capsules before participating in the evaluation. Eighteen of the 20 evaluators opened the capsules and evaluated the similarity of the compounds. For the ZZKZ capsule similarity evaluation, 13 evaluators correctly identified the placebo (**Table 9**). If the score in a single evaluation was <5 points, it was identified as a difference. The ZZKZ capsule placebo was generally consistent or indefinitely different in appearance and content characteristics with the investigational drug, with some taste and odor differences.

### Method 2

A total of 20 evaluators participated in the comparative evaluation of the placebo simulation effect of ZZKZ capsules; three evaluators in the experimental group had previously taken the capsules. The patients in both groups who participated in the evaluation opened the capsule for discrimination, and the results of appearance, contents, odor, and taste are shown in **Table 10**. Eight evaluators in the combination group identified the placebo, and nine evaluators in the two investigational drugs group mistook the investigational drug as a placebo. Since psychological effects were ruled out, the investigational drug was not considered to be different from the placebo in appearance, but there were some differences between the two in taste, content traits, and odor.

### Method 3

A total of 36 evaluators (16 male, 20 female; age range 18–76 years, mean age 41.72 ± 13.403) participated in the comparative evaluation. None of them had taken the investigational drug before completing the evaluation. The evaluators selected one different sample or two identical samples from each test package regarding appearance, texture, color, odor, and taste. The number of evaluators with correct judgment was less than half of the total, so the comprehensive evaluation result was pass for BLWT granules vs. placebo (**Table 11**).

## DISCUSSION

An ideal placebo has no active ingredients but is identical to the investigational drug in organoleptic properties. In clinical investigations of western medicine, the active ingredients are clear, so the placebo only needs to use the corresponding excipients (e.g., starch, glucose, etc.) and the difficulty coefficient is not high (Qi et al., 2008). However, for TCM studies, the Chinese materia medica composition is often several or even dozens of components, and many traditional forms (e.g., decoctions, pills and powders) have special odors and tastes, and ensuring that the placebo is similar can be

S. Comprehensive assessment	S = 9.4	S < 18	Pass

difficult. There is large variability, which makes placebo preparation even more difficult. Special consideration should be given to the design of a placebo to ensure a good simulation effect.

In actual clinical trials, uniform criteria are often used for the specification, packaging, usage, and dosage of the placebo and investigational drug. The evaluation mainly focuses on whether the placebo has drug activity and whether it is consistent with the investigational drug in terms of appearance, color odor, and taste. Nevertheless, there is no recognized evaluation method for placebo quality evaluation. In addition to avoiding placebo effects, attention should also be paid to nocebo effects during double-blind RCTs. The nocebo effect is defined as a harmful result of patients' doubts or

negative expectations about the treatment (Blasini et al., 2018). Evidence has been found that both the placebo and nocebo effects can substantially affect the efficacy of the drug as well as nondrug treatments (Amanzio et al., 2001; Aslaksen et al., 2015). Therefore, nocebo effects can affect the accurate determination and evaluation of therapeutic drugs. Determining how to scientifically and consistently design placebos and evaluate their simulation effects is particularly important.

Although the objective evaluation method can make the data more objective and reduce the degree of deviation, there are some differences between the objective evaluation method and clinical practice. The patients' potential psychological factors cannot be

100% simulated, affecting the test results. Also, the standardization and objective quantification of simulation effects still need to be improved (Wang et al., 2003). So, the present study used the artificial evaluation method. By pre-investigating a small number of target evaluators in advance, researchers can predict whether they will distinguish the difference between the placebo and the experimental drug in the actual clinical study. Considering whether the placebo's simulation effect would be affected if there were simultaneous exposure to two drugs, we provided three different contrast evaluation methods. All of them enabled identifying potential differences between the two samples, and they all have some differences. For the first method, the evaluators knew that there must be a placebo included, so they would pay more attention to finding the differences between the two, and the probability of unblinding was increased. The second method used to deal with this limitation was semi-randomized and evaluated if the two (the investigational drug and placebo, or two investigational drugs) were the same. To make this judgment, both the difference and the consistency, or both of them, had to be considered, making up for the limitation of the first method that only looked for different points. The difference reflects the inconsistencies between the two and the investigational drug, and the consistency expresses the degree of the similarities between the two and the investigational drug. With smaller differences comes higher consistency. The purpose of the evaluation was achieved by using one of the analyses in actual operation. Nevertheless, semi-randomization may also produce some biases, because of the infeasibility of true randomization in a strict sense. The third method adopted complete randomization, eliminating nonuniformity error, order error caused by the sampling method, and allocation error due to improper allocation. It also reduced subjective and objective biases by combining the blinding approach, thus significantly improving data reliability. We believe that the completely random simulated evaluated better whether the placebo was more consistent with the experimental drug by discussing several comparative evaluation methods. In the actual clinical application, we suggest that the combination of independent and comparative evaluation can be closer to the real double-blind placebo-controlled studies, so as to avoid the placebo and nocebo effects to the greatest extent. Nevertheless, evaluators may have different psychological tendencies and have varying sensitivities to the organoleptic properties of Chinese materia medica so that the manual evaluation method can be affected by subjective factors. Also, in this study, the sample size was small, and more samples are needed for verification.

Concerning the evaluation criteria, there are currently two primary forms. One compares the investigational drug and placebo in terms of shape, color, odor, taste and other aspects to determine whether the differences were significant. The second is to define the value of either artificially, but there is no uniform definition of evaluation criteria cut-off values. This study was mainly based on the relevant literature and statistical indicators in early-stage investigations. There are some doubts about the scientific validity and reliability of this approach, which must be continuously explored in the future.

The literature suggests that evaluators should be asked to indicate whether they think they took the investigational drug or placebo after the trial. The statistical analyses should then estimate and adjust for postrandomization confounding factors that could influence

treatment effect according to the causal inference framework to obtain the unbiased efficacy estimate and more easily explain the estimate (Hubbard et al., 2012). At present, there is little evidence that RCTs are actually double-blinded (Hrobjartsson et al., 2007). Our next focus will be to investigate whether it is necessary to specify the evaluation results of the placebo simulation effect along with articles, which should provide better references to readers.

## CONCLUSION

A blind method is an essential link to a high-quality TCM clinical trial. The simulation effect of the placebo will directly affect whether the blind method can be realized. Evaluation of the TCM placebo's simulation effect can judge whether the placebo preparation achieves complete consistency in visual attributes, dosage form features and smell/taste attributes. We proposed an independent evaluation method and three comparative evaluation methods, and three dosage forms (oral liquid, capsule and granule) were tested. Regardless of the methods can evaluate well the simulated effect of placebos, in actual clinical trials, we suggest that independent evaluation and comparative evaluation (method 3) should be combined to reflect better whether the placebo is truly blind. This study can provide a new choice for the simulation evaluation of TCM placebo in the future and further improve the quality of TCM clinical trials.

*Grona styracifolia* (Osbeck) Merr. (GS), a popular folk medicine, is clinically applied to treat nephrolithiasis. In this study, a urinary metabolic analysis was performed in a mouse model of renal calcium oxalate (CaOx) crystal deposition to identify the differentially altered metabolites in mice with oxalate-induced renal injury and explore the therapeutic mechanisms of GS against nephrolithiasis. Twenty-four mice were randomly divided into the control, oxalate and GS-treated groups. A metabolomics approach based on ultra-high-performance liquid chromatography coupled with quadrupole-time-of-flight mass spectrometry (UHPLC-Q-TOF/MS) was used to analyze the metabolic profiles of the urine samples. In addition, network pharmacology analysis was performed with different databases. As a result, the protective effects of GS were verified by measuring biochemical parameters and detecting crystal deposition. Fifteen metabolites were identified as the differentially altered metabolites in mice with crystal-induced renal injury. Most were involved in amino acid and fatty acid metabolism. Thirteen of these metabolites showed a reversal trend following GS treatment. A component-target-metabolite network was further constructed and nine overlapping target proteins of GS and the differentially altered metabolites were discovered. Among these proteins, the expression of estrogen receptor 2 (ESR2) in renal tissues was significantly down-regulated while androgen receptor (AR) expression was obviously increased in the oxalate group compared with the control group. These changes were reversed by the GS treatment. In conclusion, GS exerts its therapeutic effect by regulating multiple metabolic pathways and the expression of ESR and AR in mice with oxalate-induced renal injury.

## INTRODUCTION

Kidney stone disease, also known as nephrolithiasis, is a common disease jeopardizing the health of 7–13% of the population worldwide (Sorokin et al., 2017). Nephrolithiasis is considered a systemic disease because of its significant association with chronic kidney disease, cardiovascular events and metabolic syndrome (including type 2 diabetes, obesity, hypertension and dyslipidemia), as reported by numerous epidemiological studies (Sakhaee, 2008). Calcium oxalate (CaOx) is the most common inorganic matrix found in kidney stones and crystals. CaOx crystals, an early form of kidney stones, have also been shown to cause apoptosis in renal tubular cells (Mulay et al., 2013). The supersaturation of the urine is the first step in the formation of kidney crystals, followed by the progression of nucleation, growth and aggregation (Kolbach-Mandel et al., 2015). Renal injury induced by kidney stones has been observed throughout the process of stone formation. Metabolic disturbances are also promoted by crystal-induced renal injury. Thus, metabolic disturbances resulting from renal injury during crystal formation should be addressed.

*Grona styracifolia* (Osbeck) H. Ohashi and K. Ohashi (GS), a popular traditional medicine (also known as “Guang Jin Qian Cao” in Chinese), is widely distributed in southern China and is clinically applied to treat nephrolithiasis. GS has been shown in a previous study to alleviate CaOx deposition in a murine model and has been reported to effectively relieve the apoptosis of tubular cells and prevent the oxidative stress changes induced by crystals (Zhou et al., 2018). However, no studies have been performed to evaluate the effects of GS on nephrolithiasis from the perspective of metabolism.

Metabolomics is a scientific study of the systemic metabolic changes in complex living systems in response to pathophysiological stimuli and has been effectively applied to reveal metabolic changes in diverse types of renal injury (Fan et al., 2018). In addition, the concept of network pharmacology has been developed due to the rapid development of bioinformatics. Network pharmacology is more effective for establishing a “compound-protein/gene-disease” network and revealing the regulatory effects of small molecules in a high-throughput manner. This approach is very powerful for the analysis of drug combinations, especially traditional medicinal herbs (Zhang et al., 2019). A combination of network pharmacology and metabolomics can establish the relationships of herb targets and endogenous metabolic responses to further reveal the molecular mechanisms of the herb based on a component-target-metabolite network. In the present study, a urinary metabolomics-based approach integrated with network pharmacology was conducted to investigate the potential effects of GS on a mouse model of crystalline nephropathy characterized by renal CaOx deposition.

## MATERIALS AND METHODS

### Preparation and Quality Control of GS

*Grona styracifolia* (Osbeck) H. Ohashi and K. Ohashi (GS) was purchased from Anguo (Hebei, China) and was authenticated by Prof. Lianna Sun (School of Pharmacy, Navy Medical University,

Shanghai, China). The purchased herbs were extracted using standard methods according to the Chinese Pharmacopoeia (Yu et al., 2015). First, the entire GS plant was ground into a powder and was filtered through a 250 µm mesh. Next, 200 g of the powder was extracted with 1,000 ml of 80% methanol for 2 h using an ultrasonicator. The extract solution was filtered and then concentrated using a rotary evaporator, followed by drying to a powder under a vacuum at 60°C. The GS was parallel-extracted six times and the average yield of the methanol extract was 13.1% (w/w).

The ultra-high-performance liquid chromatography coupled with quadrupole-time-of-flight mass spectrometry (UHPLC-Q-TOF/MS) approach was used to test the reproducibility of GS extraction. Based on previous research and the literature (Zhou et al., 2012; Yu et al., 2015), four major constituents of GS, including schaftoside, isovitexin, luteolin, and apigenin, were selected for further analysis. The relative standard derivation (RSD) values of the peak areas of each component of the product were calculated in six parallel extracts of GS. The standard substances (NatureStandard, Shanghai, China) of these four constituents were also analyzed for comparison. A detailed description of the methodology is provided in the Supplemental Materials section (**Supplementary Methods S1**).

### Cell Model and Treatment

The human proximal tubular cell line, HK-2 cells were obtained from the ATCC (Manassas, United States). Cells were incubated with sodium oxalate (NaOx) at 1 mM for 12 h to establish a cell model. Potassium citrate (K3Cit) is known for preventing the formation of kidney stone and was used as a positive control. HK-2 cells were divided into five groups (six wells per group): control groups (no treatment), model group (NaOx), K3Cit group (NaOx +1.0 mg/ml K3Cit), 25 µg/ml GS group (NaOx +25 µg/ml GS), 50 µg/ml GS group (NaOx +50 µg/ml GS) and 100 µg/ml GS group (NaOx +100 µg/ml GS). The levels of IL-6 and TNF-α in the cell supernatant were detected using ELISA kits (MultiSciences, Hangzhou, China). Simultaneously, lactate dehydrogenase (LDH) release was determined according to the instructions provided with the kits (Jiancheng Bioengineering, Nanjing, China).

### Animal Experiment and Sample Collection

This experiment was approved by the Animal Ethics Committee of Navy Medical University (license: SCXK (Hu) 2017-0004) and was performed in accordance with the Guiding Principles for the Care and Use of Laboratory Animals. Twenty-four wild-type male C57B/L6 mice aged seven to eight weeks were purchased from the Shanghai SLAC Laboratory Animal Co., Ltd. (production license: SCXK (Hu) 2017-0005), provided with standard food and water, and housed at a temperature of 20–25°C and relative humidity of 55–65%. After one week, the 24 mice were randomly divided into four groups: the control group, oxalate group, oxalate + low dose GS group and oxalate + high dose GS group ( $n = 6$ ).

The mice were intraperitoneally injected with 100 mg/kg glyoxylate once daily for seven days to establish the oxalate-induced renal injury model ( $n = 18$ ), while the mice in the control

group received an equal volume of saline. Two days after the first injection of glyoxylate, the mice received a daily gastric perfusion of the GS extract at a low dose of 10 ml/kg (equivalent to 500 mg/kg body weight of the whole plant powder,  $n = 6$ ) and a high dose of 20 ml/kg (equivalent to 1,000 mg/kg body weight of the whole plant powder,  $n = 6$ ) for five consecutive days, while the mice in the control and oxalate groups received an equal volume of saline. After the last gavages, all the mice were placed in metabolic cages for 24 h to collect urine samples, which were stored at  $-80^{\circ}\text{C}$  until the biochemical and metabolic analysis. Then, the mice were all anesthetized with sodium thiopental. Blood samples were collected and separated by centrifugation at 3,000 rpm for 10 min and stored at  $-80^{\circ}\text{C}$  until the biochemical analysis. After *in situ* cardiac perfusion, the right kidneys were immediately removed and stored at  $-80^{\circ}\text{C}$  until further biochemical analysis and western blot. Next, the left kidneys were removed and fixed with 10% buffered formalin for pathological analysis.

## Biochemical Analysis and Detection of Crystal Deposition

Serum creatinine (SCr) and blood urea nitrogen (BUN) levels were detected using creatinine assay and urea assay kits, respectively (Jiancheng Bioengineering, Nanjing, Jiangsu, China). The urine calcium and creatinine levels were measured using kits (Jiancheng Bioengineering, Nanjing, Jiangsu, China) and the ratio of urine calcium to creatinine (UCa/Cr) was calculated. The renal tissues were placed in prechilled normal saline and phosphate-buffered saline (PBS, pH = 7.4) to produce 10% kidney homogenates. Then, calcium contents in renal tissues were determined with kits (Jiancheng Bioengineering, Nanjing, Jiangsu, China).

The kidney samples were embedded in paraffin and sectioned at a thickness of 3  $\mu\text{m}$ . The deposition of CaOx crystals in representative sections was identified using a polarizing microscope.

## Reverse Transcription-Quantitative Polymerase Chain Reaction

Total RNA was extracted from the renal tissues using TRIzol reagent (Invitrogen, Carlsbad, CA, United States) according to the manufacturer's instructions. The RNA concentration and purity were determined by measuring the absorbance at 260/280 nm. Reverse transcription kits (Vazyme, Nanjing, Jiangsu, China) were used to reverse transcribe RNA into cDNAs. The expression of kidney injury molecule 1 (KIM-1; forward: 5'-ATG AATCA-GATTCAAGTCTTC-3' and reverse: 5'-TCTGGTTTG TGAGTCCATGTG-3') was determined using the SYBR Green PCR kit (Yeesen, Shanghai, China).

## UHPLC-Q-TOF/MS Analysis of Urine Samples

The UHPLC-Q-TOF/MS analysis was performed on an Agilent 1,290 Infinity LC system equipped with an Agilent 6,538 Accurate Mass Quadrupole Time-of-Flight mass spectrometer (Agilent

Technologies, Santa Clara, CA, United States). Chromatographic separations were performed at  $40^{\circ}\text{C}$  on an ACQUITY UPLC HSS T3 column (2.1 mm  $\times$  100 mm, 1.8  $\mu\text{m}$ , Waters, Milford, MA, United States). The mobile phase consisted of 0.1% formic acid (A) and ACN modified with 0.1% formic acid (B). The optimized UPLC elution conditions were as follows: 0–1 min, 2% B; 1–6 min, 2–20% B; 6–9 min, 20–50% B, 9–13 min, 50–95% B; and 13–15 min, 95% B. The post time was set to 5 min for system equilibration. The flow rate was set to 0.35 ml/min, and the injection volume was 4  $\mu\text{L}$ . The auto-sampler was maintained at  $4^{\circ}\text{C}$ .

An electrospray ionization source (ESI) was used both in positive and negative mode. The optimized conditions were as follows: capillary voltage, 4 kV in the positive mode and 3.5 kV in the negative mode; drying gas flow, 11 L/min; gas temperature,  $350^{\circ}\text{C}$ ; nebulizer pressure, 45 psig; fragmentor voltage, 120 V; and skimmer voltage, 60 V. Data were collected in the profile mode from 50 to 1,100 m/z. Potential metabolites were further analyzed using MS/MS, and the collision energy ranged from 10 to 40 eV.

## Data Processing and Statistical Analysis

The raw UPLC data were converted into a common data format (mzData files) using Agilent Mass Hunter Qualitative software, in which the isotope interferences were excluded with a threshold set to 0.1%. The XCMS program (<http://metlin.scripps.edu/download/>) was used for peak detection, retention time (RT) alignment and peak integration to generate a visual data matrix. After filtering the ions based on an 80% rule, the data from each sample were normalized to the total intensity to correct for the MS response shift. Then, the three-dimensional data, including RT-m/z pair, sample name, and normalized ion intensity, were imported into SIMCA-P software (version 11.0, Umetrics, Umea, Sweden) for principle component analysis (PCA) and partial least squares discriminate analysis (PLS-DA). The variable importance in the projection (VIP) values were generated and represented the contribution to the intergroup discrimination of each metabolite ion. Metabolite ions with VIP values greater than 1.0 were selected for further analysis.

All data are presented as the means  $\pm$  standard errors of the means (SEM). Statistical significance of the mean values was assessed using a one-way analysis of variance (ANOVA) or the Kruskal-Wallis H test as appropriate to assess differences among groups in SPSS 17.0 statistical software (SPSS Inc., Chicago, IL, United States) under the conditions of  $p < 0.05$ .

## Identification of Metabolites

The identification of potential urinary metabolites is important and challenging. Therefore, we identified the mass metabolites in a stepwise manner. First, we confirmed the ions based on the extracted ion chromatogram (EIC). Second, we input the accurate molecular mass of the ions into online databases, such as Metlin (<http://metlin.scripps.edu/>), Human Metabolome Database (<http://www.hmdb.ca/>), and the Mass Bank (<http://www.massbank.jp/>), to search for possible metabolites. Third, we compared the MS/MS spectra with the MS/MS information from databases to verify the structure of some putative metabolites.

## Network Analysis

The 15 main compounds of GS and their potential targets were acquired as described in our previous research (Hou et al., 2018). In the present study, the interacting proteins of differentially altered metabolites were further searched using the Search Tool for Interactions of Chemicals (STITCH, <http://stitch.embl.de>) database (Szklarczyk et al., 2016). Subsequently, the interacting proteins of differentially altered metabolites were pooled with the targets of components of GS to construct the component-target-metabolite network using Cytoscape software (<http://cytoscape.org>).

## Western Blot

Acquired renal tissues were homogenized in lysis buffer (KeyGEN, Nanjing, China) containing protease inhibitors and phosphatase inhibitors. The lysates were centrifuged at 12,000 rpm for 5 min at 4°C and the supernatant was collected. The protein concentrations of mixed lysates were determined using a BCA protein assay kit (Thermo Fisher Scientific). Equal amounts of total protein were separated on SDS-PAGE gels and transferred onto nitrocellulose membranes (GE Healthcare Life Sciences). After blocking, the membrane was incubated with rabbit polyclonal anti-ESR2 (1:1,000, Boster Biological Technology), anti-ESR1 (1:1,000, Santa Cruz Biotechnology), anti-AR (1:500, Cloud-Clone), anti-MAOB (1:1,000, Wuhan USCN), anti-PGR (1:1,000, Abcam), anti-GBA (1:1,000, Wuhan USCN), anti-THRB (1:1,000, Abcam), anti-ALB (1:1,000, Cell Signaling Technology), anti-CMA1 (1:1,000, Wuhan USCN) and anti-GAPDH (1:1,000, Wuhan USCN) antibodies at 4°C overnight. After washes with TBST, the membrane was incubated with a fluorescent dye-conjugated secondary anti-rabbit antibody (1:10,000, Licor) for 60 min at room temperature. The signals were visualized using the Odyssey Infrared Imaging System (Licor, NE, United States) and quantitatively analyzed by normalizing them to GAPDH levels using ImageJ software.

## Immunohistochemical Staining

For IHC staining, renal sections were incubated at 4°C overnight with primary antibodies against ESR2 (1:50; Cloud-clone, Wuhan, Hubei, China) and AR (1:50; Cloud-clone, Wuhan, Hubei, China), and then washed with PBS. The specimens were subsequently incubated with an HRP-conjugated goat anti-rabbit antibody (1:500, Proteintech, Chicago, IL, United States) at 37°C for 1 h. Next, the sections were stained with 3,3'-diaminobenzidine (DAB; Boster, Wuhan, Hubei, China) for 6 min.

## RESULTS

### Quality Control of the GS Extract

The GS was parallel-extracted six times, and an UHPLC-Q-TOF/MS approach was used to test the reproducibility of the extraction of GS. As shown in **Figures 1A,B**, the EIC of the four standard substances and the GS extraction visually showed a very similar profile of retention time, which demonstrated that all of these

standard substances could be found in the GS extraction. Each RSD value of the peak area was below 3.2%, as shown in **Table 1**, which indicated that the UHPLC-Q-TOF system was stable and repeatable and that the extraction of GS was reproducible and reliable. Tandem mass spectrometry (MS/MS) was further performed and was shown to be matched between the standard substances and GS extraction (**Figures 1C,D**). More information about the MS/MS is provided in the Supplemental Materials section (**Supplementary Figure S1**).

### Cell Model and Treatment

LDH is a cytoplasmic enzyme that can be released outside when cells are damaged or dead. The number of injured and dead cells is proportional to the level of LDH released to the culture medium. As shown in **Supplementary Figure S2A**, the release of LDH in NaOx-treated cells was significantly higher than that in the control group. The treatment of GS and K3Cit (as a positive control) significantly inhibited the LDH release stimulated by oxalate. The secretion of TNF- $\alpha$  and IL-6 of the oxalate-stimulated HK-2 cells was significantly increased, compared with nontreated cells. However, the secretion of these cytokines was significantly inhibited by the treatment of GS and K3Cit (**Supplementary Figures S2B,C**).

### Biochemical Analysis

The levels of SCr, BUN, UCa/Cr, renal KIM-1 mRNA and the calcium contents in renal tissues in the oxalate group were markedly increased compared to the control group, but were significantly reduced by the GS treatment, especially at a high dose (**Figures 2A–E**).

### Detection of Crystal Deposition

Using a polarizing microscope, CaOx crystal deposition was clearly present in the renal corticomedullary junction in the oxalate group, while the crystal deposition was obviously alleviated by the GS treatment, especially at a high dose (**Figure 2F**).

### Metabolic Profile of Urine

A UHPLC-Q-TOF/MS analysis was performed in both positive and negative modes to explore the metabolic changes in the pathological process of oxalate-induced kidney injury and the mechanism of the protective effects of high-dose GS. As shown in the total ion chromatogram (TIC) and the corresponding spectra collected in positive mode of the control group, oxalate group and oxalate + high-dose GS group were similar (**Figure 3** and **Supplementary Figure S3**). After preprocessing the data, PCA was performed to extract systematic variations and to visualize the general relationships between the control group, oxalate group and oxalate + high-dose GS group (**Figure 4A** and **Supplementary Figure S4A**). Furthermore, PLS-DA was applied to screen the potential metabolites, and the three-dimensional score plot showed that the oxalate group was obviously separated from the control group (**Figure 4B** and **Supplementary Figure S4B**). However, the oxalate + high-dose GS group was close to the control group, revealing that GS rectified the metabolic deviations and protected against crystal-induced kidney injury.

<sup>a</sup>The peak area of each standard substance.

The MS-based identification of the potential metabolites was conducted using online databases. Fifteen metabolites that were differentially present between the control group and oxalate group were finally identified as differentially altered metabolites associated with crystal-induced renal injury (Table 2). Among these metabolites, creatine and pantothenic acid were verified based on the MS/MS spectra (Figure 5). These fifteen endogenous metabolites were mainly involved in amino acid metabolism and fatty acid metabolism. A metabolic network covering all of the differentially altered metabolites was constructed to comprehensively understand the metabolic disturbances

that accompanied the occurrence of crystalline nephropathy (Figure 6). In addition, these differentially altered metabolites were further analyzed using network pharmacology.

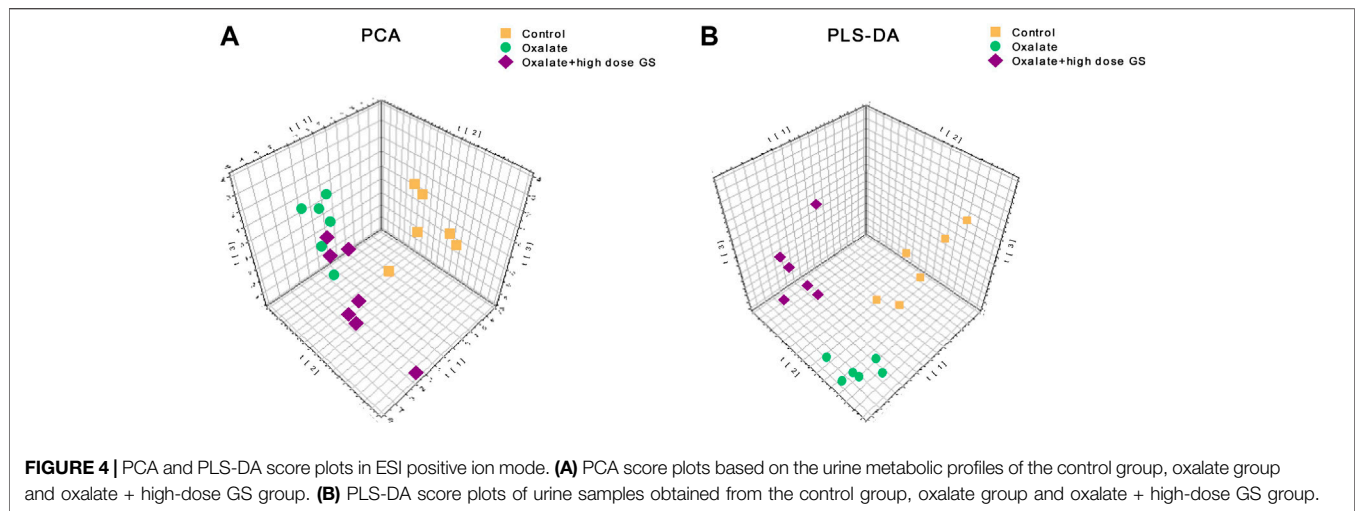

Among the 15 metabolites associated with renal injury, the trends of 13 metabolites were reversed by the GS intervention. The level of L-tyrosine methyl ester decreased after oxalate stimulation and displayed a significant tendency to be reversed by GS treatment. In addition, levels of L-fucose increased considerably in response to oxalate stimulation and exhibited a significant tendency to be corrected to a normal level after GS treatment.

The levels of Scr (A) and BUN (B) in the serum, UCa/Cr (C) in the urine, renal KIM-1 mRNA (D) and calcium contents (E) in the renal tissues in the control group, oxalate group, oxalate + low-dose GS group, and oxalate + high-dose GS group. (F) Detection of renal CaOx crystal deposition in the four groups with a polarizing microscope. The results are presented as means  $\pm$  SEM. Statistical comparisons were performed using a Newman-Keuls test (\* $p < 0.05$  compared with the control group and # $p < 0.05$  compared with the oxalate group).

**FIGURE 3 |** Representative TIC obtained for the ESI-positive ion in the control group (A), oxalate group (B) and oxalate + high-dose GS group (C).

## Network Pharmacology Analysis

Potential targets of the components of GS were previously acquired using PharmMapper Server (Hou et al., 2018). Proteins that interacted with differentially altered metabolites were obtained from the STITCH database (**Supplementary Table S1**). Nine overlapping related proteins interacting with GS and metabolites were identified by constructing a Venn diagram (**Figure 7A**). A component-target-metabolite network was constructed with Cytoscape software to visually reveal the interactions among the components of GS, target proteins and differentially altered metabolites (**Figure 7B** and **Supplementary Table S2**). In the network, nine overlapping target proteins, including ESR2, ESR1, AR, MAOB, PGR, GBA, THRB, ALB and CMA1, were identified for further analysis. This network indicated that the components of GS might regulate multiple metabolic pathways through multiple targets to exert various therapeutic effects.

## Validation of Potential Targets

The nine overlapping proteins were further verified by western blotting. As illustrated in **Supplementary Figure S5**, a significantly decreased level of ESR2 and increased level of AR were observed in the oxalate group. These changes were reversed by the GS treatment. However, the expression of the other seven overlapping proteins was not significantly different.

The expression of ESR2 and AR was further investigated using IHC staining, and the expression of ESR2 in the tubular cells was significantly decreased in the oxalate group compared with the control group, but was increased by the GS treatment, especially at a high dose (**Figure 8A**). In addition, AR expression in the nuclei of tubular cells was obviously increased in the oxalate group compared to the control group, and this change was reversed by GS, especially at a high dose (**Figure 8B**).

## DISCUSSION

### Amino Acid Metabolism

Amino acid metabolism participates in the processes of protein synthesis and degeneration, energy supply, gluconeogenesis,

ketogenesis and biosynthesis of some signaling molecules. In the model group, the levels of several amino acids and their endogenous relative metabolites were noticeably changed. In our study, the involved pathways, including tyrosine metabolism, lysine metabolism, tryptophan metabolism, arginine metabolism and glutamate metabolism, were substantially altered.

As an essential amino acid in mammals, tryptophan was shown to play a notable role in the pathological processes of many kidney diseases, such as chronic kidney disease and nephrotoxicity, because it can be further transformed into many biological molecules and has an important function in homeostasis (Bossola and Tazza, 2015). In the model group, levels of L-tyrosine methyl ester, serotonin and 5-hydroxyindoleacetic acid, the endogenous biological derivative of tryptophan, were reduced (Fernandez-Canon et al., 2002). Based on our present work, we propose that the metabolism of these amino acids is inseparably connected with oxalate-induced renal injury. Levels of all of these amino acids were restored to the normal level after the intervention with GS, indicating that GS has therapeutic efficacy in maintaining normal tryptophan metabolism.

Tyrosine is a semi-essential amino acid in our body, along with tryptophan, and it is also an aromatic amino acid that has been documented to be associated with renal diseases (Zhan et al., 2002). In the model group, the levels of 3-methoxytyrosine and L-tyrosine methyl ester were significantly decreased. In contrast, GS treatment significantly increased the levels of those metabolites, suggesting that the disturbed metabolic state in the urine from mice with oxalate-induced crystal-related kidney injury was in the process of returning to normal after the GS intervention.

Both 1, 3-dimethyluracil and N2, N2-dimethylguanosine are metabolites of glutamic acid and were reduced in the model group. Meanwhile, they were shifted toward the baseline level in the control group after the GS treatment. Glutamic acid was recognized many years ago as a basic amino acid participating in protein biosynthesis that is converted into  $\alpha$ -ketoglutarate through multiple pathways, and it is an essential metabolic intermediate in the tricarboxylic acid cycle (TCA) (Curthoys, 2001). Therefore, the changes in the levels of 1, 3-dimethyluracil

and N2, N2-dimethylguanosine may indicate that energy metabolism was affected during the pathological process.

L-arginine plays important roles in the body, as it participates in the disposal of ammonia and is converted to glucose and glycogen under conditions of an inadequate energy supply.

Furthermore, arginine is also the precursor of creatine in the urea cycle (Karamat et al., 2015). Levels of serotonin, creatinine and pantothenic acid, the metabolic derivatives of arginine, were decreased in the crystal kidney injury group. Arginine is transformed into acetyl-coenzyme A through pyruvate, which

acts as the starting point for a series of physiological reactions known as the TCA (Schneider et al., 2011). The abnormal levels of these metabolites were rectified by GS, which further normalized amino acid metabolism. Therefore, we have many reasons to speculate that the therapeutic efficacy of the targeted GS intervention against crystal-induced kidney injury is mainly mediated by normalizing the disordered TCA through changes in the arginine and glutamate metabolic pathways.

## Fatty Acid Metabolism

Fatty acid metabolism has a direct relationship with the energy supply in organisms through fat mobilization and  $\beta$ -oxidation. In this process, L-carnitine is a key factor because it helps transport long-chain fatty acids into the mitochondrial matrix for the utilization of fatty acids through  $\beta$ -oxidation (Knottnerus et al., 2018). Therefore, an increased intracellular level of carnitine provides an additional energy supply. In the model group, levels of propionyl-L-carnitine, a product of the enzymatic esterification of carnitine, increased significantly, which indicated the presence of a pathological process induced by the glyoxylate intervention. The subsequent CaOx deposition pushed the organism into a high metabolic state to satisfy the energy requirement by increasing the  $\beta$ -oxidation process in the mitochondria. However, large quantities of reactive oxidants were produced during the process of  $\beta$ -oxidation, leading to severe oxidative injury to the renal epithelial cells.

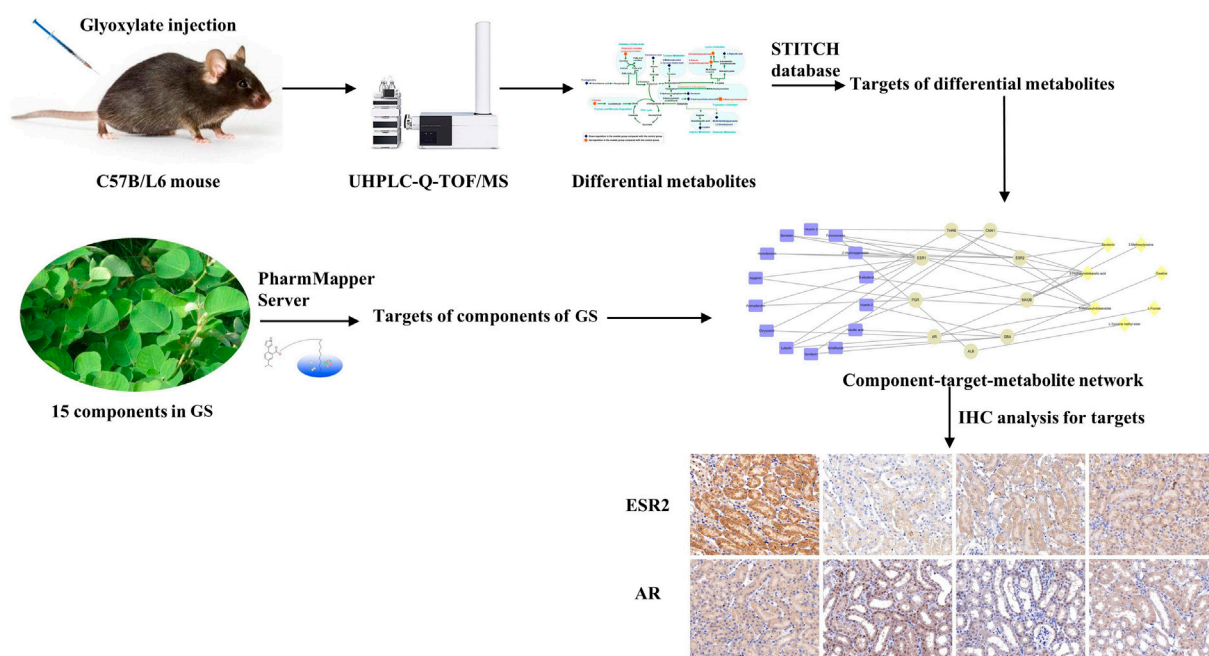

Following treatment with GS, the increased propionyl-L-carnitine level was significantly reduced, suggesting that the disordered fatty acid metabolism induced by glyoxylate was in the process of returning to a normal state.

## Component-Target-Metabolite Network Analysis

According to the network construction, we identified nine overlapping proteins might play important roles in the therapeutic effects of GS on CaOx crystal-induced renal injury. Interestingly, ESR1, ESR2 and AR are the predicted targets of the components of GS among these overlapping targets. Since nephrolithiasis is more common in men than in women, sex hormones and their receptors may play important roles in kidney stone formation and CaOx crystal-induced renal injury. Estrogen has been indicated to protect against kidney stone formation by lowering urinary CaOx saturation through a decrease in the urinary excretion of calcium and oxalate (Heller et al., 2002). In addition, ESR2 was reported to suppress renal CaOx crystal deposition by reducing hepatic oxalate biosynthesis and to alleviate crystal-induced injury by inhibiting reactive oxygen species production (Zhu et al., 2019b). However, androgen and AR signaling may promote kidney stone formation and aggravate renal injury since the plasma testosterone level and AR expression in the kidneys are up-regulated in men with nephrolithiasis (Li et al., 2010). Similarly, a previous study suggested that AR increased

**FIGURE 8 |** The expression of ESR2 (**A**) and AR (**B**) in the renal tissues from the control group, oxalate group, oxalate + low-dose GS group, and oxalate + high-dose GS group detected using IHC staining.

**FIGURE 9 |** Roadmap of this study.

CaOx crystal deposition by increasing oxalate biosynthesis and oxidative stress (Liang et al., 2014). Moreover, the loss of AR suppressed renal CaOx crystal deposition by promoting M2 macrophage recruitment/polarization (Zhu et al., 2019a). In our study, ESR2 expression in renal tissues was down-regulated while the AR expression in the nuclei of tubular cells was increased in the oxalate group compared with the control group, changes that were reversed by GS. Therefore, we speculated that GS might exert its protective effect on CaOx crystal-induced renal injury by activating ESR2 and decreasing the nuclear translocation of AR.

## CONCLUSION

In the present study, GS was verified to alleviate renal injury induced by CaOx. The roadmap of this study is shown in **Figure 9**. We employed an integrative pharmacology-based strategy combining network pharmacology and metabolomics to decipher the underlying mechanism. Fifteen metabolites involved in amino acid and fatty acid metabolism were identified as potential biomarkers of crystal-induced renal damage and the changes in the levels of 13 metabolites were reversed by the GS intervention. By integrating network pharmacology, a component-target-metabolite network was constructed. Among the nine overlapping target proteins, two crucial targets (ESR2 and AR) were differentially expressed in the kidney of oxalate group, but these trends were reversed by the GS treatment. In conclusion, GS exerts its therapeutic effect by regulating multiple metabolic pathways and the expression of ESR and AR in mice with oxalate-induced renal injury. Our findings might help us consider novel potential targets when treating nephrolithiasis and obtain a better understanding of the mechanism underlying the curative effect of GS.

**Background:** Clinical research found that *Hedysarum Multijugum Maxim.-Chuanxiong Rhizoma* Compound (HCC) has definite curative effect on cerebral ischemic diseases, such as ischemic stroke and cerebral ischemia-reperfusion injury (CIR). However, its mechanism for treating cerebral ischemia is still not fully explained.

**Methods:** The traditional Chinese medicine related database were utilized to obtain the components of HCC. The PharmMapper were used to predict HCC's potential targets. The CIR genes were obtained from Genecards and OMIM and the protein-protein interaction (PPI) data of HCC's targets and IS genes were obtained from String database. After that, the DAVID platform was applied for Gene Ontology (GO) enrichment analysis and pathway enrichment analysis. Finally, a series of animal experiments were carried out to further explore the mechanism of HCC intervention in CIR.

**Results:** The prediction results of systematic pharmacology showed that HCC can regulate CIR-related targets (such as AKT1, MAPK1, CASP3, EGFR), biological processes (such as angiogenesis, neuronal axonal injury, blood coagulation, calcium homeostasis) and signaling pathways (such as HIF-1, VEGF, Ras, FoxO signaling). The experiments showed that HCC can improve the neurological deficit score, decrease the

## INTRODUCTION

Cerebrovascular disease is a common disease in the clinic, which seriously endangers human health and life. As the population of aging increases, the morbidity, mortality and disability rate of cerebrovascular disease were increasing year by year (Thomas, 1996; Sacco and Rundek, 2012; Liu et al., 2015). Among them, ischemic cerebrovascular disease accounts for a large proportion. The key to cerebral ischemia treatment is to quickly restore cerebral blood perfusion and maintain smooth blood flow (Frizzell, 2005; Behravan et al., 2014). However, the brain injury may be further aggravated after the restoration of blood flow perfusion, that is cerebral ischemia-reperfusion injury (CIR). Ischemia-reperfusion injury (IRI) refers to the pathological phenomenon that the degree of tissue damage is increased after the blood supply to the ischemic tissue is restored for a certain period of time (Wu et al., 2018). The harm of CIR is huge. It involves many complicated links and factors, which has been the focus of scientists' research for many years. With the deepening of the research, while looking for neuroprotective drugs, a variety of comprehensive intervention strategies for CIR such as mild hypothermia, atmospheric hyperbaric therapy and ischemic preconditioning and ischemic postconditioning were also proposed (Lapi and Colantuoni, 2015; Patel and McMullen, 2017; Leech et al., 2019); the drugs include: N-methyl-D-aspartic acid (NMDA) receptor antagonist, Ca<sub>2</sub> + channel blocker, ICAM-1 antibody, CDP-choline, and so on (Lapi and Colantuoni, 2015; Patel and McMullen, 2017). At present, natural plant ingredients have been found to improve microcirculation barriers after CIR, and Chinese medicine formulations have gradually become a new direction for new drug development (Wang et al., 2019).

*Hedysarum Multijugum Maxim.-Chuanxiong Rhizoma* Compound (HCC) was first used by the First Affiliated Hospital of Hunan University of Chinese Medicine. Clinical research showed that HCC has definite curative effect on cerebral ischemic diseases (such as ischemic stroke and CIR), and its clinical effective rate is over 90% (Ge, 2014). This Chinese medicine formula is composed of *Hedysarum Multijugum Maxim.* [Leguminosae; *Astragali Radix* (Huang Qi)], *Ligusticum striatum* DC. [Apiaceae; *Chuanxiong Rhizoma* (Chuan Xiong)], *Pheretima Aspergillum* (E.Perrier) [Megascolecidae; *Pheretima* (Di Long)], *Bombyx Batryticatus* [A desiccated body formed by the 4–5 instar larvae of *Bombyx mori* Linnaeus (family: *Bombycidae*) infected with white *Beauveria bassiana* (Bals.) Vuillant; (Jiang Can)], and can reduce serum tumor necrosis factor (TNF) - $\alpha$  and plasma thromboxane B2 (TXB2) levels and increase plasma 6-Keto-

PGF1 $\alpha$  (He et al., 2002). Our previous research also found that HCC can protect neurons in the hippocampal CA<sub>2</sub> region by regulating Fpn expression to balance iron levels after cerebral ischemia. This suggests that imbalance of intracellular iron balance may be a new mechanism of cerebral ischemia (Liao et al., 2015). However, the mechanism of HCC in treating cerebral ischemia is still not fully explained. Systematic pharmacology is an emerging discipline based on the intersection and integration of multidisciplinary technologies such as classic pharmacology, computer technology, bioinformatics, and network pharmacology, which systematically studies the interactions between drugs and the human body at multiple levels, including molecules, cells, organs, and networks (Zeng et al., 2017; Zeng and Yang, 2017; Bao et al., 2019; Yang et al., 2019a; Yang et al., 2019b). Our previous research used systematic pharmacological strategies to reveal the mechanism of Chinese medicine formula in the treatment of complex diseases in the fields of oncology and cardiovascular (Zeng et al., 2017; Zeng and Yang, 2017; Bao et al., 2019; Yang et al., 2019a; Yang et al., 2019b). Therefore, this study hopes to reveal the complex mechanism of HCC through a systematic pharmacology strategy (integrating network pharmacology experimental pharmacology).

## MATERIALS AND METHODS

### HCC's Compounds Collection

The components of HCC were collected from the traditional Chinese Medicine (TCM) Database at Taiwan (<http://tcm.cmu.edu.tw/zh-tw/>) (Chen et al., 2014) and the Traditional Chinese Medicine Systems Pharmacology Database (TcmSPTM, <http://tcmssp.com/tcmssp.php>) (Ru et al., 2014). The components with oral bioavailability (OB)  $\geq 30\%$ , Caco-2 permeability  $> -0.4$  and drug-likeness (DL)  $\geq 0.18$  were considered as the potential bioactive compounds of HCC (Walters and Murcko, 2002; Ano et al., 2004; Hu et al., 2009; Xu et al., 2012; Ru et al., 2014). Meanwhile, since the application of biological models to predict HCC compounds has limitations (Metodiewa et al., 1997), a large number of references were searched to supplement oral absorbable compounds with pharmacological activity (Shi et al., 2014; Tong et al., 2019). The components of HCC were shown in Table 1.

### HCC's Potential Targets Prediction and CIR Genes Collection

The molecular structure was drawn by ChemBioDraw according to their structure in SciFinder (<http://scifinder.cas.org>) and saved

**TABLE 1 |** Components of HCC.

Drug name	Species	Family	Components
<i>Astragali Radix</i> (Huang Qi)	<i>Hedysarum Multijugum Maxim</i>	Leguminosae	1,7-Dihydroxy-3,9-dimethoxy pterocarpene, 3,9-di-O-methylinissolin, 64474–51-7, 64997–52-0, 73340–41-7, 7-O-methylisomucronulatol, astragaloside IV, Bifendate, Calycosin, Calycosin 7-O-glucoside, Formononetin, Hederagenin, Isodalbergin, Isorhamnetin, Jaranol, Kaempferol, Mairin, Ononin, Quercetin
<i>Chuanxiong Rhizoma</i> (Chuan Xiong)	<i>Ligusticum striatum DC.</i>	Apiaceae	Butylidenephthalide, Butylphthalide, Chlorogenic acid, Coniferyl Ferulate, Ferulic acid, Ligustilide, Ligustrazine, Mandenol, Myricanone, Perolylrine, Senkyunolide A, Senkyunolide H, Senkyunolide I, Senkyunone, Sitosterol, Wallichilide
<i>Pheretima</i> (Di Long)	<i>Pheretima Aspergillum (E.Perrier)</i>	Megascolecidae	4-Guanidino-1-butanol, Cholesteryl ferulate, Guanosine, Hyrcanoside, Xanthinin
<i>Bombyx Batryticatus</i> (Jiang Can) <sup>a</sup>	-	-	Bassianin, Beauvericin, Ecdysterone, Ergotamine, Lupeol acetate

<sup>a</sup>*Bombyx Batryticatu* is the desiccated body formed by the 4–5 instar larvae of *Bombyx mori* Linnaeus (family: Bombycidae) infected with white *Beauveria bassiana* (Bals.) Vuillant.

as “mol2” file format. The “mol2” files of HCC’s components were input into PharmMapper (<http://lilab-ecust.cn/pharmmapper>) for potential targets prediction (Wang X. et al., 2017). OMIM database (<http://omim.org/>) and Genecards (<http://www.genecards.org>) were utilized to collect the CIR-related disease genes and targets (Hamosh et al., 2005; Stelzer et al., 2016). The PDB ID number of HCC’s protein target and the name of CIR-related targets were input into UniProt KB (<https://www.uniprot.org/uniprot/>) to obtain the official gene symbol of each target. (see **Supplementary Table S1** and **Supplementary Table S2** in Supplementary Material).

## Network Construction and Analysis Methods

The protein-protein interaction (PPI) data of targets were obtained from String 11.0 (<http://string-db.org/>) (Szklarczyk et al., 2015). The CIR gene, HCC compounds and potential targets, and PPI data were imported into Cytoscape 3.7.1 software (<https://cytoscape.org/>) for network construction (Bader and Hogue, 2003). The networks were analyzed by the plugin MCODE to obtain cluster. The definition and the methodology of acquisition of clusters were described in our previous work (Zeng et al., 2017; Zeng and Yang, 2017; Bao et al., 2019; Yang et al., 2019a; Yang et al., 2019b), such as “Exploring the Pharmacological Mechanism of Quercetin-Resveratrol Combination for Polycystic Ovary Syndrome: A Systematic Pharmacological Strategy-Based Research” (Yang et al., 2019a) and “Uncovering the Pharmacological Mechanism of *Astragalus Salvia* Compound on Pregnancy-Induced Hypertension Syndrome by a Network Pharmacology Approach” (Zeng et al., 2017).

The HCC targets and CIR genes in the network were input into the Database for Annotation, Visualization and Integrated Discovery (DAVID, <https://david-d.ncicrf.gov>, ver. 6.8) for Gene Ontology (GO) enrichment analysis and pathway enrichment analysis (Huang et al., 2009).

## Experimental Materials Instruments and Reagents

Instruments: BX51 optical microscope, Motic Image Advanced 3.0 image analysis system (Olympus, Japan); Tgradient PCR

instrument (Biomatra); KD2258 paraffin slicer (Zhejiang Jinhua); LEICA DM LB2 binocular microscope (Leica, Germany); JY3002 electronic balance (Shanghai Precision Scientific Instrument Co., Ltd.); HHS-2 electronic constant temperature stainless steel Water bath (Shanghai Nanyang Instrument Co., Ltd.); S2-93 automatic double pure water distiller (Shanghai Yarong Biochemical Instrument Factory). Eppendorf benchtop cryogenic microcentrifuge (Eppendorf Inc.); high speed benchtop centrifuge (Beckman Inc.); micropipette (Eppendorf Inc.) ultrapure water meter (Millipore Inc.); ultra clean bench (Suzhou Purification Equipment Co., Ltd.); –80°C ultra-low temperature refrigerator (Zhongke Meiling Cryogenic Technology Co., Ltd.). Column: Welch Ultimate XB-C18 (HS), 4.6 x 250 nm. 5 µm; High Performance Liquid Chromatograph: Agilent, Germany angilent1260 (Diode Array Detector).

Reagents: TRIzol was purchased from Invitrogen Inc., United States; RT-PCR kit was purchased from MBI Inc., United States; HIF-1α (batch number: bs-0737R), VEGF (batch number: bs-1957R) and VEGFR (batch number: bs-0565R) antibody were purchased from Beijing Boasoen Biotechnology Co., Ltd.; vWF monoclonal antibody (batch number: F3520), rhodamine red (lot number: 83697), isothiocyanate fluorescent yellow (FITC, batch number: P5282) were purchased from Sigma Inc., United States; BrdU monoclonal antibody (NA61) was purchased from Chemicon, United States; immunohistochemistry kit was purchased from Beijing Boasoen Biotechnology Co., Ltd.; Standards: Ligustrazine Hydrochloride 110817–201608, ferulic acid 110773–201614, astragaloside 110781–201717, all from China Food and Drug Testing Institute.

## Animal

One hundred and twenty (120) Sprague-Dawley (SD) rat with 7 ~ 8 week old and body weight 280~300 g (without limited to male and female) were purchased from Shanghai Xipuer-Bikai Laboratory Animal Co., Ltd. [Animals permit number: SCXK (Shanghai) 2018–0016]. All animals were housed in clean cages and housed under a 12 h light/dark cycle at a temperature of 21–25°C and a humidity of 45–65%. Free drinking, feeding, and adaptive feeding for 1 week. The experiment was approved by the Ethics Committee of Hunan University of Chinese Medicine

(Changsha, China) (Approval No: 201404163). Animal experiments are strictly in accordance with the ethics committee guidelines and laboratory animal care and use guidelines.

### Preparation of HCC Extract

*Hedysarum Multijugum Maxim.* (Specimen number: 2014062101), *Chuanxiong Rhizoma* (Specimen number: 2014062410), *Pheretima* (Specimen number: 2014062205), *Bombyx Batryticatus* (Specimen number: 20140622307), with ratio 4:1:1.5:1.5, was purchased from the Chinese Pharmacy of the First Affiliated Hospital of Hunan University of Chinese Medicine. The herbs were verified by Professor Bing Dai. The HCC extract was prepared by the Department of Pharmacy, the First Affiliated Hospital of Hunan University of Chinese Medicine. The specific experimental procedure refers to our previous study (Chen, 2005). When in use, the HCC dry extract and physiological saline are formulated into an HCC solution.

### High Performance Liquid Chromatography

Three representative compounds in HCC were identified by high performance liquid chromatography (HPLC) for quality control: astragaloside IV, ferulic acid, and ligustrazine. Conditions: Ultimate XB-C18 column (5  $\mu$ m, 4.6  $\times$  250 mm), A: acetonitrile; B: 0.2% phosphoric acid-water; gradient elution flow rate: 1 ml/min; Detection wavelength: 198, 201, 280, 290, 315, 320 nm; injection volume: 10  $\mu$ l.

The HPLC of HCC is shown in **Supplementary Figure S1**. The main compounds of HCC were quantified: astragaloside IV 13.72 mg/200g, ferulic acid 2.52 mg/200g, ligustrazine 0.36 mg/200g.

## Experimental Methods

### Animal Grouping, Model Preparation and Intervention Methods

One hundred and twenty (120) rats were randomly divided into normal group ( $n = 12$ ), sham operation group ( $n = 12$ ), CIR model group ( $n = 48$ ) and HCC group ( $n = 48$ ). The model group and the HCC group were divided into four subgroups (1, 3, 5, and 7 days after reperfusion) with 12 rats in each group. All animals were trained for 3 days with reference (Bederson et al., 1986; Huang et al., 2009) before modeling. The specific method is: suspending the tail of the rat about 1 m from the ground, and observing the flexion of the forelimb. The cages where the animals are kept are marked with letters, and the drugs are also marked with letters, and they are kept by a third person before the end of the experiment. The animal experiment operator, data collector, and indicator tester do not know the group and intervention drugs.

Scoring criteria: 0 points: Rat forelimbs extended to the ground, no other symptoms; 1) point: The forelimb of the injured hemisphere of the rat suffered from flexion, and its posture changed from slight lumbar flexion and a certain degree of adduction to the shoulder of the elbow, to complete flexion of the waist and elbow and internal rotation of the shoulder; 2) points: Put the rat on a piece of soft plastic paper,

lift the tail, apply a soft force on the shoulder, and the resistance of the rat to the external force which causes it to slide toward the diseased side is weakened; 3) points: The rat has a clear consciousness, making a rear-end movement to the right or falling to the right; 4) points: accompanied by disturbance of consciousness, no spontaneous activity; 5) points: death. The entire test process takes 3–5 min, and the rats with scores of 1–3 were enrolled. When the rat died and the sample size was insufficient, random replacement was performed. The left middle cerebral artery occlusion (MCAO) model was prepared by referring to Longa et al. (1989). Rats were fasted before operation and anesthetized. The body temperature was maintained by a constant temperature circulating water system. The rat had a median neck incision, exposed the left external carotid artery and its branches (occipital artery and superior thyroid artery) and the common carotid artery bifurcation. The occipital artery and the superior thyroid artery were ligated, and the carotid artery bifurcation was cut at the bifurcation of the common carotid artery and a smooth nylon thread ( $1.85 \pm 1.5$ ) cm with a diameter of 0.26 mm was inserted into the internal carotid artery. Stop sending the line when the resistance is felt, and record the time. Two hours after the middle cerebral artery was blocked, the suture was withdrawn to restore perfusion. The sham operation group only inserted the fishing line about 1 cm, and the others were the same as the model group. The success rate of modeling is about 80%, and the failure model is randomly replaced. After the model is prepared, the animals are kept in cages.

Administration method: HCC group: the dose given to rats was calculated according to the animal body surface area dose conversion algorithm, the formula is  $D2 = D1 \times R2 \div R1$  ( $D2$  is the desired dose,  $D1$  is the known dose,  $R1$  is the corresponding known value, and  $R2$  is the ratio of the surface area of the corresponding animal body). The daily dose for rats (0.72 g/ml, 1 ml/100 g) is equivalent to twice the dose for adults. It was calculated from the ratio of 80 g of the daily dose of a 70 kg adult to the body surface area of 300 g rat. The first dose was given 2 h after waking anesthesia. The HCC group was intragastrically administered with HCC extract, and the rest were given the same amount of physiological saline, and were given once a day for 7 days.

### Specimen Collection and Section Preparation

One (1) hour after the last administration, the rats were anesthetized with 1% sodium pentobarbital (2.75 ml/kg, intraperitoneal injection), and then sacrificed by cervical dislocation. The brain tissue was then quickly collected. The specimen was divided into two parts, one was rinsed with 1‰ DEPC water and immediately placed in liquid nitrogen; the other was fixed in 4% paraformaldehyde to make a 5  $\mu$ m thick paraffin section for HE staining, immunohistochemical staining and BrdU/vWF fluorescence double labeling.

### Detection Indicators and Methods

#### Neurological Deficit Score

Neurological deficits were assessed by a five-point, four-point scoring method by Longa et al. (1989). 0 points: no symptoms of

neurological deficits; 1) point: When the rat is suspended from the tail, the contralateral forelimb of the lesion is flexed and raised, the shoulder is adducted, and the elbow is straight; 2) points: rotate to the opposite side of the lesion; 3) points: fall to the opposite side of the lesion; 4) points: no spontaneous activity and decreased level of consciousness. The score was performed at 1, 3, 5, and 7 days after surgery. Rats with a score of 1–3 were selected for inclusion in the results.

### Volume of Cerebral Infarction

The volume of cerebral infarction was assessed by TTC staining. The brain tissues were and placed in a refrigerator at  $-20^{\circ}\text{C}$  for 10 min. Then the brain tissue was deceived and placed in a 1% TTC solution, strictly protected from light, incubated at  $37^{\circ}\text{C}$  for 30 min, and then placed in 10% formaldehyde for 3 h. The stain-free area is infarct tissue. The area of infarct size was calculated by multimedia color image analysis system. The infarct volume was calculated according to formula  $V = S \times D$  ( $S$  is the infarct area of each slice and  $D$  is the slice thickness). The infarct size of each brain slice was measured on a computer by area measurement software, and the sum of the infarct volumes of all brain slices was the total volume of the infarct.

### Microvessel Density Detection

Microvessels were observed by immunohistochemical methods, and microvessel density (MVD) counts were performed according to Weidner et al. (1991). The test was carried out according to the instructions of the immunohistochemistry kit. vWF is labeled as a brownish-yellow particle in the cytoplasm of vascular endothelial cells, and any endothelial cell or endothelial cell cluster that is stained brown by the vWF antibody is considered to be a blood vessel count. Using the MIAS medical image analysis system, five sections were taken at each time point, and each section was selected for 4 high-magnification ( $\times 400$ ) fields around the same cortical ischemic area for microvessel counting. Referring to the Weidner counting method, the number of microvessels per  $1\text{ mm}^2$  was calculated and then averaged. The results of 15 slices per group at each time point were obtained.

### Immunofluorescence Staining for Expression of BrdU and vWF

After BrdU is dissolved in normal saline, the dose is determined at 100 mg/kg/day, and intraperitoneal injection is performed. The sections of brain tissue were immersed in 3%  $\text{H}_2\text{O}_2$  deionized water for 10 min; washed with PBS for 5 min  $\times$  3 times; immersed in 2 mol/L HCl at  $37^{\circ}\text{C}$  for 15 min. Then, the sections were wash with PBS for 5 min  $\times$  3 times; 5% goat serum was blocked at room temperature for 30 min, and the liquid was aspirated. After that, BrdU monoclonal antibody (1: 100) 10  $\mu\text{l}$  were added and incubated in  $37^{\circ}\text{C}$  water bath. Then, FITC (luminescence wavelength 520–530 nm, yellow-green light) staining was performed,  $37^{\circ}\text{C}$  water bath for 30 min, after washing, the sections were blocked with 5% goat serum at room temperature for 30 min vWF antibody (1: 100) 10  $\mu\text{l}$  were added and incubated in  $37^{\circ}\text{C}$  water bath for 3 h. Rhodamine

(light emission wavelength 570–590 nm, red light) staining was performed,  $37^{\circ}\text{C}$  water bath for 30 min. Finally, the slices were packaged with glycerin and observed with an OLYMPUS BX51 fluorescence microscope by the corresponding color filters at 520 and 580 nm, respectively. FITC is green and rhodamine is red. The image is taken in Key Lab of Hunan Province for Prevention and Treatment of Cardio-cerebral Diseases with Integrated Traditional Chinese and Western Medicine, Hunan University of Chinese Medicine, and the images obtained under the two excitation lights are superimposed to obtain a yellow signal as a common signal.

### Detection of HIF-1 $\alpha$ , VEGFA and VEGFR mRNA Levels

The total RNA was extracted from the infarcted side of the brain by the guanidinium isothiocyanate method. The mRNA expression was determined by Reverse Transcription-Polymerase Chain Reaction (RT-PCR).

PCR product analysis: 5  $\mu\text{l}$  PCR amplification products were analyzed on 2.5% agarose gel electrophoresis (voltage 50 V, 30–45 m, ethidium bromide staining). The electrophoresis strips were taken under UV light and the negatives were scanned with a laser density scanner. The expression levels of HIF-1 $\alpha$ , VEGF and VEGFR mRNA were calculated using the following formula: Relative product content = HIF-1 $\alpha$  (VEGF, VEGFR) amplification product optical density value/GAPDH amplification product optical density value  $\times$  100%. The Primers were designed with reference to the computer gene library nucleotide sequence data, and were synthesized by Shanghai Shengong Bioengineering Co., Ltd. (Table 2).

### Detection of HIF-1 $\alpha$ , VEGFA and VEGFR Protein by Immunohistochemistry

The brain tissue was embedded by paraffin, sliced (5  $\mu\text{m}$ ), conventional dewaxed. Then it was soaked in 3% hydrogen peroxide for 10 min at room temperature and washed twice with distilled water. After heat repairing the antigen, the primary antibody (rabbit anti-VEGF 1:300; rabbit anti-VEGFR2 1:200; rabbit anti-HIF-1 $\alpha$ 1:200) and the biotinylated secondary antibody were added sequentially. Then the horseradish enzyme-labeled streptavidin solution was added and incubated in  $20\sim 37^{\circ}\text{C}$  for 20 min. The color was developed by DAB at room temperature, and the reaction time was controlled under the microscope (5–30 min). Finally, the slices were lightly counterstained with hematoxylin, dehydrated, and transparent, and sealed with a neutral gum. The expression of HIF-1 $\alpha$ , VEGFA and VEGFR was observed under a microscope.

### Statistical Analysis

The data were processed by SPSS 19.0 statistical software, and the measurement data were expressed as mean  $\pm$  standard deviation. Variance homogeneity tests were performed for comparison between groups. If the variances are homogeneous, multiple comparisons using a completely random design analysis of variance or a grouped t test are used for data processing. If the variances are not homogeneous, the rank sum test is used.

## RESULTS AND DISCUSSION

### Potential Targets of HCC and CIR Genes

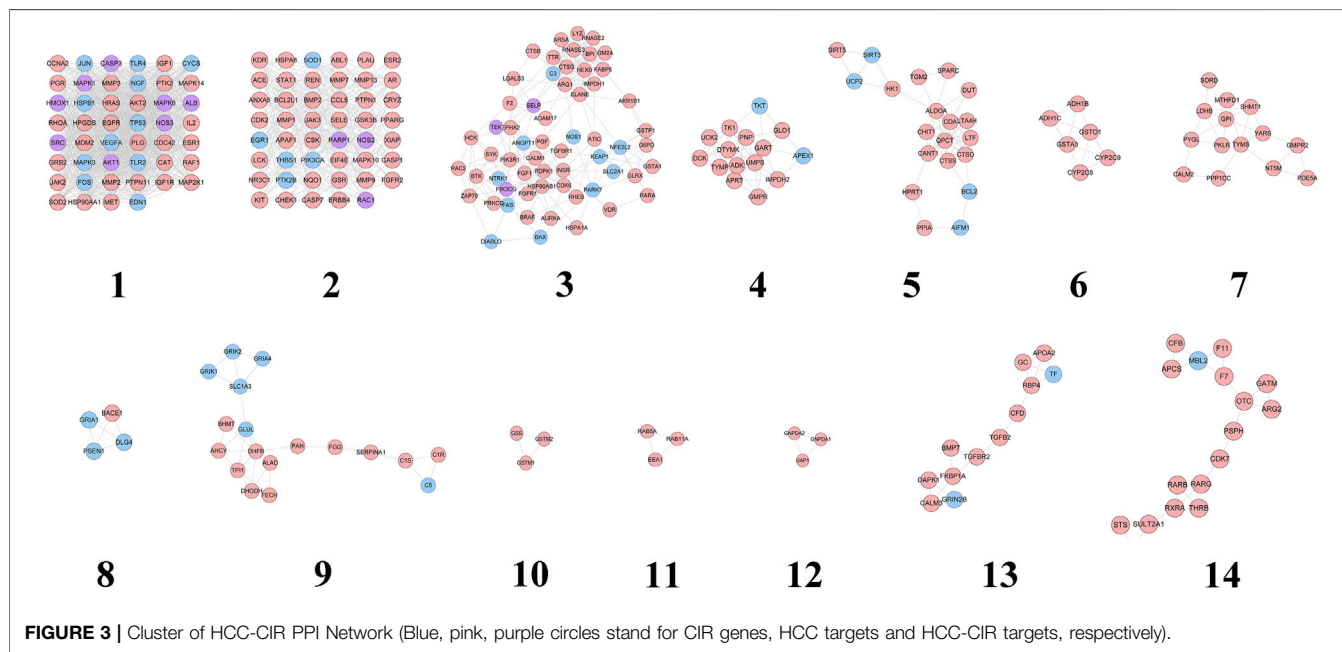

Ninety CIR-related genes were obtained from GeneCards and OMIM database (see **Supplementary Table S2**). After the potential target prediction, totally 440 potential targets were obtained. The relationship among potential compounds and potential targets was shown in **Figure 1**. This network consists of 440 compound targets, 45 potential compounds and 8,759 edges. The targets near the center are regulated by more compounds than ones in the peripheral. For example, the targets in the center are: AR (45 edges), BACE1 (45 edges), CA2 (45 edges), CDK2 (45 edges), F2 (45 edges), FKBP1A (45

edges), GSK3B (45 edges), GSTA1 (45 edges), GSTP1 (45 edges), HSD17B1 (45 edges), MAPK14 (45 edges), PRKACA (45 edges), AKR1B1 (44 edges), CCNA2 (44 edges), HSP90AA1 (44 edges), MMP3 (44 edges), PDE4D (44 edges), PTPN1 (44 edges), AKR1C3 (43 edges), FGFR1 (43 edges), LCK (43 edges), METAP2 (43 edges), PDPK1 (43 edges); the targets in the peripheral (ADAMTS4, ADORA2A, CLIC1, FGF1, GATM, GLRX, LTF) are regulated only by one compound. The compounds in herbs can regulate multiple targets. The top five compounds in each herb are: *Hedysarum Multijugum Maxim.*: Astragaloside IV (298 edges), Calycosin 7-O-glucoside (295 edges), Ononin (294 edges), Bifendate (162 edges), Isorhamnetin (151 edges); *Chuanxiong Rhizoma*: Senkyunolide

## HCC-CIR PPI Network Analysis

### HCC-CIR PPI Network

HCC potential targets, CIR genes and their PPI data were input into Cytoscape to construct HCC-CIR PPI network. This network contains 502 nodes 75 CIR gene nodes, 412 HCC target nodes and 15 HCC-CIR targets nodes) and 7,762 edges (**Figure 1**) The top 20 targets of degree are selected and divided into three categories: 1) CIR targets: TP53 (189 edges), VEGFA (166 edges), MAPK3 (164

**FIGURE 4 |** Bubble chart of biological processes (X-axis stands for fold enrichment).

**FIGURE 5 |** Bubble Chart of Signaling Pathway (X-axis stands for fold enrichment).

edges), JUN (133 edges), CYCS (109 edges); 2) HCC genes: EGFR (155 edges), HSP90AA1 (135 edges), HRAS (127 edges), IGF1 (126 edges), CAT (123 edges), MMP9 (122 edges), ESR1 (116 edges), RHOA (104 edges), MAPK14 (102 edges); 3) HCC-CIR targets: ALB (215 edges), AKT1 (205 edges), MAPK1 (156 edges), SRC (143 edges), CASP3 (141 edges), MAPK8 (137 edges).

### Clusters of HCC-CIR PPI Network

The HCC-CIR PPI network was analyzed by MCODE, and returns 14 clusters (Table 3 and Figure 3).

These genes in each cluster were input into DAVID database to undergo GO enrichment analysis. After that, several biological processes were obtained. Cluster 1 is associated with negative regulation of neuronal apoptosis, nitric oxide production and metabolism, angiogenesis, hypoxia induction, neurotrophicity, platelet activation, and CIR-related signaling pathways (such as NF-kB signaling pathway). Cluster 2 is related to cell proliferation, hypoxia-induced, cell migration, and CIR-related signaling pathways (ERK1/2 signaling and PI3K signaling, EGF receptor signaling, and VEGF receptor signaling pathways). Cluster 3

**TABLE 4 |** Effect of HCC on the score of neurological deficits in rats after CIR at different time points ( $n = 5$ ,  $x \pm s$ ).

Group	1 day	3 days	5 days	7 days
Normal	0	0	0	0

HCC	$1.5 \pm 1.00^a$	$0.5 \pm 0.35^b$	$0.4 \pm 0.54$	$0.4 \pm 0.54$

<sup>a</sup>compared with the Sham operation group,  $p < 0.05$ .<sup>b</sup>compared with the CIR model group,  $p < 0.05$ .

mainly involves inflammation, platelet activation, nerve cell survival, angiogenesis, oxidative stress, neuronal axonal injury, hypoxia-induced stress, blood coagulation, calcium homeostasis. Cluster 4 is associated with nucleic acid metabolism. Cluster 5 is related to oxidative stress, neuronal apoptosis, ischemia induction, cytokines and NF- $\kappa$ B signaling pathway. Cluster 8 mainly includes the biological processes of synaptic transmission. Cluster 9 is associated with chemical synapses and neurotransmitters. Cluster 13 mainly involves angiogenesis. Cluster 6, 7, 10, 11, 12, 14 do not return CIR-related biological processes (see **Supplementary Table S3**).

Since cluster 1 is the most important one, it is used as an example to show its main biological processes on bubble chart (**Figure 4**).

### Pathway of HCC-CIR PPI Network

Thirty-four CIR signaling pathways are obtained. The signaling pathway is arranged according to the degree of enrichment (based on  $p$ -value) and count, and the Neurotrophin signaling pathway is found to have the highest enrichment and contained 34 targets ( $p$ -value =  $7.15 \times 10^{-14}$ ; Count = 34). According to the sorting, the other signaling pathways (top 10) are: Ras signaling pathway ( $p$ -value =  $6.74 \times 10^{-13}$ ; Count = 46), Estrogen signaling pathway ( $p$ -value =  $2.82 \times 10^{-12}$ ; Count = 29), Rap1 signaling pathway ( $p$ -value =  $1.49 \times 10^{-11}$ ; Count = 42), VEGF signaling pathway ( $p$ -value =  $2.54 \times 10^{-11}$ ; Count = 22), FoxO signaling pathway ( $p$ -value =  $2.86 \times 10^{-10}$ ; Count = 31), HIF-1 signaling pathway ( $p$ -value =  $3.04 \times 10^{-10}$ ; Count = 26), Insulin signaling pathway ( $p$ -value =  $6.15 \times 10^{-10}$ ; Count = 31), PI3K-Akt signaling pathway ( $p$ -value =  $6.46 \times 10^{-10}$ ; Count = 53), T cell receptor signaling pathway ( $p$ -value =  $4.18 \times 10^{-9}$ ; Count = 25) (See **Figure 5**). (**Supplementary Table S4**).

Through chemical informatics technology, combined with the prediction and analysis of active ingredients and potential targets, protein interaction analysis and gene annotation enrichment analysis, we systematically explored the pharmacological substance basis and potential biological mechanism of HCC for CIR. Estrogen signaling pathways are involved in CIR's blood-brain barrier, neuroprotection, and oxidative stress

(Yang et al., 2005; Wiklund et al., 2012). VEGF signaling pathway is involved in angiogenesis after CIR (Sun et al., 2015; Ho et al., 2017). FoxO signaling pathway is involved in oxidative stress in CIR (Yoo et al., 2012; Zhou et al., 2019). HIF-1 signaling pathway is involved in the induction of hypoxia after CIR (Singh et al., 2012). Insulin signaling pathways are involved in vascular endothelial apoptosis (White et al., 2000). The PI3K-Akt signaling pathway and T cell receptor signaling pathway are involved in cell damage of CIR (Huang et al., 2007; Zhou et al., 2015). HCC may play a therapeutic role by regulating these CIR-related signaling pathways.

Recent studies have also shown that *Astragalus* injection can promote cerebral vascular regeneration in CIR rats, the mechanism of which may be that *Astragalus* injection activates the HIF-1 $\alpha$ /VEGF signaling pathway (Wu et al., 2016).

Astragaloside IV can promote the proliferation and differentiation of neural stem cells in the hippocampus, inhibit the activation of astrocytes and microglia after CIR in rats and the release of inflammatory factors, and protect the integrity of the blood-brain barrier (Qu et al., 2009; Li et al., 2017; Huang et al., 2018; Li et al., 2018). It can also increase the expression of brain-derived neurotrophic factor (BDNF), vascular endothelial growth factor (VEGF) and VEGF receptor 2 (VEGFR2) after CIR, promote the formation of new blood vessels, improve the survival environment of nerve cells, and inhibit apoptosis or necrosis of ischemic hypoxic neurons (Yang L. et al., 2019). Astragaloside IV may protect CIR by reducing catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) activity, malondialdehyde (MDA) content in brain tissue, lactate dehydrogenase (LDH) and creatine kinase (CK) content in

**FIGURE 10 |** Expression of BrdU and vWF [(A): sham operation group; (B): Model group; (C): HCC group. The areas indicated by the arrows are BrdU (green) and vWF (red)].

**FIGURE 11 |** The Expression of VEGF, VEGFR and HIF-1α mRNA (compared with the normal group, \* $p < 0.05$ , \*\* $p < 0.01$ ; compared with the Sham operation group,  $\Delta p < 0.05$ ,  $\Delta\Delta p < 0.01$ ; compared with CIR group  $\blacktriangle p < 0.05$ ).

serum, and reduce the expression of NF- $\kappa$ B protein in the brain due to CIR (Shao et al., 2014). This also indirectly confirms the reliability of our reverse pharmacophore docking technology in chemical informatics. Ligustrazine, as the main compound of Chuanxiong Rhizoma, can alleviate the energy metabolism disorder of CIR (Wang Z. et al., 2017), reduce excitatory amino acid toxicity, inhibit apoptosis and the synthesis of inflammatory cells and pro-inflammatory cytokines IL-1 and TNF- $\alpha$ , and fight against inflammatory damage caused by IL-1 and TNF- $\alpha$  (Wang A. et al., 2017; Zhao et al., 2018). Ligustrazine

can also induce adrenocortical hormone production, control multiple links of the inflammatory response, increase SOD activity in the brain, reduce NOS expression, and affect nitric oxide (NO) content (Peng et al., 1996; Zhou et al., 2000; Wang A. et al., 2017).

In addition, this study also found that there may be a potential synergy between HCC active compounds. For example, astragaloside IV and ferulic acid can jointly regulate: AURKA, CBS, HPGDS, RAC2, DCK, PDE4B, AMY1A, OTC, CCL5, ANG, AGXT, AMD1, ELANE, PDE4D, PTPN1, MMP3, RARG, UCK2, AMY2A, REN, PDE5A, HMGCR, SHMT1, F7, ADK, GLO1, LYZ, RHOA, EPHA2, TPI1, et al. Ferulic acid and ligustrazine can jointly regulate: HSP90AA1, PDE4D, GPI, MME, FKBP1A, AR, DCK, ABO, CCNA2, AMY1B, GSTP1, EGFR, F2, PPP1CC, PDE4B, SDS, PDPK1, GLO1, LCK, CA2, PRKACA, AMY1C, PIM1, REN, HDAC8, GCK, MMP3, MAPK10, CYP2C9, GSTT2, et al. Recent research has confirmed some of our results. Wang (2012) found that electrospun fibers carrying astragaloside IV and ferulic acid can promote angiogenesis. Gong et al. Found that astragaloside IV and ferulic acid can improve blood lipids, protect the cardiovascular system, and have anti-atherosclerotic effects in New Zealand rabbits (Gong and Huang, 2017). In terms of angiogenesis, ligustrazine combined with astragaloside IV can promote angiogenesis of chick embryo chorionic urea capsule (Zhang et al., 2010). Yang et al. Found that the combination of Hedysarum Multijugum Maxim. And Chuanxiong Rhizoma can significantly improve the morphology of hypoxic rat brain microvascular endothelial cells (RBMVECs), effectively enhance the activity of SOD, inhibit the G1/S phase arrest of RBMVECs induced by hypoxia, significantly reduce cell apoptosis, and reduce the expression of caspase-3 and caspase-8 genes (Yang et al., 2015). The results of their orthogonal experiments showed that the preferred combination was ligustilide 5  $\mu$ g/ml, ligustrazine 10  $\mu$ g/ml, ferulic acid 20  $\mu$ g/ml, calycosin 10  $\mu$ g/ml, astragaloside IV 10  $\mu$ g/ml (Yang et al., 2015). These have brought

**FIGURE 12 |** The Expression of VEGF (immunohistochemistry staining, 400 x) (A1): Model group 1 day; (A2): HCC group 1 day; (B1): Model group 3 days; (B2): HCC group 3 days; (C1): Model group 5 days; (C2): HCC group 5 days; (D1): Model group 7 days; (D2): HCC group 7 days. (E): Sham operation group; The arrow points to positive expression).

huge opportunities for the research and development of new drugs in the future.

## The Effect of HCC on The Score of Neurological Deficit in Rats

The scores of neurological deficits of rats in the sham operation group were 0 points 1 day to 7 days after reperfusion. At 1 d, the scores of neurological deficits in HCC group and CIR model group were higher than those in sham operation group ( $p < 0.05$ ), but the difference between the two groups had no statistical significance. At 3 d, the scores of the neurological deficits in the HCC group were lower than those in the CIR model group ( $p < 0.05$ ). At 5 d and 7 d, the scores of the HCC group and CIR model group decreased, but the scores of CIR model group was still higher than that of sham operation group ( $p < 0.05$ ). The results are shown in **Table 4**.

## Pathological Changes

For the volume of cerebral infarction in rats: after staining with TTC, the uninfarcted area was red and the infarcted area was white. No significant cerebral infarction was seen in the sham operation group. There was no significant difference in cerebral infarction volume between HCC group and model group at 1 d ( $p > 0.05$ ). Compared with model group in the same phase, cerebral infarction volume of

the HCC group decreased from 3 days to 7 days ( $p < 0.05$ ). See **Figure 6** and **Table 5**.

The results of HE staining showed that the morphology and structure of the cerebral cortex and hippocampus of the sham operation group were basically normal. In the model group, most of the cells in the cerebral cortex and hippocampus showed pyknosis and vacuole-like changes in nuclei. In the HCC group, there were significantly more normal cells in the cerebral cortex and hippocampus than in the model group, and only a few cells showed nuclear constriction changes (**Figures 7, 8**).

## The Effect of HCC on Brain MVD in Rats

The microvessels were irregular in shape and the lumen was surrounded by endothelial cells stained with brownish yellow. In the hemispheric cortex of cerebral infarction, the expression of vWF-stained vascular endothelial cells increased significantly. At 1 day after CIR, the number of microvessels in CIR group and HCC group was increased compared with the sham operation group, but the difference was not statistically significant ( $p > 0.05$ ). Compared with the sham operation group, the number of microvessels in the HCC group increased at 3 days ( $p < 0.05$ ); At 5 and 7 days, the number of microvessels in the HCC group increased significantly ( $p < 0.01$ ). The CIR group also showed an upward trend. At 7 days, the MVD of the CIR group was higher than that of the sham operation group ( $p < 0.05$ ) (**Figure 9** and **Table 6**).

**FIGURE 13 |** The Expression of VEGFR (immunohistochemistry staining, 400 × (A1): Model group 1 day; (A2): HCC group 1 day; (B1): Model group 3 days; (B2): HCC group 3 days; (C1): Model group 5 days; (C2): HCC group 5 days; (D1): Model group 7 days; (D2): HCC group 7 days. (E): Sham operation group; The arrow points to positive expression).

### The Expression of Brdu and vWF

Under immunofluorescence, the Brdu and vWF double-stained signals appeared in the CIR group, and it was considered that there were neovascular endothelial cells. The number of positive signals in the HCC group was higher than that in the CIR group, indicating that the number of new blood vessels increased after drug treatment (Figure 10).

### The Expression of VEGF, VEGFR and HIF-1α mRNA

Compared with the normal group and the sham operation group, the expression of VEGF, VEGFR and HIF-1α mRNA in the CIR group was enhanced ( $p < 0.01$ ,  $p < 0.05$ ). Compared with the model group, the expression of VEGF mRNA increased on the 5th and 7th day in HCC group ( $p < 0.05$ ), and the expression of HIF-1α mRNA increased at each time point ( $p < 0.05$ ). (Figure 11).

### The Expression of VEGF, VEGFR and HIF-1α Protein

The positive expression of VEGF and VEGFR-2 is light yellow cytoplasm with brownish brown particles. HIF-1α is positive for brown-yellow particles mainly in the nucleus and a small amount

in the cytoplasm. Compared with the normal group and the sham operation group, the expression of VEGF protein was increased on 5 days of the CIR group ( $p < 0.05$ ), the expression of VEGFR protein was increased on 7 days ( $p < 0.05$ ), and the expression of HIF-1α protein was increased on 3 and 5 days ( $p < 0.05$ ). Compared with the CIR group, the expression of VEGF protein was increased on 1 and 3 days of the HCC group ( $p < 0.01$ ), the expression of HIF-1α protein was increased on 1 day ( $p < 0.01$ ), and the expression of VEGFR protein was increased on 5 days ( $p < 0.01$ ). (Table 5 and Figures 12–15).

The effect of HCC on CIR angiogenesis was discovered through a systematic pharmacological method in previous section. Then, animal experiments were carried out to clarify the mechanism of HCC, and further explored the upstream pathways that HCC promotes VEGF expression. Current research found that vascular endothelial cells play an important role in vascular regeneration and maintenance of vascular morphology and function. The upstream of VEGF expression is regulated by a variety of factors. Under hypoxia, HIF-1α can promote the regeneration of blood vessels, and HIF-1α can also be used as a regulator to promote the expression of downstream VEGF (Lee et al., 2017; Chen et al., 2018; Fan et al., 2019). This experimental pharmacology section explores whether HCC can promote VEGF expression by up-regulating HIF-1α. The results showed that after CIR, the express of HIF-1α mRNA and protein increased, and HCC could further promote this effect. After

**FIGURE 14 |** The Expression of HIF-1 $\alpha$  (immunohistochemistry staining, 400  $\times$  (A1): Model group 1 day; (A2): HCC group 1 days; (B1): Model group 3 days; (B2): HCC group 3 days; (C1): Model group 5 days; (C2): HCC group 5 days; (D1): Model group 7 days; (D2): HCC group 7 days. (E): Sham operation group; The arrow points to positive expression).

**FIGURE 15 |** The Expression of VEGF, VEGFR and HIF-1 $\alpha$  proteins (compared with the normal group, \* $p < 0.05$ , \*\* $p < 0.01$ ; compared with the Sham operation group,  $\Delta p < 0.05$ ,  $\Delta\Delta p < 0.01$ ; compared with CIR group  $\blacktriangle p < 0.05$ ).

CIR, the changes in VEGF and VEGFR were the same as above. Compared with the model group, the difference in HIF-1 $\alpha$  mRNA expression in the HCC group increased on the first day after CIR, while the difference in VEGF mRNA expression appeared on the fifth day.

## CONCLUSION

The systematic pharmacology prediction results showed that HCC may regulate CIR-related targets (such as AKT1, MAPK1, CASP3, EGFR), biological processes (such as inflammation, platelet activation, nerve cell survival, angiogenesis, oxidative stress, neuronal axonal injury, hypoxia-induced stress, blood coagulation, calcium homeostasis) and signaling pathways (such as HIF-1, VEGF, Ras, FoxO signaling). The experiments also showed that HCC may promote angiogenesis by up-regulating the expression of HIF-1 $\alpha$ /VEGF and VEGFR, and finally achieves the role of prevention and treatment of CIR. Hence, this research may provide new reference information for the treatment of CIR by Chinese medicine.

## Declare

The work described has not been submitted elsewhere for publication, in whole or in part, and all the authors listed have approved the manuscript that is enclosed.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Ethics Committee of Hunan University of Chinese Medicine (Changsha, China).

## AUTHOR CONTRIBUTIONS

KY, LZ, YC, XZ, AG and JG are responsible for the study concept and design. KY, LZ, XZ, SW, AG are responsible for data analysis and interpretation in the network pharmacology section; SW, YC and JG are responsible for data analysis and interpretation in experiments. KY, LZ, YC, XZ, AG drafted the paper; JG supervised the study; all authors participated in the analysis and interpretation of data and approved the final

paper. XZ, KY, LZ, YC, SW, AG should be considered joint first author.

## FUNDING

This work is supported by the National Natural Science Foundation of China (No. 81774174) and the National Key Research and Development Project of China (No. 2018YFC1704904).

**Objective:** According to the treatment records of Yang deficiency syndrome (YDS) with characteristic decoction pieces of lateral root of *Aconitum carmichaelii*—Yinfupian (YF) in traditional Chinese medicine prepare school, known as “Jianchangbang”. The aim of this study was to investigate differences in the composition and therapeutic mechanism of the unprocessed lateral root of *Aconitum carmichaelii* (ULRA) and its processed product (YF).

**Methods:** Ultra-performance liquid chromatography-quadrupole time-of-flight mass spectrometry and orthogonal partial least squares discriminant analysis method were used to determine and screen the main components of ULRA and YF. Changes in the histological structure and morphology of gonads in rats were observed using hematoxylin-eosin. Enzyme-linked immunosorbent assay was used to determine the contents of serum cyclic adenosine monophosphate and cyclic guanosine monophosphate in YDS rats treated with ULRA and YF. Tandem mass tag proteomics analysis was used to identify the differentially expressed proteins in YDS rats treated with ULRA and YF.

**Results:** Both ULRA and YF exerted certain therapeutic effects on rats with YDS. They improved the gonadal morphology and increased the contents of serum cyclic adenosine monophosphate and cyclic guanosine monophosphate. After processing of ULRA into YF, the content of C19-diester-diterpenoid alkaloids decreased (converted into C19-monoester-diterpenoid alkaloids and C19-alkylol amine-diterpenoid alkaloids), whereas that of C20-diterpene alkaloids increased. Proteomics analysis showed that cytochrome P450 and aldehyde oxidase 3 (AOX3) were downregulated, whereas cathepsin G (CTSG) was upregulated in rats with YDS. Treatment with ULRA mainly downregulated the expression of  $\alpha$ -actinin, fast skeletal troponin, creatine kinase, and myosin. Treatment with YF mainly upregulated the expression of mitochondrial ribosomal protein and mitochondrial inner membrane protein.

**Conclusion:** ULRA and YF exerted good therapeutic effects on YDS; the main difference in components between these preparations was in C19-diterpenoid alkaloids. ULRA

mainly acts on the muscle contraction-related proteins and is closely related to inflammation and myocardial injury. YF mainly acts on the mitochondrial proteins and is closely related to adenosine triphosphate energy metabolism.

**Keywords:** *Aconitum*, preparation, chemical components, pharmacology, proteomics, yang deficiency

## INTRODUCTION

Yang deficiency syndrome (YDS) is a physical state characterized by chilly sensation (i.e., cold limbs) and dysfunction of the viscera. The main clinical manifestations are “dread cold, coolness of extremities, fatigued body and lack of strength, depression, hypomnesia, clear and large amount of urine” (Shi et al., 2018). This condition is associated with heart failure, hypothyroidism, chronic gastritis, primary nephrotic syndrome, infertility, and other diseases (Xia et al., 2010; Yang et al., 2010; Zou et al., 2011; Fan, 2014; Weng, 2014). Physiological, biochemical, and genomic studies on YDS (Zhang et al., 2019) have shown that YDS is associated with hypofunction of the hypothalamic-pituitary-adrenal, hypothalamic-pituitary-thyroid, and hypothalamic-pituitary-gonad axes, as well as disturbance of the cyclic nucleotide system and immune function. Polymorphisms of susceptibility genes in patients with YDS have been linked to the levels of cyclic adenosine monophosphate (c-AMP) and cyclic guanosine monophosphate (c-GMP), memory, metabolic energy status, and immune function (Yao et al., 2015).

*Aconitum* had been used medicinally and as a poison in both Western and Eastern countries for centuries. It is currently used medicinally in different parts of the world, such as China and Solčavsko (Slovenia) (Zhou et al., 2014; Povšnar et al., 2017). The lateral root of *Aconitum carmichaelii* (LRA) is termed “Fuzi” in traditional Chinese medicine; it is also called “Bushi” and “Kyeong-PoBuja” in Japan and Korea, respectively. It has shown efficacy in reviving the Yang for resuscitation, tonifying fire, and helping Yang, as well as dispersing cold and relieving pain (Chinese Pharmacopoeia Commission, 2020). The application of LRA has a long history, with remarkable therapeutic effects. The primary active component of *Aconitum* is alkaloid, mainly used to treat rheumatoid arthritis and cardiovascular diseases (Zhou et al., 2014). The diterpenoid alkaloids of LRA can be divided into diester, monoester, and alkylol amine alkaloids, according to the presence or absence of an ester bond at the C4 and C8 positions (Hu et al., 2010). Alkylol amine alkaloids and other water-soluble nitrogen-containing organic compounds are collectively referred to as water-soluble alkaloids. It has been reported that higenamine (Kosuge and Yokota, 1976), coryneine chloride (Konno et al., 1979), salsolinol (Cheng and Liang, 1982), uracil (Nizhenkovska, 2015), and fuzinoside (Li et al., 2015) are the cardiotonic active components of LRA. In recent years, further studies have shown that the water-soluble diterpenoid alkaloids found in LRA, including beiwutinine, mesaconine, karakoline, aconine, isotalatizidine, hyaconine, and 3-deoxyaconine, are cardiotonic active components (He et al., 2014a; He et al., 2014b; Wang et al., 2014). Fuziline, neoline (Xiong et al., 2012), talatisamine (Chen

et al., 2014), and neoline also have significant analgesic effect (Suzuki et al., 2016). Songorine exerts anti-inflammatory, analgesic, and anti-anxiety effects (Yu et al., 2014; Khan et al., 2018). Fuziline has demonstrated efficacy against shock and improves myocardial ischemia (Gong et al., 2016). In addition, the water-soluble alkaloids found in LRA have anti-arrhythmic and anti-hypertensive effects (Fujita et al., 2009; Li et al., 2014). Therefore, this plant has broad prospects for the development of new drugs and applications. For centuries, Fuzi has been effectively used in treating various diseases associated with YDS. Jianchangbang is an ancient school of medicine in the south of China. Its method of preparing LRA through steaming with ginger juice is unique and famous. It is well established that Yinfulian (YF) has high efficacy and low toxicity, and is suitable for the treatment of YDS in clinical practice. At present, the impact of the components of *Aconitum* on proteins related to YDS remains unclear. The aim of this study was to investigate changes in the components of LRA before and after preparation, content of serum cyclic nucleotides, gonadal tissue morphology, and the relationship between components and proteins in rats with YDS. The proteomic changes in liver tissue were detected using tandem mass tag (TMT) mass spectrometry (MS). Proteomics may provide new information for high-throughput analysis, and it has been used in investigating the pathogenesis of YDS with great coverage of the proteome (Huang and Liang, 2005; Lu et al., 2012; Li et al., 2017). These research studies provide new data for the therapeutic value of LRA and its processed products in diseases related to YDS, and promote the development of new potential biomarkers for abnormalities related to Yang deficiency.

## MATERIALS AND METHODS

### Preparation of Medicinal Materials

Salted LRA (LRA soaked in bitter water; Batch No. 20180918) and ginger (fresh rhizomes of *Zingiber officinale Roscoe*) was purchased from the Chinese medicinal materials market of Zhangshu (China). All materials were authenticated by Professor Qianfeng Gong of Jiangxi University of Traditional Chinese Medicine (Nanchang, China). Unprocessed LRA (ULRA) was obtained by rinsing the salted LRA. ULRA was moistened with 15% fresh ginger juice (quality %) for 12 h and steamed for 8 h to obtain YF.

Administered solution: ULRA and YF were respectively soaked in water ( $\times 10$  their volume) for 1 h, boiled for 30 min, and filtered. The obtained residues were soaked again in water ( $\times 6$  their volume), boiled for 30 min, and filtered. The filtrates were combined and concentrated to 1.2 g/ml. The concentrated solution was stored at 4°C.

**FIGURE 1** | HPLC chromatograms of various alkaloids. **(A)** Standards; **(B)** YF; **(C)** ULRA; (1), Benzoylmesaconine; (2), Benzoylhypaconine; (3), Benzoylaconine; (4), Mesaconitine; (5), Aconitine; (6), Hypaconitine; HPLC, high performance liquid chromatography; ULRA, unprocessed lateral root of *Aconitum carmichaelii*; YF, Yinfupian.

**Standard solution:** All standards (Weikeqi biotech Co., Ltd., Chengdu, China) were weighed and added isopropanol-dichloromethane (1:1) mixed solution to prepare solution contained 10.32 µg/ml aconitine (Batch NO. 130723), 37.38 µg/ml mesaconitine (Batch NO.130402), 5.75 µg/ml hypaconitine (Batch NO. 130509), 33.34 µg/ml benzoylaconine (Batch NO. 130516), 7.92 µg/ml benzoylmesaconine (Batch NO. 130505), and 5.38 µg/ml benzoylhypaconine (Batch NO. 130401).

**Sample solution for HPLC:** ULRA and YF were respectively soaked in water ( $\times 10$  the volume) for 1 h, boiled for 30 min, and filtered. The obtained residues were soaked again in water ( $\times 6$  the volume), boiled for 30 min, and filtered. The filtrates were combined, concentrated and dried into powders. The powders

(2 g) of ULRA and YF decoction mixed with ammonia (3 ml), and immersed in isopropanol-ethyl acetate (1:1) mixed solution (50 ml) extracted under ultrasonic condition for 30 min, and then filtered. The filtrate (25 ml) evaporated to dryness under 40°C and low pressure condition. The obtained residue dissolved by isopropanol-dichloromethane (1:1) mixed solution (5 ml), and then filtrated through a filter membrane (0.22 µm).

**Sample solution for UPLC-quadrupole-TOF-MS:** The medicine (100 g of ULRA or YF) and 15 times the volume of water ( $\times 15$  their volume) were placed into round bottom flasks, soaked for 30 min, subjected to heat reflux, decocted for 30 min, filtered and concentrated to 1 g/ml. Subsequently, 5.0 ml of the above concentrated solutions were transferred into 50 l volumetric flasks. Water was added to

**TABLE 1 |** Calibration curves of various alkaloids.

Alkaloids	Regression equations	$R^2$
Aconitine	$Y = 0.2050X + 0.3294$	0.9994
Mesaconitine	$Y = 0.3915X + 0.4621$	0.9992
Hypaconitine	$Y = 0.4043X + 0.8154$	0.9996
Benzoylaconine	$Y = 0.6271X + 0.3214$	0.9992
Benzoylmesaconine	$Y = 0.7897X + 0.7180$	0.9996
Benzoylhypaconine	$Y = 0.3405X + 0.1127$	0.9993

dissolve the concentrated solution. The supernatants were filtered using a 0.22-microporous membrane. The primary filtrates were discarded and the remaining filtrates were stored as sample solution.

## Conditions of Chromatography and Mass Spectrometry

An Ultimate 3000 high performance liquid chromatography (HPLC) (Dionex, Sunnyvale, CA, United States), equipped with a PDA-3000 diode array ultraviolet detector (Dionex, Sunnyvale, CA, United States) and a chromeleon workstation was used. Symmetry C18 column (5  $\mu$ m, 4.6 mm  $\times$  250 mm, Waters Corporation, Milford, MA, United States) was used to determine the six alkaloids standards and the components of ULRA and YF.

The following gradient system was used with 100% acetonitrile (solvent A) and 0.04 mol/L Ammonium acetate aqueous solution (PH = 10, Adjusted by ammonia water) (solvent B): 0–8 min: 18% of A; 8–35 min: linear 18–35% of A; 35–45 min: linear 35–45% of A; 45–55 min: linear 45–50% of A; 55–65 min: linear 50–55% of A; 65–75 min: 55% of A. The flowing rate was 1.0 ml/min, the detection wavelength was at 235 nm, the column temperature was at 35°C, and the injection volume was 20  $\mu$ l. The chromatograms are shown in **Figure 1**.

An ultra-high performance liquid chromatography (UPLC) tandem four-stage rod time-of-flight (TOF) mass spectrometer (Triple TOF 5600+; AB Sciex), equipped with an Analyst1.6 Chromatographic workstation and MS analysis software (PeakView v1.2; AB Sciex), was used. Nexera UPLC LC-30 (Shimadzu Corporation, Kyoto, Japan) and ACQUITY UPLC® BEH C18 column (1.7  $\mu$ m, 2.1 mm  $\times$  100 mm; Waters Corporation, Milford, MA, United States) were used to determine the components of ULRA and YF.

The gradient system was 0.1% formic acid aqueous solutions (solvent A)-100% acetonitrile (solvent B): 0–25 min, 95–60% A; 25–32 min, 60–5% A; 32–35 min, 5–95% A; Experiment: Positive Ion Mode, Electron Spray Ionization, ionization temperature: 500°C, curtain gas: 40 psi, ion source gas1: 50 psi, ion source gas2: 50 psi, ion spray voltage: 5,500 eV, collision energy: 40 eV, declustering potential: 100 eV, mass scan range:  $m/z$  100–1,000. The flow rate was 0.5 L/min, the column temperature was 40°C, and the injection volume was 2  $\mu$ l.

## Calibration of Six Alkaloids and Method Evaluation

Standard samples of alkaloids were prepared into appropriate concentration, and the calibration curve for each alkaloid was

performed with six quantities by plotting the peak area vs. the concentrations of the alkaloids. The results of all calibration curves are shown in **Table 1**.

Precision and stability was calculated within 24 h ( $n = 6$ ) with the standard solution of the six alkaloids. Repeatability and average recovery was tested by sample solutions of ULRA and standard solutions of the six alkaloids, and they were injected six times. All indexes of method evaluation evaluated by calculating the relative standard deviation (RSD) (**Table 2**).

## Data Collection and Analysis of Ultra-High Performance Liquid Chromatography-Quadrupole-Time-of-Flight-Mass Spectrometry

The original data were imported into MarkView v1.2.1 and PeakView v1.2 software (both from AB Sciex) to determine the retention time, mass-to-charge ratio, intensity data, and information of two-stage MS (MS2). The total ion chromatogram of ULRA and YF is shown in **Figure 2**. Subsequently, the data were imported into Simca-p 14.1 software. To observe the contour differences between groups and more effectively identify differences in markers, orthogonal partial least squares discriminant analysis (OPLS-DA) was performed. This analysis yielded the OPLS-DA score chart and similarity-plot (S-plot) diagram, which could directly reflect the contribution rate of differences between groups. The markers with variable important in projection (VIP) > 1 and  $p$ -values < 0.05 were considered potentially highly related to differences in the decoction pieces. The qualitative analysis of these markers was performed by comparing evidence from the literature and data retrieved from databases.

## Experimental Animal Treatments and Sample Collection

The animal study was approved by the Ethics Committee on Laboratory Animals of Jiangxi University of Traditional Chinese Medicine. Sprague-Dawley rats (24 males and 24 females, each weighing 200  $\pm$  20 g; laboratory animal license no. 3700920018,748) were purchased from Jinan Pengyue Experimental Animal Breeding Co., Ltd. (Jinan, China) (license key number: SCXK (Lu) 2014 0007). All rats after acclimatizing in normal atmospheric temperature for 5 days and divided randomly into four groups containing equal numbers of male and female animals, namely the blank (B) group ( $n = 12$ ), model (M) group ( $n = 12$ ), ULRA group ( $n = 12$ ), and YF group ( $n = 12$ ).

Rats in the model and treatment groups received *Rheum officinale* (dried roots and rhizomes of *Rheum officinale* Baill) powder 1.0 g and goldthread (dried rhizomes of *Coptis chinensis* Franch) powder 1.0 g (namely, 2 g of herb powder/8 ml water suspension, 1 ml/100 g body weight, once daily for 7 days, at the same time) through oral gavage. After the administration, the rats were subjected to exhaustive swimming once daily to establish the model of YDS. Rats in the blank group received the same amount of distilled water daily through oral gavage. On day 8, rats in the

**TABLE 2 |** RSD of method evaluation for various alkaloids ( $n = 6$ ).

Alkaloids	Precision (%)	Stability (%)	Repeatability (%)	Average recovery (%)
Aconitine	1.08	0.38	0.35	0.16
Mesaconitine	0.75	0.52	0.43	0.63
Hypaconitine	0.25	0.73	0.86	1.40
Benzoylaconine	0.65	0.46	0.74	0.59
Benzoylmesaconine	0.54	0.23	0.65	0.30
Benzoylhypaconine	1.02	0.35	0.47	1.30

treatment groups received ULRA and YF concentrated solution at 12 g (crude medicine)/kg (bodyweight) per day. Rats in the blank and model groups received the same amount of distilled water by oral gavage for 7 days.

Blood samples were collected from the abdominal aorta after anesthesia using 5% pentobarbital sodium (5 mg/100 g bodyweight, intraperitoneally). Next, the liver tissues were rapidly excised, frozen in liquid nitrogen, and stored at  $-80^{\circ}\text{C}$  for protein extraction. Subsequently, testicular and ovarian tissues were excised, sectioned, embedded in paraffin, and stained with hematoxylin-eosin. Serum was separated by centrifugation at 3,000 rpm for 5 min at  $4^{\circ}\text{C}$  after standing for 15 min to detect c-Amp and c-GMP using enzyme-linked immunosorbent assay kits (LOT: 20191108; Nanjing Jiancheng Bioengineering Institute, Nanjing, China). Throughout the experimental period, there was no occurrence of death in the animals. At the end of the experiment, euthanasia was performed under anesthesia with sodium pentobarbital. The data are expressed as the mean  $\pm$  standard deviation, and comparison between groups was performed using one-way analysis of variance.

## Tandem Mass Tag-Based Proteomics

Liver tissues were added to SDT lysis buffer (4% sodium dodecyl sulfate [SDS; 161-0302; Bio-Rad, Hercules, CA, United States]; 100 mM Tris-HCl [A6141; Sigma, Saint Louis, MO, United States]; 1 mM dithiothreitol [DTT; 161-0404; Bio-Rad, Hercules, CA, United States]; pH 7.6), transferred into a 2-ml centrifuge tube with an appropriate amount of quartz sand (MP 6910-050; MP Biomedicals, Santa Ana, CA, United States) and 1/4-inch ceramic bead (MP 6540-034; MP Biomedicals, Santa Ana, CA, United States), and crushed into homogenate ( $24 \times 2$ , 6.0 M/S, 60 s, twice) using a MP fastprep-24 homogenizer (MP Biomedicals). Samples were subjected to ultrasound with an ultrasonic crusher (JY92-II; Scientz, Ningbo, China) (power: 80 W, duration: 10 s, intervals: 15 s, repetitions: 10) and placed in boiling water for 15 min. The homogenate was centrifuged at  $14,000 \times g$  for 40 min, the supernatant was filtered with a 0.22- $\mu\text{m}$  membrane, and the filtrate was collected. The bicinchoninic acid (BCA) method (BCA quantitative Kit; P0012; Beyotime, Nanjing, China) was used for protein quantification. The samples were stored at  $-80^{\circ}\text{C}$ .

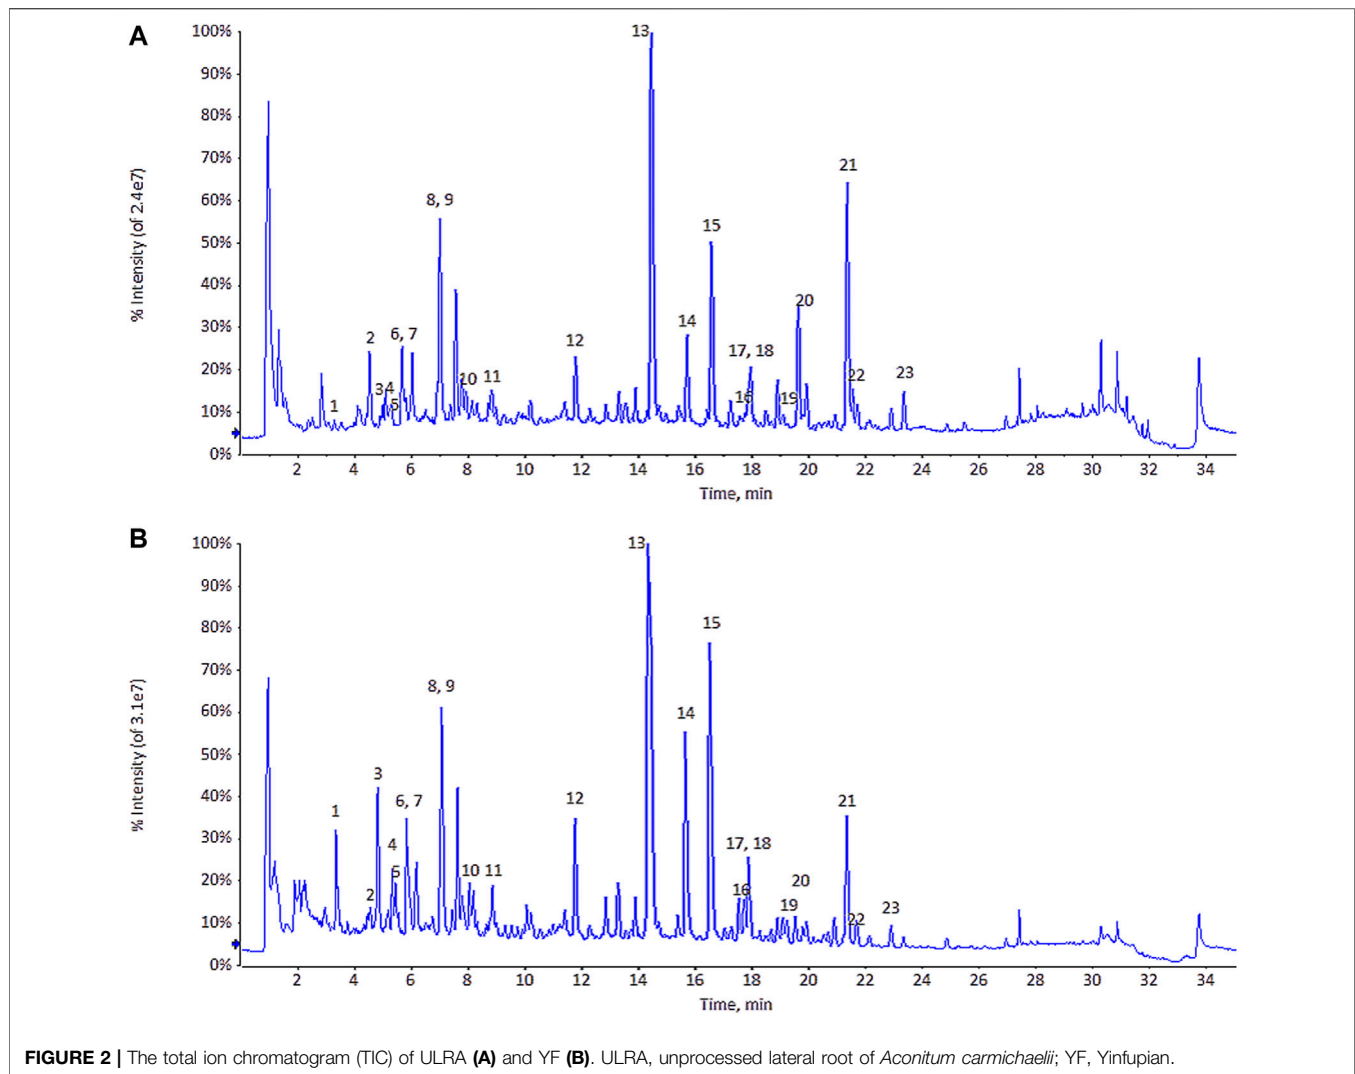

Protein from each group (20  $\mu\text{g}$ ) was added to 5 $\times$  buffer solution (10% SDS, 0.5% bromophenol blue, 50% glycerin, 500 mM DTT, 250 mM Tris-HCl, pH 6.8) and placed in boiling water for 5 min. Next, 12.5% SDS-polyacrylamide gel

electrophoresis (constant current, 14 Ma, 90 min; eps601; GE Healthcare, Marlborough, MA, United States) and Coomassie brilliant blue staining were performed.

Protein solutions (30  $\mu\text{l}$ ) were obtained from each group. DTT was added to reach a final concentration of 100 mM. Subsequently, the solutions were placed in boiling water for 5 min and cooled to room temperature. Uric acid (UA) buffer (200  $\mu\text{l}$ ; 8 M urea [161-0731 Bio-Rad]; 150 mM Tris-HCl; pH 8.0) was added, mixed well, transferred into a 10 kDa ultrafiltration centrifuge tube (Sartorius, Gottingen, Germany), and centrifuged at  $14,000 \times g$  for 15 min; the filtrate was discarded (this step was repeated once). Iodoacetamide buffer (100  $\mu\text{l}$ ; 100 mM iodoacetamide [163-2109; Bio-Rad] in UA) was added, oscillated at 600 rpm for 1 min, reacted in the dark at room temperature for 30 min, and centrifuged at  $14,000 \times g$  for 15 min. UA buffer (100  $\mu\text{l}$ ) was added and centrifuged at  $14,000 \times g$  for 15 min; this step was repeated twice. Subsequently, 100 mM triethylammonium bicarbonate (TEAB) buffer (100  $\mu\text{l}$ ) was added, and the mixture was centrifuged at  $14,000 \times g$  for 15 min; this step was repeated twice. Trypsin buffer (40  $\mu\text{l}$ ; 4  $\mu\text{g}$  trypsin [317107; Promega corporation, Madison, WI, United States] in 40  $\mu\text{l}$  100 mM TEAB buffer) was added, oscillated at 600 rpm for 1 min, and placed at  $37^{\circ}\text{C}$  for 16–18 h. The collection tubes were replaced, the samples were centrifuged at  $14,000 \times g$  for 15 min;  $\times 10$  diluted 100 mM TEAB buffer (40  $\mu\text{l}$ ) was added, and the samples were centrifuged again at  $14,000 \times g$  for 15 min; the filtrates were collected for peptide quantification (OD280).

Peptides (100  $\mu\text{g}$ ) were obtained from each sample and labeled according to the instructions provided by the manufacturer (TMT Mass Tagging Kits and Reagents; Thermo Fisher Scientific, Waltham, MA, United States). The labeled peptides in each group were mixed in equal amount and graded using a high pH reversed-phase spin column. Following lyophilization, peptides (100  $\mu\text{g}$ ) were diluted in 0.1% trifluoroacetic acid (T6508; Sigma) (300  $\mu\text{l}$ ), transferred to the high pH reversed-phase spin column, and centrifuged to collect the flow-through compositions. After adding 300  $\mu\text{l}$  of pure water, the washed compositions were collected by centrifugation, and gradient elution was performed. Following lyophilization, the samples were re-dissolved in 0.1% formic acid (06450; Fluka, Seelze, Germany) (12  $\mu\text{l}$ ), and the concentration of the peptide was determined at OD280.

Each sample was separated by HPLC Easy nLC (Thermo Fisher Scientific) at a nl flow rate. Buffer solution A was 0.1% formic acid aqueous solution, while buffer solution B was 0.1%

**FIGURE 2 |** The total ion chromatogram (TIC) of ULRA (A) and YF (B). ULRA, unprocessed lateral root of *Aconitum carmichaelii*; YF, Yinfupian.

formic acid acetonitrile aqueous solution (acetonitrile was 84%). The chromatographic column was equilibrated with 95% A solution. The sample was loaded from the automatic injector to the loading column (Acclaim PepMap100, 100  $\mu\text{m} \times 2\text{ cm}$ , nanoViper C18; Thermo Fisher Scientific) and separated by the analytical column (EASY column, 10 cm, ID75  $\mu\text{m}$ , 3  $\mu\text{m}$ , C18-A2; Thermo Fisher Scientific) at a flow rate of 300 nl/min. For gradient elution, the linear gradient of solution B ranged 0–55% for 0–80 min, 55–100% for 80–85 min, and 100% for 85–90 min.

The samples were separated by chromatography and analyzed using a Q-Exactive mass spectrometer (Thermo Fisher Scientific). The analysis time was 60 min. The detection method was positive ion mode; scanning range of the parent ion was 300–1,800 m/z; resolution of primary MS was 70,000 at 200 m/z; AGC target was 3e6; primary maximum IT was 10 ms; number of scan ranges was 1; and dynamic exclusion was 40.0 s. The mass-to-charge ratios of polypeptide and polypeptide fragments were collected using the following method: 10 MS2 scans were collected after each full scan; the MS2 activation type was higher-energy collisional dissociation; isolation window was 2 m/z; resolution of

secondary MS was 35,000 at 200 m/z (TMT6plex, Thermo Fisher Scientific); microscan was 1; secondary maximum IT was 60 ms; normalized collision energy was 30 eV; and underfill was 0.1%.

The raw data of MS were obtained in RAW files, and identified and quantitatively analyzed by Mascot2.2 and Proteome Discoverer 1.4 (Thermo Fisher Scientific). Blast2GO (Götz et al., 2008) was used to perform the Gene Ontology (GO) annotation of the target protein set. The Kyoto Encyclopedia of Genes and Genomes (KEGG) Automatic Annotation Server (Moriya et al., 2007) was used to perform the KEGG pathway annotation of the target protein set. The target protein sequence was classified through KEGG Orthology (KO) by comparison with data obtained from the KEGG GENES database. Information on the pathway involved in the target protein sequence was automatically obtained according to the KO classification. Fisher's exact test was used to compare the distribution of each GO classification or KEGG pathway in the target protein set, as well as the overall protein set for

**FIGURE 3 |** Results of content determination of six alkaloids ( $n = 3$ ). (1), Benzoylmesaconine; (2), Benzoylhypaconine; (3), Benzoylaconine; (4), Mesaconitine; (5), Aconitine; (6), Hypaconitine.

evaluating the significance level of protein enrichment of a GO term or KEGG pathway. Firstly, the quantitative information of the target protein set was normalized (normalized to the  $[-1, 1]$  region). Secondly, the Cluster 3.0 software was used to classify the two dimensions of sample and protein expression (distance algorithm: Euclidean; connection mode: average linkage). Finally, the hierarchical clustering heat map was generated using the Java Treeview software, and the gene symbol of the target protein was obtained from the database of the source of the target protein sequence. These gene symbols were used in the IntAct (<http://www.ebi.ac.uk/intact/main.xhtml>) or Search Tool for the Retrieval of Interacting Genes (STRING; <http://string-db.org/>) database to search for direct and indirect interactions between target proteins; the interaction network was generated and analyzed using the Cytoscape 3.2.1 software.

## RESULTS

### High Performance Liquid Chromatography Analysis of Alkaloids Contents in Unprocessed Lateral Root of *Aconitum carmichaelii* and Yinfulpian

The contents of six alkaloids in ULRA and YF are calculated by the calibration curves (Table 1), and the results are shown in Figure 3. When comparing of ULRA with YF, the contents of aconitine, mesaconitine, and hypaconitine in YF were lower than those of them in ULRA. The contents of benzoylaconine, benzoylmesaconine, and benzoylhypaconine in YF were obvious higher than those of them in ULRA. The diester alkaloids (aconitine, mesaconitine, and hypaconitine) in “FuZi” were decreased after “FuZi” processed into YF, and the diester alkaloids may turned into monoester alkaloids, therefore the contents of benzoylaconine, benzoylmesaconine, and benzoylhypaconine in YF are high.

### Analysis of Markers of Differential Components

In the OPLS-DA analysis, there were no abnormal samples that were excluded (all samples were within the confidence interval). The score and S-plot chart, which can directly reflect the differences between two groups and the contribution rate of differences in components, were obtained. All the samples of the score chart were clearly distinguished, suggesting that the two groups of samples were significantly different (Figure 4). Two principal components were obtained:  $R^2X = 0.701$ ,  $R^2Y = 0.999$ ,  $Q^2 = 0.991$ . In the S-plot chart (Figure 5), closer proximity to the two corners of the S-plot indicated a larger VIP value of the variable (i.e., the component with great difference).

According to the data obtained by HPLC-quadrupole-TOF-MS, a comparative analysis was performed between the ULRA and YF groups. The VIP value of the OPLS-DA model principal component (threshold value  $> 1$ ) and the  $p$ -value of the  $t$ -test (threshold:  $< 0.05$ ) were used to screen different components, combined with literature, MassBank database, and other searches. The structure of the differential substances was finally identified as representative of the difference in components (Table 3).

Identification of components: The inference process was illustrated using chuanfumine as an example. Compound 1 produced  $394.3 [M+H]^+$  with high sensitivity at 40 eV collision energy. In the MS2 spectrum, the peak produced  $376.2479 [M+H-H_2O]^+$ ,  $358.2385 [M+H-2H_2O]^+$ , and  $340.2278 [M+H-3H_2O]^+$ , according to the literature (Liu et al., 2011; Zhang et al., 2012). There was no  $[M+H-CH_3OH-H_2O]^+$ , which is a characteristic ion of karakolidine ( $C_{22}H_{35}NO_5$ ). Therefore, it was inferred that compound 1 was chuanfumine.

### Histomorphological Changes in the Gonads of Rats Induced by Yang Deficiency Syndrome

Ovarian and testicular tissues were obtained from female and male rats, respectively. In the blank group, the histological

**FIGURE 4 |** OPLS-DA score chart of ULRA and YF groups. Green dots are ULRA group, and blue dots are YF group. OPLS-DA, partial least squares discrimination analysis; ULRA, unprocessed lateral root of *Aconitum carmichaelii*; YF, Yinfupian.

structure of the testes was normal, and the division of spermatogenic cells in the seminiferous tubules was active with rich and obvious layers (**Figure 6A**). In the model group, the number of spermatogenic cells and sperm cells was significantly lower, and the arrangement was loose with vacuoles (**Figure 6B**).

Compared with the model group, the number of spermatogenic cells and sperm cells in the ULRA and YF groups was significantly increased and orderly arranged, similar to the blank group, and recovered significantly (**Figures 6C,D**).

In the blank group, the number and morphology of ovarian follicles at all levels were normal; the ovarian follicles grew actively, and there were abundant layers of granulosa cells (**Figure 7A**). In the model group, the volume of the ovary decreased, and the number of ovarian follicles and granulosa cells in different layers decreased significantly (**Figure 7B**).

Compared with the model group, the ovarian volume and the number of granulosa cells in the ULRA group increased (**Figure 7C**). The volume of ovary and the number of

granulosa cells, corpus luteum, and ovarian follicles increased in the YF group (Figure 7D).

## Serum cyclic Adenosine Monophosphate and cyclic Guanosine Monophosphate Levels in Rats with Yang Deficiency Syndrome

Compared with the blank group, the levels of c-AMP and c-GMP in the model group were significantly decreased. There was no significant difference between the ULRA and model groups. Compared with the model group, the levels of c-AMP in the YF group increased significantly, whereas those of c-GMP exhibited an upward trend.

## Differentially Expressed Proteins

According to the standard of expression <1.2-fold (upregulated by >1.2-fold or downregulated by <0.83-fold) and *p*-value <0.05, a total of 4,673 differentially expressed proteins were identified. The number of differentially expressed proteins in each group is shown in Table 4.

## Gene Ontology Analysis

The results of GO analysis for the blank group vs. the model group revealed that the functions of these potential targets are related to numerous biological processes that may be important for the occurrence and development of YDS. The top 20 generally changed GO terms were compared. The most significantly enriched biological process terms were associated with detoxification, stress response to metal ion,

cellular response to zinc ion, lauric acid metabolic process, and arginine catabolic process. With respect to molecular function, the most significantly enriched terms included iron ion binding, heme binding, tetrapyrrole binding, arachidonic acid binding, icosanoid binding, and icosatetraenoic acid binding. For the cellular component, the most enriched terms were delta DNA polymerase complex, C-fiber, histone locus body, cytoskeleton, nuclear inner membrane, and DNA polymerase complex (Figure 8A).

Comparison of the ULRA and model groups showed that the most enriched biological process terms were associated with muscle contraction, muscle system process, myosin filament assembly and organization, myofibril assembly, sarcomere organization, and cellular component assembly involved in morphogenesis. The representative terms related to molecular function were actin binding and structural constituent of muscle. For the cellular component, the most enriched terms were myofibril, contractile fiber, sarcomere, and muscle myosin complex (Figure 8B).

In the YF group vs. model group analysis, the most significantly enriched biological process terms were associated with muscle contraction, cell fate specification, myosin filament assembly and organization, sarcomere organization, and cellular component assembly involved in morphogenesis. The most significantly enriched molecular function terms were associated with actin binding and transmembrane transporter activity. The representative terms related to cellular component were supramolecular structure,

**FIGURE 6 |** Testis histological changes of male rats in each group (HE×400). **(A)** Blank group; **(B)** Model group; **(C)** ULRA group; **(D)** YF group. HE, hematoxylin-eosin staining; ULRA, unprocessed lateral root of *Aconitum carmichaelii*; YF, Yinfulpian.

contractile fiber part, keratin filament, and myofibril (Figure 8C).

## Kyoto Encyclopedia of Genes and Genomes Analysis

The KEGG analysis demonstrated that a number of pathways were significantly enriched in the model group compared with the blank group. These included some classical pathways, such as the nicotinate and nicotinamide metabolism, peroxisome proliferator activated receptor (PPAR) signaling pathway, drug metabolism cytochrome P450 (CYP), steroid hormone biosynthesis, arachidonic acid metabolism, and retinol metabolism (Figure 9A).

Comparison of the ULRA and model groups revealed that the inflammatory mediator regulation of transient receptor potential (TRP) channels, hypoxia inducible factor 1 (HIF1) signaling pathway, tight junction, glycolysis/gluconeogenesis, and cardiac muscle contraction were significantly enriched according to the differentially expressed proteins. Moreover, we found some disease-related pathways, such as type I diabetes mellitus, hypertrophic cardiomyopathy, dilated cardiomyopathy, allograft rejection, graft-versus-host disease, autoimmune thyroid disease,

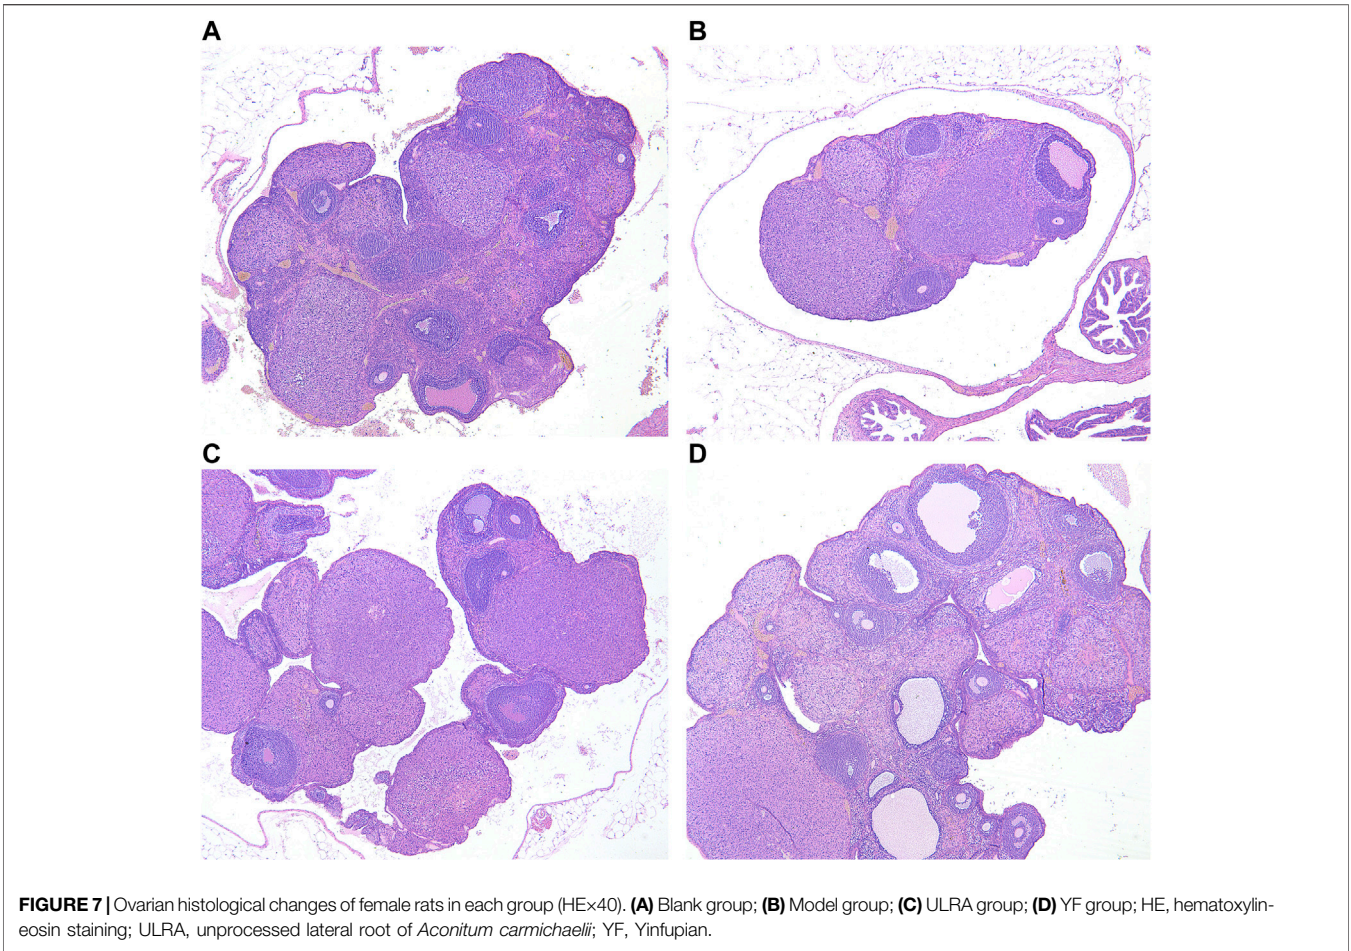

and African trypanosomiasis, which indicate that raw aconite has a potential application in other diseases (Figure 9B).

Comparison of the YF and model groups showed neuroactive ligand-receptor interaction and nucleotide excision repair (Figure 9C).

## Protein-Protein Interaction

To investigate the interactions between differentially expressed proteins in each group, several protein-protein interaction networks were established based on differentially expressed proteins using the Cytoscape v3.2.1 software. Comparison of the model and blank groups revealed complex interactions with CYP 4A2 and 4A8 (downregulation), aldehyde oxidase 3 (AOX3) (downregulation), cathepsin G (CTSG) (upregulation), fatty acid binding protein 5 (FABP5) (upregulation), lysozyme 2 (LYZ2) (upregulation), etc. In the comparison of the ULRA and model groups, the protein network based on differentially expressed proteins revealed complex interactions with actinin alpha 3 (ACTN3) (downregulation), actinin alpha 2 (ACTN2) (downregulation), troponin C2 fast skeletal type (TNNC2) (downregulation), troponin I2 fast skeletal type (TNNI2) (downregulation), troponin T3 fast skeletal type (TNNT3) (downregulation), creatine kinase M-type (CKM) (downregulation), myosin light chain 1 (MYL1) (downregulation), myosin heavy chain 1 (MYH1) (downregulation), etc. Comparison of

**TABLE 4 |** Protein expression results.

Comparison (group)	Upregulation	Downregulation	All
B vs. M	30	35	65
ULRA vs. M	27	135	162
YF vs. M	52	46	98

Note: Upregulation, upregulated differentially expressed proteins; Downregulation, downregulated differentially expressed proteins; All, all differentially expressed proteins; B, blank group; M, model group; ULRA, unprocessed lateral root of *Aconitum carmichaelii*; YF, Yinfulpian.

the YF and model groups showed complex interactions with keratin 5 (KRT5) (upregulation), KRT16 (upregulation), KRT17 (upregulation), KRT72 (upregulation), mitochondrial ribosomal protein L28 (MRPL28) (upregulation), MRPL4 (upregulation), MRPL38 (upregulation), OXA1L mitochondrial inner membrane protein (OXA1L) (upregulation), etc.

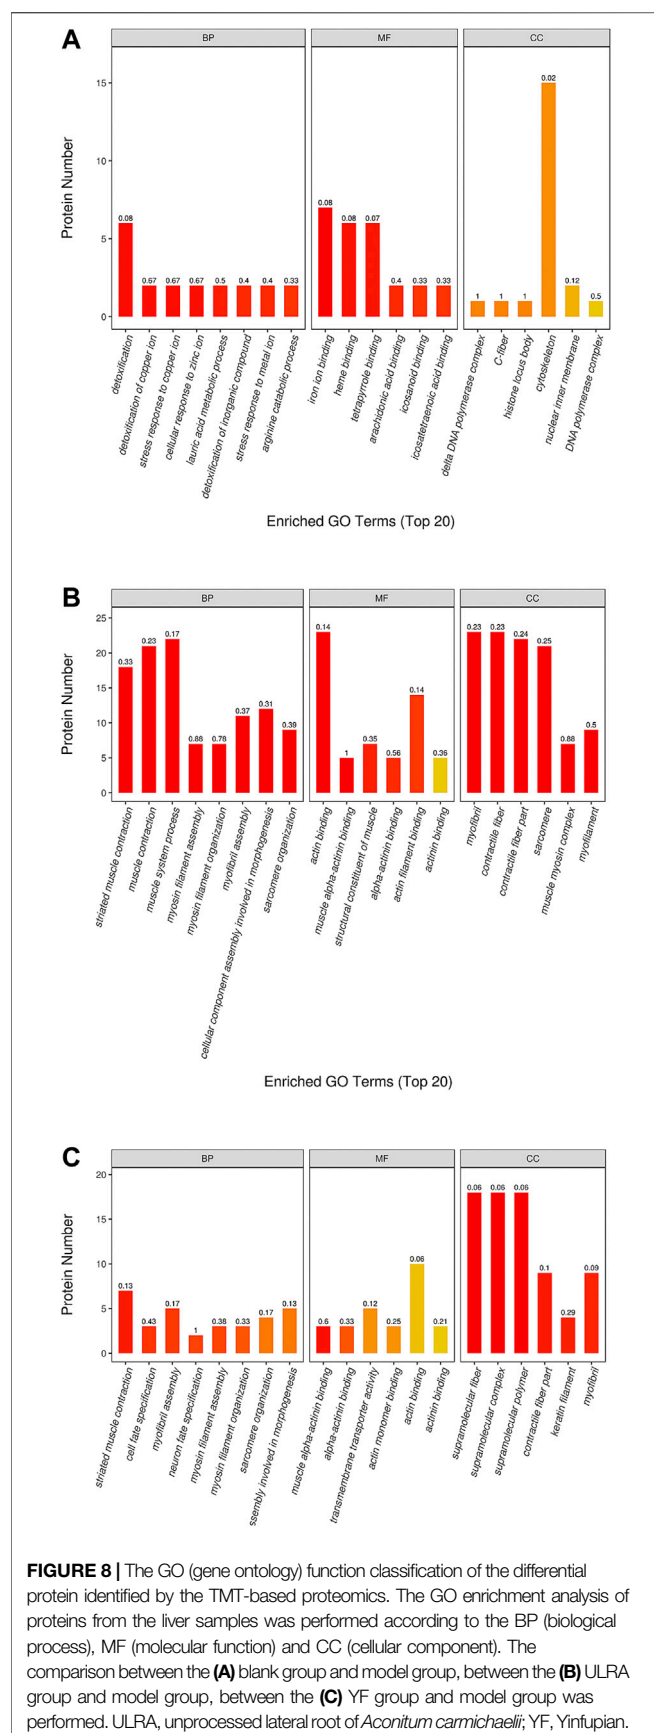

DISCUSSION

*Aconitum* alkaloids can be rapidly absorbed and widely distributed in the body. There is a large quantity of C19-diester-diterpenoid alkaloid (C<sub>19</sub>DDA) in ULRA; C<sub>19</sub>DDA has

been associated with acute toxicity. Hydrolysis of C<sub>19</sub>DDA into C19-monoester-diterpenoid alkaloid (C<sub>19</sub>MDA) decreases the toxicity. Through further hydrolysis, the alkaloids are converted into C19-alkylol amine-diterpenoid alkaloid (C<sub>19</sub>ADA) with almost no toxicity (Huang et al., 2015; Wu et al., 2018). According to the results of composition analysis (Table 1), the levels of mesaconitine, hypaconitine, aconitine, and other C<sub>19</sub>DDAs were significantly decreased in YF compared with the ULRA. In contrast, the levels of C<sub>19</sub>MDAs (e.g., benzoylaconine, benzoylhypaconine, benzoylmesaconine), C<sub>19</sub>ADAs (e.g., fuziline, mesaconine, and neoline), and C20-diterpene alkaloids (e.g., chuanfumine and songorine) were significantly increased. The components of *Aconitum* alkaloids underwent obvious changes in the process of preparation. Hydrolysis of C<sub>19</sub>DDA reduced the toxicity of ULRA, while the increase in the levels of C<sub>19</sub>MDA, C<sub>19</sub>ADA, and C20-diterpene alkaloid also ensured the pharmacological activity. This confirmed the importance of preparation in reducing the toxicity and increasing efficiency of ULRA in terms of chemical composition.

Previous studies have shown that YDS can affect gonad and related functions, as well as damage male testicular function and female ovarian function (Nakada and Adachi. 1999; Liu et al., 2018; Song et al., 2019). The vitality of spermatogenic cells and

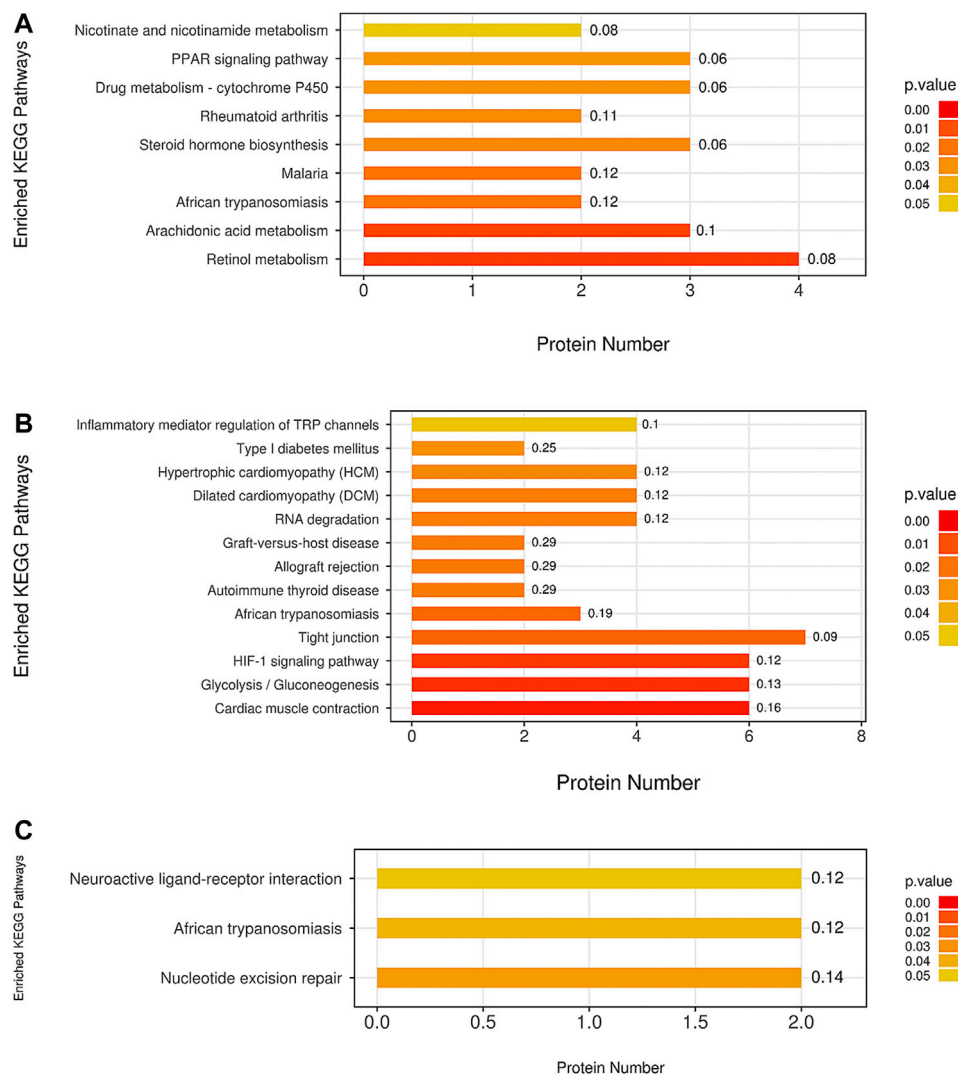

ovarian cells in the testes and ovaries of rats with YDS was inhibited, and the numbers of cells were significantly reduced (Figures 3, 4). Moreover, following treatment with ULRA and YF, the morphology of the testes and ovaries recovered well in rats with YDS, suggesting good efficacy.

c-AMP is a signal transduction substance formed by the dephosphorylation of adenosine triphosphate (ATP) under the catalysis of adenylate cyclase. It activates protein kinase (PKA) and phosphorylates target cell proteins, thus regulating the cell response. c-GMP is another signal transduction substance formed by guanosine triphosphate under the catalysis of guanylate cyclase. It activates protein kinase PKG and phosphorylates proteins in target cells, thus regulating cell reaction. Both transduction substances, termed cyclic nucleotides, are involved in regulating the physiological function and metabolism of cells. They have a wide range of biological effects and participate in a variety of physiological and pathological processes. During this period, numerous neurotransmitters, hormones and some active substances need to exert their corresponding physiological effects on target cells through cyclic nucleotides (Burhenne et al., 2011; Rondina and Weyrich, 2012). The content of c-AMP and c-GMP in rats with YDS decreased significantly, thereby leading to the inhibition of physiological function and metabolism to a certain extent. The body reaction caused by this change was consistent with the symptoms of YDS, and YF could significantly increase the content of c-AMP and c-GMP (Figures 10, 11). The above results indicate that YF has an obvious therapeutic effect on YDS.

The GO and KEGG pathway enrichment analyses revealed that YDS mainly affects detoxification, heme-related compositions (i.e., iron ion, heme, tetrapyrrole) binding, response to metal ion, CYP, steroid hormone biosynthesis, nicotinate and nicotinamide metabolism, PPAR signaling pathway, as well as the combination and metabolism of some unsaturated fatty acids. The present findings are consistent with those of previous research studies on YDS (Zhang et al., 2019; Liang et al., 2020). GO analysis showed that both ULRA and YF influenced the movement of muscle tissues. KEGG pathway analysis found that ULRA mainly affects the inflammatory mediator regulation of TRP channels, HIF1 signaling pathway, tight junction, glycolysis/gluconeogenesis, and cardiac muscle contraction, and was related to some disease-related pathways, such as type I diabetes mellitus, hypertrophic cardiomyopathy, dilated cardiomyopathy, allograft rejection, graft-versus-host disease, autoimmune thyroid disease, and African trypanosomiasis. YF was mainly associated with neuroactive ligand-receptor interaction and nucleotide excision repair. The above results may be closely related to the content of alkaloids in RAC. The high content of C<sub>19</sub>DDA in ULRA has been linked to strong anti-inflammatory activity (Hikino et al., 1982; Komoda et al., 2003), anti-tumor activity (Du et al., 2013; Ji et al., 2016), and damage to myocardial cells (Ma et al., 2018). The high content of C<sub>19</sub>MDA in YF exerts a protective effect on nerve cells (Jiang et al., 2012). C<sub>19</sub>ADA can increase the viability of myocardial cells, and improve myodynamia and ventricular diastolic function (Liu et al., 2012; Xiong et al., 2012).

**FIGURE 9 |** The pathway analysis of all differentially expressed proteins was based on the KEGG (Kyoto Encyclopedia of Genes and Genomes) database. The comparison between the (A) M group and B group, between the (B) ULRA group and model group, and between the (C) YF and model groups was performed. ULRA, unprocessed lateral root of *Aconitum carnichaelii*; YF, Yinfulpian.

CYP has two main biological functions. The first is the metabolism of heterologous substances. Lipid soluble drugs can only be excreted after biotransformation in the kidneys (Modi and Dawson, 2015). CYP can reduce the hydrophobicity of compounds and form intermediate metabolites for easy excretion. The second function is the biosynthesis of bioactive molecules, including the metabolism of steroids, vitamins, and fatty acids (Albertolle and Guengerich, 2018). The CYP4A family metabolizes arachidonic acid into  $\omega$ -hydroxyeicosatetraenoic acid in kidneys (Ying et al., 2008). 20-hydroxyeicosatetraenoic acid plays an important role in skeletal muscle and vascular myogenic response, and regulates blood circulation (Imig et al., 1996). In addition, studies have shown that specific inhibition of CYP4A can treat myocardial injury induced by advanced glycation end product (Wang

et al., 2019). Aldehyde oxidase is an important enzyme system involved in drug metabolism (Garattini et al., 2003). *In vivo* studies showed that CTSG inhibitors decreased cardiac inflammation and improved cardiac function after myocardial ischemia-reperfusion injury (Hooshdaran et al., 2017), indicating that CTSG may promote inflammation. FABP is a sensitive marker for the early diagnosis of myocardial infarction (Mad et al., 2007; Figiel et al., 2008). Following the occurrence of myocardial ischemia, fatty acids are mobilized to supply energy, thereby increasing the levels of heart-type FABP. LYZ is widely distributed in the human body because of its antibacterial, antiviral, anti-inflammatory, and immunity-enhancing properties (Eichenberger et al., 2010).

The downregulation of CYP and AOX in the model group may indicate that YDS can inhibit the metabolic activities in the body.

Upregulation of CTSG expression can aggravate the inflammatory reaction. The upregulation of FABP and LYZ may be related to the self-regulation and response of the body in the state of YDS. CYP was downregulated in the ULRA group compared with the model group. This finding was consistent with those of previous studies stating that  $C_{19}$ DDA can inhibit the activity of CYP and affect its mRNA levels. Its toxic targets are ion channels, substructures, enzymes, and receptors (Yen and Ewald, 2012; Chang et al., 2019). The expression of AOX3 was significantly increased in the ULRA group compared with the model group. The levels of CTSG were significantly decreased in the YF group compared with the model group, suggesting that YF may exert an anti-inflammatory effect by downregulating the expression of CTSG.

Together,  $\alpha$ -actinin and actin form the main cytoskeleton protein of cells, maintain the special morphology of cells, and endow the cells with toughness and strength (Dixon et al., 2003). For myocardial cells, actinin is located on the myocardial cell membrane and Z-band through a variety of actin connexins to perform myocardial contractile and diastolic functions.  $\alpha$ -actinin is one of the connexins; following change,  $\alpha$ -actinin directly affects the systolic and diastolic functions of myocardial cells and leads to myocardial remodeling. Spatial regularity disorder of  $\alpha$ -actinin-2 has been found in cardiac myocytes of patients with heart failure (Dobrev and Nattel, 2010), indicating that the plasticity of  $\alpha$ -actinin-2 may occur in cardiac structural remodeling. TNNT contains the binding site of protomyosin; TNNT is an inhibitor of actin ATPase, which inhibits the interaction between actin and myosin. TNNT binds to  $Ca^{2+}$  and regulates the interaction between TNNT, TNNT, and other components of the systolic system (Perry, 1998; Perry, 1999). Creatine kinase (CK) is closely related to energy metabolism in mammals. It is involved in glycolysis control, mitochondrial

respiration, and energy supply for muscle contraction. CK is one of the key enzymes in the metabolism of the ATP-creatine phosphate system. Its role is to catalyze the reversible transfer of a high-energy bond between ATP and creatine phosphate (Cheng et al., 2020). Myosin is the structural protein and the main contractile protein of the myocardium. It is composed of two heavy chains and four light chains. Typically, the body can produce immune tolerance to myosin. However, under pathological conditions, myosin can be an autoantigen causing an autoimmune reaction, stimulating the production of anti-myosin antibody, and mediating myocardial immune injury. Studies (Wang et al., 2003) suggested that myosin can be an autoantigen mediating myocardial injury, which can transform myocarditis into dilated cardiomyopathy.

Studies have shown that aconitine can inhibit the expression of  $\alpha$ -actinin (Zhang et al., 2020). This may be due to the effects of aconitine on protein expression in the myofilaments of cardiomyocytes, resulting in dysfunction of myofilaments; this may be the mechanism of aconitine-induced cardiotoxicity. The expression levels of troponin and CK were downregulated in the ULRA group, indicating that ULRA could inhibit the contraction and relaxation of muscle. Moreover, the downregulation of myosin may be involved in the anti-inflammatory effect of ULRA.

Mammalian mitochondrial ribosomal proteins are synthesized in cytoplasmic ribosomes and transported to mitochondria by special protein complexes. They are combined with rRNA and assembled into ribosomes. Moreover, they are responsible for the translation of 13 membrane proteins encoded by mitochondrial DNA and participate in the oxidative phosphorylation reaction (Christian and Spremulli, 2011; De et al., 2015). Mitochondrial

inner membrane protein is essential for the activity and assembly of cytochrome oxidase; it is also necessary for the correct biogenesis of ATP synthase and complex I in mitochondria (Bonnefoy et al., 1994; Stiburek et al., 2007).

In the YF group, the expression of Mammalian mitochondrial ribosomal proteins was significantly upregulated. Studies have shown that benzoylaconine can increase the mitochondrial quality and induce mitochondrial biogenesis in mice by activating the adenosine monophosphate-activated protein kinase (AMPK) signaling cascade (Deng et al., 2019). It is suggested that YF can promote the production of ATP, and the increase in benzoylaconine is an important step for mitochondrial energy metabolism.

As a medicinal plant with documented efficacy and toxicity, the chemical composition and effects of LRA have been investigated in recent years, shedding light on its material basis and the pharmacological and toxicological mechanisms. However, further studies are warranted to overcome some current limitations. Regarding chemical constituents, despite the availability of detailed studies on various alkaloids, the extraction of many compounds remains difficult, and there are challenges in the hydrolysis and transformation of C<sub>19</sub>DDA, C<sub>19</sub>MDA, and C<sub>19</sub>ADA. Therefore, it is necessary to further investigate the dynamic transformation law of different types of alkaloids to increase efficiency and reduce toxicity in the process of component transformation. Concerning medicinal activity, although the overall pharmacological and toxicological effects of LRA have been extensively studied, there is a lack research on the target mechanism of most monomer compounds. Hence, it is

necessary to further clarify the mechanisms of interaction between multiple components and multiple targets.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found at [iProX (www.iprox.org), ID: PXD026321].

## ETHICS STATEMENT

The animal study was reviewed and approved by Ethics Committee on Laboratory Animals of Jiangxi University of Traditional Chinese Medicine.

## AUTHOR CONTRIBUTIONS

H-IT and HC performed the experiments, analyzed the data, and wrote the manuscript. F-pG and S-hY revised the manuscript. L-yZ and JZ designed the research and performed the analyses.

Xinglou Chengqi (XLCQ) decoction, composed of three botanical drugs and one inorganic drug, is used in clinics during the treatment of acute stroke complicated with Tanre Fushi (TRFS) syndrome in China. However, its active ingredients and the molecular mechanism have not been clarified. So, we aimed to preliminarily characterize its chemical constituents and investigate its pharmacological mechanisms using an integrative pharmacology strategy, including component analysis, network prediction, and experimental verification. We employed UPLC-QTOF-MS/MS to describe the chemical profile of XLCQ, Integrative Pharmacology-based Network Computational Research Platform of Traditional Chinese Medicine (TCMIP v2.0, <http://www.tcmip.cn/>), to assist in identifying the chemical components and predict the putative molecular mechanism against acute stroke complicated with TRFS, and LPS-stimulated BV-2 cells to verify the anti-neuroinflammatory effects of luteolin, apigenin, and chrysoeriol. Altogether, 197 chemical compounds were identified or tentatively characterized in the water extraction of XLCQ, 22 of them were selected as the key active constituents that may improve the pathological state by regulating 27 corresponding targets that are mainly involved in inflammation/immune-related pathways, and furthermore, luteolin, apigenin, and chrysoeriol exhibited good anti-neuroinflammatory effects from both protein and mRNA levels. In summary, it is the first time to employ an integrative pharmacology strategy to delineate 22 constituents that may improve the pathological state of stroke with TRFS by regulating 27 corresponding targets, which may offer a highly efficient way to mine the scientific connotation of traditional Chinese medicine prescriptions. This study might be a supplement for the deficiency of the basic research of XLCQ.

## INTRODUCTION

Stroke, characterized by a high incidence rate, high mortality, and a high disability rate, is a devastating cerebrovascular event that occurs as a result of cerebral vascular occlusion (ischemic stroke) or burst/bleeding (hemorrhagic stroke), leading to cerebral blood flow disruption, physical disability, and multiple functional impairment, which seriously threatens human health and quality of life (Feigin et al., 2016). At present, the main treatment to ischemic stroke is early thrombolysis to restore blood flow and achieve vascular recanalization, but most patients cannot get thrombolytic therapy due to the limitation of treatment time window or other contraindications. Therefore, it is particularly urgent to find safe and effective drugs for stroke prevention and treatment with a clear mechanism.

Traditional Chinese medicine (TCM), characterized by lower side effects, is often thought to be an alternative pharmacotherapy for prevention and rehabilitation intervention of ischemic stroke in China (Liu et al., 2018). As early as in 1981, Academician Yongyan Wang observed that about 74.2% of stroke patients were accompanied by “Tanre Fushi” (TRFS) syndrome (Wang, 1981) that manifests as abdominal distension, constipation, bad breath, and dry throat, and then he developed the “Huatan Tongfu” treatment strategy in the following year (Wang et al., 1982). In 1986, he created “Huatan Tongfu” decoction, which was later renamed as “Xinglou Chengqi” (XLCQ) decoction, to treat acute stroke in clinics. At the same time, the indication and opportunity for the correct application of XLCQ decoction were given (Wang et al., 1986). XLCQ decoction is composed of three botanical drugs and one inorganic drug, namely, *Trichosanthes kirilowii* Maxim. (Gualou, GL) 30–40 g, *Arisaema erubescens* (Wall.) Schott (Dannanxing, DNX) 6–10 g, *Rheum palmatum* L. (DaHuang, DH) 10–15 g, and *Natrii sulfas* (Mangxiao, MX) 10–15 g. The main component of *Natrii sulfas* is  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ , which belongs to a mineral medicine.

Accumulating clinical practices have proven that the effective power of the Western medicine treatment for acute stroke could be enhanced obviously when combined with XLCQ, especially when the patient is suffering with TRFS (Chen et al., 2017; Zhen, 2017; Liu and Lei, 2019; Wang et al., 2020a; Han, 2020; Jiang et al., 2020; Lu and Wang, 2020; Yao et al., 2020). Although XLCQ has almost been used for 40 years in clinics, its chemical composition has not been systematically characterized, and its pharmacological mechanism is limited to anti-inflammatory (Du et al., 2009; Wand, 2016; Zhen, 2017; Zhao et al., 2018), anti-free radical injury (Wu and Jiang, 2005; Zhou et al., 2016), inhibition of neuronal damage (Liu et al., 2012a; Yu et al., 2018), and anti-neuronal apoptosis (Liu et al., 2012b).

Therefore, in the present study, we aimed to describe the chemical profiles and explore the underlying pharmacological mechanisms of XLCQ acting on stroke with TRFS through the following scheme, as shown in **Figure 1**: 1) analyzing XLCQ chemical components by UPLC-QTOF-MS/MS, 2) collecting the information of chemical components from Integrative Pharmacology-based Network Computational Research Platform of Traditional Chinese Medicine (TCMIP v2.0, <http://www.tcmip.cn/>), 3) predicting the putative targets of the

identified components and collecting the genes of stroke and TRFS from TCMIP, 4) constructing a “component targets-stroke/TRFS genes” network to select the candidate targets and the main active components of XLCQ, 5) functional enrichment analysis for investigating the underlying molecular mechanisms of XLCQ acting on stroke complicated with TRFS, and 6) verifying the anti-neuroinflammatory effects of luteolin, apigenin, and chrysoeriol based on LPS-simulated BV-2 cells.

## MATERIALS AND METHODS

### Chemicals and Reagents

HPLC-grade acetonitrile and methanol were purchased from Merck KGaA (Darmstadt, Germany); HPLC-grade formic acid from Sigma-Aldrich (St. Louis, MO, United States); chloroform (100068), isopropanol (80109218), and anhydrous alcohol (10009218) from Sinopharm (Beijing, China); and DEPC-treated water (sc-204391) from Santa Cruz Biotechnology (CA, United States). Deionized water (18.2 MΩ cm) was purified by a Milli-Q system (Millipore Co., Billerica, United States). *Trichosanthes kirilowii* Maxim. (place of production: Hebei Province; batch number: 190112010), *Arisaema erubescens* (Wall.) Schott (place of production: Sichuan Province; batch number: D180903001), *Rheum palmatum* L. (place of production: Sichuan Province; batch number: 18111201), and *Natrii Sulfas* (place of production: Sichuan Province; batch number: DD0181) were purchased from Shengshi Baicao Pharmaceutical Co., Ltd. and authenticated by Mrs. Xirong He, a research assistant of China Academy of Chinese Medical Sciences (Beijing). The voucher specimens were deposited in the Institute of Chinese Materia Medica, China Academy of Chinese Medical Sciences.

Fetal bovine serum (FBS, 10270–106), penicillin–streptomycin (10,000 U/mL, 15140122), and 0.05% trypsin-EDTA (1X, 25300–054) from Gibco BRL Co. (Boise, Idaho, United States); Dulbecco’s Modified Eagle’s Medium-high glucose (DMEM/High Glucose, SH30022.01) from HyClone Laboratories (Logan, UT, United States); dry powder of phosphate-buffered saline (PBS, P1010), dimethyl sulfoxide (DMSO, D8371), and sterile deionized water (F0025) from Solarbio Life Sciences (Beijing, China); lipopolysaccharide (LPS, 0111:B4, L2630) from Sigma-Aldrich Crop. (St. Louis, MO, United States).

Luteolin (BT1191), apigenin (BT443), and chrysoeriol (BT2582) were borrowed from Beijing Beite Renkang Biomedical Technology Co., Ltd. (Beijing, China); IL-1β (CSB-E08054m) and TNF-α (CSB-E04741) ELISA kits from Cusabio (Beijing, China); CCK-8 kit from Dojindo (Kumamoto ken, Japan); and TB Green® Premix Ex Taq™ (RR420A) from TAKARA BIO INC. (Chiryu Shi, Japan).

### Preparation of Herbal Extracts

The prescription is composed of GL, DNX, DH, and MX with a dose proportion of 15:3:5:5. GL and DNX were soaked in 10 volumes of water for 60 min before boiling for 30 min. Then DH was added and boiling was maintained for another 30 min. MX

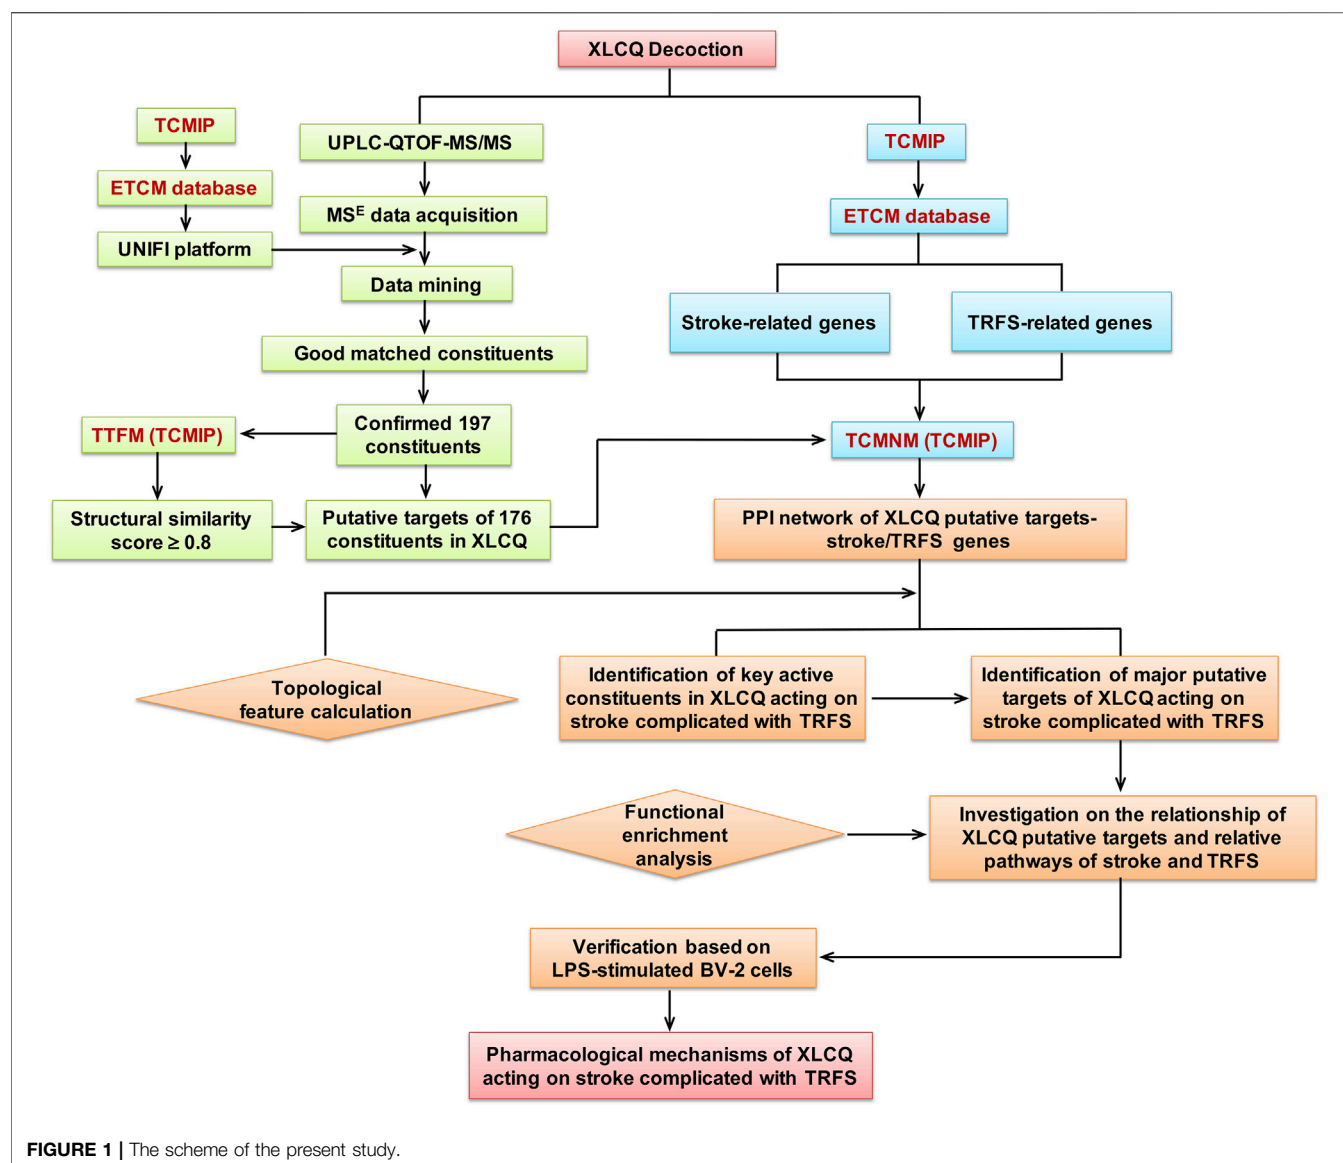

FIGURE 1 | The scheme of the present study.

was dissolved in the decoction that was filtered by eight layers of gauze. The residue was boiled with 8 volumes of water for another 30 min, and the decoction was filtered as before. The two combined filtrates were freeze-dried (Lab-1D-80E; Beijing boyaikang Experimental Instrument Co., Ltd., Beijing, China) at  $-80^{\circ}\text{C}$  with a paste rate at 26.96%, and the powder was pressed through a 60-mesh sieve. The fine powder was dissolved into 10 volumes of 70% MeOH and extracted with an ultrasonic wave for 15 min before 1- $\mu\text{l}$  aliquots were transferred to autosampler vials for analysis.

## Instrumentation and UPLC-QTOF-MS/MS Conditions

The analysis was performed on a Waters Acquity UPLC I-Class system (Waters Corp., Milford, United States) equipped with a binary pump, an online vacuum degasser, an autosampler, and an

automatic thermostatic column oven, coupled with a Waters Xevo G2-S Q-TOF Mass System (Manchester, United Kingdom) equipped with electrospray ionization (ESI). The data were recorded by Masslynx V4.1 (Waters Corporation, Milford, United States). Unifi software (Waters Corporation, Milford, United States) was used for peak detection and compound preliminary identification.

Chromatographic separation was performed on a Waters Acquity UPLC HSS T3 column (100 mm  $\times$  2.1 mm, i.d., 1.8  $\mu\text{m}$ ) maintained at  $35^{\circ}\text{C}$ , and a linear gradient of (A) 0.1% (v/v) formic acid in deionized water and (B) acetonitrile containing 0.1% (v/v) formic acid was used for the elution procedure, as follows: 0–3 min, 0.2–2% B; 3–5 min, 2–5% B; 5–6 min, 5–8% B; 6–10 min, 8–16% B; 10–10.2 min, 16–19% B; 10.2–14.5 min, 19–25% B; 14.5–15 min, 25–30% B; 15–15.5 min, 30–40% B; 15.5–18 min, 40–50% B; 18–20 min, 50–70% B; 20–21 min, 70–98% B; 21–24 min, 98% B; 24–24.1 min, 98–0.2%

B; and 24.1–26 min, 0.2% B. The flow rate was set at 0.5 ml/min, and a 1- $\mu$ l aliquot was set as the injection volume.

The QTOF-MS data were collected in a full scan auto mode from 0 to 26 min in both positive and negative ion modes. Based on the best response for most of the compounds, the optimal parameters were set as follows: mass range, 50–1,500 Da; source temperature, 100 °C; desolvation temperature, 450 °C; desolvation gas flow, 900 l/h; sampling cone, 40 V; ESI<sup>−</sup> capillary voltage, 2.5 KV; and ESI<sup>+</sup> capillary voltage, 0.5 KV. At low CE scan, the auto MS collision energy was 6 eV. At high CE scan, the collision energy was 30–50 eV ramp for ESI<sup>+</sup> and 80–100 eV ramp for ESI<sup>−</sup>.

Leucine enkephalin was employed as lock mass at a concentration of 200 pg/ml in acetonitrile (0.1% formic acid): H<sub>2</sub>O (0.1% formic acid) (50:50, v/v) for the positive ion mode ([M + H]<sup>+</sup> = 556.2771) and negative ion mode ([M − H]<sup>−</sup> = 554.2615) via a lock spray interface.

## Data Processing

UPLC-QTOF-MS/MS system was controlled by the Masslynx 4.1 platform. The MS<sup>E</sup> data collected in a continuum mode were processed using the apex peak detection and alignment algorithms in UNIFI 1.8, which enabled quasi-molecular ion peaks, salt adduct ions, and dehydration fragment ions to be analyzed as a single entity. The analysis process includes data acquisition, data mining, library searching, and report generation.

The information of chemical components GL, DNX, and DH including molecular name, molecular formulas, molecular weights, and chemical structures (mol. format) was collected from ETCM (Xu et al., 2019) (<http://www.nrc.ac.cn:9090/ETCM/>), as a customized library listed in **Supplementary Excel S1**, to assist the chemical identification, which were transferred to the UNIFI form later (**Supplementary Excel S2**). The additive ions of [M + H]<sup>+</sup>, [M + K]<sup>+</sup>, [M + Na]<sup>+</sup>, [2M + H]<sup>+</sup>, and [M − e]<sup>+</sup> were selected in a positive ion mode and [M + COOH]<sup>−</sup>, [M − H]<sup>−</sup>, and [2M − H]<sup>−</sup> in a negative ion mode. A margin of error up to 5 mDa/10 ppm for identified components was allowed, and the matched components would be

generated as predicted fragments from the structure. For unmatched components, the functional module of elemental composition and mass fragment could further assist the chemical identification. Based on the isotopic abundance, the elemental composition calculator could provide a number of possible formulas for an accurate mass peak. Mass fragment could provide fragment structures which assist the chemical identification. The final list of possible formulas could provide relative confidence denoted by an i-FIT score and 0.8 as the threshold value.

## Prediction of the Putative Targets of Chemical Constituents Available in XLCQ

The mol. formats of identified compounds were uploaded to the customer center of TCMIP to predict the putative targets using TCM target prediction and function analysis module (TTFM) according to the chemical structure similarity comparison with known drugs on the market. In order to improve the prediction accuracy, we set the structural similarity score at 0.80 (moderate–high similarity) to select the constitute–putative target pairs (Mao et al., 2019).

## Network Construction of XLCQ Putative Target-Stroke/TRFS Gene

To investigate the relationship of XLCQ putative targets and stroke/TRFS genes, we collected a list of stroke-related genes and TRFS-related genes from disease-related gene database of TCMIP. The key words of stroke were “stroke, ischemic stroke, brain injury, cerebral ischemia, and cerebral hemorrhage.” TRFS syndrome was a combination of Yang Ming Fushi syndrome, phlegm heat obstructing lung syndrome, and wind-phlegm syndrome. So, the symptomatic phenotypes of three syndromes were used as the key words to collect the related genes, including “fever, delirium, abdominal pain, dysphoric mood, hyperhidrosis, constipation, wheezing, cough, vertigo, vomiting, abnormality of salivation, syncope, facial paralysis, and hemiplegia.”

An interaction network of XLCQ putative target–stroke/TRFS-related gene was constructed based on the links among the three gene sets using the TCM Association Network Mining Module (TCMNM) of TCMIP, which directly exhibits the major hub network according to three topological features of each node gene, including “degree,” “betweenness,” and “closeness.” Generally, the node that has the degree value 2-fold the median, and betweenness and closeness value 1-fold the median is selected as the major hub.

## Network Visualization and Functional Enrichment Analysis

To better exhibit the common targets among XLCQ, stroke, and TRFS, the Venn diagram was performed using the “Calculate and draw custom Venn diagrams” website (<http://bioinformatics.psb.ugent.be/webtools/Venn/>). To better exhibit the interactions of the major hubs, the network visualization was performed using CytoScape V3.8.0. To elucidate the biological functions of XLCQ putative

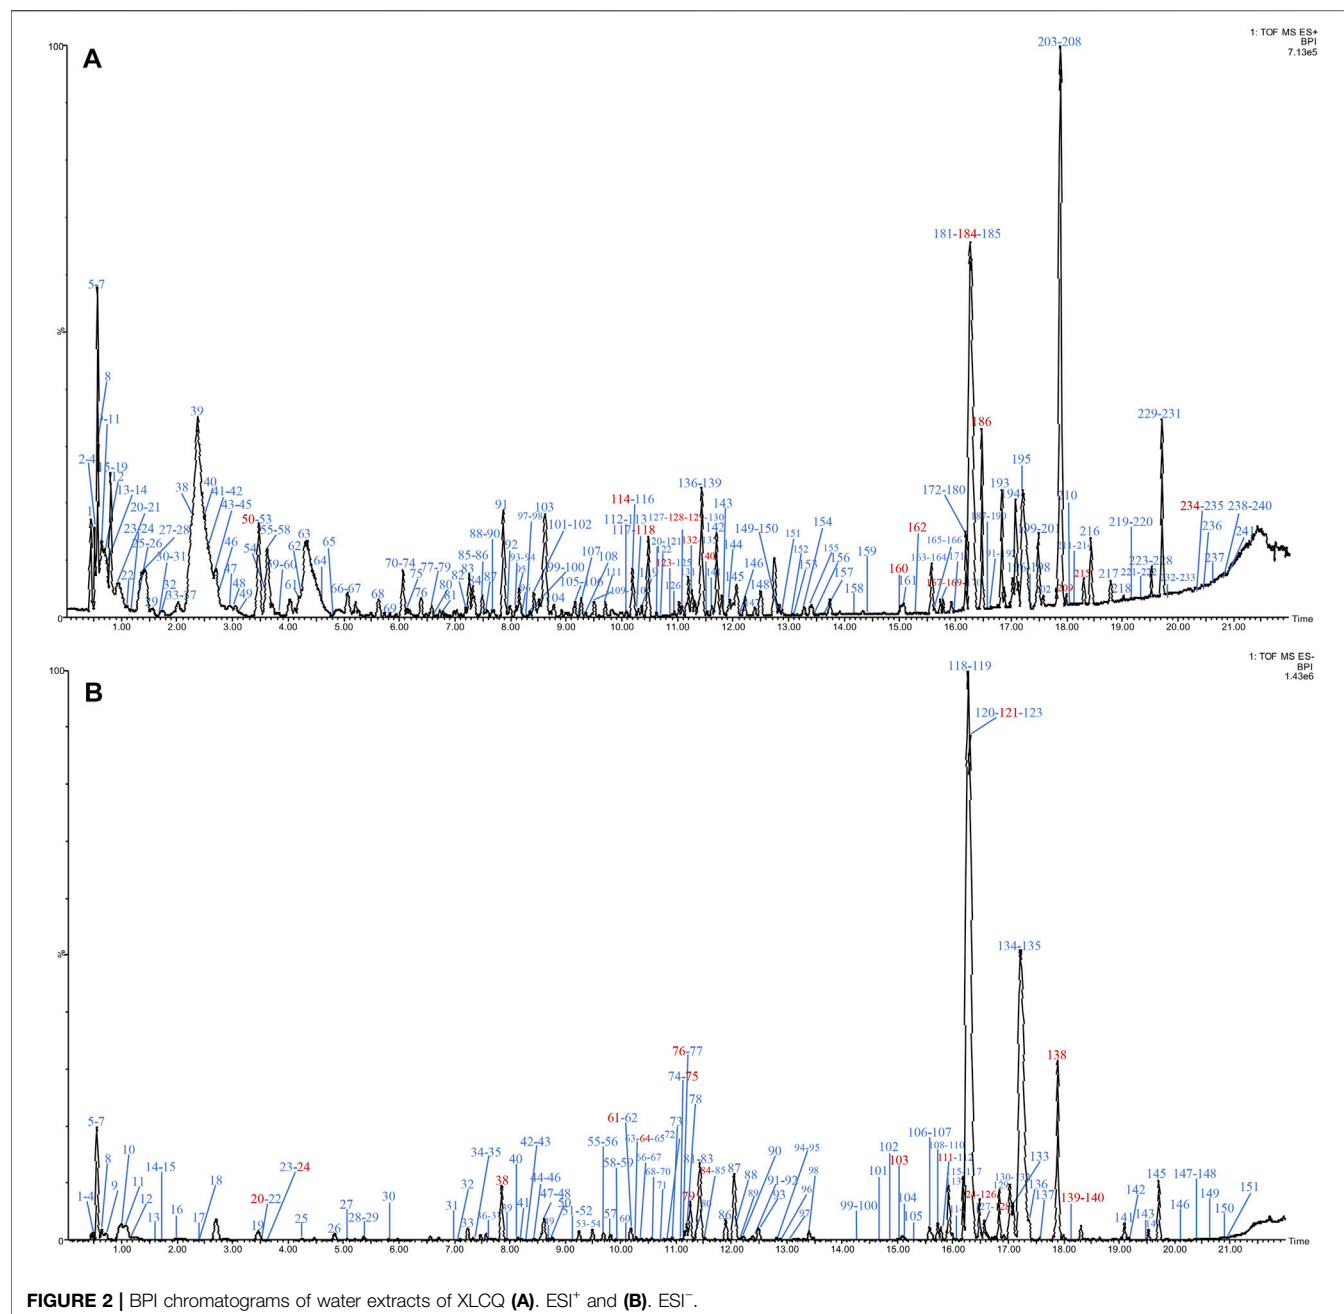

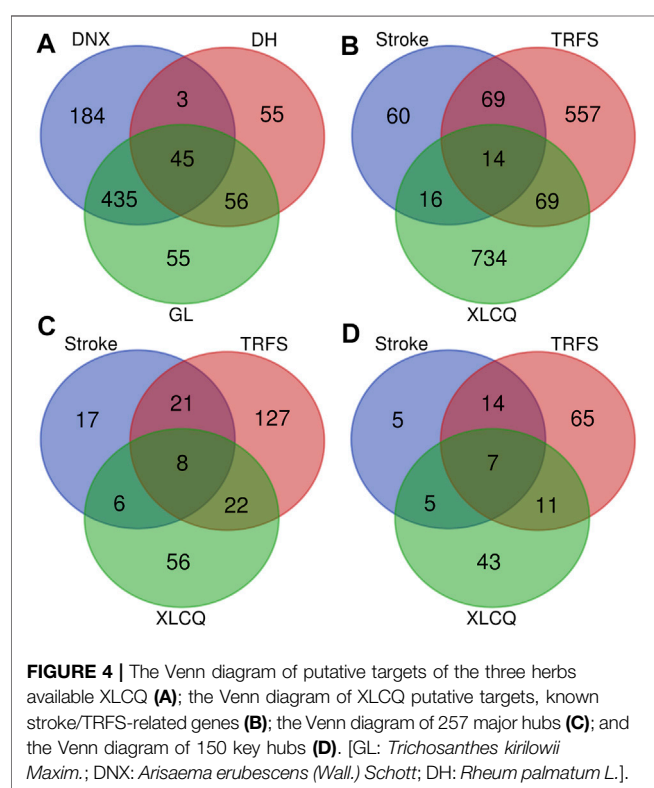

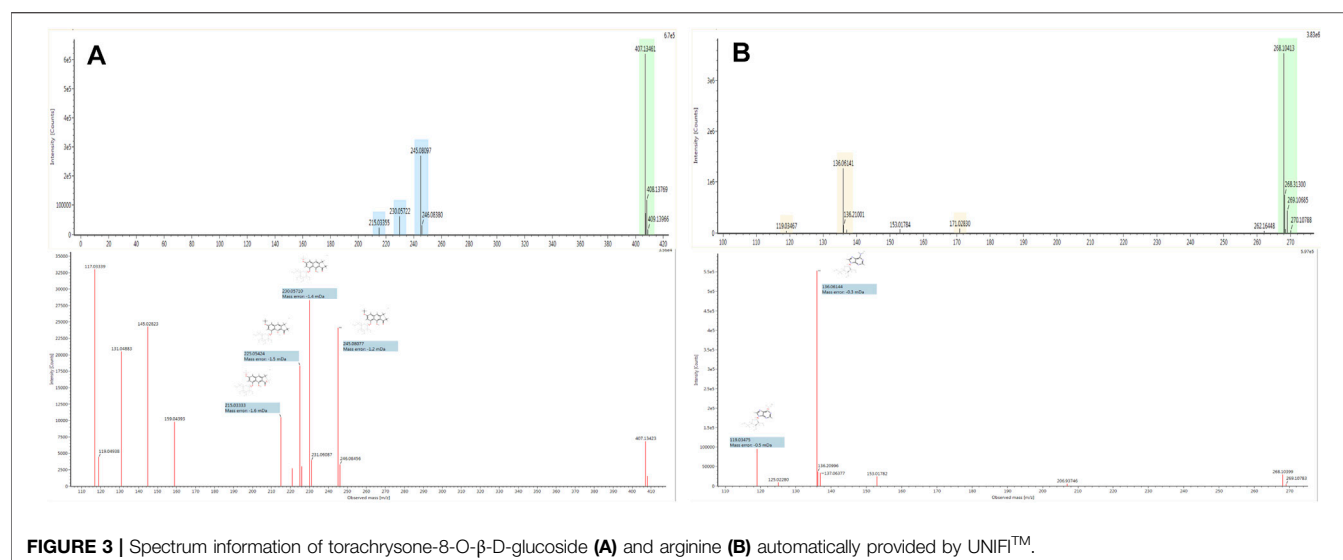

FIGURE 2 | BPI chromatograms of water extracts of XLQC (A). ESI<sup>+</sup> and (B). ESI<sup>-</sup>.

targets, the functional enrichment analysis was performed using the database for annotation, visualization, and integrated discovery (DAVID) v6.8 (<https://david.ncicrf.gov>).

## Cell Viability Evaluation

Murine BV-2 microglia cells were obtained from the Institute of Materia Medica-Chinese Academy of Medical Science (Beijing, China) and cultured in DMEM supplemented with 10% heat-inactivated FBS and antibiotics (100 U/ml streptomycin and 100 U/ml penicillin) at 37°C in an

incubator [Sanyo MCO-18AIC (UV), Osaka, Japan] with a humidified atmosphere containing 5% CO<sub>2</sub> and 95% O<sub>2</sub>. BV-2 cells were plated in 96-well plates with density at  $1 \times 10^4$  cells/well and incubated in the abovementioned conditions for 24 h. Luteolin, apigenin, and chrysoeriol solutions were added to different wells with final concentrations at 80, 40, 20, 10, and 5  $\mu$ M and incubated for another 24 h. Cell viability was evaluated by a CCK-8 kit, and the absorbance was determined at 450 nm 2 h later by a ThermoFisher Scientific Multiskan FC Microplate Reader (MA, United States).

## Drug Treatment

BV-2 cells were plated in 24-well plates with the density at  $1.5 \times 10^5$  cells/well and incubated for 24 h. Luteolin, apigenin, and chrysoeriol solutions were added with final concentrations at 10  $\mu$ M and incubated for 1 h. Then LPS was added to induce neuroinflammation with a final concentration of 1  $\mu$ g/ml, and incubated for another 24 h. Finally, the supernatant was collected by centrifugation at

12,000 r and 4 °C for 10 min, which was used for IL-1 $\beta$  and TNF- $\alpha$  analyses according to the instructions of ELISA kits.

## Real-Time Reverse Transcription–Polymerase Chain Reaction (RT-qPCR)

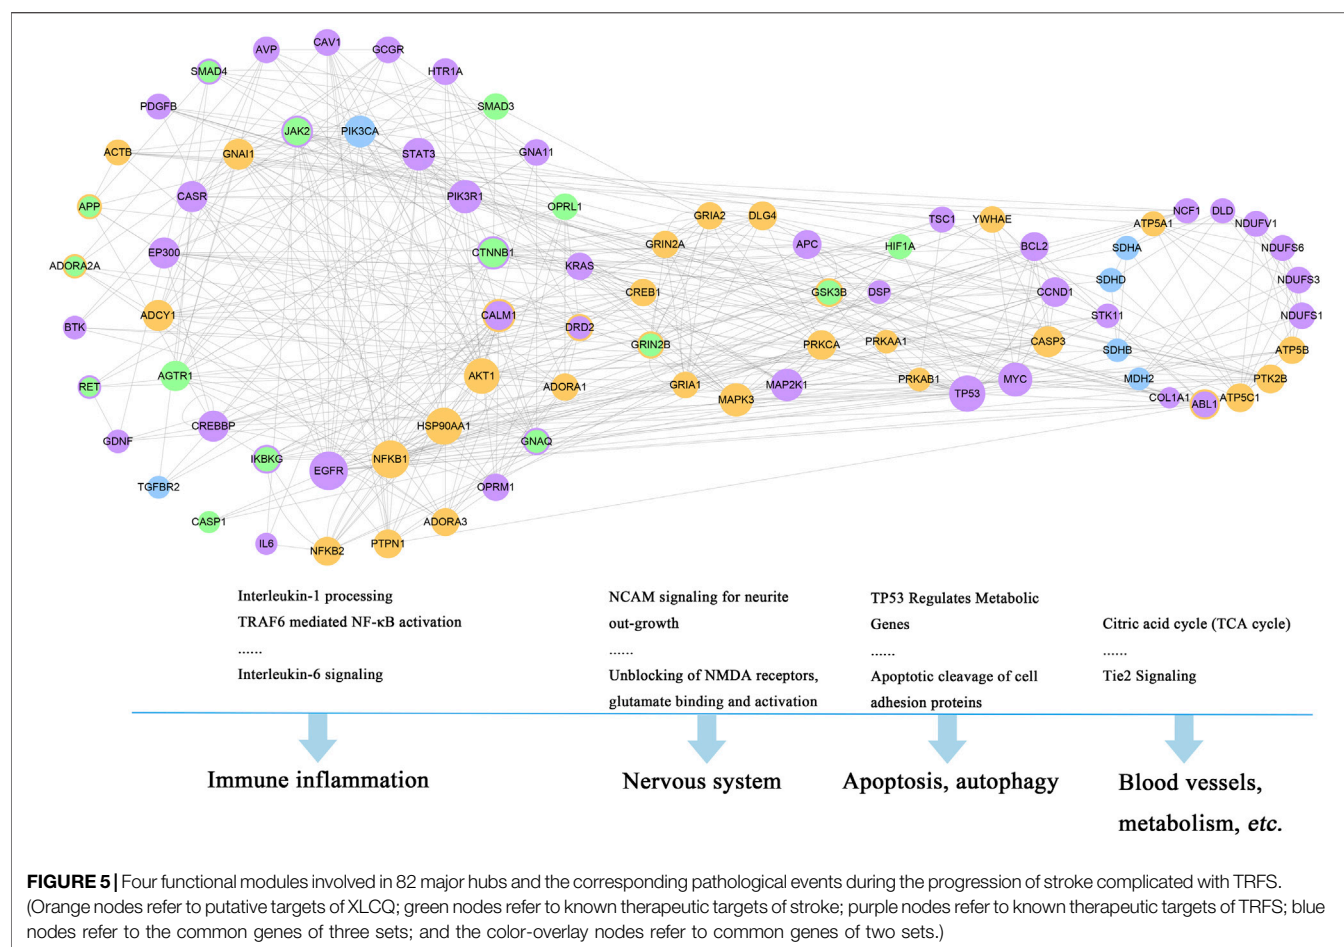

The total RNA was isolated using TRNzol Universal Reagent (TIANGEN, DP424, China), and 1  $\mu$ g RNA was reverse-transcribed to cDNA using FastKing gDNA Dispelling RT SuperMix (TIANGEN, KR118-02, China) by Veriti 96-Well Thermal Cycler PCR (Thermo Fisher, 4375786, United States) according to the manufacturer's instructions. A single-stranded cDNA was amplified by PCR with primers for IL-1 $\beta$ , TNF- $\alpha$ , PIK3CA, AKT1, NFKB1, NFKB2, CREB1, HSP0AA1, and  $\beta$ -actin, whose primer sequences are shown in Table 1. PCR was performed using a real-time fluorescence quantitative PCR instrument (Roche, LightCycler480 II, Germany) by the following two-step PCR amplification procedure: 1 cycle of pre-degradation at 95°C for 30 s, 40 cycles of denaturation at 95°C for 5 s (ramp rate: 4.4°C/s), and then, annealing and extension at 60°C for 30 s (ramp rate: 2.2°C/s, acquisition mode: single).  $\beta$ -actin was selected as an internal control to evaluate the expression of the eight genes. Primers were purchased from Beijing Qingke Biotechnology Co., Ltd. (Beijing, China).

## RESULTS

### Characterization and Identification of Chemical Constituents Available in XLCQ

The base peak intensity (BPI) chromatograms of water extraction of XLCQ corresponding to the positive and

negative ion modes are shown in **Figure 2**. The  $MS^E$  raw data obtained by UPLC-QTOF-MS/MS were processed using the UNIFI 1.8 software automatically to quickly identify the constituents by matching the detailed information with the customized library (**Supplementary Excel S2**). Altogether, a total of 197 compounds (152 in  $ESI^+$  and 116 in  $ESI^-$ ) were identified or tentatively characterized, of which 56 originated from GL, 63 from DNX, and 78 from DH. The detailed information of chemical compounds is listed in **Supplementary Tables S1, S2**, containing RT, M/Z, error, response, adducts, formula, name, fragments, category, and origination. The identified constituents, especially the isomers, were verified by the characteristic fragments reported in the literatures. Taking two compounds as examples, the secondary fragment information was exhibited in detail. The ion at RT = 15.56 and  $[M-H]^- = 407.1334$  was primarily identified as torachrysone-8-O- $\beta$ -D-glucoside ( $C_{20}H_{24}O_9$ ) in  $ESI^-$  after searching in the scientific database of UNIFI collected from ETCM, and the main fragments were  $m/z$  245.0600  $[M-H-Glc]^-$ , 230.0560  $[M-H-Glc-CH_3]^-$ , 215.0324  $[M-H-Glc-2CH_3]^-$ , 159.0431  $[M-H-Glc-2CH_3-2CO]^-$ , and 141.0483  $[M-H-Glc-2CH_3-3CO]^-$  (**Figure 3A**), which were consistent with the literature report (Gao, 2012). In the same way, ion at

RT = 3.46 and  $[M + H]^+ = 268.1046$  was primarily identified as arginine ( $C_{10}H_{13}N_5O_4$ ) in  $ESI^+$ , and the main fragments were  $m/z$  136.0624 and 119.0349 (**Figure 3B**), corresponding to loss  $-C_5H_7O_4$  and  $-NH_3$  in turn, which were consistent with the literature report (Wang and Han, 2018).

## Putative Targets of Chemical Constituents Available in XLCQ

Altogether, a total of 833 putative targets were predicated based on the chemical structures of 197 primarily identified compounds using the TCM Target Prediction and Function Analysis Module of TCMIP (**Supplementary Excel S3**). Only 176 compounds (52 from GL, 51 from DNX, and 73 from DH) had putative targets when the Tanimoto score was set at 0.8 (moderate~high similarity). The putative targets of GL, DNX, and DH were 591, 667, and 159, respectively. Interestingly, the three herbs had a number of common putative targets according to the prediction, indicating the potential drug-drug interactions through their common targets (**Figure 4A**).

## The Gene Set of Stroke and TRFS Syndrome

A total of 159 stroke-related genes and 709 TRFS-related genes were collected from the disease-related gene database of TCMIP

**TABLE 2 |** Active constituents of XLCQ and their putative targets.

<sup>a</sup>The number is corresponding to **Supplementary Tables S1, S2**.

(**Supplementary Excel S3**). The distribution of the 1519 genes was exhibited in the Venn diagram (**Figure 4B**), with XLCQ 734, stroke 159, and TRFS 709. Whereas “stroke” was a disease, “TRFS” was a syndrome, and there were still 83 common targets, indicating they may have the possible effects targets. XLCQ had 30 common targets with that of stroke and 83 with that of TRFS, indicating the possible direct targets of XLCQ acting on stroke complicated with TRFS. The common targets of XLCQ with TRFS were more than those of XLCQ with stroke, indicating that the therapeutic effect of XLCQ on TRFS may be stronger than that of stroke.

## Underlying Mechanisms of XLCQ Acting on Stroke Complicated With TRFS Syndrome

To illustrate the underlying mechanisms of XLCQ acting on stroke complicated with TRFS, an interaction network of drug

target genes and disease/syndrome-related genes was constructed based on the interactions among three gene sets using the TCM Association Network Mining Module of TCMIP, and the network topological features were calculated automatically by TCMIP. Altogether, 257 hubs were selected, and detailed information is provided in **Supplementary Excel S3**. The target distribution of the 257 genes was exhibited in the Venn diagram (**Figure 4C**). The target number of XLCQ, stroke, and TRFS was 92, 52, and 178, respectively, with 30 common targets between XLCQ and TRFS, 14 between XLCQ and stroke, and 29 between stroke and TRFS.

To improve the prediction accuracy, 150 major hubs whose degree value  $\geq 12$  were selected from the 257 hubs (**Supplementary Excel S3**, marked in red). Among them, 31 nodes were stroke-related genes, 97 were TRFS-related genes, and 66 were XLCQ putative targets (**Figure 4D**).

**FIGURE 6 |** Pathway enrichment analysis of key effect genes of XLCQ in the treatment of stroke complicated with TRFS.

The functional enrichment analysis of the 150 genes was investigated by DAVID v6.8. Altogether, 85 pathways were obtained based on the Reactome Pathway Database. Among them, 52 pathways (**Supplementary Excel S3**, marked in bold) containing 82 genes were involved in the corresponding pathological events during the progression of stroke and TRFS, which were divided into four functional modules, including immune inflammation module, nervous system module, apoptosis, and autophagy module (Figure 5).

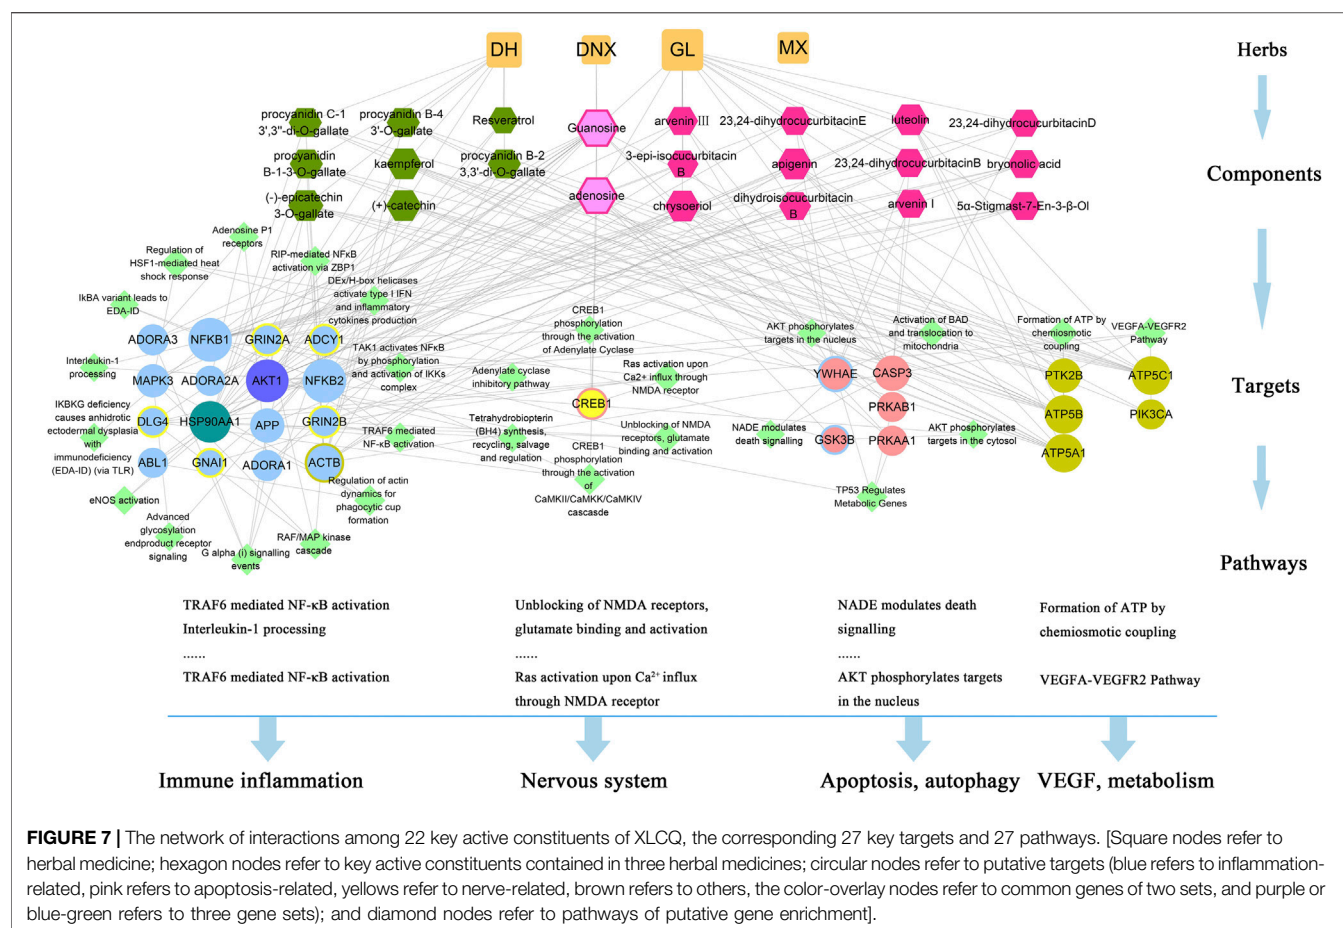

### Selection of Key Active Constituents of XLCQ Acting on Stroke Complicated With TRFS Syndrome

There were 60 chemical components corresponding to 150 major hubs. According to the number of major hubs and its frequency appearing in different pathways, the threshold was set at 2 and 13. That was, if a chemical constituent had more than two hubs and simultaneously the frequency of these hubs was more than 13, this chemical constituent was regarded as a key active constituent of XLCQ acting on stroke complicated with TRFS. Altogether, a total of 22 key active constituents and 28 corresponding targets were selected (Table 2). Twenty-seven of the 28 putative targets were enriched in 27 pathways (Figure 6, **Supplementary Excel S3**). The multi-dimensional network of 22 key active

constituents, the corresponding 27 key targets, and 27 pathways was constructed as shown in (Figure 7). The GO functional analysis showed that these targets were mainly involved in immune inflammation (regulation of cellular response to heat, Fc- $\gamma$  receptor signaling pathway involved in phagocytosis), the growth and development of the nervous system (ionotropic glutamate receptor signaling pathway, adenosine receptor signaling pathway, and cellular response to nerve growth factor stimulus), apoptosis (negative regulation of apoptotic process, MAPK cascade), and signal transduction (Figure 8).

### Luteolin, Apigenin, and Chrysoeriol Reduce the Release of IL-1 $\beta$ and TNF- $\alpha$ in LPS-Stimulated BV-2 Cells

The CCK-8 assay kit was employed to evaluate the cytotoxicity to select the appropriate concentration of luteolin, apigenin, and chrysoeriol. As shown in Figure 9A, apigenin showed cytotoxicity to BV-2 cells at 40  $\mu$ M, and luteolin and chrysoeriol showed cytotoxicity at 20  $\mu$ M, so 10  $\mu$ M was selected for a later anti-inflammatory study. Pro-inflammatory cytokine levels of IL-1 $\beta$  ( $p < 0.0001$ ) and TNF- $\alpha$  ( $p < 0.05$ ) were significantly increased after BV-2 cells were stimulated by LPS (1  $\mu$ g/ml) for 24 h, and reversed by pretreatment with luteolin, apigenin, and chrysoeriol at 10  $\mu$ M for 1 h, suggesting these three compounds had anti-neuroinflammatory activities (Figure 9B).

## Luteolin, Apigenin, and Chrysoeriol Downregulate the mRNA Expression of IL-1 $\beta$ , TNF- $\alpha$ , PIK3CA, AKT1, NFKB1, NFKB2, CREB1, and HSP0AA1

As shown in **Figure 10A**, the mRNA expression of IL-1 $\beta$ , TNF- $\alpha$ , PIK3CA, AKT1, NFKB1, and NFKB2 was 7.4-fold, 7.1-fold, 4.3-fold, 1.5-fold, 3.2-fold, 10.7-fold, 1.6-fold, and 2.3-fold increases, respectively, after the LPS stimulation, while pretreatment with these three compounds significantly reversed the above states. The pathway diagram is shown in **Figure 10B**.

## DISCUSSION

In the present study, 197 chemical compounds were identified or tentatively characterized in the water extraction of XLCQ analyzed by UPLC-QTOF-MS/MS, and 176 of them had putative targets (Tanimoto score  $\geq 0.8$ ). *Natrii sulfas* had no putative targets as sodium sulfate was hydrolyzed to produce sulfate ion, which was not easily absorbed by the intestinal wall. *Natrii sulfas* remains in the intestine as a hypertonic solution to

prevent the absorption of water in the intestine and increases the intestinal volume, thus causing mechanical stimulation and promoting the secretion of the intestinal wall. Subsequently, the heat pathogens and toxins in the body are discharged from the body. 833 putative targets corresponding to 176 components were predicted (Tanimoto Score  $\geq 0.8$ ) using TCMIP, and 159 stroke-related genes and 709 TRFS-related genes were collected from TCMIP. Twenty-two key active constituents were selected based on the interactions among the three abovementioned gene sets, which may improve the pathological state of stroke patients with TRFS syndrome by regulating the 27 corresponding targets that mainly involved in inflammation-immune-related pathways. Luteolin, apigenin, and chrysoeriol, as the predicted components, exhibited good anti-neuroinflammatory effects based on LPS-stimulated BV-2 cells.

"Integrative pharmacology" is an interdisciplinary science that comprehensively explores the interactions between the multiple constituents of TCM and the body at multiple levels (Xu et al., 2021). TCMIP, as an important part of integrative pharmacology, is an intelligent data mining platform that integrates big data management and pharmacology computing services, which consists of five databases and seven functional modules. The five database resources

come from the encyclopedia of TCM (ETCM) (Xu et al., 2019), an international authoritative database, which provides the basic information of TCM, including chemical compounds, putative targets, corresponding disease, and syndrome. The seven functional modules can be used to query and mine the biological basis and mechanisms of disease, syndrome, and TCM.

Among the 22 constituents, ten of them have been reported to exert some protective effect on experimental cerebral

ischemia (Table 2, marked in red), and their mechanisms were involved in several stroke-related targets and pathways, which was consistent with our corresponding targets and pathways. Guanosine, adenosine, luteolin, and kaempferol were reported to play a protective role in ischemic stroke by reducing neuroinflammation, oxidative stress, and excitotoxicity (Zhao et al., 2011; Bettio et al., 2016; Luo et al., 2019; Wang et al., 2020b). Apigenin protects from cerebral ischemia by reducing apoptosis and

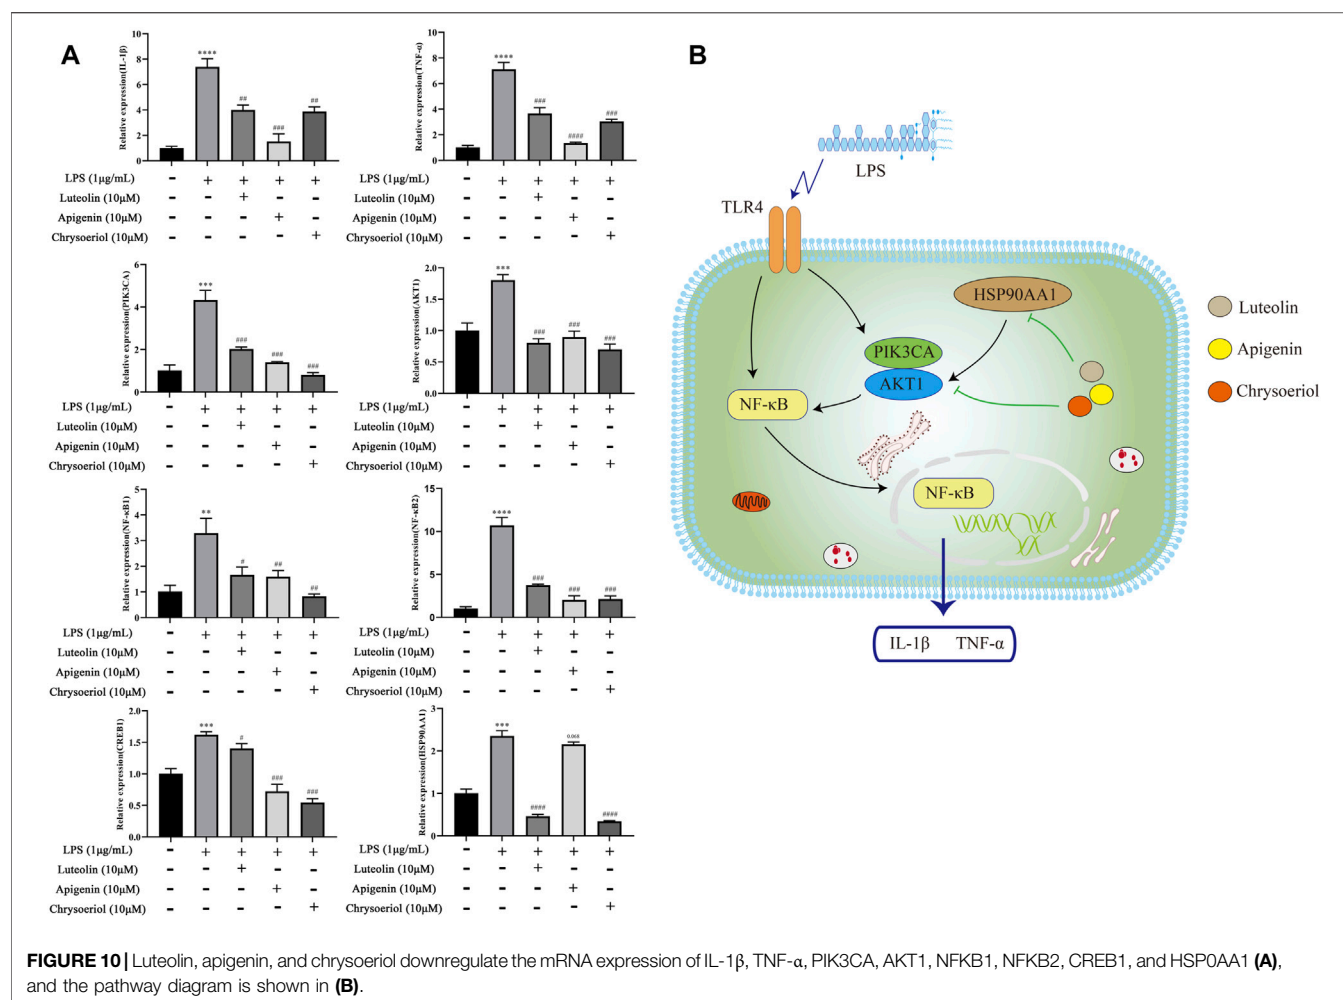

**FIGURE 9 |** Luteolin, apigenin, and chrysoeriol prevents the neuroinflammatory response by LPS in BV-2 cells. Cytotoxicity was detected by the CCK-8 assay (A). IL-1β and TNF-α levels were detected by ELISA kits (B). (Mean ± SD,  $p < 0.05^{*}$ ,  $p < 0.0001^{****}$ /#####).

autophagy to promote cell regeneration through the Caveolin-1/VEGF pathway (Zachary, 2005; Pang et al., 2018; Cárdenas-Rivera et al., 2019). (–)-Epicatechin 3-O-gallate alleviated ischemia-reperfusion injury by promoting cell proliferation, angiogenesis, and migration, and inhibiting cell apoptosis and autophagy (Fu et al., 2019). (+)-Catechin could inhibit inflammatory biomarkers or cytokines, such as C-reactive protein, Lp-PLA2, IL-6, and TNF-α, to reduce ischemic injury (Tu et al., 2018). Resveratrol, a multifunctional biological polyphenol, was regarded as a potential drug for stroke-related diseases, which could alleviate hemorrhagic brain injury by inhibiting neuronal apoptosis (Zhao et al., 2019). It was reported that bryonolic acid could inhibit  $\text{Ca}^{2+}$  influx and regulate the gene expression in the  $\text{Ca}^{2+}$ -CaMKII-CREB signaling pathway against cerebral ischemia (Que et al., 2016). Finally, procyanidins exert antioxidant activity against traumatic brain injury (Mao et al., 2015). The mechanisms of these ten chemical components covered most aspects of the pathological process of stroke, and the target and pathway information involved were consistent with our prediction results (Table 2; Figure 6), suggesting an integrative pharmacology strategy has certain prediction accuracy.

AKT1 and PIK3CA had high frequency in our study, and were involved in several signaling pathways, including TP53-regulated metabolic genes, AKT phosphorylates targets in the nucleus, AKT phosphorylates targets in the cytosol, activation of BAD and translocation to the mitochondria, eNOS activation,

tetrahydrobiopterin (BH4) synthesis, recycling, salvage and regulation, and VEGFA-VEGFR2 pathway, which associated with apoptosis, inflammation, and nerves, and basically covers all mechanisms of stroke/TRFS, suggesting PI3K/Akt signaling pathways may play an important role in stroke formation (Yu et al., 2016; Lv et al., 2017; Pompura and Dominguez-Villar, 2018; Wen et al., 2018). PIK3CA was the only common target of key constituents and candidate stroke/TRFS targets, which may play an extremely important role in the treatment of XLCQ acting on stroke complicated with TRFS and needed to be focused on in the further experiment. MAPK3 was involved in encoding the proteins of the MAP kinase family. NFKB1 and NFKB2 were involved in encoding the NF-κB protein complex, which is an important nuclear transcription factor in cells, participating inflammatory response, immune response, apoptosis, stress response, etc. (Oeckinghaus and Ghosh, 2009; Mitchell et al., 2016). GSK3B was involved in the inflammation-related pathway regulation of HSF1-mediated heat shock response and apoptosis-related pathway AKT 101ylates targets in the cytosol. ATP5C1, ATP5A1, and ATP5B were involved in encoding a subunit of mitochondrial ATP synthase (Neupane et al., 2019). ADORA3, ADORA2A, and ADORA1, as adenosine receptors, were involved in inflammatory response, neuroprotection, apoptosis, and other intracellular signaling pathways (Chen et al., 2006; Blackburn et al., 2009; Sebastião and Ribeiro, 2009; González-Fernández et al., 2014; Feliu et al., 2019). CASP3 and HSP90AA1 were involved in the process of apoptosis and inflammation

(Triantafyllou et al., 2001; Creagh et al., 2003; Khurana and Bhattacharyya, 2015; Man and Kanneganti, 2016).

According to the prediction results, the rest 9 of the 22 constituents may be involved in anti-inflammatory, regulating energy metabolism, and antiapoptotic by regulating NFKB1, NFKB2, ATP5C1, ATP5A1, AKT1, HSP90AA1, *etc.* (Table. 2). We select three compounds (luteolin, apigenin, and chrysoeriol) with high response values (Supplementary Tables S1, S2) to perform some verification experiments. Luteolin and apigenin have been reported to restore ischemic brain injury of rodents (Ha et al., 2008; Luo et al., 2019). Chrysoeriol has been reported to reverse skin inflammation (Wu et al., 2020), arthritis (Ananth et al., 2016), and macrophage inflammation (Yoon and Park, 2021), except for neuroinflammatory effects. Inflammatory cascade is one of the major characteristics of stroke. Therefore, we evaluated their anti-neuroinflammatory effects based on LPS-stimulated BV-2 cells. TLR4 and PI3K/Akt signaling pathways were involved in regulating the activation of microglia and related cytokines in the process of neuroinflammation (Troutman et al., 2012; García et al., 2016; Rahimifard et al., 2017; Zhong et al., 2020). Excessive secretion of proinflammatory cytokines from BV-2 leads to a detrimental effect on neuronal cells (Wang et al.,

2019). In our study, luteolin, apigenin, and chrysoeriol at 10 μM inhibited the release of IL-1β and TNF-α, as well as downregulated the mRNA expression of IL-1β, TNF-α, PIK3CA, AKT1, NFKB1, NFKB2, CREB1, and HSP90AA1. The TCM prescription emphasizes the synergistic effect of multi component, especially when treating complex diseases. An important research content of integrative pharmacology strategy is network prediction and verification. We delineate 22 key active constituents based on the integrative pharmacology strategy. Each component may only work for a certain link, and functional superposition of multiple components plays an overall effect. We selected three components with a high content for verification, which, of course, do not represent the efficacy of the whole prescription or directly reduce the infarct volume. Similarly, these three compounds are common in other botanical drugs and may have other effects.

In the present study, we just did some basic research about XLCQ, but the particular interactions between the active constituents and the corresponding targets, and if the 22 compounds could represent the whole prescription, still need to be verified in the near future.

## CONCLUSION

It is the first time to systematically analyze the chemical composition of XLCQ and to explore the pharmacological mechanisms of XLCQ acting on stroke complicated with TRFS using an integrative pharmacology strategy. The twenty-two key active constituents may improve the pathological state by regulating 27 corresponding targets that are mainly involved in inflammation-immune-related pathways. The integrative pharmacology strategy may offer a highly efficient way to mine the scientific connotation of traditional Chinese medicine prescriptions. This study might be a supplement for the deficiency of the basic research of XLCQ.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**; further inquiries can be directed to the corresponding author.

## AUTHOR CONTRIBUTIONS

PW and HX performed the experimental design, and PW drafted the manuscript. PW and SW performed the analysis of chemical

constituents. PW and HC performed the analysis of network pharmacology. HC and XD performed the cell experiment. LZ helped to identify the chemical constituents. HY participated in the design and coordination. All authors read and approved the final manuscript.

## FUNDING

This work was supported by grants from the National Natural Science Foundation of China (Grant Nos. 81774201 and 81830111), the National Key Research and Development Program of China (2017YFC1702104 and 2017YFC1702303), and the Youth Innovation Team of Shaanxi Universities and Shaanxi Provincial Science and Technology Department Project (No. 2016SF-378). The funding agencies had no role in the study design, the collection, analysis, or interpretation of data; the writing of the report; or the decision to submit the article for publication.

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2021.598200/full#supplementary-material>

Mechanism Analysis of Shenfu  
Injection in the Treatment of Idiopathic  
Pulmonary Fibrosis.  
Front. Pharmacol. 12:670146.  
doi: 10.3389/fphar.2021.670146

**Background:** Idiopathic pulmonary fibrosis (IPF) is disease with high mortality, and its effective treatment is limited. Shenfu injection is a traditional Chinese medicine which can improve circulation and protect cells. In this study, we aimed to investigate the feasibility and mechanism of Shenfu injection in the treatment of IPF.

**Methods:** The components and targets of Shenfu injection were mainly retrieved from the Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform (TCMSP) database. The targets of Shenfu injection were standardized by UniProt database. The Genecards and OMIM databases was used to search for IPF-related genes. The Venn diagram of gene intersection was drawn using the OmicStudio tools, and the protein-protein interaction network was visualized using the Cytoscape 3.7.2 software. Moreover, the metaspape online software was applied to explore the enriched Gene Ontology (GO) terms and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways, and the Cytoscape 3.7.2 software was used to construct the target-pathway network. Molecular docking was used to visualize the interactions between the main active compounds and targeted proteins. Animal experiments were performed to validate the effects and mechanisms of Shenfu injection.

**Results:** We obtained 46 co-targets of Shenfu injection and IPF. Among the hub target genes, several genes with important functions were enriched, including TNF, IL-6, IL-1B, TP53, JUN, CASP3 and CASP8. The pathway enrichment analysis for the hub target genes identified pathways in infection/inflammation, apoptosis and cancer. Molecular docking results showed that the main active compound Ginsenoside Re had high affinity to the core target proteins. These results suggested that Shenfu injection may have a positive effect in the treatment of IPF. Consistent with this finding, animal experiments showed that Shenfu injection significantly reduced pulmonary fibrosis in a mouse model with inhibition of

**Abbreviations:** GO, gene ontology; IPF, idiopathic pulmonary fibrosis; KEGG, kyoto encyclopedia of genes and genomes; PPI, protein-protein interaction; TCMSP, traditional chinese medicine systems pharmacology database and analysis platform.

apoptosis and inflammation by downregulating IL-1 $\beta$ , caspase-3 and phosphorylated NF- $\kappa$ B.

**Conclusion:** Our results demonstrated that Shenfu injection efficiently alleviate bleomycin-induced pulmonary fibrosis through multi-targets in inflammation-, apoptosis- and cancer-related pathways, which provided first evidence and reference to the feasibility of Shenfu injection in the treatment of IPF.

**Keywords:** idiopathic pulmonary fibrosis, Shenfu injection, network pharmacology, inflammation, apoptosis

## INTRODUCTION

Idiopathic pulmonary fibrosis (IPF) is a progressive fibrosis lung disease with the clinical symptoms of cough and progressive dyspnea. It is common in old men with median age of 65 years. For patients with IPF, the median survival time after diagnosis is between 2 and 4 years (Richeldi et al., 2017). At present, lung transplantation is the only effective treatment for IPF. Pirfenidone and nintedanib are recommended to treat IPF (Behr et al., 2018). However, many patients can hardly afford the burden of lung transplantation and drugs.

Shenfu injection is a traditional Chinese medicine injection that has been approved in 1987 (approval code: SFDA approval number Z20043117, package: 50 ml per bottle) and applied in clinical for 30 years. It is taken from Shenfu decoction and used in clinical acute conditions such as shock, cardiopulmonary resuscitation and heart failure. A prospective randomized controlled study aimed at efficacy and safety found that Shenfu injection can improve 28- and 90-days survival, shorten hospital stays, improve clinical outcomes in patients and has no serious drug-related adverse reactions (Zhang et al., 2017b). Shenfu injection also enhances cellular immunity. Another study in sepsis or septic patients found that Shenfu injection reduced the duration of vasopressor use and ICU stay, increased CD4<sup>+</sup> and CD8<sup>+</sup>T cell counts in peripheral blood (Zhang et al., 2017a). In a clinical research, Shenfu injection was used to treat elderly severe pneumonia. It could decrease the blood level of IL-6, TNF- $\alpha$  and IL-8, improve the vital signs of the patients, shorten the ICU hospital stays and reduce the mortality of the patients (Lv et al., 2017). Cumulative studies have shown that Shenfu injection possesses anti-inflammatory effect through multiple targets and pathways, especially inhibiting the NF-kappa B (Li et al., 2016). Ginsenoside is considered as the effective compound in Shenfu injection. Researchers found that Ginsenoside Rd could down-regulate caspase-3 expression and decrease the expression level of IL-6, TNF- $\alpha$  and IL-1 $\beta$  in a rat model of Alzheimer disease. It also has the function of anti-inflammation, anti-oxidation and anti-apoptosis (Liu et al., 2012).

Network pharmacology analyze drug effect through multiple disciplines, which provides a method to discover drugs for complex diseases (Hopkins, 2007). Shenfu injection can be used in the treatment of acute respiratory distress syndrome and acute exacerbation of chronic obstructive pulmonary disease as recommended by expert consensus. Therefore, we explored the feasibility and mechanism of Shenfu injection for the treatment of IPF using network pharmacology analysis and experiments in IPF mouse model. In this study, we performed network pharmacology analysis on the Shenfu injection in the

treatment of IPF, and used protein-protein network analysis and enrichment analysis to identify hub genes and potential pathways, which may help to better understand the mechanism of Shenfu injection in the treatment of IPF. We further validated that Shenfu injection could significantly reduce pulmonary fibrosis in a mouse model.

## MATERIALS AND METHODS

### Collection of Compounds and Target Genes for Shenfu Injection

Since Shenfu injection is used by intravenous injection, all of its components were analyzed. Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform (Ru et al., 2014) (TCMSP) were used to collect all compounds of Panax ginseng C.A. Mey (hongshen) and Aconitum carmichaelii Debeaux (fuzi). Because the Chinese names of hongshen and Fuzi have special latin names in database of TCMSP, we used Ginsen Radix Et Rhizoma Rubra (hongshen) and Aconiti Lateralis Radix Praeparata (Fuzi) to obtain their related target proteins (Table 1). Then the target proteins were standardized to human-related genes through the Uniprot database (UniProt Consortium, 2018).

### Screening of Idiopathic Pulmonary Fibrosis-Related Genes

We utilized “idiopathic pulmonary fibrosis” as a keyword to collect genes from the Genecards (<https://www.genecards.org/>) and OMIM (Hamosh et al., 2005) databases on April 2020, and chose “*Homo sapiens*” as the species option.

### Screening of Idiopathic Pulmonary Fibrosis-Related Genes Targeted by Shenfu Injection

The Venn diagram visualizing the intersection of genes between Shenfu injection and IPF was drawn by the OmicStudio tools at <https://www.omicstudio.cn/tool>.

### Analysis of Protein-Protein Interaction Network

The String database (Szklarczyk et al., 2019) was used to analyze the PPI network of the intersected target genes, organism was selected as “*Homo sapiens*” and the minimum required interaction

**TABLE 1 |** Information of Shenfu injection.

Latin name	English name	TCMSP name	Chinese name	Origin of place
<i>Panax ginseng</i> C.A. Mey	<i>Radix ginseng rubra</i>	<i>Ginseng Radix Et Rhizoma Rubra</i>	Hongshen	Jilin, China
<i>Aconitum carmichaelii</i> Debeaux	<i>Aconitine</i>	<i>Aconiti Lateralis Radix Praeparata</i>	Fuzi	Sichuan, China

**TABLE 2 |** Quality analysis of Shenfu injection (Batch Number: 18120501007).

Item	Content	Quality control
Finger print consistency	0.9	≥0.9
Total saponins	1.0 mg/ml	0.7–1.7 mg/ml
Ginsenoside Rg1	0.1 mg/ml	≥0.08 mg/ml
Ginsenoside Re	0.1 mg/ml	≥0.06 mg/ml

\*Data were derived from product inspection report of Ya'an 999 Pharmaceutical Group Co. Ltd. Sichuan Province, China.

score was selected as “medium confidence 0.4.” Moreover, the Cytoscape 3.7.2 software was used to visualize the PPI network.

## Enrichment Analysis of Target Genes

The Metascape platform (Zhou et al., 2019) online analytical tool was used for gene functional enrichment and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment. The hub genes were uploaded to the online tool and the significant pathways or functions were obtained based on the minimum overlap value of three and *p* value cutoff less than 0.01. Then the Cytoscape 3.7.2 software was applied to visualize the network of KEGG pathways and related target genes.

## Molecular Docking

The docking studies of the representative compounds and targets were performed with AutoDock 4.2. The BIOVIA Discovery Studio (San Diego: Dassault Systèmes) was used for pre-processing the chemical structures and biomolecules. The metal ions and/or substrate molecules (if any) were kept in the binding pocket of the targets. The Lamarckian genetic algorithm search was employed for the docking. The key residues of the binding pocket were kept flexible. The center of the binding pockets of the individual targets was selected for the grid placement. A total of 60 runs along with 2.5 million energy evaluation steps were employed. The representative pose selection was carried out based on the cluster analysis of the docked poses. The PyMOL Molecular Graphics System (Version 1.8.4.0, Schrödinger, LLC) and PLIP webserver (Salentin et al., 2015) were used for the visualizations and graphics generations.

## Shenfu Injection

Shenfu injection (batch number:18120501007) is a solution extracted from *Panax ginseng* C.A.Mey and *Aconitum carmichaelii* Debeaux. Its quality meets the standard of China Food and Drug Administration (approval No: WS3-B-3427-98-2013 and P.ZL.205-001) (Table 2). *Panax ginseng* C.A.Mey and *Aconitum carmichaelii* Debeaux were soaked and extracted to the solution respectively, then mixed together to form Shenfu injection. The specimens were stored in the herbarium of Ya'an 999 Pharmaceutical Group Co. Ltd. (Sichuan Province, China).

## Pulmonary Fibrosis Mouse Model

C57BL/6 mice (male, 25 ± 2 g, 8–9 weeks old, Vital River Laboratory Animal Technology Co., Ltd. Beijing, China) were fed with the standard diet under SPF conditions (60–70% humidity, 24 ± 1°C, 12/12 h dark-light cycle). The mice were divided into three groups (8 mice per group): control group, model group and Shenfu injection therapy group. Intratracheal instillation of bleomycin (Zhejiang HISUN Pharmaceuticals Co., Ltd.) was used at 15 USP/kg to induce pulmonary fibrosis in mice. Intraperitoneal injection of Shenfu injection (Ya'an 999 Pharmaceutical Group Co. Ltd. Sichuan Province, China) was given at 10 ml/kg once daily after bleomycin injection from day 1 to day 7. The dosage of Shenfu injection was based on a previous study (Xu et al., 2020). The animals were sacrificed on day 4 (*n* = 3 mice per group) or 14 (*n* = 5 mice per group). The left lung was used for hematoxylin-eosin staining, Masson's trichrome stain, Sirius red staining, immunohistochemical staining and TdT-mediated dUTP nick end labeling (TUNEL) staining; and the right lung was used for Western blot. The Animal Studies Committee of China-Japan Friendship Hospital (Approval certificate number: zryhy12-20-07-2) approved all the animal experiments in our study. All experimental procedures were performed according to the Principles of Laboratory Animal Care.

## Histological Staining and Immunostaining

The left lung of mice was dehydrated, paraffin-embedded and cut into 4-μm sections. Then the lung sections were subjected with H&E staining, Masson's trichrome stain, Sirius red staining and immunohistochemical staining. Primary antibodies used were anti-α-SMA (ab124964, Abcam) and anti-collagen I (ab88147, Abcam).

## TUNEL Staining

The apoptotic cells in the lung tissues were detected by TUNEL staining (CF488 TUNEL Cell Apoptosis Detection Kit, Servicebio) according to the manufacturer's instructions. Frozen lung sections (4-μm) were defrosted for 20 min at room temperature, permeabilized with 0.2% Triton X-100 for 5 min on ice, and washed twice for 5 min in PBS. Then the samples were stained with TUNEL reaction mixture for 60 min at 37°C in dark, washed twice for 5 min in PBS and mounted with Mounting Medium with DAPI (ab104139, Abcam). The slides were visualized and fluorescent images were captured with fluorescence microscope (ZEISS).

## Western Blot

The right lungs of mice were lysed and the protein concentrations were measured by BCA Protein Assay Kit (P0010, beyotime). An

\*Data were from the TCMSP database and a reference using column-switching HILIC-RPLC-MS/MS system as in the identification method (Song et al., 2015).

equivalent amount of protein samples were separated by 4–15% BeyoGel™ Plus Precast PAGE (Polyacrylamide gel electrophoresis) Gel (P0465S, beyotime), electrotransferred to PVDF membranes and incubated for 2 h at room temperature with primary antibodies: caspase-3 antibody (9662, Cell Signaling Technology), IL-1 $\beta$  antibody (31,202, Cell Signaling Technology), Phospho-NF- $\kappa$ B p65 antibody (3033, Cell Signaling Technology), NF- $\kappa$ B p65 antibody (BS1253, Bioworld) and GAPDH antibody (60004-1-Ig, Proteintech). Then, the membranes were incubated with secondary antibodies for 1 h at room temperature and exposed with the ChemiDoc XRS + System (Bio-Rad). The results were quantified using ImageJ system (1.52a).

### Quantitative Real-time PCR (qPCR)

Total RNA was extracted using the Trizol reagent according to the manufacturer's instructions (15596026, Invitrogen), and transcribed into cDNA (11120ES60, Yeasen). qPCR was performed using SYBR Green Master Mix (11202ES08, Yeasen), and analyzed on the ABI-7500 Real-Time PCR System. PCR primer sequences were listed in **Supplementary Table 1**.

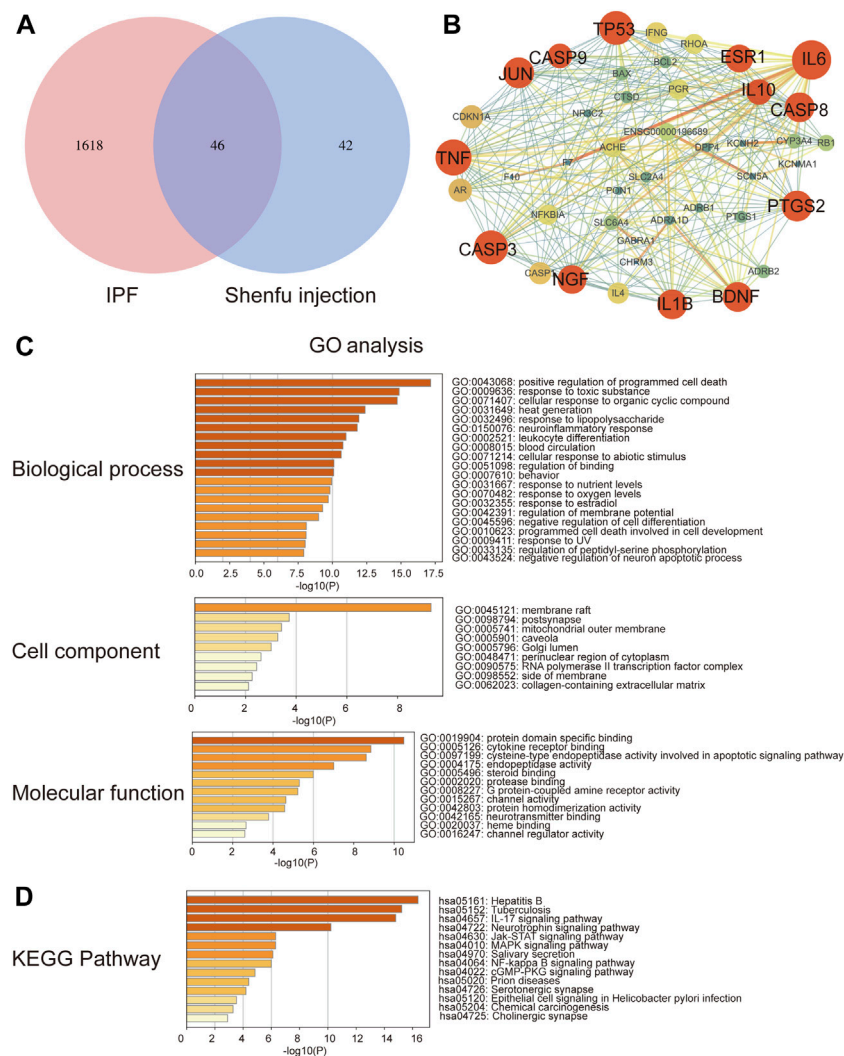

### Statistical Analysis

Data were presented as mean  $\pm$  standard deviation (SD). Group comparisons were analyzed with one-way ANOVA after Shapiro-Wilk normality test for normality and Bartlett's test for the homogeneity of variance. The analysis was performed by GraphPad Prism 8. *p* value <0.05 was considered statistically significant.

## RESULTS

### Compounds and Target Genes for Shenfu Injection

We obtained 137 compounds and 119 target proteins of Shenfu injection from TCMSP after duplicates exclusion. In addition to the hydrophobic compounds, we also list the hydrophilic compounds including mainly amino acids and nucleosides identified by column-switching HILIC-RPLC-MS/MS system (Song et al., 2015) (**Table 3**). Since the hydrophobic compounds were considered to be the main active ingredients, we identified 88 target genes based on the 137 compounds obtained from TCMSP after standardization on the Uniprot database.

**FIGURE 1 |** Network pharmacology analysis of Shenfu injection and IPF. **(A)** The intersection of targeted genes between Shenfu injection and IPF shown as Venn diagram. **(B)** The PPI network analysis: the node represents the protein and the edge represents the connection between proteins; the size of the node represents the importance of the gene in the network. **(C)** GO enrichment analysis of potential targets genes including biological process, cellular components and molecular function. **(D)** KEGG pathway enrichment analysis of the top 14 pathways.

## Idiopathic Pulmonary Fibrosis-Related Genes

We first identified 2793 genes from the Genecards database, and then we retained 1396 genes with median target score greater than or equal to 4.86 (Target Score: maximum:124.57; minimum: 0.24; median:4.86). In addition, we obtained 322 genes from the OMIM database. Finally, a total of 1664 genes were obtained after eliminating the duplicates.

## Gene Intersection of Shenfu Injection and Idiopathic Pulmonary Fibrosis

In order to obtain the intersected genes between Shenfu injection and IPF, we performed a venn analysis on the target genes of Shenfu injection and IPF. As shown in **Figure 1A**, a total of 46

genes were identified as intersected genes of Shenfu injection and IPF.

## Protein-Protein Interaction Network Analysis of Gene Intersection

To explore the relationship of the target genes, we constructed a PPI network using the string database. The PPI network contained 46 nodes and 272 edges and the average node degree was 11.8. We further visualized the PPI network by Cytoscape 3.7.2 software (**Figure 1B**). The red circles represent the hub genes. The bigger the circle, the more important the gene is in the PPI network. In the PPI network, the clustering coefficient was 0.613, and the network density and centralization were 0.288 and 0.454, respectively. Considering that the higher the node degree, the more important it is in the

**TABLE 4 |** Characterization parameters of hub genes.

Target gene	Degree	Betweenness centrality	Closeness centrality
IL6	31	0.2075	0.7544
TNF	28	0.0782	0.6825
TP53	26	0.0498	0.6615
CASP3	26	0.0475	0.6615
JUN	23	0.0185	0.6143
PTGS2	23	0.0210	0.6324
CASP8	22	0.0178	0.5811

\*Data were analyzed by Cytoscape 3.7.2 software.

network, we then selected the degree of node as the evaluation parameter. As a result, we screened out 13 hub genes including IL-6, TNF, TP53, CASP3, JUN, PTGS2, CASP8, IL-1B, BDNF, NGF, ESR1, IL10 and CASP9 with degrees higher than average (median degree = 16) (Table 4).

## Gene Ontology and Kyoto Encyclopedia of Genes and Genomes Pathway Enrichment Analysis

The GO analysis enriched 1048 biological processes, 34 cellular components and 67 molecular function items ( $p < 0.01$ ) by using the Metascape platform (Figure 1C). Among the top five enrichments, in biological processes, genes were involved in cell death and response to stimuli, including positive regulation of programmed cell death, response to toxic substance, cellular response to organic cyclic compound, heat generation and response to lipopolysaccharide. In the cellular components, genes were enriched in the membrane-associated subcellular structures, including membrane raft, postsynapse, mitochondrial outer membrane, caveola and Golgi lumen. In the molecular functions, genes were enriched in protein domain specific binding; exogenous signal transduction pathways, including cytokine receptor binding and steroid binding; apoptosis-related functions including cysteine-type endopeptidase activity involved in apoptotic signaling pathway and endopeptidase activity.

Moreover, we performed KEGG enrichment analysis and found that the hub genes were mainly involved in infection and inflammation pathways. The top five enrichments include hepatitis B, tuberculosis, IL-17 signaling pathway, JAK-STAT signaling pathway and neurotrophin signaling pathway (Figure 1D).

## Network of Target Genes and Pathways

After obtaining the pathways from the Metascape platform, we further used Cytoscape 3.7.2 software to visualize the relationships between the pathways and genes. As shown in Figure 2A, the red circles represent the target genes and the purple diamonds represent the pathways. There were 89 nodes in the network (55 pathways, 34 target genes), and the median of genes degree was 16.5. Among them, target genes with degrees

higher than average were TNF, JUN, IL-6, IL-1B, NFKBIA, TP53, CASP3, IFNG, BCL2, CASP8 and BAX (Table 5), which may be important targets for Shenfu injection in the treatment of IPF. The median of pathways degree was nine. Pathways with degrees higher than average included pathways in cancer, infection/inflammation including tuberculosis, hepatitis B and IL-17 signaling pathway; and apoptosis (Table 6).

## Molecular Docking of Active Compounds and Targeted Proteins

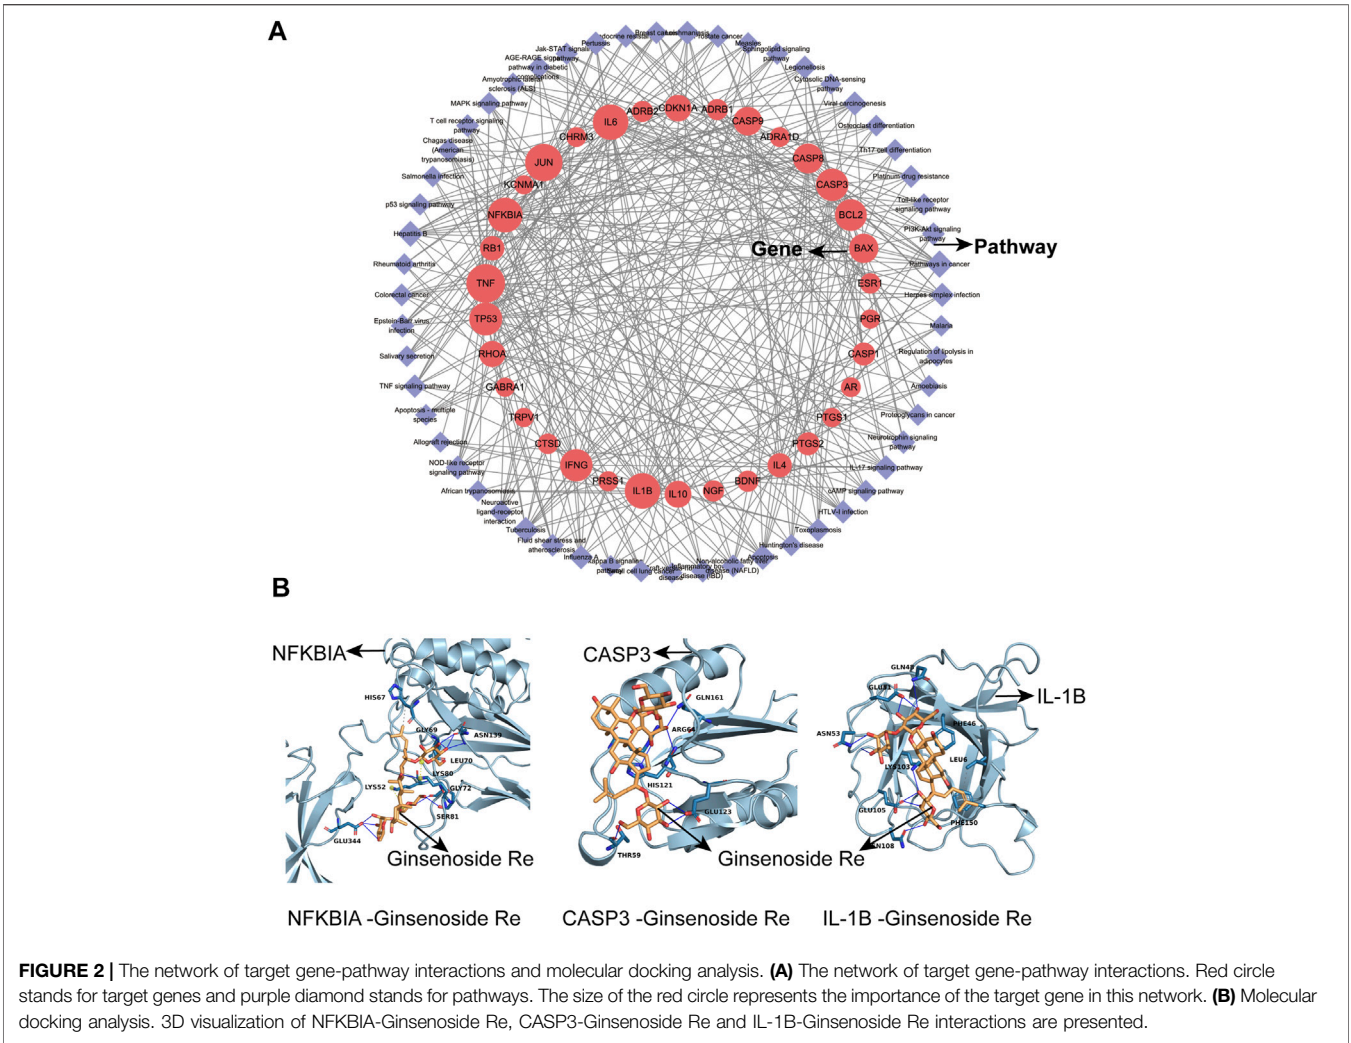

We used Cytoscape 3.7.2 software to analyze active compounds (Table 7). We selected compounds including beta-sitosterol, beta-elemene, myristic acid, TMPEA and the main content Ginsenoside Re as active compounds targeting TNF, IL-6, IL-1B, CASP3 and NFKBIA proteins. Generally, the negative value of the docking score means that they can bind to each other, and the positive value means that they cannot bind. The smaller the score value, the stronger the binding force is. Molecular docking results showed that these five compounds could bind to the target proteins. The docking score of Ginsenoside Re- NFKBIA was  $-9.046$  kcal/mol, Ginsenoside Re- CASP3 was  $-9.273$  kcal/mol, and Ginsenoside Re- IL-1B was  $-7.806$  kcal/mol, showing that Ginsenoside Re had a relatively strong affinity with NFKBIA, CASP3 and IL-1B (Figure 2B). These results indicated that Shenfu injection may be functional in the treatment of IPF by targeting NFKBIA, CASP3 and IL-1B by its main content Ginsenoside Re. The docking details were recorded in Table 8 and Supplementary Table 2.

## Shenfu Injection Reduces BLM-Induced Pulmonary Fibrosis in Mice

We established bleomycin-induced pulmonary fibrosis on a mouse model. H&E staining of lung sections showed that bleomycin induced destruction of alveolar structures in mice, and the alveolar space was filled with fibrous tissue (Figure 3A). Shenfu injection-treated group showed lower score than bleomycin-treated group as assessed by Ashcroft scoring ( $p < 0.05$ , Figure 3F). Masson's trichrome staining showed the deposition of extensive collagen fibers in the lung interstitium (Figure 3B). Sirius red staining showed birefringent red collagen I and green collagen III under polarized light microscopy (Figure 3C). Shenfu injection treatment remarkably ameliorated these pathological injuries and alleviated collagen deposition (Figure 3G,H). The expression of  $\alpha$ -SMA and collagen I was analyzed by immunohistochemical staining on the lung sections. Our data showed that the expression of  $\alpha$ -SMA and collagen I increased in bleomycin-treated group, and Shenfu injection treatment significantly inhibited the expression of  $\alpha$ -SMA and collagen I in the lung sections compared with bleomycin-treated group (Figure 3D,E,I,J).

## Shenfu Injection Reduces Pulmonary Fibrosis by Inhibiting Inflammation and Apoptosis

To verify the mechanisms of Shenfu injection in the treatment of pulmonary fibrosis proposed by network pharmacology analysis,

**TABLE 5 |** Target gene network and node characterization parameters.

Target gene	Degree	Betweenness centrality	Closeness centrality
TNF	32	0.1041	0.4607
JUN	30	0.1537	0.4809
IL6	27	0.0689	0.4334
IL-1B	27	0.0571	0.4251

BAX	17	0.0221	0.3777

\*Data were analyzed by Cytoscape 3.7.2 software.

we performed TUNEL staining to observe the apoptotic cells in the lung sections, qPCR to examine the mRNA level of NFKBIA, CASP3, and IL-1B, and Western blot to examine the expression levels of inflammation-related proteins, including caspase-3, IL-1 $\beta$ , phosphorylated NF- $\kappa$ B and total NF- $\kappa$ B in the lung tissues from the three groups. The results showed that the number of

TUNEL-positive cells increased in BLM-treated group compared with the control, and Shenfu injection significantly reduced the number of TUNEL-positive cells induced by BLM treatment. (Figure 4). The mRNA and protein level of caspase-3 was also upregulated in BLM-treated group, and could be reversed in Shenfu injection-treated group ( $p < 0.05$ , Figure 5A,D,G). These results indicated that BLM treatment could induce apoptosis in pulmonary cells, and Shenfu injection inhibited the apoptosis process, which may be one of its mechanisms to alleviate subsequent pulmonary fibrosis.

For the regulation of inflammatory process, we found that BLM treatment upregulated the protein and mRNA level of IL-1 $\beta$ , and Shenfu injection treatment significantly reduced the increased expression of IL-1 $\beta$  ( $p < 0.05$ , Figure 5A,E,H). In addition, BLM treatment upregulated mRNA level of NF- $\kappa$ B, and Shenfu injection treatment significantly reduced the mRNA level. Interestingly, the total protein level of NF- $\kappa$ B did not changed significantly. Since the phosphorylated NF- $\kappa$ B is the active form of this protein, we detected the protein level of phosphorylated NF- $\kappa$ B. It increased in BLM-treated group, and this increasement was significantly inhibited by Shenfu injection

**TABLE 6 |** KEGG Pathway network and node characterization parameters.

(Figure 5A–C,F), indicating that instead of affecting the total protein amount of NF- $\kappa$ B, Shenfu injection may function through inhibiting its phosphorylation. The above results together demonstrated that inhibition of inflammatory response is another mechanism of Shenfu in the treatment of pulmonary fibrosis.

## DISCUSSION

Shenfu injection is a pure Chinese patent medicine modified from the classical Chinese medicine “Shenfu decoction” and extracted from ginseng and Fuzi by using the modern pharmaceutical technology. As “Extension of Famous Medical Prescriptions” records: “There is nothing as good as ginseng to nourish acquired Qi, and there is nothing as good as Fuzi to replenish innate Qi,” Shenfu injection is mainly used in infectious diseases, haemorrhage, hemorrhagic shock and other Yang Qi burst off Syndromes in clinics. It is also applied in the Qi deficiency Syndrome, such as cough, shock, panic, stomachache, diarrhea and so on. In traditional Chinese medicine, IPF is considered to be in the category of pulmonary arthralgia and cough, and its root is Qi deficiency of the lung and spleen. Therefore, Shenfu injection might have some effects on IPF based on the theory of traditional Chinese medicine. Based on the studies with

modern medical research methods, the therapeutic mechanism of Shenfu injection could be attributed to the promotion of cell repair and inhibition of cell apoptosis, as well as inhibition of inflammation, oxidation, ischemia and hypoxia (Liu et al., 2012; Lv et al., 2017; Chen et al., 2020). For instance, a recent study found that Shenfu injection inhibited TLR4/NF- $\kappa$ B signaling pathway, reduced systemic inflammatory response and played a protective role in the post-resuscitation myocardial dysfunction (Gu et al., 2021). Apoptosis of alveolar epithelial cells and the abnormal repair of alveolar injury is considered to be the pathological basis of IPF, while inflammation plays an important role in the induction and acute exacerbation of IPF. These characteristics are also consistent with the therapeutic mechanism of the Shenfu injection.

In this study, network pharmacological analysis revealed 46 genes correlated with Shenfu injection and IPF. The results indicated that Shenfu injection has a potential therapeutic effect on IPF, and its curative effect may be exerted through anti-inflammation and anti-cell apoptosis, involving pathways in tuberculosis, hepatitis B, apoptosis and IL-17 signaling.

As IL-6 and TNF co-stimulate MIP1- $\alpha$  expression of alveolar macrophages in bleomycin-induced mice, researchers proposed that IL-6 and TNF are part of the cytokine network in bleomycin-induced pulmonary pathophysiology (Smith et al., 1998). IL-6 and TNF- $\alpha$  polymorphism analysis in IPF patients showed that

**FIGURE 3 |** Shenfu injection alleviates pulmonary fibrosis. Representative photomicrographs of H&E staining (A) ( $n = 5$ ), Masson's trichrome staining (B) ( $n = 3$ ) and Sirius red staining (C) ( $n = 3$ ). Scale bar: 50  $\mu$ m. The results are expressed as mean  $\pm$  SD ( $n = 3$  mice per group). \*\*\* $p < 0.001$ , \*\* $p < 0.01$ .

IL-6 and TNF- $\alpha$  genes differed between the IPF and normal population and both related to the progression of IPF (Pantelidis et al., 2001). In lung tissue specimens, TNF- $\alpha$  and IL-1 $\beta$  were overexpressed in acute pulmonary fibrosis while presented a low expression level in old IPF patients, suggesting that TNF- $\alpha$  and IL-1 $\beta$  may be involved in the initiation of pulmonary fibrosis. Besides, the serum and BALF level of IL-1 $\beta$  is higher in IPF patients than healthy controls (Pan et al., 1996; Barlo et al., 2011). Shenfu injection alleviated lung injury in a rat systemic inflammatory response syndrome model by inhibiting NF- $\kappa$ B activation and decreasing the plasma level of IL-6 and TNF- $\alpha$  (Wang et al., 2008). In a vascular endothelial cell damaging model, Shenfu injection could increase the level of Bcl2 protein and reduce caspase-3 and Bax levels, demonstrating that Shenfu injection has the function of anti-apoptosis and anti-oxidance (Hong et al., 2015). The molecular docking results showed that compounds of Shenfu injection could bind to these targets, especially its main content Ginsenoside Re had

strong affinity with NFKBIA, CASP3 and IL-1B. Our results showed that Shenfu injection may interfere with inflammatory response and cell apoptosis by targeting NFKBIA, CASP3 and IL-1B.

IPF has the common photomechanics of epithelial damage, abnormal repairment and epithelial-mesenchymal transition with lung cancer, and it is considered to be associated with lung cancer. Researchers observed TP53 status in surgical resection of lung cancer in IPF patients, and found that the peripheral parts of fibrotic zone had high mutation rate of TP53 gene. Another research found that lung cancer with interstitial lung diseases had high risk for pleural invasion (Kawasaki et al., 2001; Hata et al., 2017). Moreover, a meta-analysis evaluated the function of Shenfu injection by objective tumor response, disease control rate, karnofsky performance score, adverse effects and indicators of cellular immune function, and the result indicated that Shenfu injection could improve immune function of lung cancer patients and reduce adverse effect of chemotherapy (Cao

**FIGURE 5 |** Shenfu injection inhibits BLM-induced pulmonary fibrosis by targeting NF-κB, CASP3 and IL-1B. **(A)** Western blot analysis of total NF-κB, Phospho-NF-κB, caspase-3 and IL-1β in each group. **(B–E)** Quantitative analysis of total NF-κB **(B)**, Phospho-NF-κB **(C)**, caspase-3 **(D)** and IL-1β **(E)** protein levels in each group ( $n = 3$  mice per group). **(F–H)** Quantification of relative mRNA levels of NF-κB **(F)**, caspase-3 **(G)** and IL-1β **(H)** in each group ( $n = 3$  mice per group). Data are presented as mean  $\pm$  SD. \*\*\*\* $p < 0.0001$ ; \*\*\* $p < 0.001$ ; \*\* $p < 0.01$ ; \* $p < 0.05$ .

et al., 2017). The interaction mechanism between Shenfu injection and lung cancer are still unclear. A cohort study found that IPF has a high risk of lung cancer. After adjusting the risk of smoking, the rate ratio (RR) for the incidence of IPF with lung cancer was 8.25 (890 IPF patients, 5884 control participants, 95% CI 4.70–11.48) (Hubbard et al., 2000). Our results showed that Shenfu injection may exert anti-tumor function by regulating P53 and JUN, which may add beneficial effects to the treatment of IPF.

Notably, infection, inflammation and apoptosis participate in the process of IPF. Viral and bacterial infections play a role in the

process of IPF by causing alveolar injury and apoptosis. A meta-analysis from 20 studies (634 IPF patients, 653 controls) analyzed 19 virus species, demonstrating that the incidence of IPF increased by the infection of Epstein-Barr virus (EBV), cytomegalovirus (CMV), human herpesvirus 7 (HHV7) and human herpesvirus 8 (HHV8) (Sheng et al., 2020). Tuberculosis and hepatitis B are a global health problem, especially in China. Tuberculosis induces pulmonary fibrosis via macrophage apoptosis, recruiting TNF- $\alpha$ , TGF- $\beta$ , Th1 and Th2 cytokines. Chronic hepatitis B causes defective T cell to affect the immune system and accelerates the progress of live fibrosis

**FIGURE 6 |** Potential mechanism of Shenfu injection alleviating BLM-induced pulmonary fibrosis. Shenfu injection may have the function of anti-inflammation and anti-apoptosis by targeting NFKBIA, CASP3 and IL-1B, and alleviate BLM-induced pulmonary fibrosis.

(Dheda et al., 2005; Nebbia et al., 2012). Besides, researchers found that B cell activating factor (BAFF, one member of the TNF family) played a key role in bleomycin-induced lung fibrosis model by regulating the IL-1 $\beta$  and IL-17 pathway, and the expression of BAFF increased in BALF of IPF patients (François et al., 2015). Our results showed that Shenhua injection may interfere with tuberculosis, hepatitis B, apoptosis and IL-17 signaling to treat IPF.

Finally, to examine the effect of Shenfu injection *in vivo*, we used bleomycin-induced pulmonary fibrosis mouse model and applied Shenfu injection as daily treatment. Our data showed that Shenfu injection ameliorated the expression of  $\alpha$ -SMA and collagen I, and remarkably reduced pulmonary fibrosis. We further validated that Shenfu injection inhibited the mRNA level of NFKBIA, CASP3, and IL-1B, it also inhibited NF- $\kappa$ B activation and reduced the protein expression levels of caspase-3 and IL-1 $\beta$ . Interestingly, our WB result of total protein NF- $\kappa$ B did not change significantly in the BLM-treated group and the Shenfu

injection-treated group. Since the mRNA level may not always be consistent with the protein level, we considered that the total protein level of NFKBIA may be affected by other post-transcriptional modifications. At the same time, we found that Ginsenoside Re—the main component of Shenfu injection—could bind to NFKBIA and inhibit its phosphorylation. Therefore, we proposed a new mechanism from network pharmacology and our experiment that Shenfu injection may influence the activity of NFKBIA by inhibiting its phosphorylation by binding it with Ginsenoside Re, instead of affecting the total amount of NFKBIA protein. Inflammation plays an important role in IPF pathogenesis, and NF- $\kappa$ B coordinate with the expression of inflammation genes, that contribute to pulmonary fibrosis (Li and Verma, 2002). Besides, in human IPF and BLM-induced animal lung samples, excess alveolar epithelial cell apoptosis promotes pulmonary fibrosis (Hosseinzadeh et al., 2018). Our results validated the effectiveness of Shenfu injection in the treatment

of IPF, and verified its mechanism as inhibiting inflammation and apoptosis as proposed by targeting NFKBIA, CASP3, and IL-1B (Figure 6). Currently, the interaction of cancer-related pathways and IPF is not clear. How Shenfu injection ameliorates pulmonary fibrosis by regulating cancer-related genes such as JUN and TP53 is worth study in the future.

## CONCLUSION

According to network pharmacology-based analysis and animal experiment, we discovered that Shenfu injection has the therapeutic potential for IPF and provided possible mechanisms underlined. This is the first evidence for the feasibility of Shenfu injection in the treatment of IPF.

The traditional Chinese medicine *Poria cum Radix Pini* (PRP) is a fungal medicinal material that has been proven to play an important role in the treatment of arrhythmia. However, the mechanism of its effect on arrhythmia is still unclear. In this study, network pharmacology and metabolomics correlation analysis methods were used to determine the key targets, metabolites and potential pathways involved in the effects of PRP on arrhythmia. The results showed that PRP can significantly improve cardiac congestion, shorten the SV-BA interval and reduce the apoptosis of myocardial cells induced by barium chloride in zebrafish. By upregulating the expression of the ADORA1 protein and the levels of adenosine and cGMP metabolites in the cGMP-PKG signalling pathway, PRP can participate in ameliorating arrhythmia. Therefore, we believe that PRP shows great potential for the treatment of arrhythmia.

**Keywords:** arrhythmia, *Poria cum Radix Pini*, ADORA1, cGMP-PKG signalling pathway, zebrafish

## INTRODUCTION

Arrhythmia is one of the most serious diseases of the cardiovascular system. Its negative effects include not only aggravating original heart disease and affecting the quality of life of patients but also inducing sudden cardiac death, which seriously threatens the life of patients (Krittayaphong et al., 2016). Approximately 600,000 people die from sudden cardiac death in China every year and

**Abbreviations:** ADORA1, Adenosine A1 Receptor; AO, acridine orange; BA, bulbus arteriosus; BP, biological processes; CC, cellular components; CT, cycle threshold; FA, formic acid; GO, Gene Ontology; IP3R, inositol triphosphate receptor; MF, molecular functions; NOS, nitric oxide synthase; PBS, phosphate-buffered saline; PI3K/Akt, phosphoinositide 3-kinase/protein kinase B; PLS, partial least squares; PPI, protein-protein interaction; PRP, *Poria cum Radix Pini*; PRP-H, PRP high-dose group; PRP-L, PRP low-dose group; PRP-M, PRP medium-dose group; RT-PCR, reverse transcription polymerase chain reaction; SPSS, statistical program for the social sciences; SV, sinus venosus; UPLC/Q-TOF-MS, ultraperformance liquid chromatography/quadrupole time-of-flight mass spectrometry; VIP, variable importance in projection.

approximately 390,000 people die from malignant arrhythmia every year in the United States (Wang et al., 2018; Kusumoto et al., 2018). The pathogenesis of arrhythmia is complicated. Molecular biology studies have revealed cardiac autonomic nerve dysfunction, such as excitement of the vagus nerve and inhibition of sympathetic nerves (de Araújo et al., 2018; Janssens and Michels, 2019). Abnormal structure and function of ion channels can cause arrhythmia (Torrente et al., 2020). The clinical treatment of arrhythmia is based mainly on Western medicine, such as propafenone, calcium channel blockers, and  $\beta$ -receptor blockers, but medical research has shown that antiarrhythmic drugs also have arrhythmic effects and that their improper use can cause more serious adverse reactions. Although the long-term use of these drugs can relieve symptoms, it results in an unsatisfactory prognosis and may even increase mortality, so there is an urgent need to explore new anti-arrhythmia treatment strategies (Brugada et al., 2020).

*Poria cum Radix Pini* (PRP) is a traditional Chinese medicine with a long history that was first referenced in the “Famous Doctors”. PRP consists of the white part of *Poria cocos* (Schw.) Wolf with pine roots in the middle (Ping, Guixin, Spleen Channel). Research shows that PRP has significant antitumor, spleen and stomach invigoration, swelling relief, mind-calming and tranquilization, immunity-enhancing and bacterium-inhibiting effects (Changhe, 2009). Pharmacological and clinical medicine research has shown that PRP can prolong sleep time and shows a synergistic effect with pentobarbital sodium. It has a good effect on most people who exhibit insomnia and difficulty falling asleep or who wake up easily (Shah et al., 2014). In addition, it can also inhibit tumor growth and exert antitumor effects by enhancing the body's immune function. Triterpenes and polysaccharide compounds are the main active components of PRP (Xu et al., 2020; Yi et al., 2020). Studies have shown that triterpenes (poria cocoic acid) can inhibit the secretion of IL-2 and IFN- $\gamma$  and affect the killing of target cells by cytotoxic T cells and the apoptosis of cardiomyocytes (Wu et al., 2014). *Poria cocos* polysaccharides can inhibit the occurrence of cardiac hypertrophy, improve haemodynamics, enhance myocardial systolic function, improve myocardial diastolic function and increase cardiac output in rats (Zhao et al., 2020b). Ergosterol compounds also exhibit good curative antitumor effects and prevent cardiovascular diseases (Kim et al., 2019), which shows that PRP presents great potential for the treatment of arrhythmia. However, the mechanism and core pathways involved in the PRP-based treatment of arrhythmia have not yet been reported, and further investigation is needed.

Databases such as the Encyclopedia of Traditional Chinese Medicine (ETCM) and the Bioinformatics Analysis Tool for Molecular Mechanisms of Traditional Chinese Medicine (BATMAN-TCM) are commonly used for network pharmacological analysis (Gong et al., 2019; Xu et al., 2019). This study is based on the use of these databases to predict the potential targets and biological pathways of PRP-based treatment of arrhythmia. Ultra-performance liquid chromatography/quadrupole time-of-flight mass spectrometry (UPLC/Q-TOF-MS) positive and negative detection modes were used to

analyse alcohol extracts of PRP, and the main active ingredients were determined (Zhang et al., 2020). In addition, since zebrafish heart have a very similar electrophysiological behaviour to the human heart, thus, it has become a very interesting model for human heart system pathologies researches, like cardiomyopathy, arrhythmia, heart failure, structural and congenital heart disease etc (Gut et al., 2017; Cassar et al., 2020; Echeazarra et al., 2020). Specially, the advantage of zebrafish embryos is transparency which offer a possibility to observe heart physiology and pathology characteristics directly (Matrone et al., 2015; Crowcombe et al., 2016). Therefore, in our experiments, we prefer to use the BaCl<sub>2</sub>-induced arrhythmia zebrafish model to explore PRP treatment functions (Khisatmutdinova et al., 2006; Huang et al., 2013). A biological arrhythmia model in zebrafish was established with barium chloride (Liu et al., 2014). Then, through the correlation analysis of network pharmacology and metabolomics, the main pathway involved in the PRP-based treatment of arrhythmia was identified, and the mechanism of action of the PRP-based treatment of arrhythmia was further clarified through the quantitative analysis of key targets and metabolites in the pathway by reverse transcription polymerase chain reaction (RT-PCR) and metabolomics (Shi et al., 2020).

## MATERIALS AND METHODS

### Chemicals and Reagents

Verapamil hydrochloride was purchased from Shanghai Hefeng Pharmaceutical Co., Ltd. (Shanghai, China). Barium chloride was obtained from Chongqing Maoye Chemical Reagent Co., Ltd. Optimal LC grade acetonitrile was obtained from Merck (Merck, Darmstadt, Germany). Isopropanol, formic acid and nucleotides for metabolite analyses were purchased from Sigma-Aldrich (Spruce St., St Louis, MO, United States).

### Preparation of *Poria cum Radix Pini* Extracts

PRP was obtained from Shaanxi Xingshengde Co., Ltd. (Shannxi, China) and identified by Prof. Ji-Qing Bai. The specimens were deposited at Shaanxi University of Chinese Medicine (Shaanxi, China). PRP was prepared via the following steps: precise weighing of 0.8 g PRP in a 50 ml conical bottle, dilution with 25 ml methanol, weighing, soaking for 30 min, ultrasonic processing for 60 min, cooling, and weighing again. Next, the solution was brought up to the desired weight with methanol and filtered. A 15 ml aliquot was then absorbed by continuous filtration, evaporated to approximately 1 ml in an evaporation dish in a water bath, diluted with methanol in a 5 ml capacity bottle, shaken, evaporated in an evaporating pan in a water bath, and then dissolved in deionized water for animal experiments.

### Zebrafish Embryos and Treatment

Zebrafish embryos 72 h post fertilization (hpf) were purchased from Shanghai Fish Biotechnology Co., Ltd. and maintained in

Holt buffer solution (15 mM NaCl, 0.5 mM KCl, 1 mM MgSO<sub>4</sub>, 1 mM CaCl<sub>2</sub>, 0.15 mM KH<sub>2</sub>PO<sub>4</sub>, 0.05 mM Na<sub>2</sub>HPO<sub>4</sub>, 0.7 mM NaHCO<sub>3</sub>, 5% methylene blue; pH 7.5) on a 14 h light/10 h dark cycle at 28 ± 1°C and pH 7.5 ± 0.5.

Zebrafish embryos were randomized into six groups and placed on 48-well cell culture plates (ten embryos per group, five embryos per well): control, model (barium chloride sterile saline solution 2.1 µg/ml, 2 ml), positive control (model + 0.45 µg/ml verapamil hydrochloride), and three treatment groups (PRP-H: model + PRP extract 162.60 µg/ml, PRP-M: model + PRP extract 121.95 µg/ml, PRP-L: model + PRP extract 97.56 µg/ml). Technical details of the establishment protocol for the barium chloride-induced arrhythmia model establishment protocol and the PRP treatment dosage design are shown in **Supplementary File S1**. After 24 h of incubation with sterile saline solution of barium chloride, verapamil hydrochloride, or PRP extract, the morphology of the zebrafish embryo hearts was observed. All animal handling and experimental conditions were approved by the Laboratory Animal Care and Use Committee of Shaanxi University of Chinese Medicine.

## Identification of the Chemical Components of *Poria cum Radix Pini*

The concentration of PRP extract was 9.6 mg/ml. The PRP extract solution was analysed on a Waters Acquity H-Class UltraPerformance LC (Waters, MA, USA)/tandem 5600<sup>+</sup> triple-quadrupole time-of-flight mass spectrometer (QTOF-MS) system (AB SCIEX, MA, United States) using a Waters BEH C<sub>18</sub> column (50 mm × 2.1 mm, 1.7 µm) with a gradient mobile phase of 0.1% formic acid aqueous solution (A) and 0.1% formic acid-acetonitrile solution (B) at a flow rate of 0.3 ml/min and a 30°C column temperature. The gradient program was as follows: 0–1 min, 2% B; 1–42 min, 2–100% B; 42–44 min, 100% B; 44–48 min, 100–2% B; 48–50 min, 2% B. The full scan and MS/MS experiments were performed under positive and negative modes by using an electrospray ionization (ESI) ion source. Information-dependent data (IDA) acquisition mode was used to switch automatically between MS and MS/MS acquisition with the following parameters: ion spray voltage floating: +5500 or –4500 V, declustering potential (DP): 40 V, ion source gas 1 and ion source gas 2 both set as nitrogen: 50 psi, curtain gas: 35 psi, source temperature: 500°C. The scanning range of parent ions (TOF-MS) was 100–2000 m/z. The eight strongest peaks exceeding 100 cps were collected by MS<sup>2</sup>, and the scanning range was 100–2000 m/z. Data were acquired using Analyst TF software (version 1.7.1, AB SCIEX). Component identification was performed by using PeakView™ software (version 2.2, AB SCIEX) and MasterView™ software (version 1.1, AB SCIEX) coupled with the TCM library database (version 1.0, AB SCIEX).

## Network Pharmacology Prediction for *Poria cum Radix Pini* Therapy

According to the UPLC-TOF-MS/MS identification results, the screening for active components of PRP and the PRP target

prediction for arrhythmia treatment were performed by network pharmacology analysis on ETCM (<http://www.tcmip.cn/ETCM/index.php/Home/Index/>), BATMAN-TCM (<http://bionet.ncpsb.org.cn/batman-tcm/index.php>), Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform (TCMSP, <http://tcmspw.com/tcmsp.php>), Therapeutic Targets Database (TTD, <http://db.idrblab.net/ttd/>) and Genecards (<https://www.genecards.org/>) (Liu et al., 2016).

Common targets were identified between the screened active component-related targets and disease targets ('arrhythmia') by VENNY 2.1.0 (<https://bioinfo.gp.cnb.csic.es/tools/venny/>), and a relationship among these targets was generated by the STRING 11.0 database (<https://string-db.org/>). Then, the component-disease-target association network was constructed by Cytoscape software (version 3.7.2). Finally, the enrichment of Gene Ontology (GO) functions and pathways of selected key targets were examined by using the clusterProfiler package of R software (version 3.6.1) for RPR treatment function prediction (Yu et al., 2012).

## Cardiovascular Morphological Observation and Sinus Venosus-Bulbus Arteriosus Distance Measurement

After incubation with Holt buffer solution from 60 to 72 hpf, zebrafish embryos were randomly selected ( $n = 10$  each group) for the observation of cardiac morphology. The zebrafish embryos were fixed with 3% methylcellulose (AlfaAesar, Shanghai, China), and cardiac morphology observations (pericardial oedema, abnormal circulation, thrombosis, haemorrhage, etc.) and sinus venosus-bulbus arteriosus (SV-BA) distance measurement for heart tube looping quantification were performed on an ABX51 electron microscope (Olympus, Tokyo, Japan), and images were acquired under a DD71 digital camera (Olympus, Tokyo, Japan). The pericardial congestion area and the SV-BA straight line distance were calculated with ImageJ software (version 1.8.0, NIH, USA). Each experimental treatment was repeated three times (Lin et al., 2007; Gut et al., 2017; Echeazarra et al., 2020).

## Acridine Orange Staining for Apoptosis Evaluation

Acridine orange (AO) is a nucleic acid-selective metachromatic dye: AO-stained apoptotic cells show yellow-green fragments, while normal cells show uniform green or yellow-green fluorescence (Antonio et al., 2017). To evaluate the cardiomyocyte apoptosis of zebrafish embryos after barium sodium exposure and rescue treatment, five live zebrafish embryos at 96 hpf from each group were randomly selected and washed with phosphate-buffered saline (PBS, pH 7.4) to remove exposure residues and then incubated in 2.5 mg/L AO solution at 28°C in the dark for 30 min. Next, the embryos were rinsed thoroughly in PBS twice and fixed in 3% methyl cellulose solution. Images of the dorsal side of fixed zebrafish were acquired under a BX51 push-around-type electronic fluorescence microscope (Tokyo, Japan) coupled with a DD71

digital camera under a green light source. The average fluorescence density of the particle number was calculated by Image J software (Jin et al., 2019).

## Untargeted Metabolomic Analysis

### Sample Preparation

For significant endometabolite selection, 30 live 72 hpf zebrafish embryos from each group were randomly selected and washed with PBS (pH 7.4) to remove exposure residues, placed in 1.5 ml centrifuge tubes, mixed with 1 ml of PBS solution, and centrifuged at 12,000 r/min for 10 min. Next, the PBS solution was aspirated, 1 ml of 80% methanol solution was added, and the mixture was ground and centrifuged at 12,000 r/min at 4°C for 10 min. Finally, the supernatant was extracted, concentrated and freeze-dried until use.

### Untargeted Metabolomics UPLC-Q/TOF-MS Analysis

The freeze-dried zebrafish embryo sample was mixed with 250  $\mu$ l of acetonitrile:water (1:1) solution prior to untargeted metabolomics analysis. The prepared samples were separated on a UPLC-QTOF-MS/MS system using a Waters UPLC<sup>®</sup> HSS T3 C<sub>18</sub> column (2.1  $\times$  100 mm, 1.7  $\mu$ m), with a gradient mobile phase of aqueous solution +2 mM ammonium acetate+0.05% aqueous formic acid (A)-acetonitrile: isopropanol = 1:1 + 2 mM ammonium acetate-0.05% aqueous formic acid (B), at a flow rate of 0.3 ml/min and a column temperature of 40°C. The gradient program was as follows: 0–1.5 min, 2% B; 1.5–23 min, 1–60% B; 23–24 min, 60–98% B; 24–27 min, 98% B; 27–27.1 min, 27.1–33 min, 1% B. Full scans and MS/MS experiments with information-dependent data (IDA) acquisition mode were performed by using an ESI ion source with the following parameters: ion spray voltage floating: +5500 or –4500 V, declustering potential (DP): 40 V, ion source gas 1 and ion source gas 2 both set as nitrogen: 50 psi, curtain gas: 35 psi, source temperature: 500°C. The scanning range of parent ions was 70–1200 m/z. The twelve strongest peaks exceeding 100 cps were collected by MS<sup>2</sup>, and the scanning range was 70–1200 m/z. Data were acquired using Analyst TF software (version 1.7.1, AB SCIEX). Metabolites were identified by using PeakView<sup>™</sup> software (version 2.2, AB SCIEX) and MasterView<sup>™</sup> software (version 1.1, AB SCIEX) coupled with “the Accurate Mass Metabolite Spectral Library” (version 1.0, AB SCIEX). The combined score of confidence setting parameters were as follows: mass error 40%, retention time 0%, isotope 20%, library hit 40%, and formula finder 0%.

### Untargeted Differential Metabolome Screening

To identify targeted endo-metabolites, metabolite database matching data were extracted and converted to Excel files (\*.xls) for matrix formation. Then, the pretreatment matrix was subjected to SIMCA-P 14.0 (Umetrics, Sweden) software for partial least squares (PLS) analysis between the control and model groups to identify the differential metabolome that corresponded to a statistical *p* value of < 0.05 and a variable importance in projection (VIP) value of > 1.0 (Liu et al., 2019). To select the therapeutic-related endo-metabolites among the control, model, positive control, PRP-H, PRP-M and PRP-L

groups, the differential metabolome was next distinguished by PCA on the MetaboAnalyst 4.0 online platform (<http://www.metaboanalyst.ca>) (Xia et al., 2009).

### Metabolic Pathway Enrichment

Further analyses were conducted to identify and visualize the effect of the PRP extract on the metabolic pathways related to arrhythmia. The differential metabolites screened by metabolomics and the key targets predicted on the basis of network pharmacology were input into the MetaboAnalyst database, with *p* < 0.05 as the card value, and the pathway library (Kyoto Encyclopedia of Genes and Genomes (KEGG)) was selected for pathway enrichment analysis.

### Targeted Metabolites Determination

To analyse the targeted metabolomic selection results, potential metabolite markers were quantitated by comparison to the areas of the peaks for the external standards (method validation is shown in **Supplementary File S2, Supplementary Table S1**).

### Quantitative Reverse Transcriptase Polymerase Chain Reaction Analysis

After treatment at 96 hpf, zebrafish embryos were randomly selected (*n* = 30 each group) for qRT-PCR analysis. Thirty milligrams of zebrafish embryos was homogenized in TRIzol reagent (Servicebio Technology Co., Ltd., Wuhan, China) to extract total RNA. The extracted RNA was used as a template, and cDNA was synthesized by reverse transcription with appropriate primers according to the instructions of the Servicebio<sup>®</sup> RT First Strand cDNA Synthesis Kit (G3330, Servicebio, Wuhan, China). qRT-PCR was performed in an ABI 7900HT Fast Real-Time PCR system (Bio-Rad Bole Gradient, California, America). The primer sequences were as follows (ref. NM\_001128584.1, 242 bp, 60°C, Servicebio): TTC TGACCCAAAGTTCCATCCT (forward) and CTCAAACTG GCAGGTGACGAT (reverse). Levels of the Adenosine A1 Receptor (ADORA1) mRNAs were normalized to the GAPDH mRNA level and determined using the 2<sup>−ΔΔCt</sup> method, and all reactions were performed in triplicate.

### Statistical Analysis

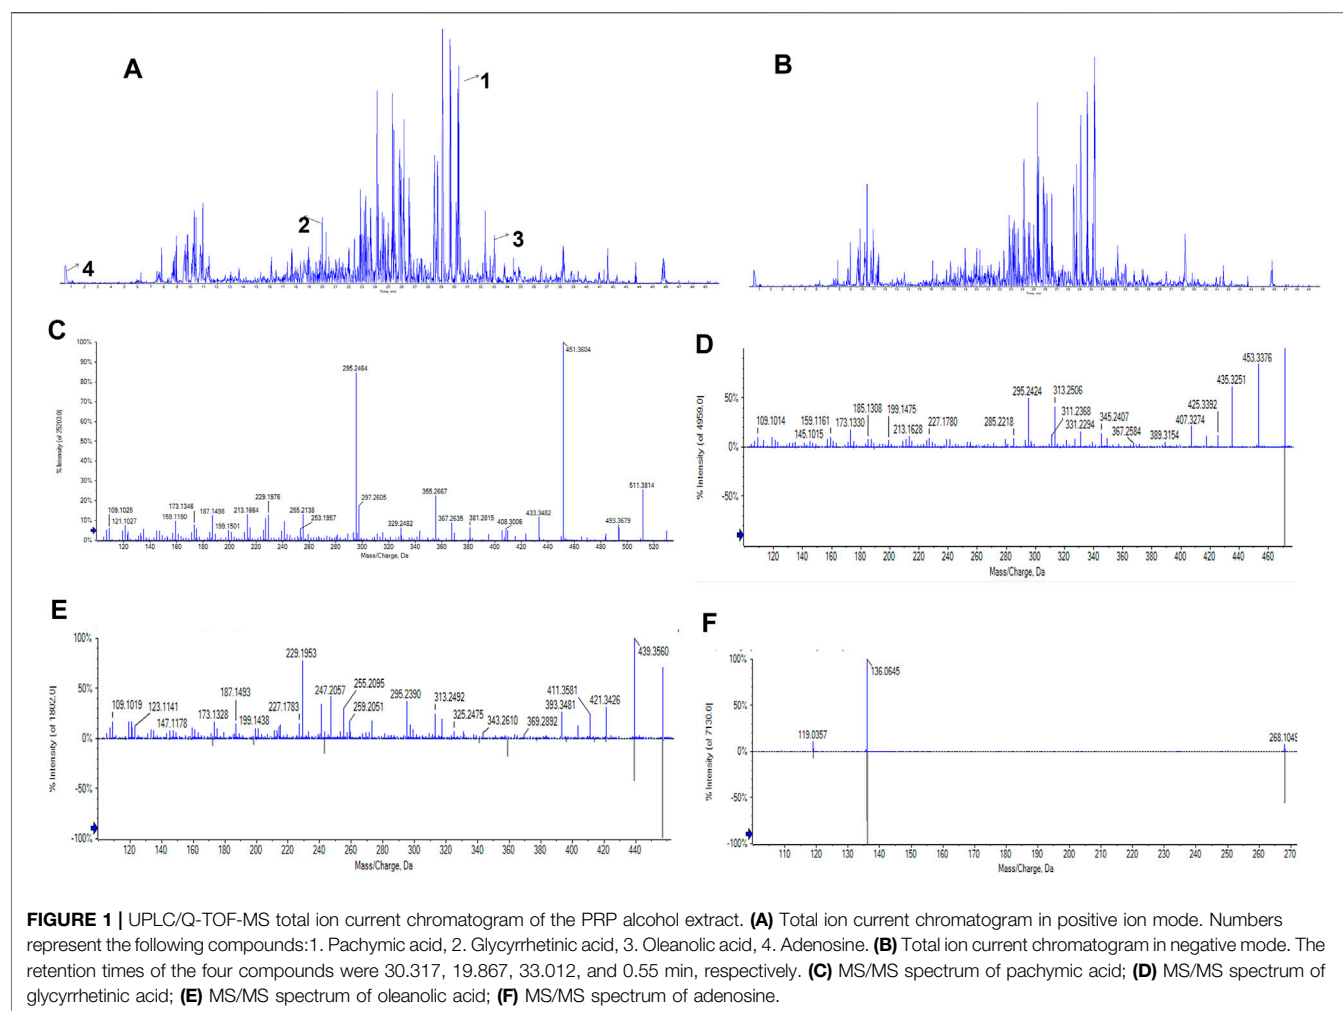

Statistical Program for the Social Sciences (SPSS) 26.0 was used for statistical analysis. All the data are expressed as the mean  $\pm$  SD. One-way analysis of variance (ANOVA) was used to compare the data among the groups. GraphPad Prism 8 software was used to generate all graphics, and *p* < 0.05 was considered statistically significant.

## RESULTS

### UPLC/Q-TOF-MS Components

#### Identification of *Poria cum Radix Pini*

Under the optimized chromatographic and mass spectrometry conditions, UPLC/Q-TOF-MS in positive and negative detection

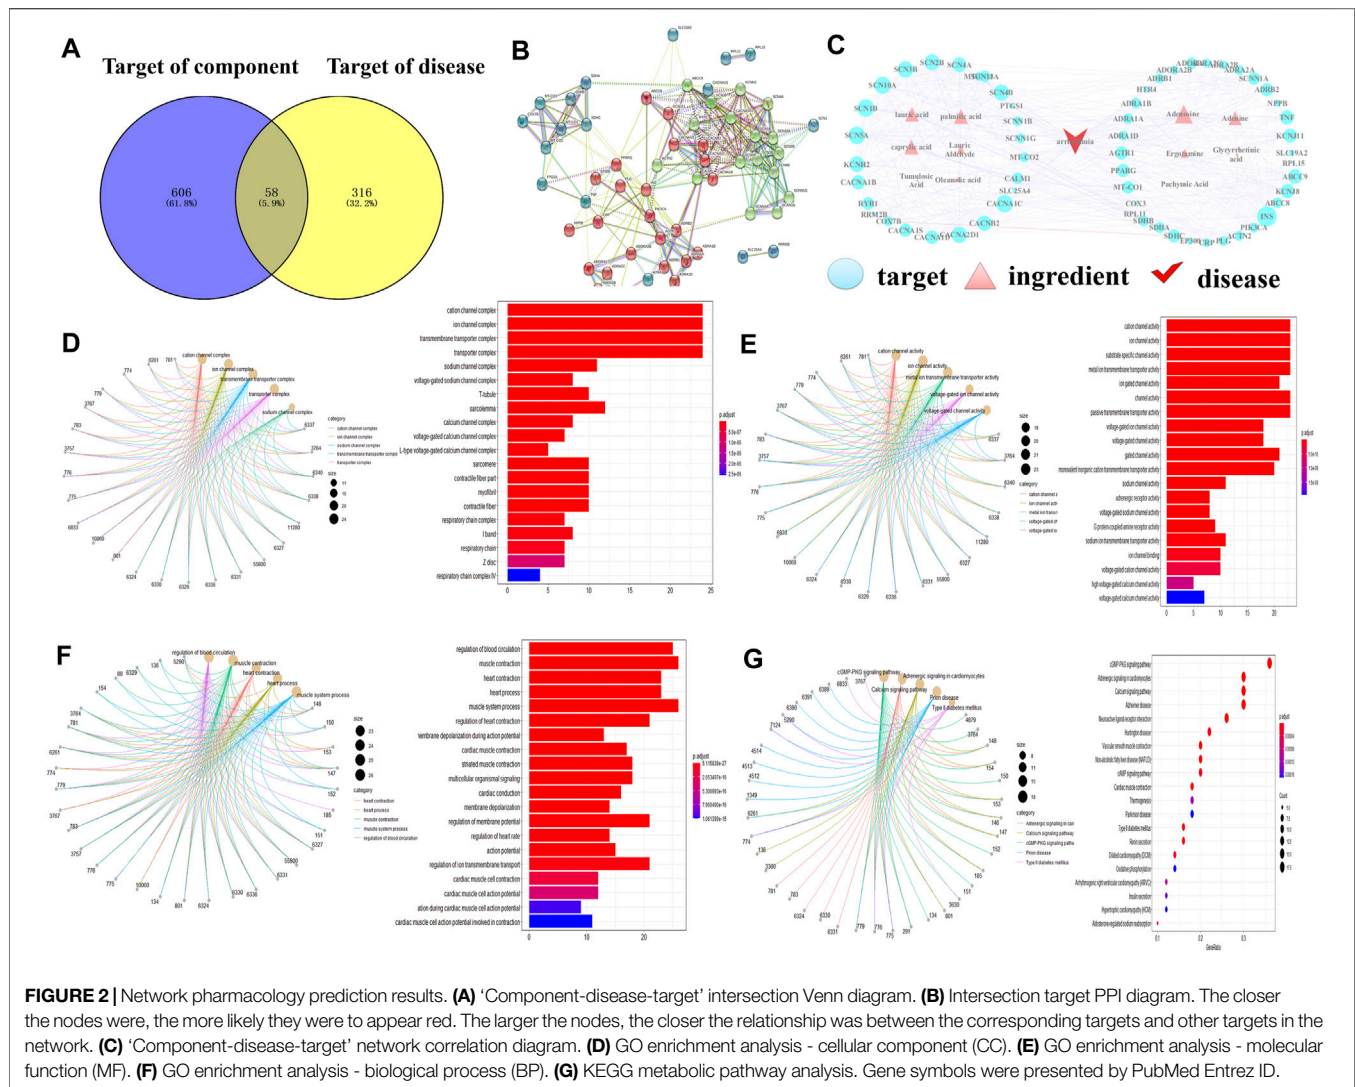

**TABLE 1 |** Chemical identification combining component characterization and database search.

Number	Name	Molecular Formula	Mass (Da)	Source

modes was used to analyse the PRP extracts (Figures 1A,B). The results showed that 31 compounds were identified in positive ion mode and 5 in negative ion mode (Supplementary File S3, Supplementary Table S2). According to the molecular weight, retention time, and MS/MS data, four compounds were identified: pachymic acid, glycyrrhetinic acid, oleanolic acid and adenosine (Figures 1C–F) (Supplementary File S3, Supplementary Table S3) (Qian et al., 2018).

## Network Pharmacological Analysis for *Poria cum Radix Pini* Therapy

By combining UPLC/Q-TOF-MS identification and database search results, 11 compounds were identified and selected (Table 1). For these compounds, 606 putative targets were predicted from the ETCM, TCMSP and Batman-TCM databases (Supplementary File S4, Supplementary Table S4). A total of 316 targets related to arrhythmia were obtained against

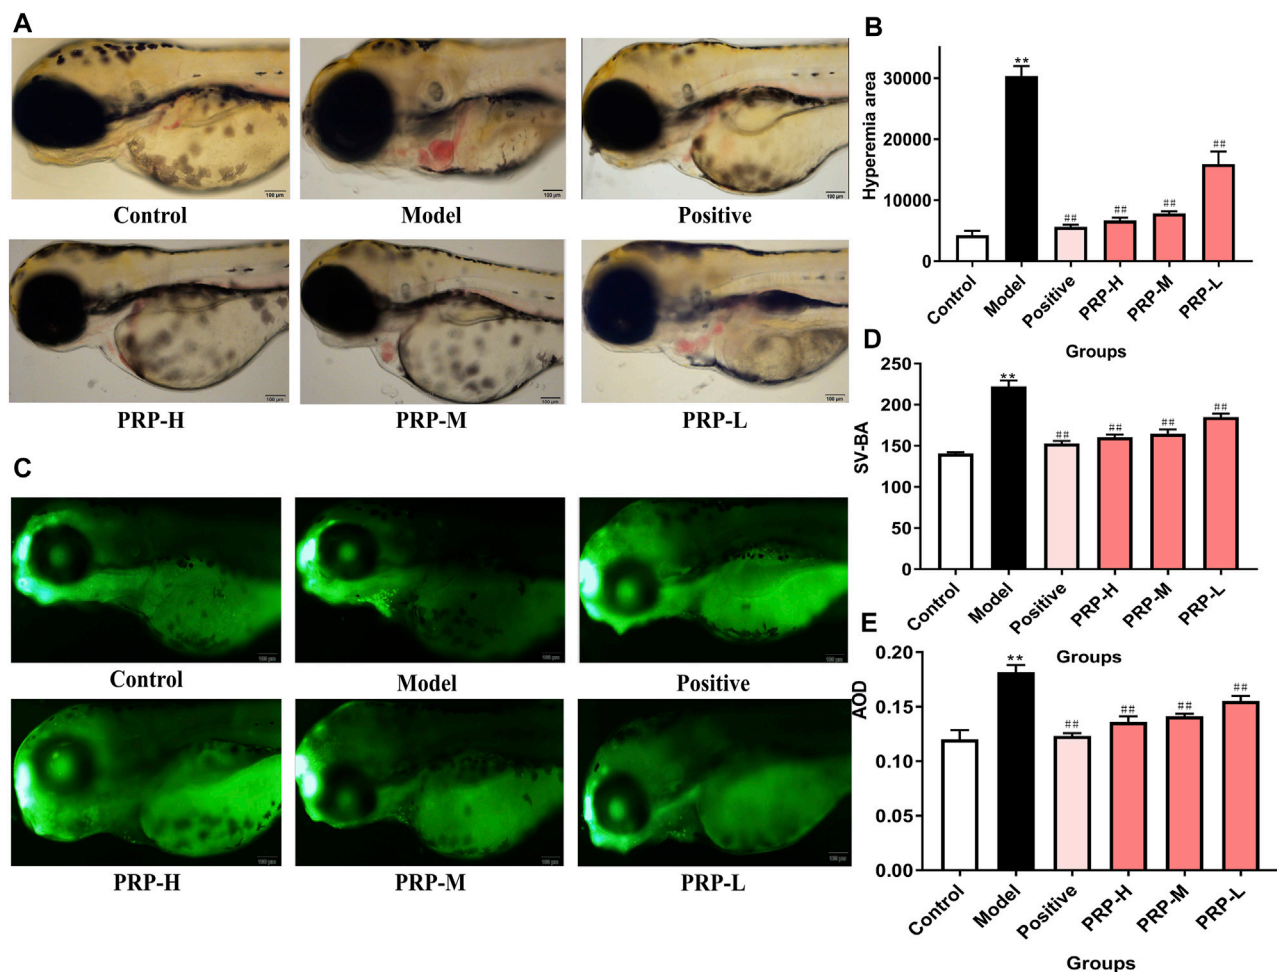

the ETCM, TTD, and GeneCards databases (Supplementary File S4, Supplementary Table S5). In Figure 2A, we first extracted 58 intersection targets from the overlaps between the disease gene set and PRP target sets (Supplementary File S4, Supplementary Table S6). In the following study, the relationships of these 58 targets were connected as a PPI network for importance evaluation (Supplementary File S4, Supplementary Table S7). As shown in Figure 2B, the PPI k-means classification results suggested that 25 genes, iADORA1, ADORA2B, ADRA1A, ADRA1B, and ADRA1D, play a more important role in arrhythmia pathology and PRP treatment.

To further explore PRP multicomponent and multitarget therapy functions, all 58 targets of the PPI network were mapped to “component-disease” connections, and then the “component-disease-target” network of PRP therapy was constructed by Cytoscape software (Figure 2C). This network included 70 nodes, which illustrated potential interplay among 1 disease type, 11 chemical components, and 58 targets. Since the node size is proportional to the importance of nodes involved in the pathway, 7 components involved in the therapy pathway,

including adenosine, palmitic acid, caprylic acid, lauric acid, and adenine. In addition, 58 targets, such as ADORA1, ADORA2B, and CACNA1B, were considered potential therapeutic targets (Supplementary File S4, Supplementary Table S8).

GO analysis revealed that the targets were significantly enriched in 581 pathways for PRP therapy, specifically “complex ion channels and transmembrane transporters”, “ion channel activity and metal ion transmembrane transport protein activity”, and “myocardial contraction, the regulation of myocardial contractility and the regulation of blood circulation” (Figures 2D–F, Supplementary File S4, Supplementary Table S9). Similarly, KEGG pathway enrichment analysis showed that the targets were significantly enriched in 193 pathways for PRP therapy, specifically the “cGMP-PKG signalling pathway” and “calcium ion signalling pathway” (Figure 2G, Supplementary File S4, Supplementary Table S10). As the GO and KEGG analyses suggested that most adenosine receptors (ADORAs) under PRP treatment were involved in arrhythmia-related pathways, these 58 targets were used to perform metabolomic joint pathway analysis.

**FIGURE 3 |** The effect of PRP on the heart development of zebrafish embryos following barium chloride treatment. **(A)** Morphological observations of the heart development of zebrafish embryos under a microscope, with the heart shown in the yellow box (X10). **(B)** The cardiac congestion area of zebrafish embryos was calculated. **(C)** The results of acridine orange staining. The apoptosis of zebrafish embryos cardiomyocytes observed under fluorescence microscopy is shown in the yellow box (X10). **(D)** The SV-BA distance was measured. **(E)** The average fluorescence density was calculated. All data are presented as means  $\pm$  SD,  $n = 6$ . \* $p < 0.05$ , \*\* $p < 0.01$ , control versus model; # $p < 0.05$ , ## $p < 0.01$ , model versus positive, PRP-H, PRP-M, and PRP-L.

## Poria cum Radix Pini can Rescue Barium Chloride-induced Cardiac Defects in Zebrafish Embryos

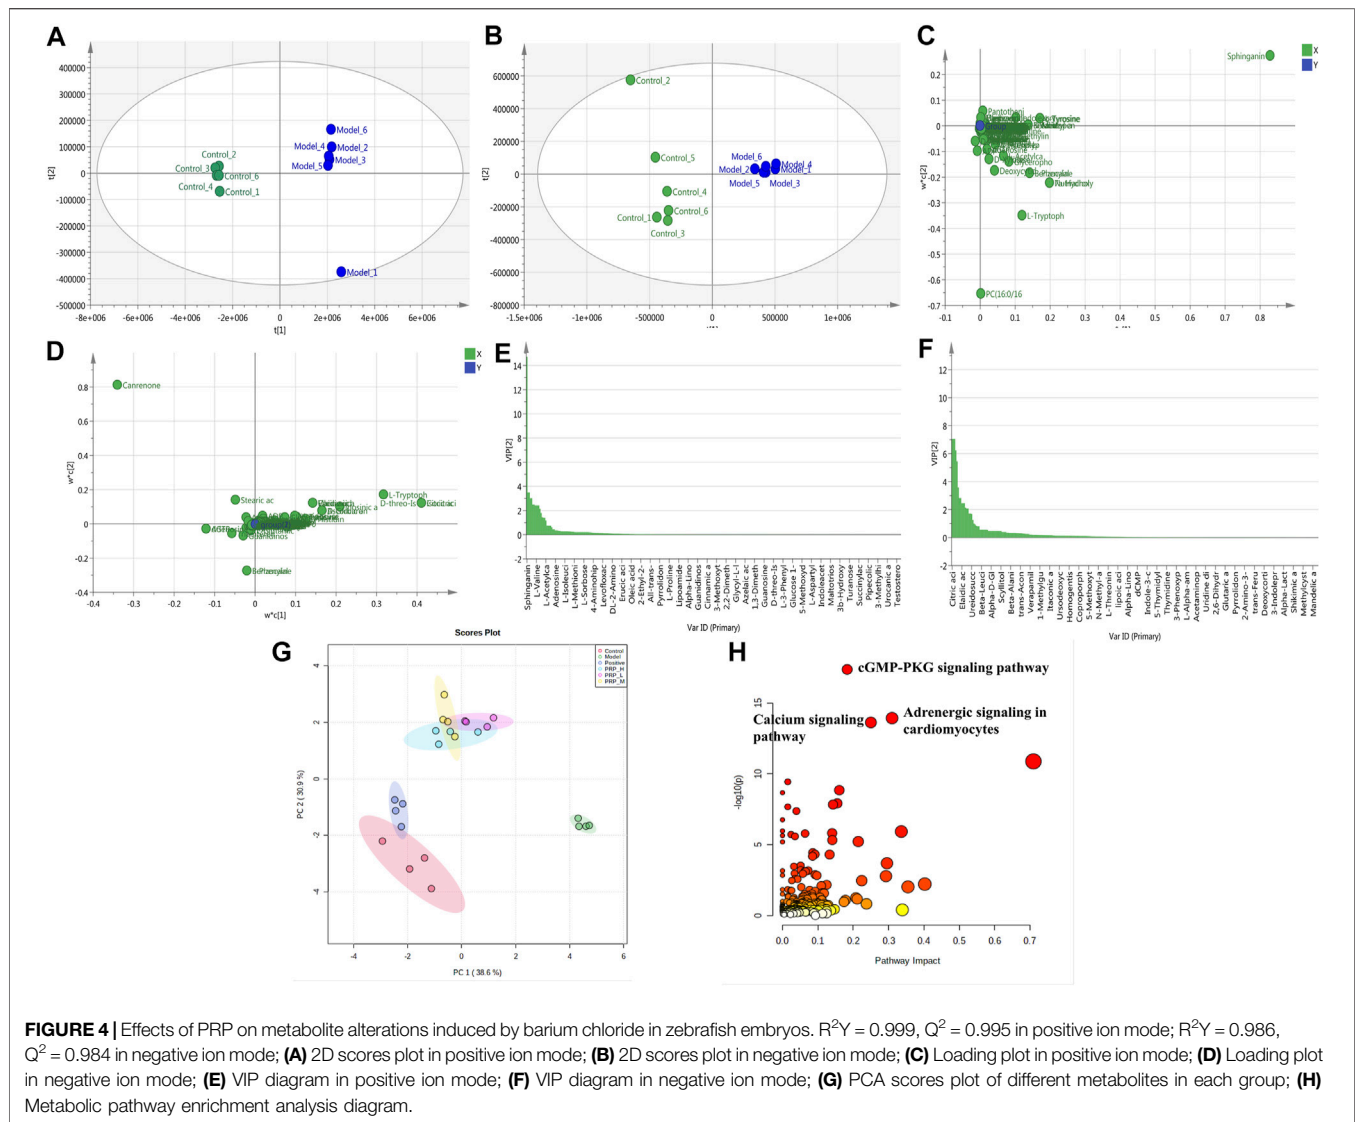

In the morphological phenotype observation, PRP extracts showed a significant and dose-dependent rescue function against barium chloride-induced morphological phenotypes (Figure 3A). Calculating the cardiac congestion area in zebrafish showed that the cardiac congestion area was 605.42% larger in the zebrafish model group than in the control group. However, the cardiac congestion areas in the positive control group, PRP-H group, PRP-M group and PRP-L group showed decreases of 81.44, 78.05, 74.22 and 47.54%, respectively, compared to that in the model group. These findings further proved that PRP can lessen the degree of cardiac congestion induced by barium chloride in zebrafish (Figure 3B, Supplementary File S5, Supplementary Tables S11, S11-1,

S11-2). Compared with the control group, the model group zebrafish showed a 58.10% increase in the SV-BA distance. Compared to the model group, the SV-BA distance in the verapamil exposure group led to a significant 31.30% decrease, while the PRP-H, PRP-M, and PRP-L treatment groups showed 27.83, 25.96, and 16.82% decreases, respectively (Figure 3D, Supplementary File S5, Supplementary Tables S12, S12-1, S12-2).

## Poria cum Radix Pini can Inhibit Cardiomyocyte Apoptosis in Zebrafish Embryos

After AO staining, compared with the control group, a large number of apoptotic cells (green debris particles) were found in zebrafish embryo hearts, and the average fluorescence density was 51.18% higher than that in the control group. At 96 hpf, the

numbers of apoptotic cells in zebrafish embryo hearts were significantly and dose-dependently decreased in the PRP treatment group. Compared to the model group, the average fluorescence density of the PRP-H, PRP-M and PRP-L groups showed declines of 25.13, 22.20 and 14.50%, respectively. These results indicated that PRP could rescue barium chloride-induced apoptosis in the hearts of zebrafish embryos in a concentration-dependent manner (Figures 3C,E, Supplementary File S5, Supplementary Tables S13, S13-1, S13-2).

### ***Poria cum Radix Pini* can Regulate Metabolite Disorders Induced by Barium Chloride in Zebrafish Embryos**

PLS analysis of the untargeted metabolome showed a distinct change in metabolite profiles between the model embryos and control embryos, represented by the substantial metabolomic perturbation of the cardiac system observed in these embryos

(three experiments, Figures 4A,B). Then, significant features were selected based on a selected criterion with an adjusted  $p$ -value cut-off of  $<0.05$ . Statistical analysis of the metabolomics data from the barium chloride-treated group and the control group indicated significant differences in ions between these two groups, as shown in the loading plot (Figures 4C,D). The VIP values were also used to calculate the feature importance by the cut-off value of weight VIP  $> 1$  (Figures 4E,F). Following the selection flow, a total of 17 potential differential metabolites were identified in positive and negative ion modes (Table 2), including amino acid components such as L-tyrosine, L-valine, L-tryptophan, indoleacrylic acid, and L-histidine and choline components such as glycerophosphocholine, L-acetylcarnitine and adenosine triphosphate.

Furthermore, to clarify whether PRP administration can regulate barium chloride-induced metabolite alterations, comparisons among the control group, model group, positive control group and PRP-H, PRP-M and PRP-L groups were

analysed by using the MetaboAnalyst database. As shown in **Figure 4G**, the PCA score plot showed obvious sample clusters among the control, model, positive control and PRP-treated groups, where the PRP-H group and PRP-M group were close to the control group but separated from the model group. The results indicated that PRP treatment could improve barium chloride-induced metabolomic profile imbalance in zebrafish embryos.

### **Poria cum Radix Pini Rescues Metabolite Profiles From the ADORA1-Mediated cGMP-PKG Signalling Pathway**

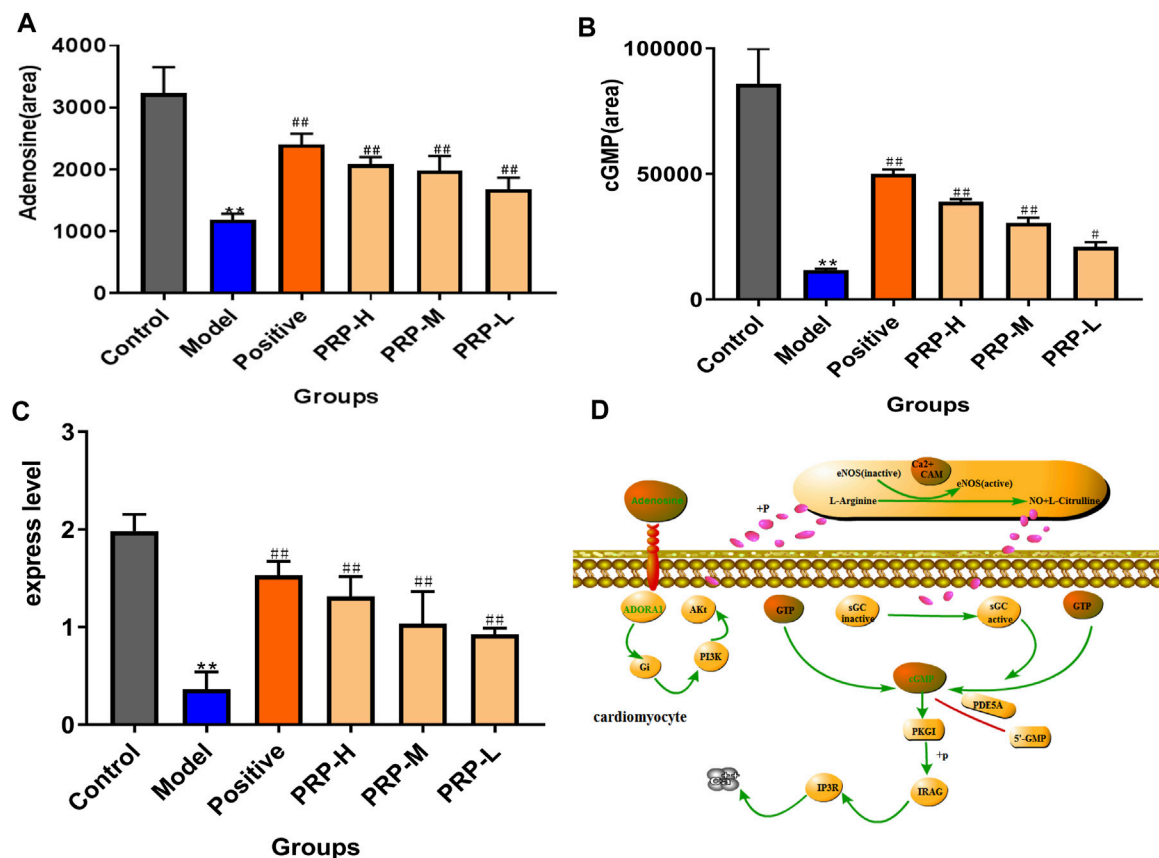

To further investigate the roles of the enriched metabolite pathways and dissect which of the screened targets contributed to these pathways, the candidate targets from the network pharmacology selection were mapped to 17 differential endometabolites by joint-pathway analysis on the MetaboAnalyst database (**Figure 4H**). Gene-metabolic pathway correlation analyses showed that the “cGMP-PKG signalling pathway” ( $p < 0.001$ ) was highly enriched among the 72 enriched metabolic pathways. In this pathway, ADORA1 is a highly ranked protein that acts as an adenosine receptor to reduce cardiomyocyte calcium overload in the occurrence of arrhythmia diseases, and adenosine and cGMP are highly ranked metabolites (Szentmiklosi et al., 2015; Deb et al., 2019).

Next, by quantifying the levels of adenosine and cGMP in embryo samples using LC-MS in multiple reaction monitoring (MRM) mode, barium chloride induced a significant decreasing trend in adenosine by 63.30% and cGMP by 78.86% compared with the control ones. PRP therapy significantly reversed these changes: the adenosine and cGMP levels in the PRP-H group were increased by 75.84 and 231.35%, in the PRP-M group were increased by 66.71 and 159.57%, and in the PRP-L group were increased by 41.71 and 78.86%, respectively (**Figures 5A,B, Supplementary File S6, Supplementary Tables S14–S15-2**). ADORA1 expression was determined using qRT-PCR assays

to examine how PRP treatment influenced barium chloride-induced arrhythmia in zebrafish embryos (**Figure 5C, Supplementary File S6, Supplementary Tables S16, S16-1, S16-2**). Interestingly, ADORA1 expression was significantly decreased by 81.65% ( $p < 0.01$ ) in the model group. PRP therapy restored ADORA1 expression at three dosages, with increases of 320.53, 261.96, 184.56 and 154.58%, respectively. The results showed that PRP could increase the expression level of ADORA1 in the cGMP-PKG signalling pathway. These findings indicated that barium chloride disturbed the cGMP-PKG signalling pathway, which resulted in arrhythmia. This was attributed to ADORA1 downregulation associated with adenosine and cGMP decline and PRP treatment rescued these trends towards an imbalance.

## **DISCUSSION**

PRP is a traditional fungal medicinal material that is often used as the key medicine for the treatment of arrhythmia. Modern pharmacological studies have shown that PRP water decoction shows a similar central inhibitory effect to synergistic pentobarbital sodium, which further demonstrates its anti-arrhythmic effects, and it can be used together with *Poria cocos* to treat heart palpitations caused by deficiencies of the heart and spleen (Shah et al., 2014). In addition, its main active components, such as triterpenoids and polysaccharides, have been proven to play an important role in the treatment of arrhythmia (Wu et al., 2014; Li et al., 2015). Studies have indicated that cardiomyocyte apoptosis plays an important role in arrhythmia, and the severity of apoptosis is positively correlated with the arrhythmia score (Niu et al., 2020). In addition, zebrafish heart congestion, an extended SV-BA distance, pericardial oedema and other cardiac morphological changes can cause heart damage and arrhythmia. In this study, by observing the heart morphology of zebrafish with arrhythmia induced by barium chloride, it was found that PRP

**FIGURE 5 |** PRP-mediated regulation of the levels of adenosine and cGMP metabolites and the expression level of ADORA1 in the cGMP-PKG signalling pathway. (A) Quantitative evaluation of adenosine metabolism; (B) quantitative evaluation of cGMP metabolic levels; (C) expression levels of ADORA1 in zebrafish determined by reverse transcription polymerase chain reaction; (D) ADORA1-mediated cGMP-PKG pathway map.

administration could significantly improve the cardiac congestion area, the SV-BA interval and the degree of myocardial cell apoptosis and promote the normal development of the heart in zebrafish, which further indicated the great potential of PRP for the treatment of arrhythmia. However, due to the complex pathogenesis of arrhythmia and the efficacy characteristics of multicomponent, multitarget and multipathway drugs, it is still a great challenge to explain the mechanism underlying the effects of PRP in the treatment of arrhythmia.

In the analysis of PPI and component-disease-target network pharmacology results, we found that the ADORA1 protein may be the main target in the PRP-based treatment of arrhythmia and that it participates in multiple signalling pathways, such as the cGMP-PKG, cAMP, and cardiac muscle contraction pathways. These pathways all play important roles in heart disease (Zhu et al., 2020). In addition, we verified through PCR that the expression levels of the ADORA1 protein in the PRP-treated groups were significantly higher than those in the model group. Studies have indicated that calcium overload in cardiomyocytes is one of the important causes of arrhythmias and that not only does adenosine affect the intracellular calcium ion current, but adenosine receptors can also cause arrhythmias by affecting

calcium ion homeostasis (Greene et al., 2016). Among the adenosine receptors, ADORA1 shows the highest affinity for adenosine, which is mainly distributed in the sinoatrial and atrioventricular nodes and the atrial muscle of the heart and can play a role in myocardial protection by regulating oxygen free radicals, heat shock proteins, interleukins and L-type calcium channels (Goldman et al., 2010). Therefore, we highlight the finding that PRP can significantly restore the high gene expression of ADORA1 and thereby play a role in the treatment of arrhythmia.

In this study, the enrichment analysis of KEGG metabolic pathways showed that PRP can regulate a variety of signalling pathways, including the cGMP-PKG signalling pathway, the adrenergic signalling pathway in cardiomyocytes, and the calcium ion signalling pathway. Among these pathways, the cGMP-PKG signalling pathway showed the highest significance and can be regarded as one of the most critical signalling pathways in the PRP-based treatment of arrhythmia. The results of network pharmacology and metabolomics correlation analysis showed that the cGMP-PKG signalling pathway was the most significant, which was consistent with the network pharmacology prediction results, indicating that PRP may participate in the treatment of arrhythmia by

regulating proteins and metabolites in the cGMP-PKG signalling pathway (**Figure 5D**). The adenosine receptor protein ADORA1 is activated and conjugates with the Gi protein to promote the phosphoinositide 3-kinase/protein kinase B (PI3K/Akt) signalling pathway. Studies have shown that the PI3K/Akt/eNOS signalling pathway has myocardial protective effects, such as antioxidative and antiapoptotic effects (Yao et al., 2014; Zhang and Zhang, 2021). NO is a factor that regulates heart relaxation. Its formation process involves L-arginine and nitric oxide synthase (NOS). Following the catalytic synthesis of NO and L-citrulline, calcium ions enter the cell and bind with calmodulin to form a complex to activate eNOS. The resulting NO diffuses into the intercellular space and crosses the membrane of adjacent target cells to activate SGC and convert GTP into cGMP (Silberman et al., 2010). cGMP activates the most important downstream target, PKG I. Activated PKG I acts on its downstream targets to regulate the inositol triphosphate receptor (IP3R) in cardiomyocytes and increase calcium ion regeneration in the sarcoplasmic reticulum, thereby inhibiting platelet activation, reducing cell apoptosis and exerting a negative inotropic effect on cardiomyocytes to protect the cardiovascular system (Zhang et al., 2007). Studies have also shown that the cGMP-PKG signalling pathway plays an important role in the cardioprotective mechanism of pretreatment and posttreatment. It can prevent cell necrosis-induced stress, reduce cell apoptosis and negative inotropic effects on cardiomyocytes, protect the cardiovascular system and reduce the occurrence of arrhythmias (Yu et al., 2018).

In the cGMP-PKG signalling pathway, the metabolites adenosine and cGMP play extremely important roles. In this study, the levels of adenosine and cGMP in zebrafish with arrhythmia were quantitatively determined after various treatments and were shown to be significantly higher in the PRP-treated groups than in the model group. These findings indicated that PRP could increase adenosine and cGMP metabolism, improve heart shape, and reduce the occurrence of arrhythmia in zebrafish. As an anti-arrhythmic drug, adenosine can induce independent potassium currents in the atrioventricular node, reduce the influx of calcium ions, slow atrioventricular conduction and reduce the occurrence of arrhythmia. Studies have indicated that inflammation and oxidative stress can be reduced by increasing adenosine levels and that drugs with such effects exert a protective effect against myocardial ischaemia-reperfusion injury in mice (Zhao et al., 2020a). The metabolite cGMP can activate protein kinase G to activate phosphodiesterase (PDE), cleave cAMP, inhibit the phosphorylation of muscle fibre membrane proteins, and reduce the intake of calcium ions through the cell membrane, thereby protecting the heart. Studies have shown that after administration, the release of cGMP in the isolated hearts of rats with myocardial ischaemia is increased, which inhibits ischaemia-induced cardiac sympathetic hyperactivity and cardiac electrophysiological instability and attenuates arrhythmia (He et al., 2020). Therefore, we believe that PRP can play a role in the treatment of arrhythmia by increasing the

metabolic levels of adenosine and cGMP in the cGMP-PKG pathway.

The main advantage of this study was that we used the methods of network pharmacology and metabolomics correlation analysis to determine the pathways underlying the effects of PRP on arrhythmia and experimentally verified the key target ADORA1 and the main metabolites adenosine and cGMP in the pathway. PRP can interfere with arrhythmia by regulating the protein level of ADORA1 and the metabolic levels of adenosine and cGMP in the cGMP-PKG pathway. The above findings indicated that PRP is a Chinese herbal medicine with great potential for preventing and reducing the occurrence of arrhythmias.

## CONCLUSION

This study used network pharmacology and metabolomics correlation analysis to explain the mechanism of PRP in arrhythmia. The results showed that PRP can significantly improve barium chloride-induced zebrafish cardiac congestion, shorten SV-BA spacing, and reduce myocardial apoptosis. By upregulating the expression level of the ADORA1 target and the metabolic levels of adenosine and cGMP in the cGMP-PKG signalling pathway, PRP plays a role in reducing arrhythmia. Therefore, we believe that PRP shows great potential as an adjuvant for the treatment of arrhythmia.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation, to any qualified researcher.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Laboratory Animal Care and Use Committee of the Shaanxi University of Chinese Medicine.

## AUTHOR CONTRIBUTIONS

Efficacy and Safety of Chinese Patent  
Medicine Combined With Oseltamivir  
in Treatment of Children With Influenza:  
A meta-Analysis.  
Front. Pharmacol. 12:682732.  
doi: 10.3389/fphar.2021.682732

**Background:** Recently, Chinese patent medicines (CPMs) have been widely used to treat children with influenza in China, with curative effects. Therefore, the efficacy and safety of such treatment require further evaluation. The present meta-analysis integrated data from several independent studies to determine overall treatment trends in children with influenza.

**Methods:** The following databases were searched for randomized controlled trials (RCTs) published from their inception to December 12, 2020: CNKI, Wanfang, SinoMed, PubMed, Cochrane library, and Embase. Two researchers independently extracted the data, assessed the methodological quality of the studies, and conducted a meta-analysis of the results using Review Manager 5.2. The results were assessed using forest plots, and publication bias was evaluated using a funnel plot.

**Results:** A total of 21 RCTs involving 2960 cases were included. Compared to oseltamivir alone, CPMs combined with oseltamivir reduced the duration of symptoms, including that of fever (mean difference [MD] = -0.64, 95% confidence interval [CI]: -0.86 to -0.41,  $P < 0.00001$ ), cough (MD = -0.82, 95% CI: -1.02 to -0.62,  $P < 0.00001$ ), nasal obstruction (MD = -0.88, 95% CI: -1.15 to -0.61,  $P < 0.00001$ ), and sore throat (MD = -0.92, 95% CI: -1.26 to -0.57,  $P < 0.00001$ ). Combined therapy also reduced the time of viral shedding (MD = -0.53, 95% CI: -0.70 to -0.36,  $P < 0.00001$ ) and the occurrence of adverse drug reactions (ADRs) (RR=0.53, 95% CI: 0.34 to 0.83,  $P = 0.005$ ).

**Conclusions:** CPMs combined with oseltamivir reduced the duration of symptoms, shortened the time of viral shedding, and reduced the number of ADRs. However, these results should be considered with caution because there was marked heterogeneity and publication bias in the research data. More rigorous RCTs should be designed to verify the effect of CPMs in children with influenza.

**Keywords:** influenza, children, Chinese patent medicine, oseltamivir, meta-analysis

## INTRODUCTION

Influenza is an acute respiratory infectious disease caused by influenza virus. The disease is common worldwide and its main symptoms include fever, cough, nasal congestion, and sore throat (National Health Commission of the People's Republic of China, 2018). During the influenza season, children are particularly vulnerable. According to data from the World Health Organization, the annual incidence of influenza in children ranges from 20 to 30% worldwide. In severe influenza seasons, the annual influenza infection rate in children can be as high as 50% (COMMITTEE ON INFECTIOUS DISEASES, 2018). Generally, children with influenza are treated using oseltamivir, peramivir, or zanamivir, with oseltamivir being the most commonly used (COMMITTEE ON INFECTIOUS DISEASES, 2019). Oseltamivir carboxylate, the active metabolite of oseltamivir, inhibits the neuraminidase activity of influenza virus and reduces transmission by preventing the release of the virus from infected cells. The best effect is achieved when drug treatment is initiated within 24 h of symptom onset. However, influenza virus has gradually developed resistance to oseltamivir (Govorkova et al., 2001; Kiso et al., 2004; Moscona, 2004; Moscona, 2009; Panning, 2013; Lina et al., 2018), and some patients have shown adverse drug reactions (ADRs) (Zhou et al., 2019). Therefore, oseltamivir may not remain a viable treatment for influenza in the long run, and new therapies should be developed to improve influenza treatment in children and reduce the use of antiviral drugs.

In Chinese patent medicines (CPMs), traditional Chinese medicine (TCM) based raw materials are processed into defined dosages and forms according to prescriptions. They are chemically stable; have a definite curative effect with relatively less toxicity and side effects; and can be carried and stored easily (Zhang, 2018). In general, children infected with influenza mostly manifest mild symptoms, such as fever, respiratory symptoms such as cough, sore throat, runny nose, and nasal congestion. A small proportion of children manifest gastrointestinal symptoms, such as nausea, vomiting, and diarrhea. The clinical symptoms of influenza in infants are often atypical. Neonatal influenza is relatively rare, but it can lead to pneumonia and symptoms of sepsis, such as lethargy, refusal to eat, and apnea. Children of different ages present different clinical manifestations at different stages of influenza. Many types of CPMs are used to treat influenza in children at different ages and disease stages (Cao et al., 2015). Such treatments have marked advantages and significant effects, reducing symptoms, shortening the disease course, and reducing complications (Yao et al., 2015; Rong et al., 2017; Wu 2018). Moreover, several RCTs have indicated that CPMs combined with oseltamivir have some curative effects in children with influenza (Xiong et al., 2020). For example, *Xiaoer Chiqiao Qingre* granules are generally used to treat children with symptoms such as fever, cough, nasal congestion, sore throat, and constipation. Evidence shows that *Xiaoer Chiqiao Qingre* granules can improve symptoms in children with acute upper respiratory tract infections and reduce the levels of inflammatory factors in the serum of these children; hence, their use can be

promoted in clinical practice (Wang, 2019). Another study has shown that *Xiaoer Chiqiao Qingre* granules have a significant antipyretic effect in children with viral upper respiratory tract infections, quickening symptom improvement and showing high drug safety (Han et al., 2018). In another investigation, *Lianhua Qingwen* granules combined with oseltamivir have been shown to shorten the time to fever resolution, reduce the duration of symptoms. The children tolerated the combined treatment, hence, they can be used in clinical practice (Wang et al., 2020). *Yinqiao San* consists of Chinese medicines, such as *Lonicera japonica* (Thunb) and *Forsythia suspensa* (Thunb, Vahl). Studies have shown that it has inhibitory effects on various viruses. In animal experiments, it slightly protected mice from influenza A virus infection. Among the 17 chemical components separated from *Yinqiao San*, the main antiviral active components were identified as lignans and flavonoids. Specifically, the active components liquiritin and arctiin have relatively weak antiviral effects, reflecting the synergistic effect of TCM prescriptions (Shi et al., 2003). To a certain extent, the above research conclusions provide evidence for the use of CPMs in the treatment of children with influenza.

As the current clinical evidence is relatively scattered, no systematic evidence is available to support the role of CPMs in influenza treatment. The present study gathered and comprehensively evaluated data from clinical trials to increase the level of evidence and, thus, better evaluate the efficacy and safety of CPMs combined with oseltamivir in the treatment of children with influenza. In brief, we conducted a meta-analysis of the available published clinical evidence.

## METHODS

### Study Registration

This systematic review was registered in the PROSPERO (registration number: CRD42020188184).

### Search Strategy

The following databases were searched from their inception to December 12, 2020: CNKI, Wanfang, SinoMed, PubMed, Cochrane library, and Embase. The following terms were searched in the abstract or title of the study (Influenza, Human OR Human Influenzas OR Influenzas, Human OR Influenza OR Influenzas OR Human Flu OR Flu, Human OR Human Influenza OR Influenza in Humans OR Influenza in Human OR Grippe) AND (Medicine, Chinese Traditional OR Traditional Chinese Medicine OR Traditional Medicine, Chinese OR Zhong Yi Xue OR Chinese Traditional Medicine OR Chinese Medicine, Traditional OR Chinese patent medicine OR Chinese Proprietary Medicine) AND (Oseltamivir OR GS 4104 OR GS4104 OR GS-4104 OR Tamiflu OR GS 4071 OR GS4071 OR GS-4071). We also manually searched for studies that met our inclusion criteria from other sources that were not included in the aforementioned databases. Two researchers (Duan N. F. and Liu B.) independently selected the eligible studies. The studies were retrieved in any language.

## Inclusion and Exclusion Criteria

This systematic review was conducted according to the Preferred Reporting Items for Systematic Review and Meta-Analysis Statement (Moher et al., 2009). The inclusion criteria were as follows: 1) RCT study design; 2) patient age >1 year and <14 years (Cao et al., 2015; Geneva, 2017); 3) treatment group treated using oral CPMs combined with oseltamivir and control group treated with oseltamivir alone; 4) main outcome of time to fever resolution; secondary outcomes of duration of cough, nasal congestion, and sore throat and time of viral shedding; and safety outcome of any ADR; 5) meeting the influenza diagnostic criteria as follows: fever accompanied by acute respiratory symptoms, such as cough, nasal congestion, or sore throat, and positive nucleic acid test results; 6) time of <48 h from symptom onset to randomization (Ma et al., 2015); 7) twice daily oral oseltamivir dosage of 30 mg in patients weighing <15 kg, 45 mg in those weighing 15–23 kg, 60 mg in those weighing 24–40 kg, and 75 mg in those weighing >41 kg; 8) treatment course of 3–7 days (Cao et al., 2015). The exclusion criteria were as follows: 1) other antiviral drugs; 2) CPM injections; 3) outcome data format that failed to meet the requirements of the statistical analysis; 4) missing data on the key outcome of time to fever resolution.

## Data Extraction and Risk of Bias Assessment

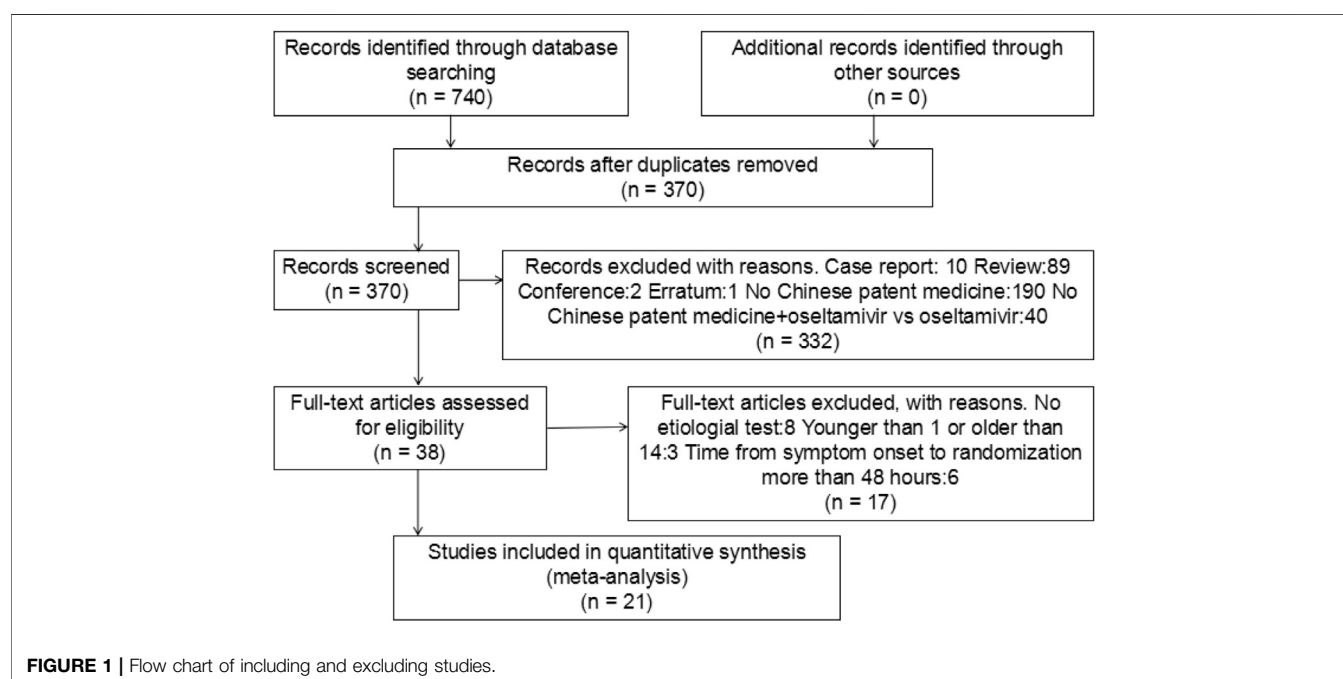

According to standard information extraction tables, two researchers (Duan N. F. and Liu B.) independently extracted the data. Throughout the process, disagreements were resolved by discussion or by involving another researcher (Lu C.). The basic information extracted from the articles included data on authors' names, publication year, published region, type of study design,

virus detection results, number of cases, age, time from symptom onset to randomization, course of treatment, randomization method, patient blinding method, researcher blinding method, inclusion and exclusion criteria, diagnostic criteria, efficacy evaluation criteria, therapeutic schedule, outcome indicators, and ADRs.

Two reviewers (Duan N. F. and Liu B.) independently assessed the risk of bias in each study using the criteria outlined in the *Cochrane Handbook*, (2019). Any disagreements were resolved by discussion or by involving another author (Lu C.). The risk of bias was assessed according to the following domains: 1) random sequence generation; 2) attrition bias; 3) allocation concealments; 4) blinding of participants and personnel; 5) blinding of outcome assessment; 6) incomplete outcome data; 7) selective outcome reporting; 8) other biases. Each potential source of bias was graded as high, low, or unclear, providing a quote from the study report and a justification of our judgment in the “risk of bias” table. In the table, red represents high risk, yellow represents unclear risk, and green represents low risk. We also added notes in the table when information on the risk of bias was related to unpublished data or correspondence with a trial author. When evaluating treatment effects, we considered the risk of bias in studies that contributed to the outcome.

## Data Synthesis and Analysis

Review Manager 5.2 software was used to produce the risk of bias summary and calculate a summary statistic for each outcome in the meta-analysis. Risk ratios (RRs), Mantel-Haenszel tests, and 95% confidence intervals (CI) were used to analyze dichotomous data. Mean difference (MD), inverse variance, and 95% CI were used to determine continuous variables. The  $I^2$  values ranged from 0 to 100% and were categorized as follows:  $I^2 < 40\%$ , might

Notes:

The "+" means positive for the influenza virus.

The outcomes are time of defervescence, the easing time of cough, the easing time of nasal obstruction, the easing time of sore throat, the time of viral shedding and adverse reactions, that are denoted by "A" "1" "2" "3" "4" and "5" respectively.

not be important; 30% <  $I^2$  < 60%, moderate heterogeneity; 50% <  $I^2$  < 90%, substantial heterogeneity; and 75% <  $I^2$  < 100%, considerable heterogeneity (Higgins and Green, 2011). A fixed-effect model was used to pool the estimates. Potential sources of heterogeneity were identified using subgroup and sensitivity analyses. A random effects model was used to aggregate the results and, thus, minimize potential clinical heterogeneity. Differences were considered statistically significant at  $p$ -values of <0.05. We conducted a subgroup analysis of each CPM (Chinese patent medicine). The results are presented as forest plots. A funnel chart was used to analyze publication bias.

## RESULTS

### Search Results and Study Characteristics

A total of 740 studies were identified using the search strategy, including 160 from CNKI, 284 from Wanfang, 194 from SinoMed, 14 from PubMed, 4 from the Cochrane library, and 84 from embase. Of these 370 duplicate studies were excluded, and 332 more studies were excluded after abstract review. Of the remaining 38 studies, 17 were excluded after full text review. Ultimately, 21 RCTs involving 2,960 cases were included (Song and Zhang, 2018; Zhang, B. Y. et al., 2018; Zhang, Y. H. et al., 2018; Su, 2019; Yin, 2019; Zhou, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Chen et al., 2019; Li, 2019; Yan, 2020; Zhu et al., 2019; Liu et al., 2020; Fang, 2018; Liu, 2018; Gao and Wang, 2020; Kuang and Wang, 2020; Du et al., 2020). The flowchart of the screening process is presented in **Figure 1**. Two researchers independently extracted the data from the literature. There were 1,485 and 1,475 cases in the treatment and control groups, respectively. All 21 RCTs were published in China and included seven kinds of CPMs: *Xiaoer Chiqiao Qingre* granules, *Kanggan* granules, *Lianhua Qingwen* granules, *Xiaoer Resuqing* granules (oral liquid), *Xiaoer Shuanghuanglian* mixture, *Siji Kangbingdu* mixture, and *Xiaoer Niu Huang Qingxin* powder. The data were published between 2018 and 2020. All cases tested positive for influenza virus. The treatment course was 3–7 days. Nine studies reported ADRs (Zhang, B. Y. et al., 2018; Yin, 2019; Zhou, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Gao and Wang, 2020). The baseline characteristics were consistent across the studies. The detailed characteristics of the studies are presented in **Table 1**.

### Methodological Quality Assessment

Assessment of the risk of bias in the 21 trials (**Figure 2**) showed that all studies implemented randomized grouping, 12 trials used random number tables, while the remaining nine trials did not report a specific random allocation method. One study (Zhou, 2019) used a blinding method, but it was unclear whether single or double blinding was implemented. The remaining studies did not provide blinding information. Regarding allocation concealment, 12 studies used a random number table method (Zhang, B. Y. et al., 2018; Su, 2019; Zhao et al., 2019; Long, 2020; Chen et al., 2019; Zhu et al., 2019; Liu et al., 2020; Fang, 2018; Liu, 2018; Gao and Wang, 2020; Kuang and Wang, 2020; Du et al.,

**FIGURE 2** | Assessment of risk of bias in the 21 trials.

2020), but it was unclear whether the randomly assigned researchers and allocation concealment researchers were third-party personnel. Therefore, the studies were rated as having an unclear risk. The remaining studies were also rated as having an unclear risk. With regard to incomplete outcome data and selective reporting, seven studies reported the results according to preset outcome indicators and were, thus, rated as having a low risk (Fang, 2018; Song and Zhang, 2018; Chen et al., 2019; Su, 2019; Zhao et al., 2019; Zhou, 2019; Zhu et al., 2019). The remaining studies failed to clarify whether the outcome indicators were established in advance and were, therefore, rated as having an unclear risk. With regard to other biases, one study was suspected of reporting plagiarized data and, therefore, was rated as having a high risk. The remaining studies showed no obvious other biases and, thus, were rated as having a low risk.

## Primary Outcome

### Time to Fever Resolution

Nineteen studies involving 2,700 cases reported the time to fever resolution (Song and Zhang, 2018; Zhang, B. Y. et al., 2018; Zhang, Y. H. et al., 2018; Su, 2019; Yin, 2019; Zhou, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Chen et al., 2019; Li, 2019; Zhu et al., 2019; Liu et al., 2020; Fang, 2018; Gao and Wang, 2020; Kuang and Wang, 2020; Du et al., 2020). The forest plot showed significant differences between the treatment and control groups (MD = -0.64, 95% CI: 0.86 to -0.41,  $p < 0.00001$ ; **Figure 3**). The heterogeneity was high ( $I^2 = 99\%$ ,  $p < 0.00001$ ). A random effects model was used to analyze the data.

## Secondary Outcomes

### Duration of Cough

Fourteen studies involving 1876 cases reported the duration of cough (Song and Zhang, 2018; Zhang, B. Y. et al., 2018; Su, 2019; Yin, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Zhu et al., 2019; Liu et al., 2020; Liu, 2018; Gao and Wang, 2020; Kuang and Wang, 2020; Du et al., 2020). The forest plot (**Figure 4**) showed significant differences between the treatment and control groups (MD = -0.82, 95% CI: 1.02 to

-0.62,  $p < 0.00001$ ), and the heterogeneity was high ( $p < 0.00001$ ,  $I^2 = 94\%$ ). The random effects model was used to analyze the data.

### Duration of Nasal Congestion

Eleven studies involving 1,245 cases reported the duration of nasal congestion (Zhang, B. Y. et al., 2018; Su, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Yan, 2020; Liu, 2018; Kuang and Wang, 2020; Du et al., 2020). The forest plot (**Figure 5**) showed significant differences between the treatment and control groups (MD = -0.88, 95% CI: 1.15 to -0.61,  $p < 0.00001$ ), and the heterogeneity was high ( $I^2 = 96\%$ ,  $p < 0.00001$ ). The random effects model was used to analyze the data.

### Duration of Sore Throat

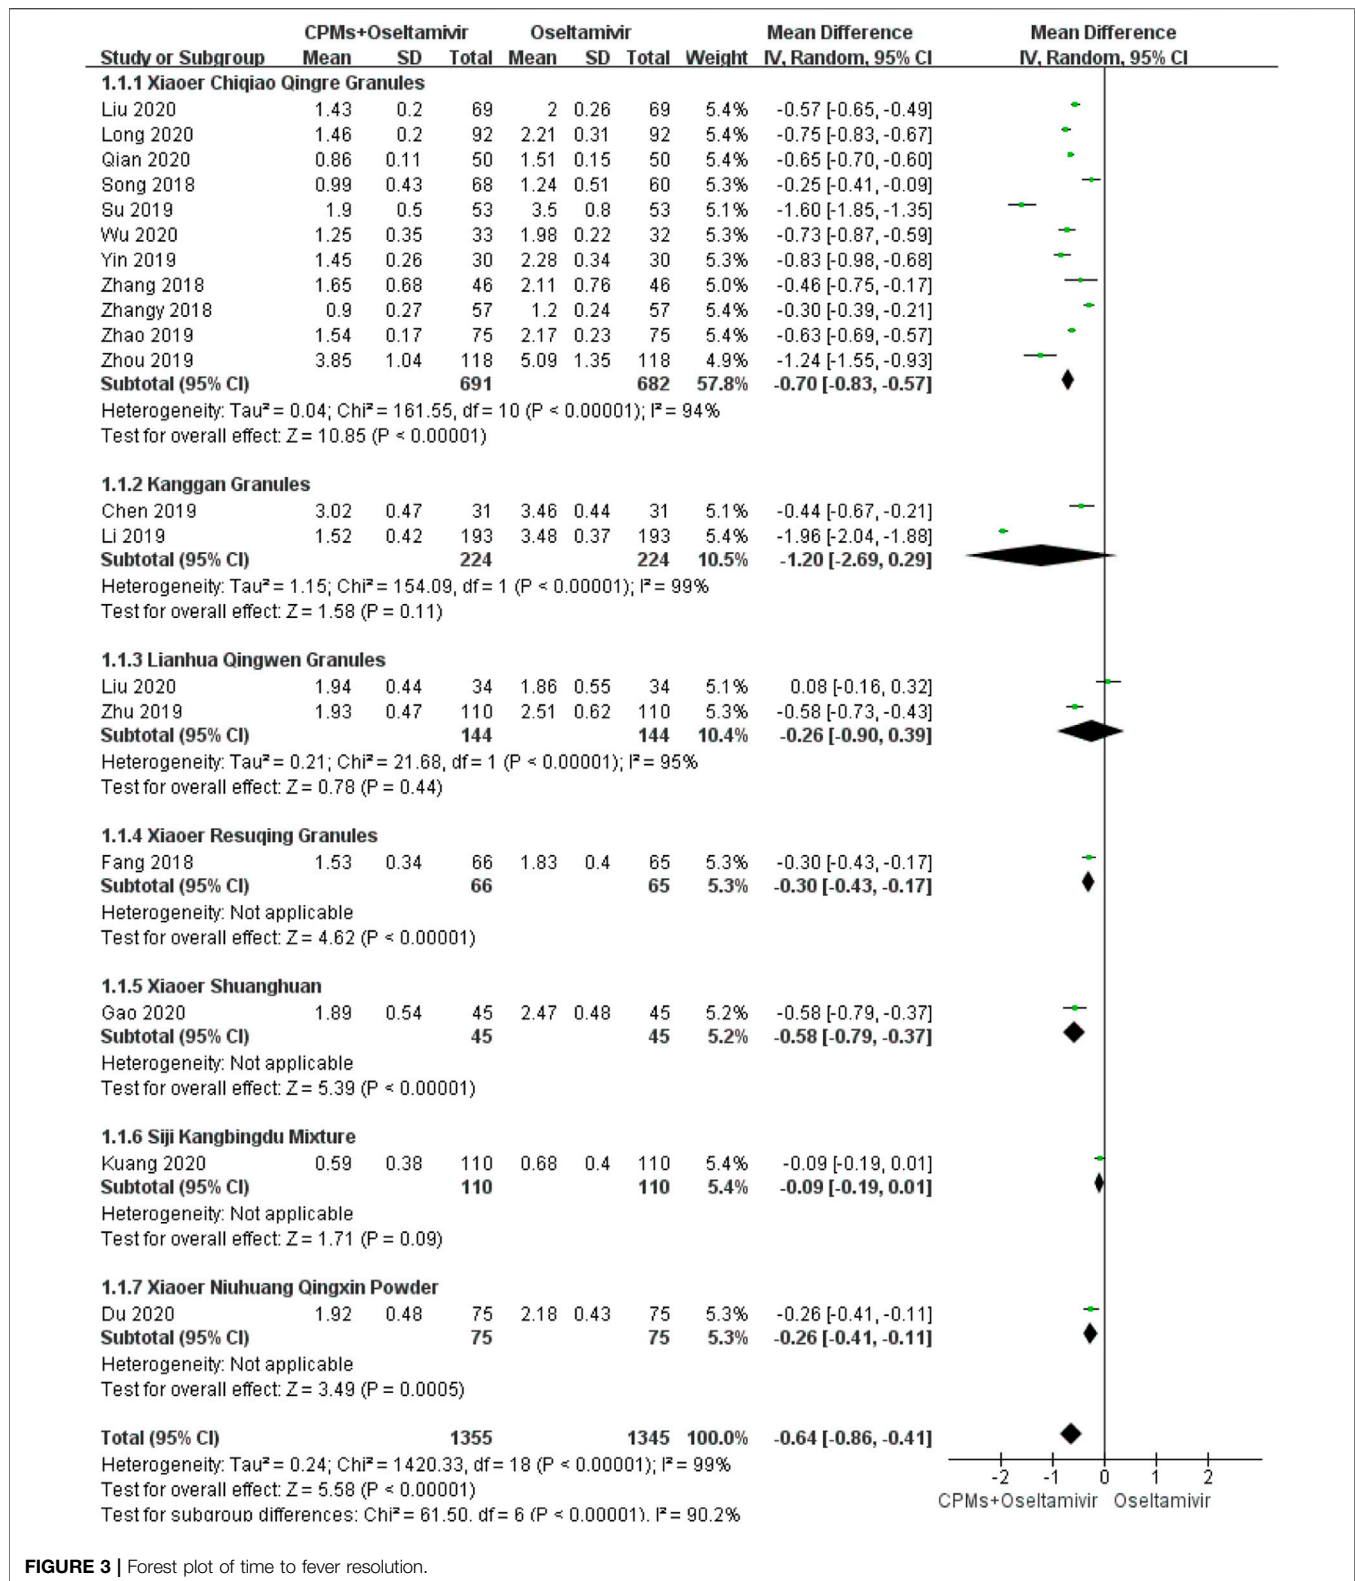

Eleven studies involving 1,365 cases reported the duration of sore throat (Song and Zhang, 2018; Zhang, B. Y. et al., 2018; Yin, 2019; Long, 2020; Liu, 2020; Wu, 2020; Yan, 2020; Zhu et al., 2019; Liu, 2020; Liu, 2018; Du et al., 2020). The forest plot (**Figure 6**) showed significant differences between the treatment and control groups (MD = -0.92, 95% CI: 1.26 to -0.57,  $p < 0.00001$ ), and the heterogeneity was high ( $I^2 = 98\%$ ,  $p < 0.00001$ ). The random effects model was used to analyze the data.

### Time of Viral Shedding

Three studies involving 626 cases reported the time of viral shedding (Liu, 2018; Zhou, 2019; Zhu et al., 2019). The forest plot (**Figure 7**) showed significant differences between the treatment and control groups (MD = -0.53, 95% CI: 0.70 to -0.36,  $p < 0.00001$ ). The heterogeneity was low ( $I^2 = 15\%$ ,  $p = 0.31$ ); therefore, we used the fixed effects model to analyze the data.

## Safety Analysis: ADRs

Nine studies involving 1,115 cases reported ADRs (Zhang, B. Y. et al., 2018; Yin, 2019; Zhou, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Gao and Wang, 2020). The forest plot (**Figure 8**) showed significant differences between the treatment and control groups (RR = 0.53, 95% CI: 0.34 to 0.83,  $p = 0.005$ ). There was no heterogeneity ( $I^2 = 0\%$ ,  $p = 0.81$ ); therefore, we used the fixed effects model to analyze the data.

**FIGURE 3 |** Forest plot of time to fever resolution.

## Subgroup Analysis

We conducted a subgroup analysis of each CPM. There were subgroup differences in terms of time to fever resolution (90.2%), duration of cough (92.4%), nasal congestion (93%), and sore

throat (81.5%). Regarding time to fever resolution, 11 studies were included in the *Xiaoeer Chiqiao Qingre* granules subgroup, with 94% heterogeneity within the subgroup, two studies were included in the *Kanggan* granules subgroup, with 99%

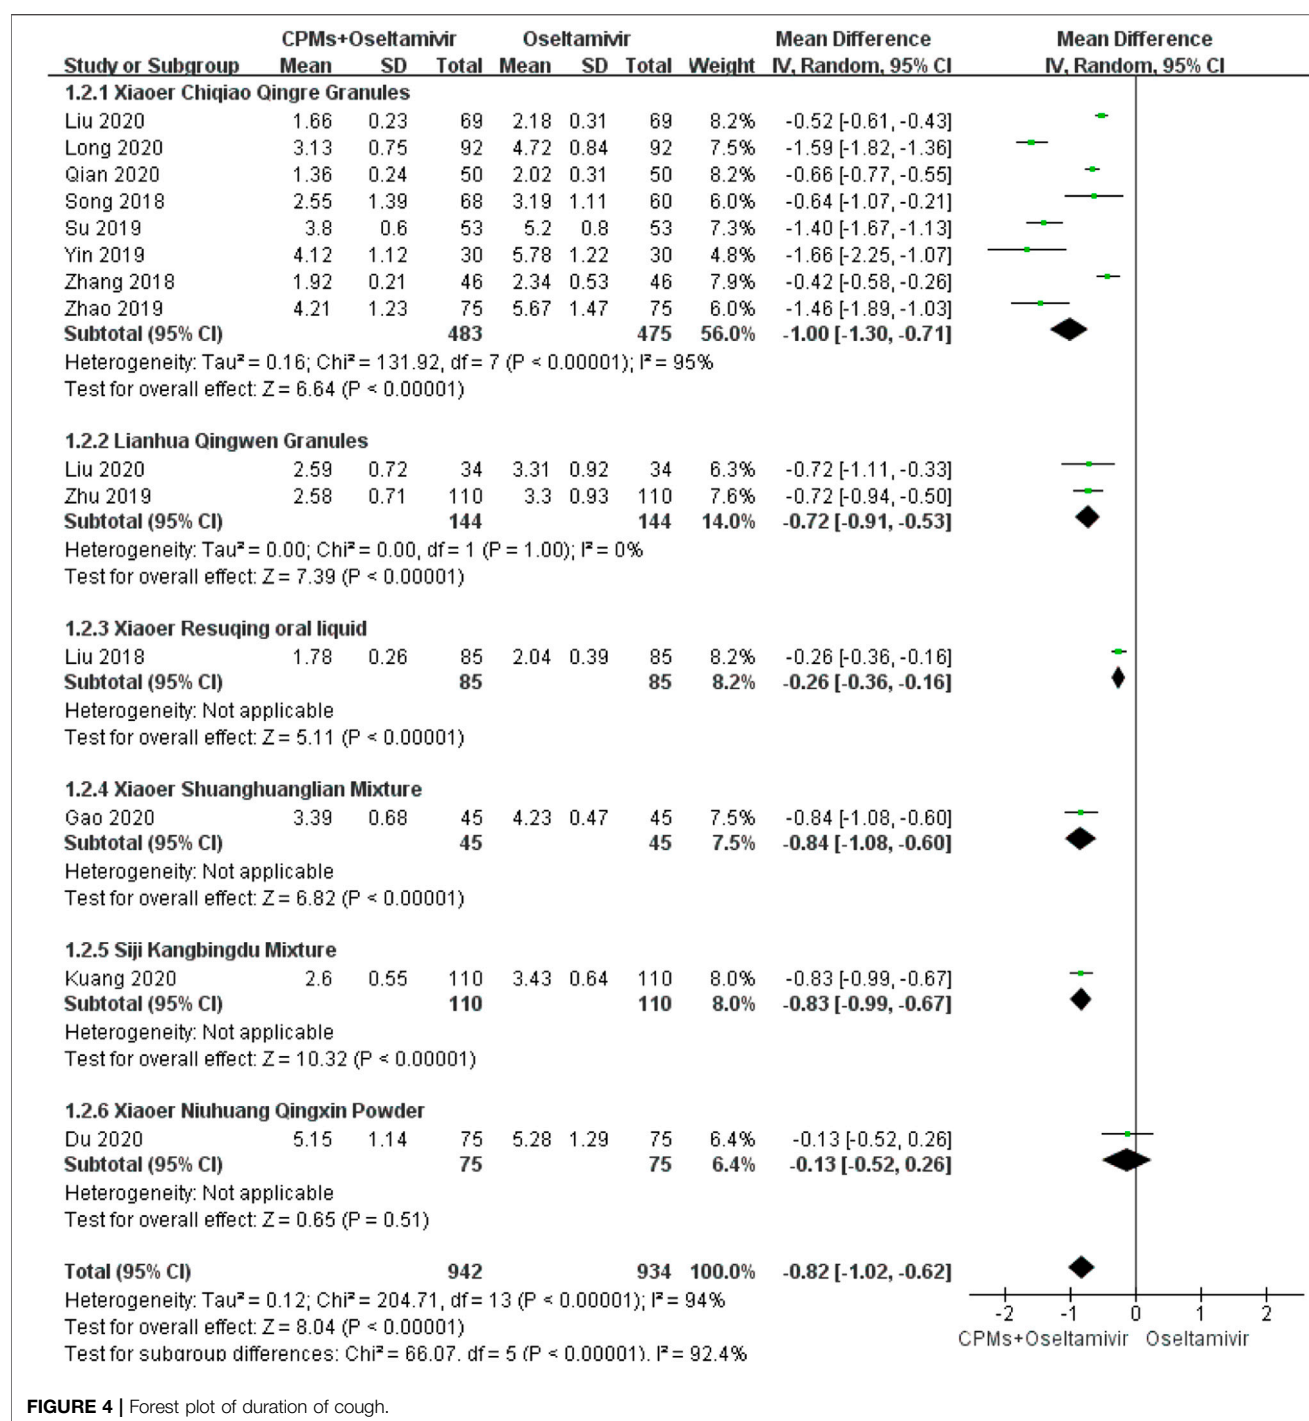

FIGURE 4 | Forest plot of duration of cough.

heterogeneity within the subgroup, and two were included in the *Lianhua Qingwen* granules subgroup, with 99% heterogeneity within the subgroup. Regarding duration of cough, eight studies were included in the *Xiaoei Chiqiao Qingre* granules subgroup, with 95% heterogeneity within the subgroup, and two studies were included in the *Lianhua Qingwen* granules subgroup, with 0% heterogeneity within the subgroup. Regarding duration of nasal congestion, seven studies were included in the *Xiaoei Chiqiao Qingre* granules subgroup, with 96% heterogeneity

within the subgroup. Regarding duration of sore throat, six studies were included in the *Xiaoei Chiqiao Qingre* granules subgroup, with 99% heterogeneity within the subgroup. The remaining subgroups had only one study each, hence, within-group heterogeneity could not be analyzed.

## Sensitivity Analysis

Sensitivity analysis was performed to investigate potential sources of heterogeneity by observing changes in data after deletion of

FIGURE 5 | Forest plot of duration of nasal congestion.

individual studies one by one. With regard to fever, cough, nasal congestion, and sore throat, the heterogeneity remained >90% after removal of individual studies one by one (details are shown in **Supplementary Table 2**). The heterogeneity results did not change significantly.

## Evaluation of Publication Bias

Time to fever resolution was used as the outcome; 19 studies were included (Song and Zhang, 2018; Zhang, B. Y. et al., 2018; Zhang, Y. H. et al., 2018; Su, 2019; Yin, 2019; Zhou, 2019; Zhao et al., 2019; Long, 2020; Liu, 2020; Qian, 2020; Wu, 2020; Chen et al., 2019; Li, 2019; Zhou, 2019; Liu, 2020; Fang, 2018; Gao and Wang, 2020; Kuang and Wang, 2020; Du et al., 2020), and the effect size MD was used as the horizontal axis to create a funnel chart (**Figure 9**). The graph was not completely symmetrical, indicating the possibility of publication bias.

## DISCUSSION

In the present meta-analysis, the MD values for fever, cough, nasal congestion, sore throat, and viral shedding were >0.5, as shown in the forest plots, indicating that the combination of drugs shortened the course of influenza by 0.5 days. The above

data reflects the trend of time reduction. In terms of ADRs, the RR was 0.53, indicating that the combination of drugs can reduce ADRs by half (Dobson et al., 2015). These results showed that, compared with oseltamivir alone, CPMs combined with oseltamivir shortened the time to fever resolution, shortened the time of symptom relief, shortened the time of viral shedding, and reduced the occurrence of ADRs, indicating that CPMs play an active role in the treatment of influenza in children. But due to the uneven quality of the current research, it will affect the reliability of the results. In order to get more accurate recommendations, we need more clinical data in the future.

However, the four outcomes of fever, cough, nasal congestion, and sore throat showed high heterogeneity. Different CPMs have different drug compositions and treatment directions, which may lead to high clinical heterogeneity (Hu et al., 2010). Therefore, we take each CPM as a subgroup and performed subgroup analysis to observe the level of heterogeneity. Differences were high among the subgroups, and subgroup analysis did not reduce the heterogeneity, possibly because there was uneven distribution among the subgroups in terms of the number of studies and cases. Except for the *Xiaoe Chiqiao*

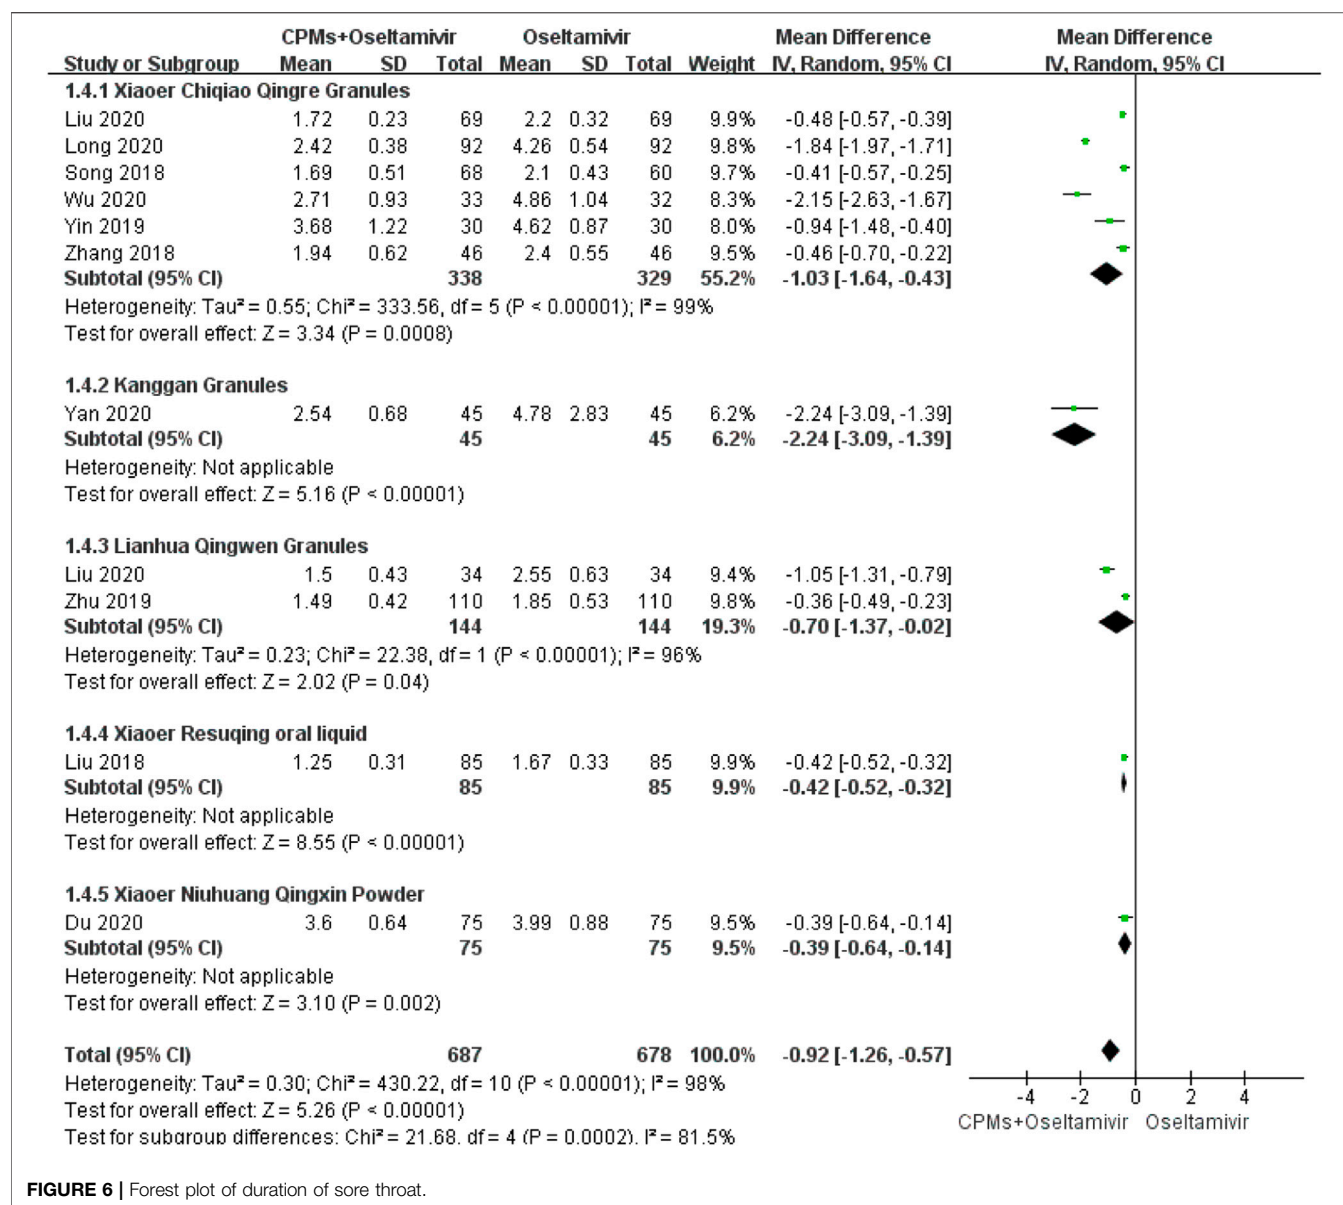

FIGURE 6 | Forest plot of duration of sore throat.

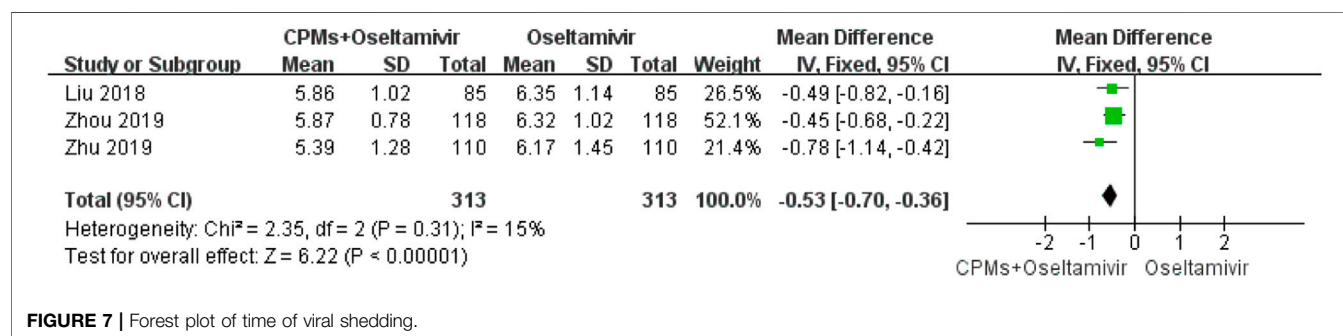

FIGURE 7 | Forest plot of time of viral shedding.

FIGURE 8 | Forest plot of ADRs.

FIGURE 9 | Funnel plot of time to fever resolution.

*Qingre* granules, *Kanggan* granules, and *Lianhua Qingwen* granules subgroups, all subgroups only included one study each; therefore, further comparative studies are needed to further evaluate the sources of heterogeneity. In the *Xiaoei Chiqiao Qingre* granules subgroup, which included the largest number of studies and cases, the heterogeneity was high. Taking time to fever resolution as an example, there were 11 studies in the *Xiaoei Chiqiao Qingre* granules subgroup, and the heterogeneity within the group was high ( $p < 0.00001$ ,  $I^2 = 94\%$ ), possibly because the statistical unit of the outcome was time; hence, it was possible that the statistician could not accurately measure time data or that the children could not accurately express their own feelings, misleading the statistician's judgment. Some studies did not clearly indicate whether the child was

hospitalized. Moreover, when children's data are reported by the family, the error is greater, resulting in inaccurate data (Kang et al., 2000).

We attempted to identify another source of heterogeneity. By contrast detailed characteristics of included studies, it was found that the reason for the large heterogeneity maybe due to the difference in age range and the fluctuation range of the time from onset of symptoms to randomization (Wang et al., 2009; Wang et al., 2008). The age range in the present study was 1–14 years, and the time from symptom onset to randomization was <48 h. Children of different ages have different immunity, and the time of appearance and disappearance of symptoms after infection also differs. Such a large age and time span may lead to greater data differences and increased heterogeneity. Therefore, we analyzed subgroups stratified according to age. However, in the included

studies, the average age of the patients was concentrated in the 5–10 years age range, and the standard deviation values of age were uneven; hence, accurate grouping was not possible (details are shown in **Supplementary Figure 10**). We also planned to use time from symptom onset to randomization in subgroup analysis, but the average time was concentrated around 24 h, and the standard deviation values were uneven in some cases; hence, accurate grouping could not be performed (details are shown in **Supplementary Figure 11**). For both sets of data, age and time from symptom onset to randomization, the values recorded in the studies were averages; hence, we could not determine the number of cases in each age subgroup and the specific time from symptom onset to randomization. More detailed information could not be obtained from the original text of each study, and no reply was received after sending the email. Both the above factors may have led to greater heterogeneity, the source of which could not be clarified. Later, we conducted sensitivity analysis and found that the heterogeneity results lacked significant changes, indicating that the included studies were relatively stable, but also that no source of heterogeneity was found. Finally, the four outcomes were combined using the random effects model. Finally, the four outcomes are combined using a random effects model. The main reason is that the RCTs of each study are not rigorous in the details of certain links. Future RCTs of children should be divided into age groups as much as possible. Every RCT should be registered. The test process and details have been carefully described to make the research more accurate and rigorous (Li et al., 2007; Liu and Xia, 2007).

To assess methodological quality, we tried to contact the corresponding authors of each study by phone or email to inquire about the details of the trials, but we did not receive responses. Therefore, it was unclear whether strict operating procedures, such as allocation concealment and blinding methods, were used during the tests. The methodological quality of the included studies was poor; therefore, the reliability of the results is questionable and it is unclear whether the studies were actual RCTs (Tang et al., 1999; Moher et al., 2009).

A comprehensive analysis of the funnel chart results revealed publication bias. There were gaps in the upper left and lower right corners of the graph, indicating that some negative results were not published. In a further search for unpublished studies, we found no unpublished negative results in previous studies, possibly because there is a lack of awareness of registration in clinical research or because there are limited studies on this subject, making it impossible to obtain comprehensive evidence and, thus, leading to publication bias.

The composition of CPMs is diverse (details are shown in **Supplementary Table 3**), and different ingredients act through different mechanisms in the human body. The combination of modern biomedical technology and TCM has shown a synergistic effect. Using omics and network pharmacology theory, researchers have gradually discovered the mechanisms of some Chinese medicines. Both *Lonicera japonica* (Thunb) and *Forsythia suspensa* (Thunb, Vahl) have significant synergistic benefits, conferring antipyretic and anti-free radical damage

effects and improving immunity (Duan and Ma, 2009; Zhou et al., 2015). The mechanisms underlying the antipyretic effects of *Bupleurum chinense* (DC) and *Scutellaria baicalensis* Georgi are regulation of PGE2 and cAMP and inhibition of the synthesis or release of the endogenous pyrogens TNF- $\alpha$  and  $\beta$ -EP (Yang, 2012; Zhu et al., 2015; Yao et al., 2018). *Forsythia suspensa* (Thunb, Vahl) has been shown to have antipyretic effects (Wang and Zhao, 2010). One experiment confirmed that phillyrin, the active ingredient of *Forsythia suspensa* (Thunb, Vahl), can inhibit influenza A virus infection, most likely by downregulating a certain gene (Duan et al., 2012). Baicalin combined with phillyrin can downregulate the expression of the influenza A virus nucleoprotein gene transfected into HeLa cells, and it showed a synergistic effect within a certain concentration range (Huang et al., 2018). Studies have found that (R, S)-goitrin in *Isatis tinctoria* L inhibits influenza virus replication by increasing the production of IFN- $\beta$  and interferon-induced transmembrane 3 (Luo et al., 2019). Modern pharmacological studies have found that *Isatis tinctoria* L has anti-inflammatory, anti-viral, antipyretic, and immunity enhancement effects, and is often used clinically to treat various infections, such as pharyngitis and tonsillitis (Yang, 2016). Studies have shown that the effect of *Platycodon grandiflorus* (Jacq.) A.DC in reducing phlegm and relieving cough is positively correlated with the content of platycodin (Xie et al., 2019). Platycodin capsules can reduce the frequency of cough and asthma, and increase the excretion of phenol red in the respiratory tract. The excretion of phenol red can indirectly reflect the amount of secretion in the respiratory tract. At this time, the amount of secretion in the respiratory tract increases, which is conducive to thinning the thick sputum attached to the respiratory tract mucosa, making it easier to fall off from the airway wall, which has the effect of reducing phlegm and relieving cough (Jin and Chen, 2015). Studies have shown that pulegone, the active ingredient of *Nepeta tenuifolia* Benth, has a good anti-inflammatory protective effect on Lipopolysaccharide poisoning model mice, which can inhibit the release of inflammatory factors and reduce inflammatory cell infiltration. The mechanism of its anti-inflammatory effect is related to the intervention and regulation of the activation of NLRP3 inflammasome (Wen, 2017). When influenza virus is combined with bacterial infection, combined prescription drugs can show the therapeutic advantage. The six CPMs included in the present study contain *Forsythia suspensa* (Thunb, Vahl). Among them, *Lianhua Qingwen* granules, *Xiaoer Resuqing* granules, and *Xiaoer Shuanghuanglian* mixture use *Lonicera japonica* (Thunb) and *Forsythia suspensa* (Thunb, Vahl) in combination. *Xiaoer Chiqiao Qingre* granules and *Xiaoer Resuqing* granules use *Bupleurum chinense* (DC) and *Scutellaria baicalensis* Georgi in combination. The drug composition of *Lianhua Qingwen* granules and *Xiaoer Resuqing* granules contains *Isatis tinctoria* L. *Nepeta tenuifolia* Benth is contained in the medicine composition of both *Xiaoer Chiqiao Qingre* granules and *Siji Kangbingdu* Mixture. By combining ancient theory and modern technology, researchers can possibly clarify the drug mechanisms of TCM, thereby guiding treatment with clinical prescription drugs.

In future clinical practice, combination medications may provide new ideas to treat children with influenza, promoting the use of CPMs and TCM for this purpose (Ru et al., 2017; Gao and Wang, 2018; Liu et al., 2019). They are especially effective at shortening the time to fever resolution and relieving the symptoms of influenza (Wang et al., 2010; Duan et al., 2011; Wang et al., 2011; He et al., 2019; Yoshino et al., 2019). This is consistent with the conclusions of the present study.

## CONCLUSION

In conclusion, the present meta-analysis demonstrated the efficacy and safety of CPMs combined with oseltamivir in the treatment of children with influenza. It provides evidence that combination therapy can be used to treat children with influenza. However, because most of the studies included in this analysis were of low quality and the analysis results showed high heterogeneity, there is no strong evidence to support this conclusion, which needs to be verified in future high-quality, well-designed, multi-center RCTs. At the same time, future studies should focus on improving objectivity in outcome measurements and methodological quality by adopting a rigorous experimental design. In future clinical research, the publication of RCTs should follow strict registration procedures, and standards should be unified as much as possible.

Sepsis is a dysregulated systemic response to infection, and no effective treatment options are available. Acacetin is a natural flavonoid found in various plants, including *Sparganii rhizoma*, *Sargentodoxa cuneata* and *Patrinia scabiosifolia*. Studies have revealed that acacetin potentially exerts anti-inflammatory and antioxidative effects on sepsis. In this study, we investigated the potential protective effect of acacetin on sepsis and revealed the underlying mechanisms using a network pharmacology approach coupled with experimental validation and molecular docking. First, we found that acacetin significantly suppressed pathological damage and pro-inflammatory cytokine expression in mice with LPS-induced fulminant hepatic failure and acute lung injury, and *in vitro* experiments further confirmed that acacetin attenuated LPS-induced M1 polarization. Then, network pharmacology screening revealed EGFR, PTGS2, SRC and ESR1 as the top four overlapping targets in a PPI network, and GO and KEGG analyses revealed the top 20 enriched biological processes and signalling pathways associated with the therapeutic effects of acacetin on sepsis. Further network pharmacological analysis indicated that gap junctions may be highly involved in the protective effects of acacetin on sepsis. Finally, molecular docking verified that acacetin bound to the active sites of the four targets predicted by network pharmacology, and *in vitro* experiments further confirmed that acacetin significantly inhibited the upregulation of p-src induced by LPS and attenuated LPS-induced M1 polarization through gap junctions. Taken together, our results indicate that acacetin may protect against sepsis via a mechanism involving multiple targets and pathways and that gap junctions may be highly involved in this process.

**Keywords:** sepsis, acacetin, network pharmacology, molecular docking, macrophage

## INTRODUCTION

Sepsis is a severe systemic inflammatory response to microbial infection, and lipopolysaccharide (LPS) is well known to induce this phenomenon (Chen et al., 2020). D-Galactosamine (GalN)-sensitized mice administered LPS and mice administered only LPS by intratracheal instillation are recognized as promising experimental models of fulminant hepatic failure (FHF) and acute lung injury (ALI) (Zhang et al., 2019; Liu et al., 2020a). Macrophage polarization is involved in the pathogenesis of sepsis, an uncontrolled inflammatory response caused by infection or acute insult (Fan et al., 2020). Excessive M1 polarization may lead to exacerbated inflammatory reactions and initiate injury in the host.

Acacetin (5,7-dihydroxy-40-methoxyflavone), an O-methylated flavone monomer, is a bioactive constituent found in various plants, including *Sparganii rhizoma*, *Sargentodoxa cuneata* and *Patrinia scabiosifolia* (Hu et al., 2020; Lu et al., 2021). Acacetin has diverse biological functions, including anti-inflammatory, antioxidant, and anti-microbial activity, and exerts protective effects on cardiac tissue and neurons (Singh et al., 2020). Various studies have reported the anti-inflammatory activity of acacetin *in vitro* and *in vivo*. For example, acacetin was shown to attenuate ALI in LPS-induced mice *via* augmenting haem oxygenase-1 (HO-1) activity (Sun et al., 2018) and to protect against GalN/LPS-induced liver injury by suppressing the TLR4 signalling pathway (Cho et al., 2014). Moreover, acacetin strongly inhibited the expression of the pro-inflammatory cytokines inducible nitric oxide synthase (iNOS) and COX-2 in LPS-activated RAW264.7 cells and in a mouse model of tetradecanoyl phorbol acetate (TPA)-induced tumours (Pan et al., 2006). These results suggest that acacetin ameliorates sepsis by inhibiting inflammation and promoting redox homeostasis, but the underlying molecular mechanism remains unclear.

Network pharmacology is an effective method for screening drug-disease targets and for predicting the possible underlying mechanisms *via* bioinformatics analyses (Li et al., 2020; Xia et al., 2020; Zhang et al., 2021). For example, acacetin was shown to be a bioactive compound in *Sparganii rhizoma*, which has anti-gastric cancer activity as determined by network pharmacology analysis (Lu et al., 2021). Acacetin is also the active ingredient in *Sargentodoxa cuneata* and *Patrinia scabiosifolia*, which improve pelvic inflammatory diseases related to dampness-heat stasis syndrome as determined by network pharmacology analysis (Hu et al., 2020). In this study, we investigated the potential targets of acacetin in subjects with sepsis and predicted the underlying mechanisms by network pharmacology coupled with molecular docking and experimental validation.

## MATERIALS AND METHODS

### Reagents

Acacetin (MedChemExpress, molecular weight: 284.26 g/mol), LPS (Sigma, 055:B5, L2880), and Gap27 (MedChemExpress) were used in the experiments.

## Animals and Model Treatment

Healthy male C57BL/6 mice (8–12 weeks old, 24–26 g) were purchased from the Animal Experimental Centre of the Fourth Military Medical University, China. All mice were bred in a specific pathogen-free animal facility at the Department of Biochemistry and Molecular Biology, School of Basic Medical Science, Xi'an Jiaotong University Health Science Center. All animal experiments were approved by the Institutional Animal Ethics Committee of Xi'an Jiaotong University (no. 2017–666). All animal experiments were performed in accordance with standard animal research guidelines. C57BL/6 mice were randomly assigned to one of six groups ( $n = 5$ ): the control group, acacetin treatment group, LPS-induced ALI model group, LPS + acacetin treatment group, LPS/GalN-induced FHF model group and LPS/GalN + acacetin treatment group. ALI was induced by the intratracheal injection of LPS (5 mg/kg) (Zhang et al., 2019), and FHF was induced by the intraperitoneal injection of GalN (800 mg/kg) and LPS (40 µg/kg) (Liu et al., 2020a). An equivalent amount of PBS was administered to mice in the control group. Two hours before the intraperitoneal injection of acacetin (50 mg/kg) to the solvent comparison and treatment groups, acacetin was dissolved in 5% core oil. The mice were sacrificed at 10 h after ALI modelling and at 6 h after FHF modelling.

## Histology

The lung and liver tissues were collected and fixed in a 4% paraformaldehyde solution for 48 h. The tissues were dehydrated, embedded in paraffin, and sliced into 5 µm-thick sections. The sections were stained with haematoxylin and eosin (H & E) reagent and visualized under a light microscope.

## ELISA

To assess the effects of acacetin on pro-inflammatory mediators, appropriate ELISA kits (Jioin, Shanghai, China) were used. The levels of the pro-inflammatory mediators TNF-α, IL-6, and IL-1β in lung and liver homogenates from LPS-induced mice were measured.

## Cell Culture

RAW264.7 macrophages were obtained from academician Rikard Holmdahl (Sweden Medical Inflammation Research of the Karolinska Institute). The cells were cultured in a thermostatic incubator at 37°C and 5% CO<sub>2</sub>. This cell line, used to screen for molecular mechanisms, was cultured in DMEM (Gibco, Thermo Fisher Scientific, Inc.) supplemented with 10% FBS (Gibco, Carlsbad, CA, United States) and 1% streptomycin/penicillin. The cells were passaged when they reached 70–80% confluence.

## MTT Assay

RAW264.7 cells were cultured in a 96-well plate at  $5 \times 10^3$  cells/well. Cells in the treatment groups were administered different amounts of acacetin (1, 5, and 10 µMol) dissolved in DMSO, while those in the model group were administered LPS (100 ng/ml), and those in the control and blank (no cells) groups were administered an equivalent amount of medium before growth for an additional 24 h. Then, MTT solution was added and

continuously incubated at 37°C for 4 h. The medium in each well was discarded, after which 150 µl of DMSO was added, and the cells were shocked on a microvibrator for 5 min. The optical density at 490 nm was determined with a plate reader (VICTOR X5, PerkinElmer, MA, United States).

## Flow Cytometry

The experimental groups were divided into a control group, an LPS model group, and treatment groups that were administered different amounts of acacetin (1, 5, 10 µMol). Groups other than the control and LPS model groups were pre-treated with acacetin for 4 h and then stimulated with LPS (100 ng/ml) for 24 h. Flow cytometry was performed on single-cell suspensions of RAW264.7 macrophages. For intracellular staining, cells were fixed and permeabilized using BD Cytotfix/Cytoperm solution (BD Biosciences, NJ, United States). The following monoclonal antibodies were used: the M1-type surface markers CD86-PE (1:150; BD Biosciences, NJ, United States) and iNOS-PEcy7 (1:150; BD Biosciences, NJ, United States). Samples were measured by flow cytometry (Guava, Millipore), and the data were analysed using Flow Jo software (TreeStar Inc., OR, United States).

## Western Blotting

The cell grouping, stimulation, and culture were carried out as described for the flow cytometry experiment. The cells were harvested and lysed with radioimmunoprecipitation assay (RIPA) buffer and phenyl methyl sulfonyl fluoride (PMSF), and the protein content was confirmed by the BCA method. Equivalent amounts of protein from each sample were loaded onto 10% SDS-PAGE gels and then transferred onto PVDF membranes (EMD Millipore, CA, United States). After being blocked with 10% skimmed milk for 2 h, the blots were probed with the following primary antibodies: CD86 (1:1,000; cat. no. ab53004; Abcam), iNOS (1:800; cat. no. ab15323; Abcam), p65 (1:1,000; cat. no. ab16502; Abcam), p-p65 (1:1,000; cat. no. ab86299; Abcam), Src (1:1,000; cat. no. 2109T; CST), p-Src (1:1,000; cat. no. 6943T; CST), Cx43 (1:1,000; cat. no. AP1541b; Abcepta) and GAPDH (1:2,000; cat. no. bs-2188R; BIOSS). The cells were gently incubated overnight at 4°C and subsequently incubated with the corresponding secondary antibodies diluted 1:5,000 with 5% skimmed milk. The membranes were washed with TBST, incubated with ECL reagent (GE Healthcare Life Sciences, United Kingdom) and developed. Quantity One software (Bio-Rad, Hercules, CA, United States) was used to analyse the collected images.

## Quantitative RT-PCR

The cell culture and stimulation were performed as described for Western blot analysis. Only one acacetin (10 µmol) treatment group was used. After stimulation, the cells were harvested with TRIzol reagent (Life Technologies, CA, United States), and total RNA was extracted and reverse transcribed into cDNA using a ReverTraAce RT kit (Thermo Fisher, MA, United States). Real-time quantitative PCR was carried out using SYBR Green Master Mix (Roche, Germany) according to the manufacturer's protocols. The following gene primer sequences were obtained from Shanghai Gene Pharma: CD86, 5'-ACGGAGTCAATG

AAGATTTTCCT-3' (forward), 5'-GATTCGGCTTCTTGTGAC-ATAC-3' (reverse); iNOS, 5'-GTTTACCATGAGGCTGAAATC C-3' (forward), 5'-CCTCTTGTCTTT-GACCCAGTAG-3' (reverse); and β-actin, 5'-CACGATGGAGGGGCCGACTC ATC-3' (forward), 5'-TAAAGACCTCTATGCCAACACAGT-3' (reverse). mRNA abundance was quantified using the Ct values obtained by 2<sup>-ΔΔCt</sup> comparative method.

## Network Pharmacology Approach

The acacetin chemical formula was imported into the Swiss Target Prediction database (<http://swisstargetprediction.ch/>) for drug-target prediction analysis, and the keyword “sepsis” was then searched in the Gene Cards database (<https://www.genecards.org/>) to identify disease targets. The overlapping targets among compound and sepsis targets were used to draw a Venn diagram.

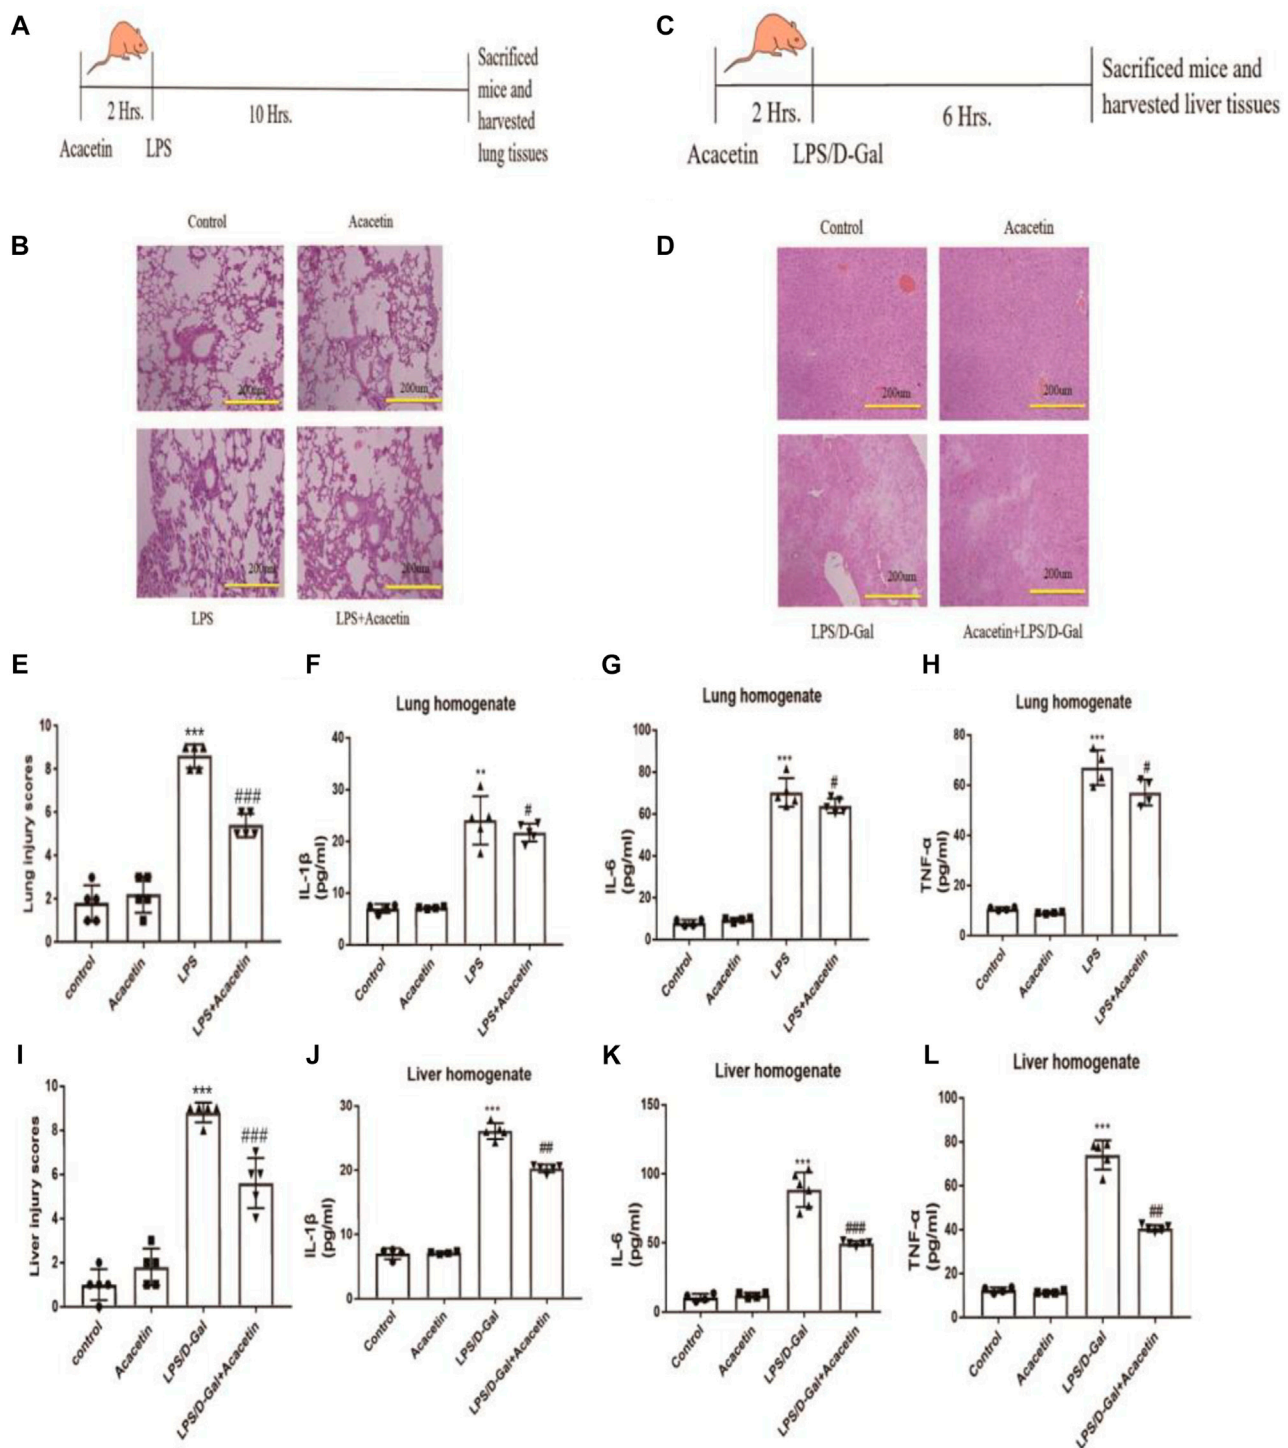

The protein-protein interaction (PPI) network was obtained by introducing these potential overlapping targets of acacetin and sepsis into the STRING database (<https://string-db.org>) with the species limited to “*Homo sapiens*” and a confidence score >0.9. The results were further visualized by Cytoscape 3.7.0. The degree of freedom was reflected by the node size and colour. Subsequently, the top four key targets were identified as hub targets based on their degree, centrality and proximity to hub proteins.

The hub targets were converted into their Ensembl gene names ([www.ensembl.org/biomart/](http://www.ensembl.org/biomart/)), and the OmicShare server (<http://www.omicshare.com/>) was then used for the analysis. The converted Ensembl gene names were used as input, and Gene Ontology (GO) enrichment and Kyoto Encyclopaedia of Genes and Genomes (KEGG) enrichment analyses were performed. The molecular function (MF), biological process (BP) and cellular component (CC) terms enriched in the targets were determined, and pathway enrichment of the top 20 pathways was visualized with the R package.

These results were summarized and loaded into Cytoscape 3.7.0 to construct the acacetin-target-GO-KEGG-sepsis network. In the network, edges represent interactions between nodes, and nodes represent drugs, diseases, BPs, pathways and targets.

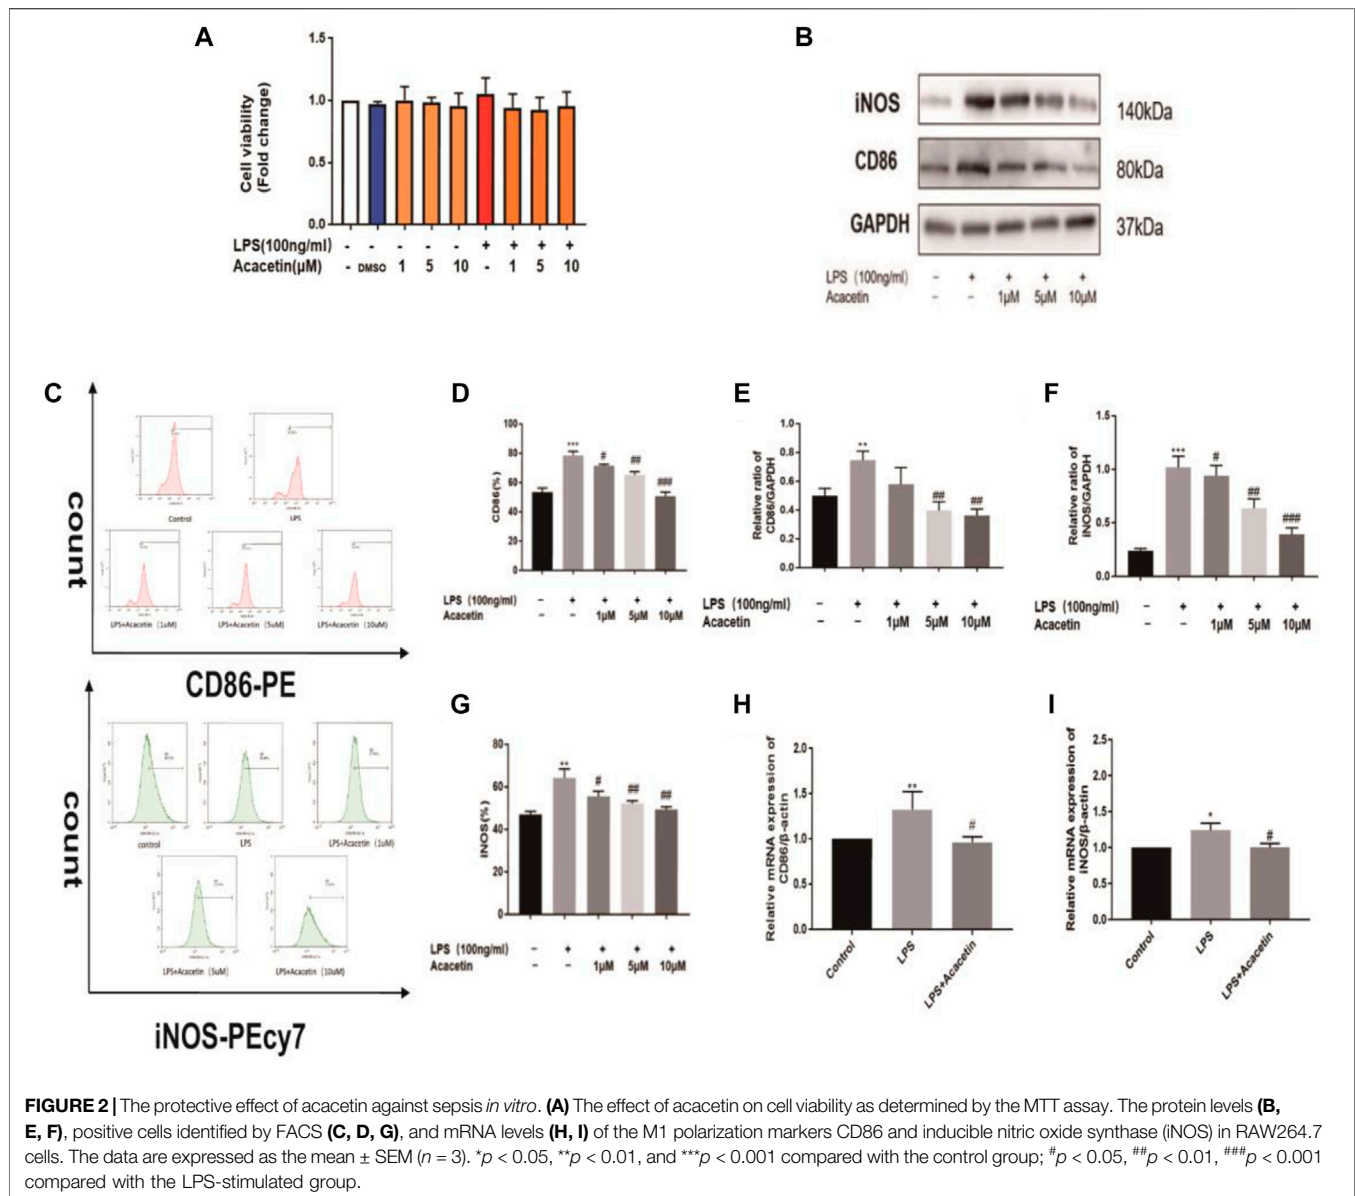

## Molecular Docking

The 3D crystal structures of ESR1 (PDB code: 5ACC), COX-2 (gene: PTGS2, PDB code: 4RRX), SRC (PDB code: 4U5J) and EGFR (PDB code: 6JZ0) were obtained from the Protein Data Bank (PDB). The 2D structure of acacetin was downloaded from the ZINC15 database (<https://zinc15docking.org/>). The original ligand active site residues were identified from the PDB coordinates and recorded. The protein structures were prepared by removing all nonreceptor atoms, including water, ions, and miscellaneous compounds, using Discover Studio Visualizer. Docking experiments were performed using CDOCKER with receptor-ligand interactions. The -CDOCKER\_INTERACTION\_ENERGY value was determined to evaluate bonding. The binding results were visualized as 3D and 2D diagrams using Discovery Studio Visualization version 4.5 (Accelrys, Inc., San Diego, CA 92121, CA, United States).

**FIGURE 1 |** The protective effect of acacetin against sepsis *in vivo*. **(A)** and **(C)** Methods to generate two inflammatory models and diagram showing the drawing time. **(B)** and **(D)** Histopathological damage to the lung (×200) and liver (×200). **(E)** and **(I)** Lung and liver injury scores. The lung **(F)** and liver **(J)** homogenate levels of IL-1β **(G)**, **(K)** IL-6 **(H)**, and **(L)** TNF-α were determined by ELISA. The data are expressed as the mean ± SEM (n = 5). \**p* < 0.05, \*\**p* < 0.01, \*\*\**p* < 0.001, compared with the control group; #*p* < 0.05, ##*p* < 0.01, ###*p* < 0.001, compared with the LPS-stimulated group.

## Statistical Analyses

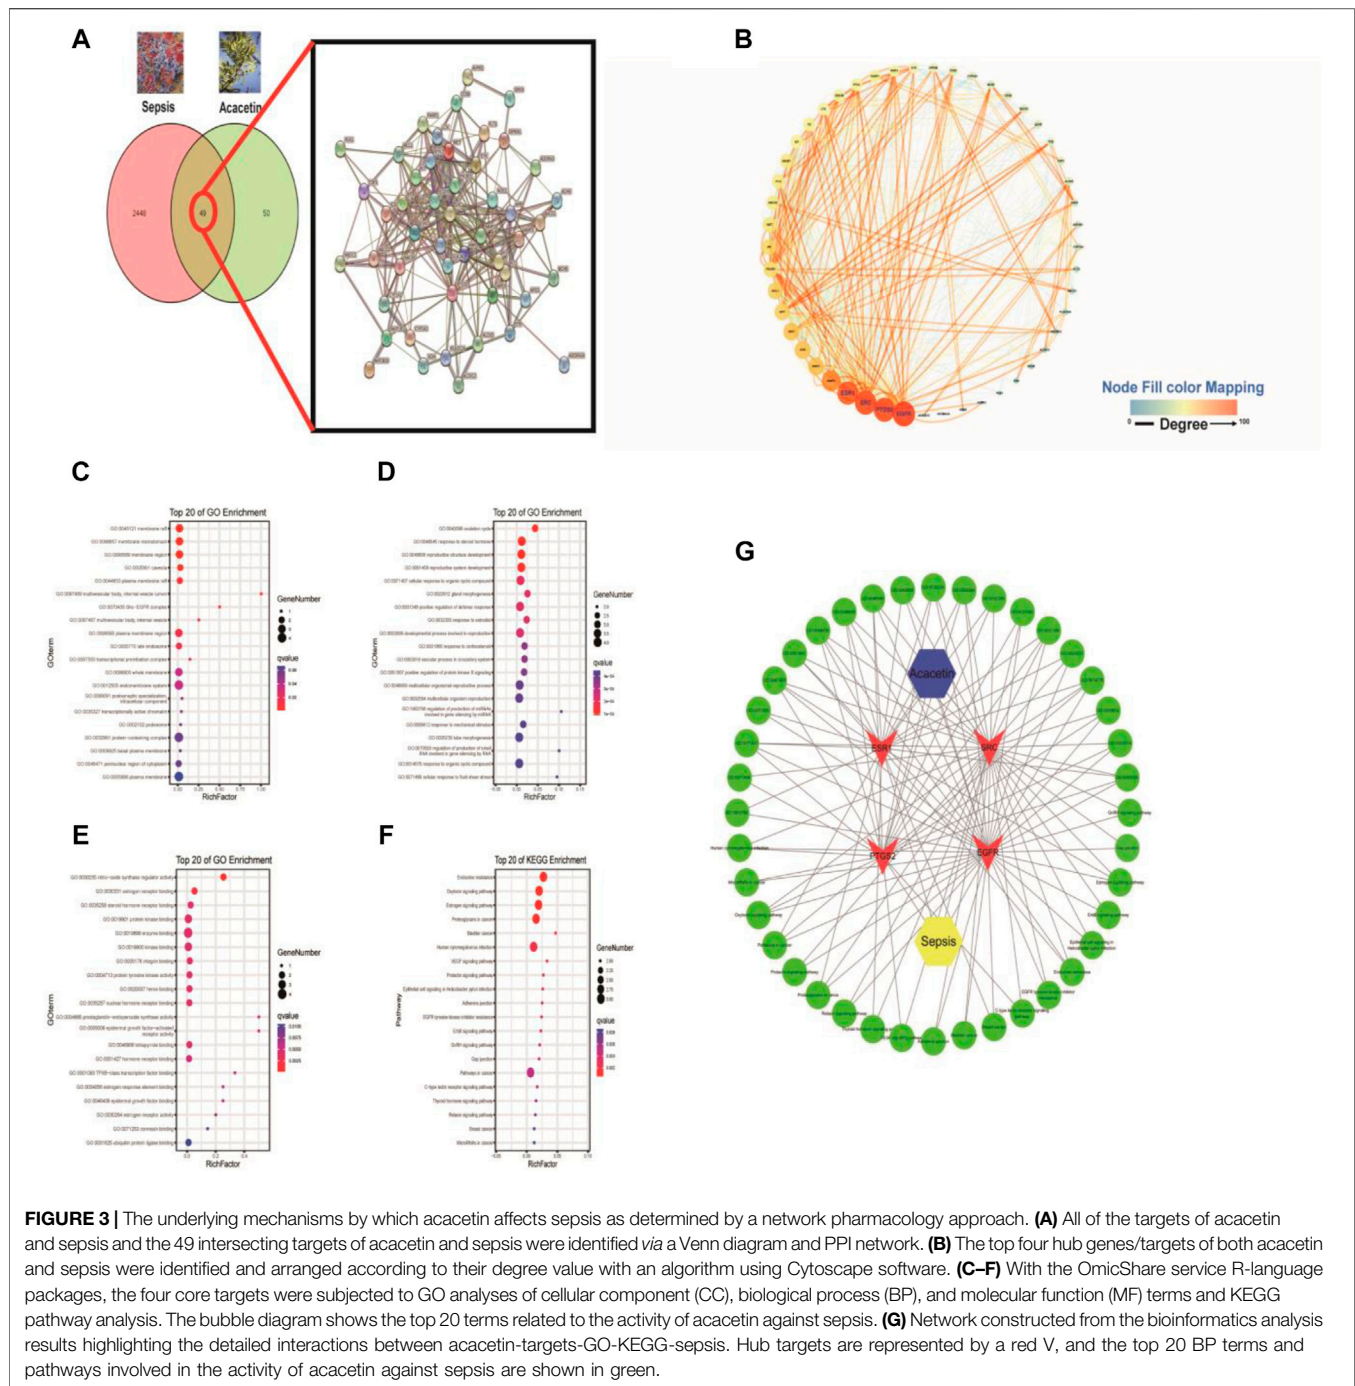

Statistical evaluations were performed using the GraphPad Prism 5 package (GraphPad Software Inc., San Diego, CA, United States). Multiple comparisons were performed by one-way ANOVA followed by Tukey's post hoc significant difference test.  $p$  values less than 0.05 indicate statistical significance.

## RESULTS

### Protective Effect of Acacetin Against Sepsis *in vivo*

To assess the protective effect of acacetin against sepsis, we utilized LPS-induced FHF and ALI models. Compared with the control group, the FHF model group showed congestion,

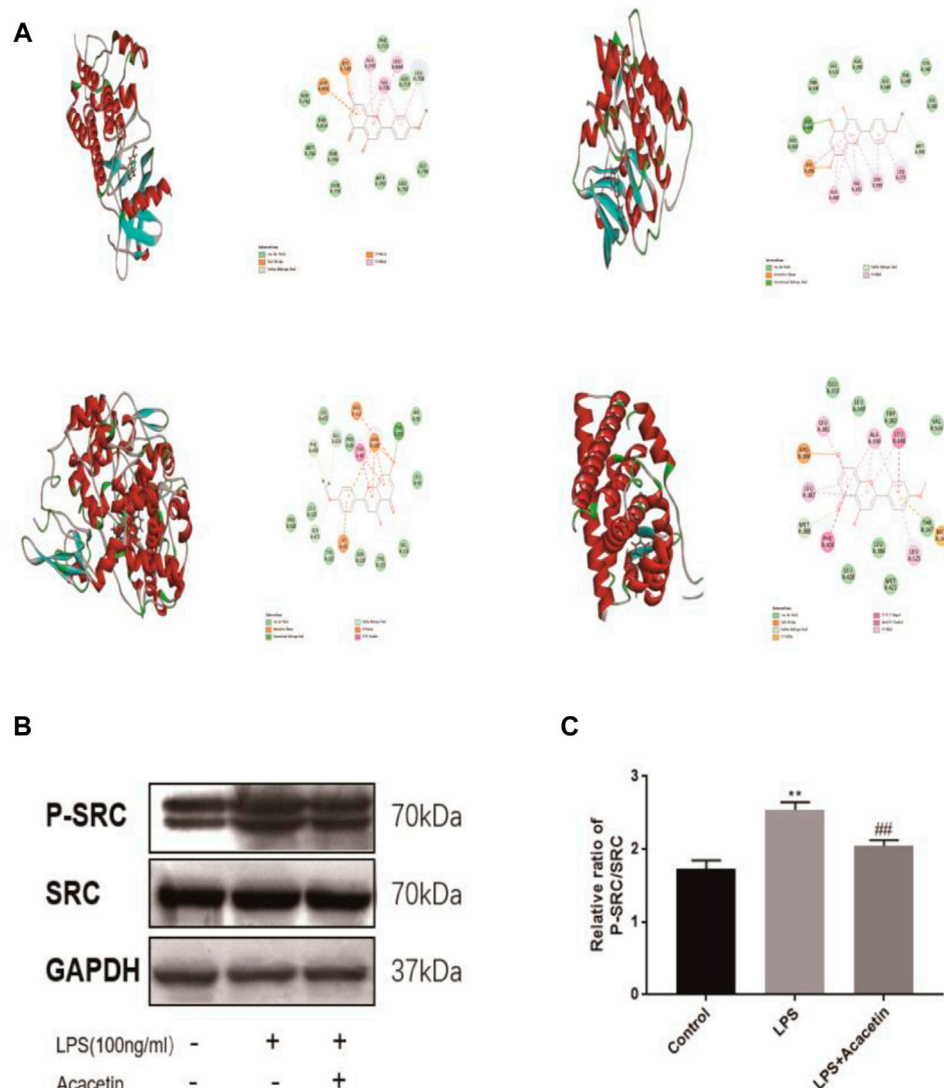

oedema, inflammatory cell infiltration, and a broadened pulmonary interval ( $p < 0.05$ ), and the ALI model group showed more inflammatory areas in the portal vein and more necrotic hepatocytes ( $p < 0.05$ ). Compared with the FHF and ALI model groups, the acacetin group showed less severe lung and liver injury symptoms as determined by HE staining (**Figures 1B,D**), and the injury scores of the acacetin group were significantly lower than those of the model group (**Figures 1E,I**;  $p < 0.05$ ). The levels of IL-1 $\beta$ , IL-6 and TNF- $\alpha$  in the liver and lung tissues of the model group were significantly higher than those in the control group tissues, while those in the acacetin group were decreased compared to those in the control group (**Figures 1F–H,J–L**  $p < 0.05$ ). These results indicated that acacetin improves liver and lung injury by decreasing the levels of IL-1 $\beta$ , IL-6 and TNF- $\alpha$ .

## Protective Effect of Acacetin Against Sepsis *in vitro*

Macrophage polarization is involved in the pathogenesis of sepsis. To assess the protective effect of acacetin on sepsis and the underlying mechanism *in vitro*, we observed its effect on M1 macrophage polarization induced by LPS in RAW264.7 cells. As shown in **Figure 2A**, treatment with 1, 5, and 10  $\mu\text{M}$  acacetin had no toxic effects, and the agent was thus used at these nontoxic concentrations in further experiments. Compared with those in

the control group, the CD86 and iNOS protein levels, number of positive cells determined by flow cytometry, and mRNA levels were increased in the LPS-stimulated group. Compared with LPS, acacetin attenuated the CD86 and iNOS protein levels (**Figures 2B,E,F**), the number of positive cells determined by fluorescence-activated cell sorting (FACS) (**Figures 2C,D,G**) and the mRNA levels (**Figures 2H,I**). Additionally, exposure to various doses of acacetin (1, 5, and 10  $\mu\text{M}$ ) attenuated the expression of CD86 and iNOS in M1-type cells in a concentration-dependent manner

**FIGURE 4 |** Molecular docking and experimental validation of acacetin binding core targets predicted by network pharmacology. **(A)** EGFR, SRC, PTGS2 and ESR1. All pictures show the 3D docking of ligands in the active binding pocket, with the hydrophobic effect area and the 2D interaction patterns between the ligands and proteins and the important interactions between the ligand atoms and amino acid residues of the proteins being displayed. **(B–C)** The expression levels of Src and phosphorylated Src were assessed via Western blotting. The data are expressed as the mean  $\pm$  SEM ( $n = 3$ ). \* $p < 0.05$ , \*\* $p < 0.01$ , and \*\*\* $p < 0.001$  compared with the control group; # $p < 0.05$ , ## $p < 0.01$ , and ### $p < 0.001$  compared with the LPS-stimulated group.

( $p < 0.05$ ). These phenomena revealed that acacetin helped to quickly reduce the CD86 and iNOS levels in M1-type macrophages.

## Elucidating the Mechanisms Underlying the Effects of Acacetin on Sepsis via a Network Pharmacology Approach

The canonical SMILES string for acacetin was input into the Swiss Target Prediction database to identify the targets of acacetin, and a total of 99 potential drug targets were found. There were 2,497 potential targets of sepsis in the GeneCards database. As shown in **Figures 3A,4** common targets were included in the acacetin-sepsis

target Venn diagram. The 49 intersectional targets were imported into the STRING database to explore the relationships among these targets (**Figure 3A**). A PPI network of the 49 common targets between acacetin and sepsis was constructed based on degree value screening, and EGFR, PTGS2, SRC and ESR1 were identified as the core targets (**Figure 3B**). GO and KEGG analyses were performed, and the core targets of EGFR, PTGS2, SRC and ESR1 were input into the Omicshare database to identify the possible mechanism by which acacetin affects sepsis. GO analysis of the CC terms showed that the four core targets were mainly associated with membrane rafts, the membrane microdomain and the membrane region (**Figure 3C**). GO analysis of BP terms showed that the four core targets were mainly related to the ovulation cycle, steroid

**TABLE 1 |** Interaction of acacetin and hub targets by discovery studio

Targets	Acacetin CDCOKER interaction energy	Positive compare CDOCKER interaction energy
EGFR	37.6692	29.7857
SRC	40.6193	58.7556
PTGS2	49.4521	34.7360
ESR1	37.7927	36.4148

hormones and reproductive structure development (**Figure 3D**). GO analysis of MF terms showed that the four core targets were mainly associated with connexin (Cx) binding, NOS activity regulation, oestrogen receptor binding and protein kinase binding (**Figure 3E**). KEGG analysis revealed that the four core targets were closely associated with the gap junction, endocrine resistance, oxytocin signalling, proteoglycans in cancer, bladder cancer and human cytomegalovirus infection pathways (**Figure 3F**). **Figure 3G** shows the acacetin-sepsis-target-GO-KEGG network.

## Molecular Docking and Experimental Validation of the Binding of Core Acacetin Targets Predicted by Network Pharmacology

Molecular docking was carried out to investigate potential binding modes and interactions between acacetin and its key targets (**Figure 4A**). For the docking interaction energy score, the targets were ranked as PTGS2 > SRC > ESR1 > EGFR (**Table 1**). The carbonyl, methoxy and hydroxy groups are thought to be the key groups that bind residues containing H donor moieties at the terminus (Zhao et al., 2019); (Lin et al., 2019); (Duan et al., 2014); (De Savi et al., 2015); (Blobaum et al., 2015) For the specific proteins in the EGFR complex, the residues involved in the formation of H-bonds included ALA 743, THR 790, VAL726, and THR 854. With regard to the SRC docking results, the key residues involved in H-bonds were MET 341, VAL 281 and LEU 393. In the ESR1 complex, THR 347 and MET343 emerged as key residues between the methoxyl group at the 4' position of acacetin and the target. In the COX-2 (PTGS2) complex, TYR 355 was identified as the only key residue involved in H-bonds. Moreover, known standard or positive molecules of the four targets were subjected to the same simulation (**Supplementary Figure S1**). The molecular docking results indicated that acacetin can interact with PTGS2, SRC, ESR1 and EGFR to form compact complexes. Src is a prototype of the highly conserved Src family kinase (SFK) proteins, and our results indicated that the expression of p-src in RAW264.7 cells was significantly increased after LPS stimulation and reduced after treatment with acacetin (**Figures 4B,C**;  $p < 0.05$ ).

## Experimental Validation of the Acacetin Binding Signalling Pathway Predicted by Network Pharmacology

Further network pharmacological analysis and GO and KEGG analyses indicated that gap junctions may be highly involved in

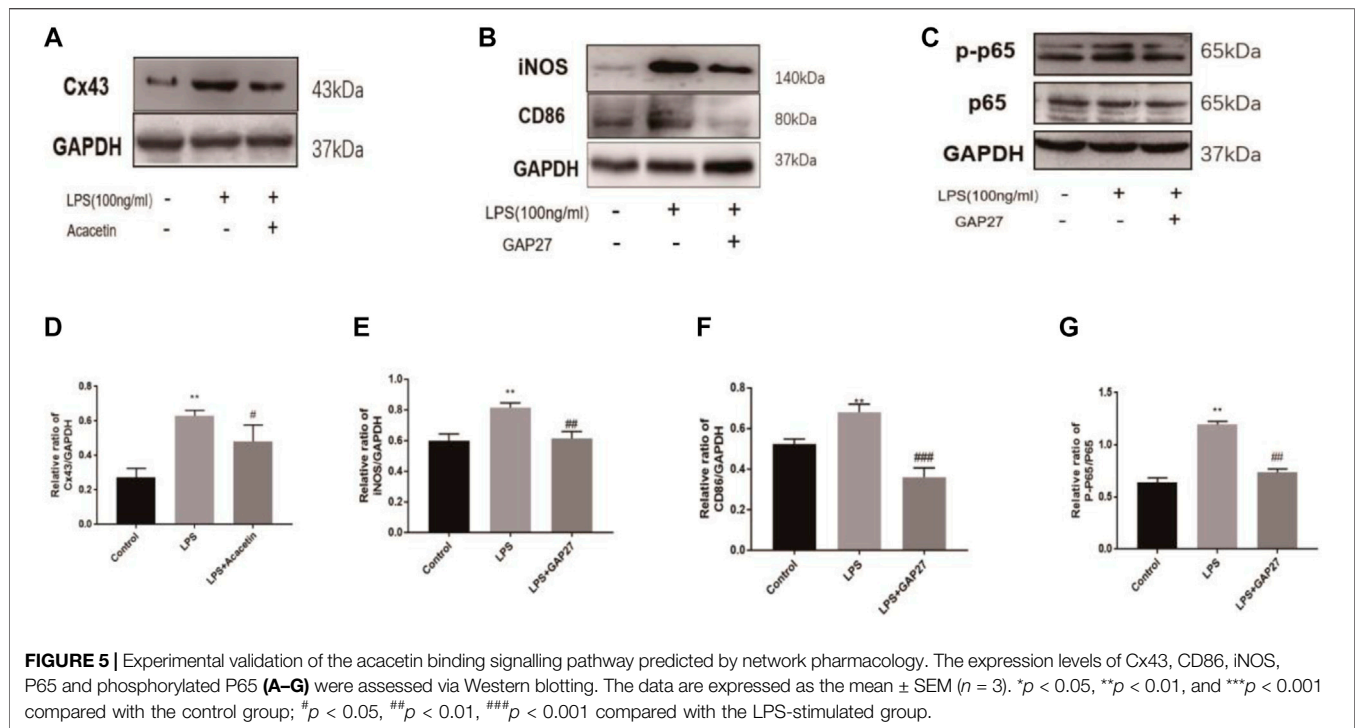

the protective effects of acacetin against sepsis. We confirmed the role of gap junctions in the effects of acacetin on LPS-induced M1 polarization in RAW264.7 cells. As shown in **Figures 5A,D**, the expression levels of Cx43 were significantly increased after LPS stimulation but reduced after treatment with acacetin. As shown in **Figures 5B,C,E,F** the protein expression levels of CD86, iNOS, p65, and p-p65 were revealed by Western blotting. Notably, p-p65, CD86 and iNOS protein expression was significantly decreased in the Gap27 group compared with the LPS group ( $p < 0.05$ ). Together, these results suggest a prospective role for gap junctions in attenuating the effect of acacetin on M1-type macrophages.

## DISCUSSION

Sepsis is a global healthcare issue and continues to be the leading cause of death from infection. In clinical practice, the use of antimicrobial agents to fight infection is key to the treatment of sepsis. Over the past few decades, natural products, such as anti-bacterial and anti-inflammatory drugs, have been used for the herbal treatment and prevention of human diseases (McBride Margaret et al., 2020). Acacetin is a natural flavonoid found in various plants, including *Sparganii rhizoma*, *Sargentodoxa cuneata* and *Patrinia scabiosifolia*. Our results indicated that acacetin improved liver and lung injury by decreasing the levels of IL-1 $\beta$ , IL-6 and TNF- $\alpha$ , and acacetin expedited the reduction in CD86 and iNOS expression in M1-type macrophages. Previous reports have indicated that acacetin has anti-inflammatory effects. For example, acacetin was shown to suppress the LPS-induced upregulation of iNOS and COX-2 in murine macrophages and TPA-induced tumour promotion in mice (Pan et al., 2006). Acacetin was also shown to attenuate mouse ALI induced by endotoxin by augmenting HO-1 activity (Wu et al., 2018) and to block kv1.3 channels and inhibit human T cell activation (Zhao et al., 2014). These results demonstrate that acacetin has anti-inflammatory and antioxidative effects on sepsis, but the underlying molecular mechanism remains unclear.

We herein further investigated the mechanisms underlying the effects of acacetin on sepsis by performing network pharmacology analysis coupled with experimental validation and molecular docking. All potential targets of acacetin and sepsis were methodically obtained, and the top four overlapping targets in the PPI network were EGFR, PTGS2, SRC and ESR1. EGFR prevents the translocation of gut-residing pathogenic and cancer-associated protein kinases and is a key target for late-onset neonatal sepsis and cancer (Knoop et al., 2020; Singh et al., 2021). Our results identified ALA 743, THR790, VAL726, THR854 and ASP855 as the key EGFR residues in the binding pocket. PTGS2, also known as COX-2, has been reported to have an anti-inflammatory effect, and acacetin can reportedly relieve sepsis by inhibiting COX-2 activity (Pan et al., 2006; Wu et al., 2018; Fatemi et al., 2020). Due to the structural specificity of the COX-2 protein, only TYR 355 was identified as the key residue involved in H-bonds.

Moreover, ESR1, as the target of the *ShenFuHuang* formulation in a zebrafish model, was associated with septic syndrome in patients with COVID-19 (Liu et al., 2020b). Our results highlighted THR 347 and MET343 as the key residues residing between the methoxyl group at the 4' position of acacetin and ESR1, which is also consistent with the binding site for the original ligand. Additionally, cellular Src is the prototype of highly conserved SFK proteins. Evidence suggests that siglec-G deficiency ameliorates hyperinflammation and immune collapse in patients with sepsis by regulating Src activation (Li et al., 2019). With regard to the Src docking results, MET 341, VAL 281 and LEU 393 were identified as the key residues of the binding pocket with the original ligand ruxolitinib. Thus, based on its prediction as a core target and its association with macrophages and sepsis, Src deserves to be further studied *in vitro*. Our western blot results suggested that phosphorylated Src plays an important role in the anti-septic activity of acacetin. Together, our results showed that acacetin had a preferential affinity for all four targets, confirming the prediction results obtained by network pharmacology analysis.

GO and KEGG analyses were performed to analyse the interactions among multiple targets and pathways, and the top 20 enriched BPs and signalling pathways were shown to be associated with the therapeutic effects of acacetin on sepsis. Membrane raft, oestrogen receptor activity, and human cytomegalovirus infection are related to the effects of acacetin on sepsis. In a previous study, lipid raft microdomains were shown to be essential components of phagolysosomal macrophage membranes and to play an essential role in

antifungal immunity (Schmidt et al., 2020). Moreover, human cytomegalovirus infection was shown to potentially impact immunity (Cox et al., 2021). Thus, our subsequent research will be performed using macrophages. Further network pharmacological analysis indicated that gap junctions may be highly involved in the protective effects of acacetin against sepsis. Cxs are basic components of gap junctions, and Cx43 is a common Cx family member that is widely expressed in immune cells and involved in a variety of immune regulatory processes (Glass et al., 2015). In a previous study, ATP release through Cx43 was reported to be important for inhibiting inflammation and bacterial burden (Balázs et al., 2015). Our results showed that the gap junction selective blocker gap27 could significantly decrease the protein expression of p-p65, CD86 and iNOS. p-p65 is the key target of the classic inflammation-related NF- $\kappa$ B signalling pathway, CD86 is a surface marker of M1-polarized macrophages, and iNOS is a pro-inflammatory molecule associated with the inflammatory process. Our previous research on Cx43 showed that carbenoxolone decreased monocrotaline-induced pulmonary inflammation in rats by decreasing the expression of Cxs in T lymphocytes (Zhang et al., 2020). Angiotensin II induced RAW264.7 macrophage polarization toward the M1 phenotype through the Cx43/NF- $\kappa$ B pathway (Wu et al., 2020). Our findings highlighted gap junctions in macrophages as a new potential target for sepsis, and most importantly, showed that acacetin inhibited the LPS-induced increase in Cx43 expression. Interestingly, the anti-inflammatory effect of acacetin via gap junctions has not been reported. Together, these results suggest that gap junctions attenuate the effects of acacetin on sepsis.

## CONCLUSION

Our results suggest that acacetin protects against sepsis *via* a mechanism involving multiple targets and pathways and that gap junctions are highly involved in this process.

**Background:** “Treating the same disease with different methods” is a Traditional Chinese medicine (TCM) therapeutic concept suggesting that, while patients may be diagnosed with the same disease, they may also have different syndromes that require distinct drug administrations.

**Objective:** This study aimed to identify the differentially expressed genes and related biological processes in dyslipidemia in relation to phlegm–dampness retention (PDR) syndrome and spleen and kidney Yang deficiency (SKYD) syndrome using transcriptomic analysis.

**Methods:** Ten ApoE<sup>−/−</sup> mice were used for the establishment of dyslipidemic disease–syndrome models via multifactor–hybrid modeling, with five in the PDR group and five in the SKYD group. Additionally, five C57BL/6J mice were employed as a normal control group. Test model–quality aortic endothelial macrophages in mice were screened using flow cytometry. Transcriptomic analysis was performed for macrophages using RNA-Seq.

**Results:** A quality assessment of the disease–syndrome model showed that levels of lipids significantly increased in the PDR and SKYD groups, compared to the normal control group,  $p < 0.05$ . Applying, in addition, hematoxylin and eosin staining of aorta, the disease model was also successfully established. A quality assessment of the syndrome models showed that mice in the PDR group presented with typical manifestations of PDR syndrome, and mice in the SKYD group had related manifestations of SKYD syndrome, indicating that the syndrome models were successfully constructed as well. After comparing the differentially expressed gene expressions in macrophages of the dyslipidemic mice with different syndromes, 4,142 genes were identified with statistical significance,  $p < 0.05$ . Gene ontology analysis for the differentially expressed genes showed that the biological process of difference between the PDR group and the SKYD group included both adverse and protective processes.

**Conclusion:** The differentially expressed genes between PDR syndrome and SKYD syndrome indicate different biological mechanisms between the onsets of the two syndromes. They have

distinctive biological processes, including adverse and protective processes that correspond to the invasion of pathogenic factors into the body and the fight of healthy Qi against pathogenic factors, respectively, according to TCM theory. Our results provide biological evidence for the TCM principle of “treating the same disease with different treatments.”

## INTRODUCTION

As life quality increases and dietary patterns change, multiple factors are beginning to give rise to a growing morbidity of dyslipidemia in humans. A recent epidemiological study has shown that dyslipidemia is closely linked to cardiovascular and cerebrovascular diseases, including coronary atherosclerotic heart disease and cerebral infarction (Li et al., 2019). It is estimated that the overall morbidity of dyslipidemia in Chinese adults has reached 40.40% and is continuing to rise (Chu et al., 2016).

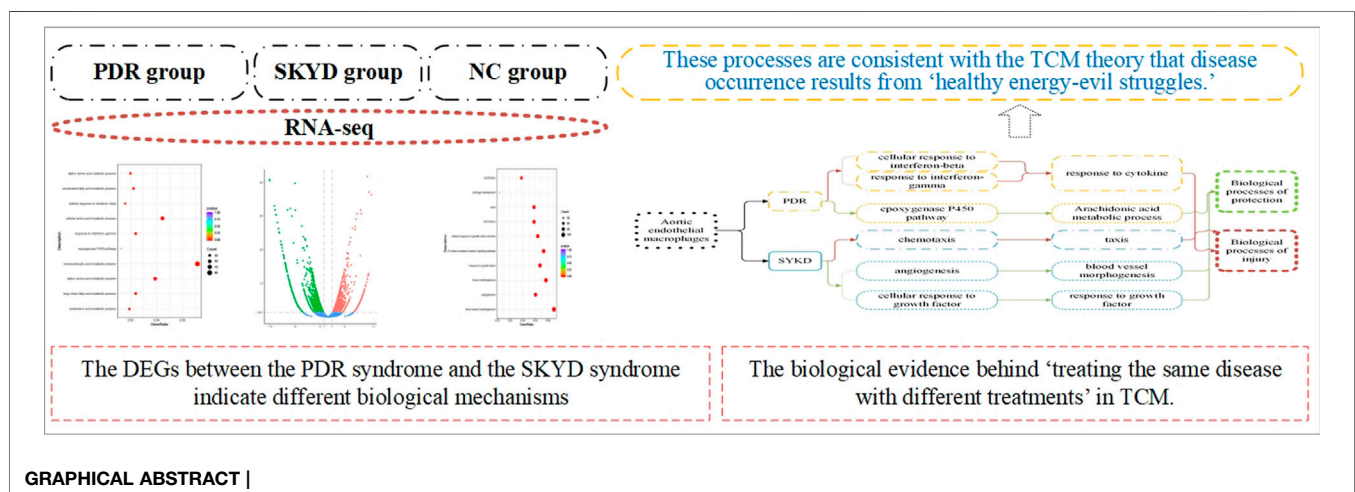

Dyslipidemia is characterized by abnormalities in the quantity and quality of lipids in the plasma, including lower high-density lipoprotein cholesterol (HDL-C) levels and higher triglyceride (TG), total cholesterol (TC), and low-density lipoprotein cholesterol (LDL-C) levels (Sarzynski et al., 2015). Lipid and cholesterol accumulation (Pantos et al., 2007) in the vascular wall may lead to endothelial dysfunction. Dyslipidemia is an independent and changeable risk factor shortening the onset time of atherosclerosis (Ciccone et al., 2011). The 2013 American College Foundation of Cardiology and American Heart Association guidelines on the management of blood lipids in atherosclerotic cardiovascular disease recommended that management of dyslipidemia is the key to controlling risk factors for ischemic cardiovascular events (Stone et al., 2014).

Numerous clinical studies and laboratory experiments have ascertained the satisfactory efficacy of TCM with respect to dyslipidemia, enriching the therapies available for the disease (He et al., 2018). Taking berberine orally has been shown to lower TG and cholesterol levels (Hu et al., 2012), and the oral administration of *Monascus* rice has also been found to significantly reduce the levels of blood lipids and to be well tolerated (Lin et al., 2005). An important effect of TCM lies in the accurate discrimination of TCM syndromes

of dyslipidemia, which is the basis of TCM diagnosis and treatment. The differentiation of syndromes is brought about through the collection of clinical information (i.e., “TCM symptoms”) of patients via integrated TCM diagnostic methods, including looking, listening, and questioning the individual, and feeling their pulse, as well as analyzing and summarizing the etiological factors and pathogenesis according to the TCM theoretical approach.

As individuals present with different TCM symptoms, dyslipidemic patients may exhibit various syndromes that can be considered different TCM subtypes of dyslipidemia. For example, spleen and kidney Yang deficiency (SKYD) syndrome and phlegm-dampness retention (PDR) syndrome are both common in patients with dyslipidemia. In addition, the vascular endothelium is responsible for delivering nutrients in a dynamic way (Eelen et al., 2020), while dyslipidemia acts as a risk factor of cardiovascular disease, potentially by promoting endothelium dysfunction—a prerequisite for the occurrence of atherosclerotic manifestations (Scicchitano et al., 2019). A critical mechanism of endothelium dysfunction is oxidative stress. Excessive nitric oxide (NO) binding with hyperoxides can form a peroxynitrite anion (ONOO<sup>-</sup>), and ONOO<sup>-</sup> triggers oxidative stress of the vascular endothelium and endothelial injury through its oxidative effect (nitric oxide) on proteins, exacerbating the endothelial injury. Accordingly, the severity of endothelial injury can be indicated by ONOO<sup>-</sup> levels.

Our team has been studying the integration of TCM differentiation and Western medicine diagnosis alongside investigating endothelial injury differences as the characteristics between SKYD syndrome and PDR syndrome in dyslipidemia. Findings from our previous research have suggested that dyslipidemic patients with SKYD syndrome and PDR syndrome exhibit different serum ONOO<sup>-</sup> concentrations,

reflecting the difference in TCM syndromes in a certain sense (Chen et al., 2016). Consequently, we theorize that different syndromes of dyslipidemia may correspond to different degrees of endothelial injury. In dyslipidemia, macrophages play a pivotal role in the process of endothelial injury. Recognizing this critical effect of macrophages, and following on from our previous study series, the present study focuses on aortic endothelial macrophages and explores the characteristics of the endothelial injury between individuals with SKYD syndrome and those with PDR syndrome as well as dyslipidemia.

In dyslipidemia, monocytes that migrate to the endothelium differentiate into macrophages via macrophage colony stimulating factors, and then damage the vascular endothelium. Macrophages consist of two subtypes, M1 and M2 macrophages (Davies and Taylor, 2015). Lactate dehydrogenase stimulates the expression of adhesion molecules and chemokines, thereby differentiating monocytes into macrophages through various pathways. M1 macrophages can release inflammatory factors that facilitate the progression of inflammation and further impair vascular endothelial cells (Pesce et al., 2009). M2 macrophages release anti-inflammatory factors that are involved in angiogenesis and tissue growth and delay the progression of inflammation (Moore and West, 2019). A prior study established that macrophages are indispensable in the formation of atherosclerosis (Yamada et al., 1998). Moreover, according to TCM theory, the two subtypes exhibit antagonistic characteristics, corresponding to “healthy Qi” (the ability to combat evils, preventing disease) versus “evil Qi” (pathogenetic factors, factors damaging healthy Qi). The interactions between healthy Qi and evil Qi are characterized by “healthy energy–evil struggles, mutually opposing and constraining, and the rule of waxing and waning” in the occurrence and development of diseases and syndromes.

Disease–syndrome combination is a significant mode for TCM diagnosis and treatment in the clinic. Furthermore, in this context, the in-depth investigation of diseases and syndromes requires biological studies using disease–syndrome animal models in agreement with the traits of TCM theories to apprehend the underlying mechanisms. The characteristics of such models, such as rigorous controls, high repeatability, and success rates, make it easier to regulate the research cycle, repetitively perform experiments, collect more data, and comprehensively analyze the data. Hence, the establishment of an appropriate disease–syndrome animal model is increasingly attracting research attention.

An important element of TCM syndrome research is the investigation of biological mechanisms and the characteristics of syndromes using animal models. Accordingly, we developed a disease–syndrome animal model in the present study for analysis. The quality of a disease–syndrome animal model can affect the accuracy and credibility of any study based on it. We employed multifactor-hybrid modeling and established dyslipidemic mouse models featuring SKYD syndrome and PDR syndrome, based on the model used in our previous study, so that the quality of the animal models could be ensured as much as possible. The disease model replicated the core physiopathologic process present during the occurrence and development of a disease, and the syndrome models each simulated the core etiology and pathology during the onset of a syndrome.

Transcriptomics is a technique used to study gene transcription and regulation related to TCM syndromes and is conducive to in-depth biological research toward a better understanding of the

pathogenesis of TCM syndromes, and so warrants more prevalent application in TCM syndrome research (Jiang and Li, 2020). Gan et al. (2020) studied Yin deficiency–heat syndrome using transcriptomics technology and obtained its potential biomarkers. Currently, though, studies concerning the characteristics of SKYD syndrome and PDR syndrome in relation to dyslipidemia are rarely reported. Our study focuses on the two-way impacts between the severity of endothelial injury and macrophages, and analyzes the differences in biological processes and signaling pathways between different TCM syndromes (subtypes) of dyslipidemia using transcriptomic techniques. Thus, this study provides a reference for in-depth mechanistic research of TCM syndromes and studies of the targets of TCM drugs.

## MATERIALS AND METHODS

**Figure 1** presents an overview of the study’s materials and methods, described in full below.

### Experimental Animals

The animals featured in the research comprised 10 apolipoprotein E knockout (ApoE<sup>−/−</sup>) mice—male, 6 weeks old, body mass about 20 ± 5 g—and five C57BL/6J mice of the same strain—male, 6 weeks old, body mass about 20 ± 5 g. All animals were raised in the Beijing Changyang Xishan Farm; the rearing environment incorporated a room temperature of 21–25°C, 50%–70% humidity, and 12 h of alternating shade. The ethics of this study were approved by the animal ethics review committee of the Institute of Basic Theories of Chinese medicine, Chinese Academy of Chinese Medical Sciences, approval no. 201908006 (Beijing, China).

### Experimental Reagents and Model-Making Feed

#### Main Reagents for the Experiment

LDL cholesterol test kit (Nanjing Jiancheng Bioengineering Institute Co., Ltd.); total cholesterol lipoprotein test kit (Nanjing Jiancheng Bioengineering Institute Co., Ltd.); HDL cholesterol test kit (Nanjing Jiancheng Bioengineering Institute Co., Ltd.); triglyceride test kit (Nanjing Jiancheng Bioengineering Institute Co., Ltd.); FITC anti-mouse F4/80 antigen (BM8.1) (Tonbo Biosciences Co., Ltd.); PE anti-human/mouse CD11b (M1/70) (Tonbo Biosciences Co., Ltd.); hematoxylin–eosin (HE) staining solution (Aijia Biotechnology Co., Ltd.).

#### Experimental Modeling Feed

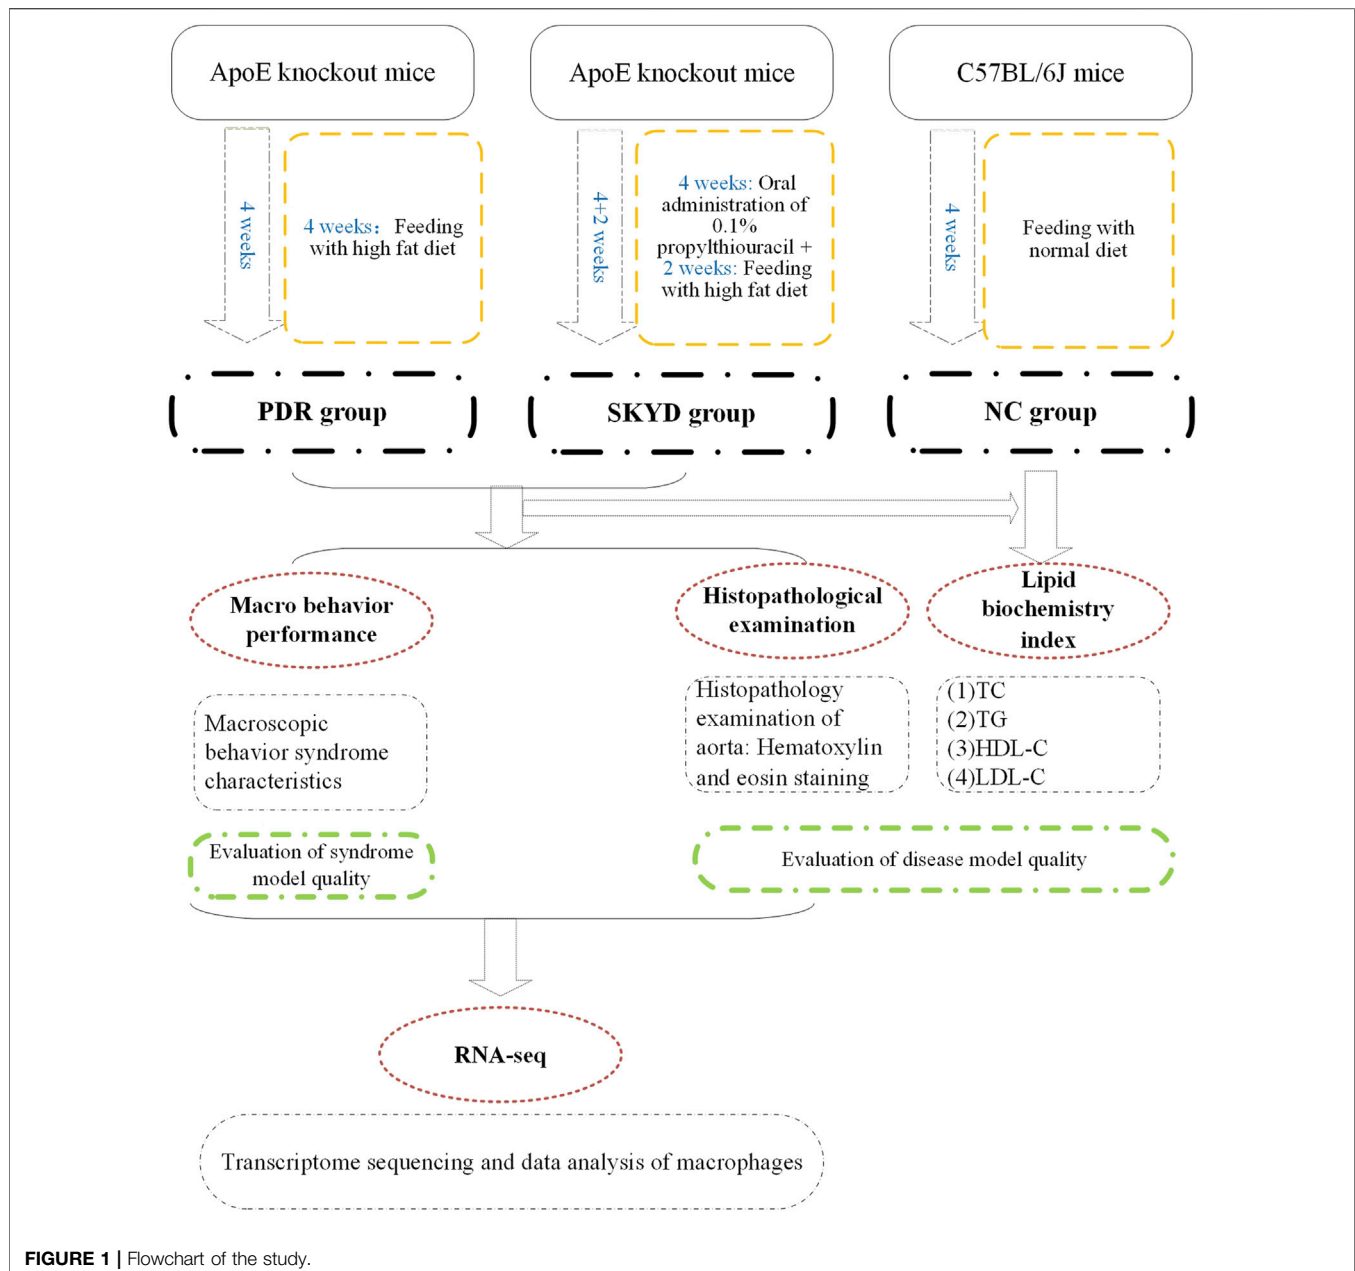

The dyslipidemic feed formula consisted of 63.6% basal feed +15% lard +20% sucrose +1.2% cholesterol +0.2% sodium cholate, provided by Beijing Keaoxieli Feed Co.

### Modeling and Evaluation Methods of Animal Models of Diseases and Syndromes

#### Modeling Methods

##### The PDR Group

Five ApoE knockout mice were randomly selected and fed a high-fat diet for 4 weeks, from Weeks 1–4 (the disease model was constructed at 2 weeks, and the syndrome model was constructed at 2 weeks).

### The SKYD Group

Five ApoE knockout mice were randomly selected and given 0.1% propylthiouracil by gavage at a dose of 10 mg/(kg·d) during Weeks 1–4 (constructing the syndrome model), and high-fat chow for 2 weeks during Weeks 5 and 6 (constructing the disease model).

### The Normal Control Group

Five C57BL/6J mice were given normal chow for modeling for a total of 4 weeks from Weeks 1–4.

### Model Evaluation Methods

Model evaluation was completed as follows: 1) evaluation of model quality of dyslipidemia by means of serum lipid index testing and aortic pathology staining; 2) evaluation of model

quality of the PDR group and the SKYD group by observing the characteristic manifestations of the syndromes.

### Sampling and Macrophage Screening Methods

Mice were fasted without water for 18 h before sampling and given anesthesia for execution.

### Animal Serum

Animals in the PDR group, the SKYD group, and the NC group, after taking whole blood, placed in conventional serum tubes, 3,000 rpm for 10 min, separated serum, divided and immediately stored in  $-80^{\circ}\text{C}$  refrigerator.

## Animal Tissues

Aortic tissues were taken from animals in the PDR group and the SKYD group.

## Macrophages

Aorta of animals from the PDR group and the SKYD group were isolated and removed intact, digested by adding trypsin, sieved and ground, digestion was terminated, centrifuged, supernatant was decanted, re-suspended by adding PBS, centrifuged again, supernatant was decanted, and labeled with FITC anti-mouse F4/80 antigen (BM8.1) and PE anti-human/mouse CD11b (M1/70), blown and re-suspended, and stored away from light. After labeling the macrophages, the macrophages were screened by fluorescence-activated cell sorting (FACS) using the MoFlo XDP Ultra-Fast Flow Cell Sorting System (Beckman Coulter Co., Ltd.). (See **Supplementary Material S1**).

## Measurement of Indicators

### General Observation of the Model

Observing and recording mental status, body hair glossiness, movement, feces, etc.

### Lipid Index Testing

Serum testing of TG, TC lipoprotein, HDL-C, and LDL-C levels in each group.

### Aortic Histopathology

Specimens were fixed in 10% neutral formalin at room temperature for 24 h. The specimens were fixed for 48 h at room temperature using freshly prepared 4% formaldehyde, followed by paraffin embedding and sectioning. Specimens were cut into 4 mm-thick sections and subjected to histological HE staining to observe the morphological features of the vascular endothelium.

After staining, the slices were photographed and examined using an optical microscope (AE41; Motic) equipped with a digital scanner (Panoramic MIDI; 3DHISTECH) to record images of the stained slices.

### Macrophage Transcriptomic Sequencing and Data Analysis

Total RNAs of macrophages were extracted in accordance with the TRIzol<sup>®</sup> manual (Life Technologies, Inc., Gaithersburg, MD, United States). Preparation of library and sequencing of transcriptomes were carried out using Illumina HiSeq X Ten (Novogene Bioinformatics Technology Co., Ltd., Beijing, China). The mapping of 100-bp paired-end reads to genes was undertaken using HTSeq v0.6.0 software, while fragments per kilo base of transcript per million fragments mapped (FPKM) were also analyzed. Raw reads from RNA-Seq libraries were trimmed to remove the adaptor sequence and the reads with adaptor contaminants and low-quality reads (the mass value Q score <5 of the base number accounts for more than 50%) and reads from N (N indicates that the base information that cannot be determined) which was >10%.

After filtering, reference genome and gene model annotation files were downloaded from a genome website browser (NCBI/UCSC/Ensembl). Indexes of the reference genome were built

using Bowtie (version 2.0.6) and paired-end clean reads were aligned to the reference genome using TopHat (version 2.0.9). Bowtie was used for a Burrows–Wheeler transform algorithm for mapping reads to the genome, and TopHat can generate a database of splice junctions based on the gene model annotation file and thus achieve a better mapping result than other non-splice mapping tools.

For the quantification of gene expression level, HTSeq (version 0.6.1) was used to count the read numbers mapped for each gene. The reads per kilo base of transcript per million mapped reads (RPKM) of each gene was calculated based on the gene read counts mapped to this gene. A differential expression analysis was performed using the DESeq R package (3.18.1). The *p* values were adjusted using the Benjamini and Hochberg method. A corrected *p* value of 0.05 and absolute fold change of 2 were set as the threshold for significantly differential expression.

Gene ontology (GO) enrichment analysis of differentially expressed genes (DEGs) was implemented using the clusterProfiler R package, in which gene length bias was corrected. GO terms with a corrected *p* value of less than 0.05 were considered significantly enriched by DEGs.

## Statistical Methods

Subject-related data were statistically processed by applying SPSS (version 19.0) statistical software. The measurement data were expressed as the mean plus or minus the standard deviation. A one-way analysis of variance with randomized group design was used for comparison between groups; Fisher's least significant difference test was used for two-way comparison, if the data variance was the same; Tamhane's test was used for two-way comparison, if the variance was not the same; and the difference was considered statistically significant at *p* < 0.05. The test level was  $\alpha = 0.05$ , and the confidence interval for parameter estimation was 95%.

## RESULTS

### General Information and Macro Behavioral Performance

Ten ApoE knockout mice and five C57BL/6J mice of the same strain without deletion were used in the experiment, with 15 mice entering into the resulting analysis. Before sampling, the mice in the PDR group had exhibited loss of body hair brightness, lethargy, and laziness; the mice in the SKYD group had showed arching of the back and curling up, tranquil, lethargy, lying down, and a propensity to pile up.

### Comparison of Blood Lipid Indexes

Evaluating the lipid indexes, compared with the NC group, TG, TC, and LDL-C levels were found to be significantly higher in the PDR group and the SKYD group, *p* < 0.05. Compared with the NC group, no significant statistical differences were perceived between the HDL-C indexes of the PDR and SKYD groups. No significant statistical differences were seen between the PDR and SKYD groups when comparing TG, TC, and HDL-C levels. Also, no statistically significant differences were found in the

comparisons of the TG, TC, HDL-C, LDL-C, and LDL-C indexes between the PDR and SKYD groups. These results are summarized in **Tables 1–4**.

## Comparison of HE Staining Examination

The aortas from the PDR group and the SKYD group were examined using HE staining. The endothelial surface of the vessels was observed to be smooth, the inner, middle, and

outer membranes showed clear, and no obvious lipid deposition or lipid streak production was seen. See **Figure 2**.

## Transcriptome Sequencing Analysis of Macrophages in Mice With Dyslipidemia Syndrome Model

### Analysis of DEGs in Macrophages of Mice With Different Syndromes of Dyslipidemia Generated by RNA Sequencing

After comparing the DEG expressions in macrophages in dyslipidemic mice with different syndromes, 4,142 genes were identified with statistical significance,  $p < 0.05$ . Among them, 1,781 genes were upregulated and 2,361 genes were downregulated. See **Figure 3**.

Through additional reference to bioinformatics information, a total of 284 DEGs were selected in this study for in-depth analysis of content related to vascular endothelial injury. In a comparison of the 74 DEGs between the PDR group and the SKYD group, the number of reads in the PDR group was statistically higher than that in the SKYD group,  $p < 0.05$ . See **Supplementary Material S2**.

### GO Enrichment Analysis of DEGs Associated With Vascular Endothelial Injury in Macrophages

Through GO enrichment analysis based on DEGs, macrophage sequencing data of mice in the PDR group and the SKYD group were analyzed, focusing on the enrichment results of biological processes related to vascular endothelial injury.

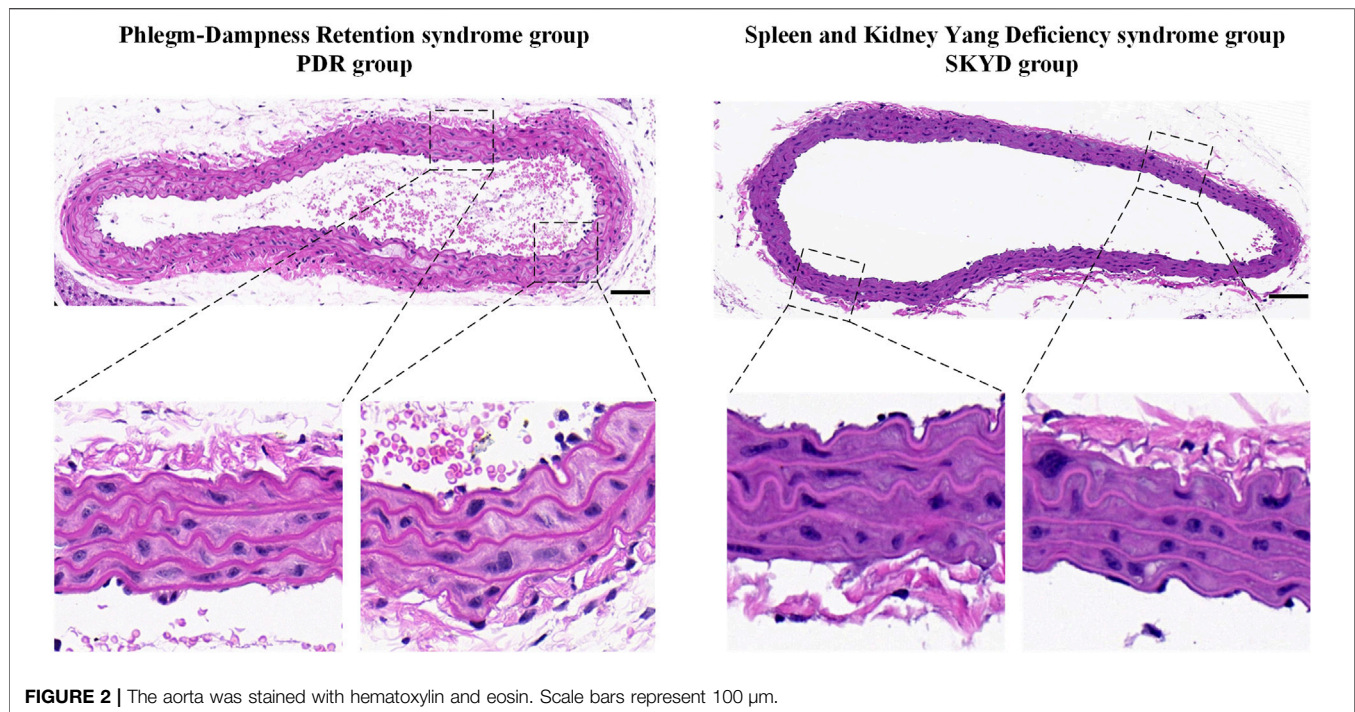

The differential pathways that were upregulated in the PDR group compared to the SKYD group primarily included the arachidonic acid (AA) metabolic process, epoxygenase P450 pathway, response to interferon-gamma, and cellular response to interferon-beta, as illustrated in **Figure 4**.

The differential pathways that were upregulated in the SKYD group compared to the PDR group primarily included blood vessel morphogenesis, angiogenesis, response to growth factor, cellular response to growth factor stimulus, chemotaxis, and taxis. See **Figure 5**.

## DISCUSSION

Dyslipidemia may significantly increase the morbidity and mortality associated with cardiovascular diseases (Lee et al., 2017). Prior research has found that effective control of blood lipid levels may reduce the possibility of relapsed coronary heart disease and its mortality (Mozaffarian et al., 2015). Therefore, proactive diagnosis and treatment for dyslipidemia, the most critical risk factor of atherosclerosis, is essential for decreasing the incidence and mortality of coronary heart disease and cerebral infarction (Rhee et al., 2019).

Treatment based on syndrome differentiation is the quintessence of TCM (Xu et al., 2021). Syndromes as a distinctive concept in TCM are the core content of the theory and provide vital evidence for treatment and prescription. TCM treatment has been shown to offer advantages in the management of dyslipidemia (Sham et al., 2014; Xu et al., 2019). The predominant mechanisms encompass inhibiting

**FIGURE 2 |** The aorta was stained with hematoxylin and eosin. Scale bars represent 100  $\mu$ m.

cholesterol absorption in the intestines and biological synthesis of endogenous lipids, regulating lipoprotein lipase activity and cholesterol transport, promoting the conversion of cholesterol into bile acids and cholesterol emission, and the regulatory effects of lipid metabolism-related transcription factors in TCM drugs (Bei et al., 2012). Syndromes represent conclusions made regarding the location and nature of the current stage of a disease, focusing on the pathological changes of the body's response state at a certain stage of a disease. In the context of the current study, the precise discrimination of exact TCM syndromes of dyslipidemia is the prerequisite and basis of TCM treatment. Therefore, TCM syndrome research is a critical link in TCM modernization, wherein biological syndrome research is most significant, providing evidence for the onset and evolution of syndromes and effective mechanisms behind specific interventions for syndromes.

RNA-Seq is a next-generation approach using high throughput sequencing available for low-abundance genomes. It is sensitive for gene structure analysis and gene expression and function assessments to unveil internal molecular mechanisms behind specific biological processes and the pathogenesis of diseases. The features of these genes consist of classic genetic features (nucleotide sequence changes) and epigenetic features (heritable phenotype changes without nucleotide sequence alterations). Transcriptomics can provide gene expression information under certain conditions and reveal the mechanism of action of specific genes, which is consistent with the TCM theory that diseases express different syndromes under the influence of internal and external causes. Our study investigated the syndrome-biological mechanism of dyslipidemia using RNA-Seq.

Our previous serum metabolomics studies of dyslipidemic patients with PDR syndrome and SKYD syndrome found that the accumulation of harmful metabolites is the predominant metabolic trait in patients with PDR syndrome, while a lack of protective metabolites is the main metabolic feature in patients with SKYD

syndrome. Further analysis has shown that oxidation and inflammatory responses are essential contributors to the different metabolic characteristics between the two syndromes (Chen et al., 2019). Thus, in-depth study of SKYD syndrome and PDR syndrome in dyslipidemia necessitates research concerning oxidation and inflammatory responses.

Macrophages are pivotal in the formation of atherosclerosis following oxidative stress damage to the vascular endothelium. M1 macrophages can promote inflammation and tissue damage, while M2 macrophages can release anti-inflammatory factors and enhance plaque stability. Endothelial dysfunction and the subsequent oxidative inflammatory reaction represent the core pathological mechanism of dyslipidemia. Macrophages are recruited toward endothelial cells, which is an early stimulus of atheromatous plaque formation (Tiwari et al., 2008) and the chief basis of the incidence of atherosclerosis. Based on our previous research, in the present study, we established the disease-syndrome animal models for and explored the characteristics of the aortic endothelial macrophages between PDR syndrome and SKYD syndrome of dyslipidemia, using RNA-Seq. Our findings from the current research are presented in the following subsections.

### Quality Assessment of the Dyslipidemia Disease Model Using Serum Lipids Analysis and HE Staining of the Aorta Revealed Success in Disease Modeling

Compared with the NC group, TG, TC, and LDL-C levels significantly increased in mice of the PDR and SKYD groups and exceeded the upper limit of the normal range, in conformity to the diagnostic criterion of dyslipidemia. The HE staining of the aorta revealed a smooth endothelial surface and clear borders between inner, medial, and outer layers in mice from the PDR and SKYD groups, without

**FIGURE 3 |** Quantitative comparison of gene expression levels in aortic macrophages of mice with dyslipidemia: PDR group vs. SKYD group.

pronounced lipid accumulation and fatty streaks. These results indicated that there were no pathological manifestations of atherosclerosis in the mice of the two groups. The HE staining results implied the satisfactory quality of the dyslipidemia modeling.

However, there were no significant differences in TG, TC, HDL-C, and LDL-C levels between the PDR and SKYD groups. Therefore, the differences in transcriptomic traits and biological results between the two groups based on RNA-Seq in subsequent studies may not be caused by the disease itself, but by syndromes (subtypes).

### Quality Assessment of the Two Syndrome Models (PDR, SKYD) Through Behavioral Tests Indicated the Feasibility of Syndrome Modeling

The characteristics of mice in the PDR group included their being fat in body shape, with a reduced brightness of hair, lethargy, slow responses, lazy to move, as well as soft, formed, and sticky feces, consistent with clinical manifestations of PDR syndrome. The behavioral features of mice in the SKYD group incorporated matted hair, slight paw and nail

coloration, shrinking of the body, tranquil, fatigue, sleepiness, sticking together, low-temperature tail, decrease in food and water intake, and loose and watery stools. These were in agreement with clinical manifestations of SKYD syndrome. These results indicate that syndrome modeling can simulate typical symptoms of the corresponding syndrome.

### Transcriptomic Data of Macrophages Showed Pro-Inflammatory Activities in the Vascular Endothelium in Dyslipidemic Mice With PDR Syndrome and SKYD Syndrome, but the Mechanisms Were Different

#### IFN- $\gamma$ and IFN- $\beta$ Expressions Were Upregulated in Macrophages in Dyslipidemic Mice With PDR Syndrome, Promoting Endothelial Inflammation

It is known that interferon gamma (IFN- $\gamma$ ) can facilitate the progression of inflammatory diseases—for example, inflammatory bowel disease and atherosclerosis. *In-vitro* and *in vivo* studies have found IFN- $\gamma$  may damage epithelial cells

**FIGURE 4 |** Different biological process of upregulation in the group with PDR syndrome compared with the group with SKYD syndrome.

**FIGURE 5 |** Different biological process of upregulation in the group with SKYD syndrome compared with the group with PDR syndrome.

and endothelial barrier integrity (Ng et al., 2015). Moreover, IFN- $\gamma$  exerts significant impacts on the biological properties of the vascular endothelial cells. It may initiate vascular remodeling around microvascular endothelial cells (Chrobak et al., 2013). Monocyte-derived macrophages are induced by the pro-inflammatory factor IFN- $\gamma$ , which are of vital significance during plaque formation. Both IFN- $\gamma$  and

macrophages are major players in oxidative stress. Just like other pro-inflammatory factors, IFN- $\gamma$  acts as a significant trigger of the synthesis and release of reactive oxygen species (Schroecksnadel et al., 2006).

Interferon beta (IFN- $\beta$ ) mRNA can effectively induce endothelial chemokine expression (Buttmann et al., 2007). It enhances endothelial cell adhesion to eosinophils mainly

through upregulating vascular cell adhesion molecule-1 and intercellular adhesion molecule-1 expressions (Kobayashi et al., 2008). IFN- $\beta$  fuels the formation of macrophage foam cells via a macrophage scavenger receptor class A (SR-A)-mediated cholesterol influx and an ATP-binding cassette transporter (ABCA1)-mediated efflux of mechanisms, thus expediting the incidence of atherosclerosis (Boshuizen et al., 2016).

Under TCM, PDR syndrome is a type of sthenia syndrome. The phlegm evil is both the pathological product and pathogenic factor, impeding the delivery and movement of Qi, thus resulting in body fluid stagnation and hydrops or damp evil accumulation and phlegm. Turbid phlegm can block the vessels and bring about damage that causes blood vessels to be blocked. This then affects the operation of Qi and blood, resulting in their poor operation, which can lead to the occurrence of diseases over time. Finally, the vascular endothelium is impaired.

Our results showed that IFN- $\gamma$  and IFN- $\beta$  expressions in macrophages were upregulated in dyslipidemic mice with PDR syndrome, and at significantly higher levels than in mice with SKYD syndrome. This finding suggests that vascular endothelial injury induced by IFN- $\gamma$  and IFN- $\beta$  overexpression in vascular endothelial macrophages is a characteristic of PDR syndrome in dyslipidemia.

### Macrophage Chemotaxis and Taxis Were Enhanced in Dyslipidemic Mice With SKYD Syndrome, Promoting Endothelial Inflammation

Macrophages are inflammatory cells, and their accumulation can stimulate cytokine and chemokine release, initiating immune responses and accelerating plaque formation (Liehn et al., 2006). The secreted chemokines infiltrate atherosclerotic plaques at an early stage (Weber et al., 2008). Despite the role in lipid accumulation, macrophage foam cells also release pro-inflammatory factors and chemokines, further stimulating vascular endothelial cells, fueling vascular endothelial inflammation, and exacerbating the disease (Kleemann et al., 2008). A prior study found that resveratrol could exert a protective effect on the heart via inhibiting endothelial cell migration and monocyte chemotaxis (Cicha et al., 2011).

The TCM mechanism of SKYD syndrome in dyslipidemia refers to spleen-kidney Yang deficiency. The spleen and kidneys are weak, which will cause the loss of Qi and Yang. The deficiency of spleen Yang and kidney Yang can lead to the loss of a warm body. The function of Qi is abnormal, which causes the decrease of its protective effect. Furthermore, as the body lacks warmth from Yang-Qi and corresponding protection, the vascular endothelium can be easily injured.

Our results showed that macrophage chemotaxis and taxis were significantly enhanced in dyslipidemic mice with SKYD syndrome, compared with the PDR mice. This finding suggests that vascular endothelial injury induced by enhanced macrophage chemotaxis and taxis was the main characteristic of the SKYD syndrome in dyslipidemia.

The above results demonstrate that different biological processes resulted in vascular endothelial injury in PDR syndrome and SKYD syndrome with dyslipidemia, indicating different injury mechanisms of the two syndromes. These results also imply that there exist biological bases behind the pathogenesis of TCM syndromes.

### Transcriptomic Data of Macrophages Showed Protection for the Vascular Endothelium in Dyslipidemic Mice With PDR Syndrome and SKYD Syndrome, but the Mechanisms Were Different

#### AA Metabolic Process and Epoxygenase P450 Pathway Levels Increased in Macrophages in Dyslipidemic Mice With PDR Syndrome, Exerting Protection Effects on the Vascular Endothelium

Growing evidence has shown that AA metabolism is crucial in maintaining vascular homeostasis, closely associated with the occurrence and development of cardiovascular diseases (Xue et al., 2015). AA is an amphiphilic compound affecting endothelial cell migration; without the involvement of receptor-specific signaling, it affects endothelial cell metabolism and membrane viscosity (Jensen et al., 2007). AA metabolic pathways are pivotal in platelet activation and gastric damage (Rukoyatkina et al., 2018). Suppressing AA metabolism can further block endothelial cell migration, inducing cell apoptosis (Jantke et al., 2004). A recent study has reported that *Panax notoginseng* saponins combined with aspirin inhibited platelet activity via enhancing AA metabolism (Wang et al., 2021).

Cytochromes P450 (CYP450) refer to a third pathway for AA metabolism (Roman, 2002). CYP450 metabolites of AA in endothelial cells may impact endothelial function. AA is metabolized by CYP450 and cyclooxygenase (COX) into bioactive eicosanoids, exerting vascular protection effects (Spiecker and Liao, 2005). AA is also metabolized by CYP450 and COX into four regioisomeric epoxyeicosatrienoic acids (EETs) used for bioprotection and cardioprotection (Xu et al., 2011). EETs have multiple nutritive functions, including the anti-inflammatory effect, in their cardioprotection (Node et al., 1999). Decreases in EETs expressions may lead to the onset of cardiovascular diseases and endothelial dysfunction (Bellien et al., 2012).

Our analysis showed significant upregulations of AA metabolic process and epoxygenase P450 pathway levels in macrophages in dyslipidemic mice with PDR syndrome, compared to the SKYD mice. These results indicate that endothelial protection from macrophages via AA and CYP450 overexpressions is another trait of PDR syndrome in dyslipidemia.

#### Biological Process Items, Including Angiogenesis, Blood Vessel Morphogenesis, Response to Growth Factor, and Cellular Response to Growth Factor Stimulus, Whose Activities Were Significantly Enhanced for Macrophages in Dyslipidemic Mice With SKYD Syndrome, Which Facilitated Angiogenesis and Vascular Repair

Angiogenesis consists of multiple, intricate, highly coordinated processes in which endothelial cells with dynamic changes are of great importance (Potente et al., 2011). Angiogenesis may occur in the pathological environment (Alvarez Arroyo et al., 1998) and be initiated by endothelial cell activation. The genetic program of endothelial cells triggers the modulation of angiogenic phenotype. Macrophages are significant regulators for tissue homeostasis, growth and repair, and morphogenesis. The growing endothelial cells can respond to extracellular signaling molecules, such as extracellular

matrix molecules, chemokines, growth factors, and cell adhesion molecules (Jeong et al., 2017). Growth factors and cytokines secreted from macrophages (Lucas et al., 2010) may promote the formation of new blood vessels via recruiting new blood vessels and modifying the extracellular matrix (Corliss et al., 2016). Vascular endothelial growth factors (VEGFs) are considered the most robust booster for angiogenesis, increasing the survival of endothelial cells and enhancing mitosis (Dvorak, 2005). Numerous studies have demonstrated that VEGFs are expressed in macrophages (Guo et al., 2018). They can stimulate assorted cell functions of endothelial cells via high-affinity binding to two tyrosine kinase receptors, VEGF receptor (VEGFR) 1 and VEGFR2 (Zachary, 2003).

Our study found that the top biological process items enriched in macrophages in dyslipidemic mice with SKYD syndrome were angiogenesis, blood vessel morphogenesis, response to growth factor, and cellular response to growth factor stimulus, whose activities were significantly enhanced, compared to the PDR group. This finding suggested that angiogenesis and vascular repair via enhancing macrophage chemotaxis and taxis are another critical feature of SKYD syndrome in dyslipidemia.

The above results indicate that vascular protection mechanisms are distinct between PDR syndrome and SKYD syndrome in dyslipidemia. This further implies different protection mechanisms in the two syndromes, which in turn further corroborates that there exist biological bases behind the pathogenesis of TCM syndromes.

According to the results presented in Sections *Transcriptomic Data of Macrophages Showed Pro-Inflammatory Activities in the Vascular Endothelium in Dyslipidemic Mice With PDR Syndrome and SKYD Syndrome, but the Mechanisms Were Different* and *Transcriptomic Data of Macrophages Showed Protection for the Vascular Endothelium in Dyslipidemic Mice With PDR Syndrome and SKYD Syndrome, but the Mechanisms Were Different*, vascular endothelial injury was induced by different biological processes in PDR syndrome versus SKYD syndrome in dyslipidemia. But there was also found to be angiogenesis and vascular repair in the pathogenetic process. The two opposite processes—*injury and repair*—are consistent with the TCM tenet that “healthy Qi and evil Qi are struggling throughout the incidence and dynamic development of diseases and syndromes.” As the injury effect outweighs the repairing effect, the state of diseases takes place.

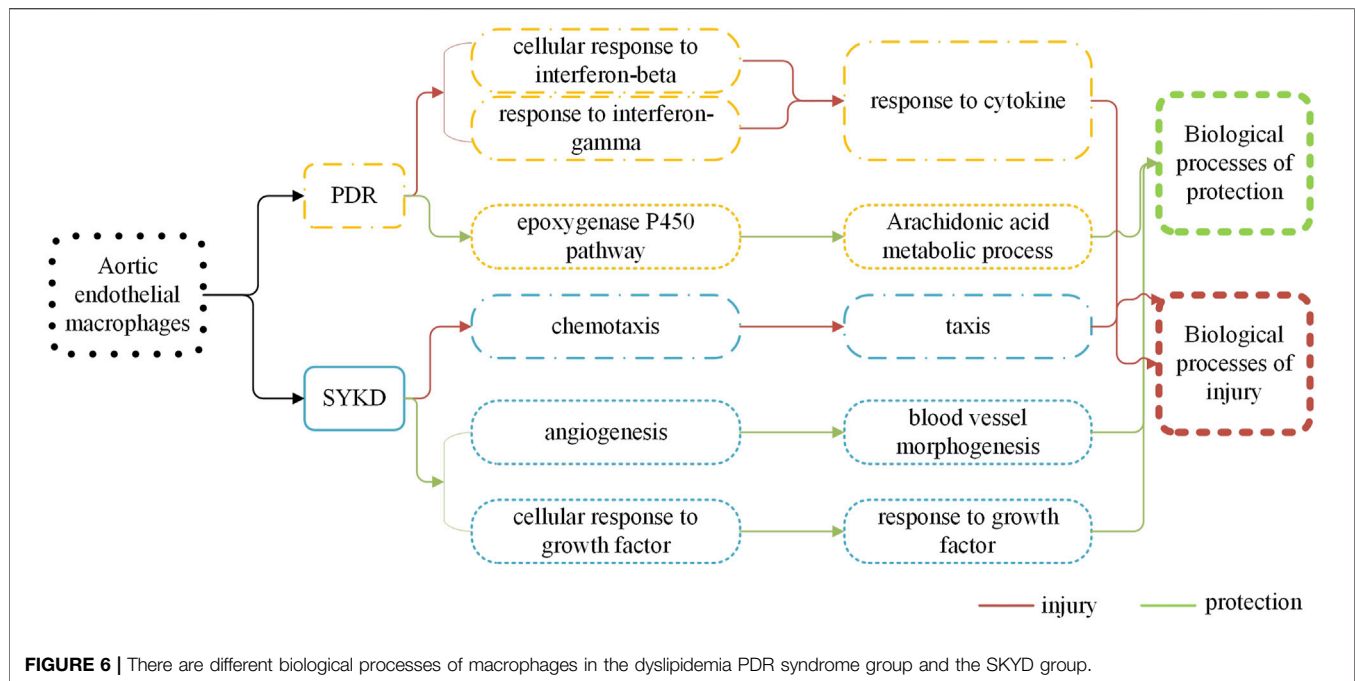

## **Different Transcriptomic Characteristics of Aortic Endothelial Macrophages Between Dyslipidemic Mice With PDR Syndrome and SKYD Syndrome are Manifested by Distinct Biological Control Processes During Both Harmful and Protective Biological Processes, Indicating Different Biological Bases Behind Different Syndromes of the Same Disease and Providing Biological Evidence for the TCM Principle of “Treating the Same Disease With Different Treatments”**

See Figure 6.

In the TCM clinic, Western medicine diagnosis is often combined with TCM syndrome diagnosis for the management of a disease. Research about the association between Western diseases and TCM syndromes is believed to be one of the most important steps for modern TCM diagnostics studies. Based on the confirmation of a Western disease, disease-syndrome research can not only elucidate the biological bases for TCM differentiation but also help to advance innovative research on the “disease-syndrome therapy formula” and thereby provide precise and rational treatment.

Previous TCM syndrome research has emphasized harmful factors in a syndrome scenario, without much attention to the body’s self-protection in this process. The present study, however, did both, focusing on an analysis of harmful factors and protective factors, and thereby providing an innovative dimension. The unity of opposites—protective and harmful effects—is achieved through dynamic balancing between healthy Qi and evil Qi via mutual conflicts, mutual restriction, and mutual repulsion. Diseases can occur when evil Qi outstrips healthy Qi, per the TCM principle that affirms, “when there is sufficient healthy Qi inside, pathogenic factors have no way to invade the body; where pathogenic factors accumulate, the parts of the body must be deficient in the healthy Qi.” TCM treatment should be implemented based on the accurate discrimination of diseases and syndromes and precisely resolve issues by correcting an imbalance between healthy Qi and evil Qi through prescriptions and formulas.

Our transcriptomic analysis of aortic endothelial macrophages in dyslipidemic mice with PDR syndrome and SKYD syndrome provided notable results, as follows. First, DEGs were identified between dyslipidemic mice with PDR syndrome versus SKYD syndrome, proving different biological mechanisms during the pathogenesis of different syndromes, from the perspective of syndrome research. Second, there were found to exist different biological processes between PDR syndrome and SKYD syndrome in dyslipidemic patients, including harmful and protective biological processes. When evil Qi invades the body to produce harmful effects, healthy Qi also responds to it and thereby generates protective responses in a syndrome scenario, which corresponds with the TCM principle that “healthy Qi and evil Qi are struggling throughout the incidence and dynamic development of diseases and syndromes.” Therefore, the occurrence of syndromes can be understood to be a result of healthy energy–evil struggles. This, in turn, may help to explain why TCM treatment for one disease with various therapies and formulas can achieve satisfactory efficacy, in that it could be attributed to different drugs targeting different biological processes. Our work offers biological mechanisms for the TCM theories “treating different syndromes with different treatments” and “formula corresponding to the syndrome.” Third, though patients may be diagnosed with the same disease (i.e., dyslipidemia), different formulas should be selected according to their particular syndromes (i.e., giving consideration to the distinct biological processes occurring within PDR syndrome vs. SKYD syndrome). Our study provides biological evidence behind the TCM principle of “treating the same disease with different treatments,” embodying the scientificity of “treatment based on syndrome differentiation.”

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: NCBI [accession: <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE180802>].

## ETHICS STATEMENT

The animal study was reviewed and approved by the animal ethics review committee of the Institute of Basic Theories of Chinese medicine, Chinese Academy of Chinese Medical Sciences, approval no. 201908006 (Beijing, China).

## AUTHOR CONTRIBUTIONS

XX and JC conceived and designed the study. JC, CY, SZ, and PL performed the modeling and evaluation of animal models of diseases and syndromes. JC, TW, ZY, and BX performed the sampling and macrophage screening. JC, CY, ZY, BX, PL, and XX acquired the data. JC, CY, ZY, and BX analyzed and interpreted data. JC and CY drafted the manuscript. PL and ZY critically revised the manuscript for important

intellectual content. All authors read and approved the final manuscript.

## FUNDING

This study was supported by the National Natural Science Foundation of China (no. 82004237), Fundamental Research Funds for the Central Universities (no. 2018-JYBZZ-JS182), Beijing University of Chinese Medicine Xin-ao Award Fund (no. 2018-XAJLJJ-026).

## ACKNOWLEDGMENTS

The authors would like to thank Tong-Jin Zhao (Institute of Metabolism and Integrative Biology (IMIB), Fudan University, Shanghai, China) for technical assistance with this study.

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fphar.2021.665635/full#supplementary-material>

*K. galanga* is an aromatic medicinal herb. It is locally to India and distributed in China, Myanmar, Indonesia, Malaysia, and Thailand. *K. galanga* is a Traditional Chinese Herb Medicine (TCHM), which has been applied to treat cold, dry cough, toothaches, rheumatism, hypertension and so on. In addition, it has been used widely as spices since its highly aromas. The aim of this review is to compile and update the current progresses of ethnomedicinal uses, phytochemistry, pharmacology and toxicology of *K. galanga*. All the data on *K. galanga* were based on different classical literary works, multiple electronic databases including SciFinder, Web of Science, PubMed, etc. The results showed that ninety-seven compounds have been identified from rhizome of *K. galanga*, including terpenoids, phenolics, cyclic dipeptides, flavonoids, diarylheptanoids, fatty acids and esters. Modern pharmacology studies revealed that extracts or secondary metabolites of the herb possessed anti-inflammatory, anti-oxidant, anti-tumorous, anti-bacterial, and anti-angiogenesis effects, which were closely related to its abundant ethnomedicinal uses. In conclusion, although previous research works have provided various information of *K. galanga*, more in-depth studies are still necessary to systemically evaluate phytochemistry, pharmacological activities, toxicity and quality control of this herb.

**Keywords:** *Kaempferia galanga* L., ethnomedicinal uses, phytochemistry, pharmacology, toxicology

## INTRODUCTION

*K. galanga* is from a dried rhizome of herb *Kaempferia galanga* L., belonging to the important family Zingiberaceae and genus *Kaempferia*. It also called sand ginger, aromatic ginger in different areas. *K. galanga* is native to India, and commonly found in China, Myanmar, Indonesia, Malaysia, and Thailand (Wang and Tang, 1980; Santhoshkumari and Devi, 1991). In Southern China, such as Guangxi, Guangdong, Yunnan are the main producing areas of *K. galanga*. In China, being a source of valuable bioactive compounds, it was used as a folk medicine due to its good curative effect on rheumatism, dry cough, colic, muscle pain, inflammations, as well as tumors (Park et al., 2005; Liu et al., 2010; He et al., 2012). In India, *K. galanga* was used in the treatment of intestinal wounds and urticarial (Nazar et al., 2008; Seth and Maurya, 2014). In Malaysia, *K. galanga* was also applied for

abdominal pain and postpartum care in woman (Hirschhorn, 1983). Moreover, it could also be used as food condiment. According to Sivarajan and Balachandran (1994), *K. galanga* was used to treat phlegm, fever, cough, meanwhile, it also exerts good effect as a diuretic, anabolic, and carminative.

To date, phytochemical studies have discovered many chemical compounds of the plant, mainly terpenoids, phenolics, diarylheptanoids and flavonoids. Also, it has revealed that the components or extracts from *K. galanga* exhibit anti-inflammatory, anti-oxidant, anti-tumorous, anti-angiogenesis, and other effects in **Figure 1** (Umar et al., 2014; Wu et al., 2015; Zhou et al., 2015; Yao et al., 2018; Srivastava et al., 2019). However, pharmacological researches mainly focus on the crude extracts and characteristic compounds especially *trans* ethyl p-methoxycinnamate. Furthermore, many active components in the extracts of *K. galanga* have not been fully investigated yet as well as the mechanisms of action. In addition, biological evaluations should take appropriate effective dose, the frequency of administration and duration of treatment into consideration. Thus, there are many issues worthy of further study.

Although previous reports provided great inspiration and help for us (Umar et al., 2011; Munda et al., 2018; Elshamy et al., 2019; Kumar, 2020), we are more concerned about the application of *K. galanga* in ethnomedicine, its relationship with phytochemistry, modern pharmacology, and its toxicity. Herein, we conducted a comprehensive review on the phytochemistry, pharmacology, toxicology and ethnomedicinal uses of *K. galanga*. We also discuss the limitations of the current studies of the herb and suggest areas of interest for potential future research. We hope to provide valuable information for future in-depth investigations and applications of the herb.

## REVIEW METHODOLOGY

The literature for this review was collected from different classical literary works, multiple electronic databases including SciFinder, Web of Science, PubMed, Science Direct, Wiley, Springer, CNKI, and PhD, MSc dissertations in Chinese and Pharmacopoeias prior to December 2020 on phytochemistry, pharmacology, toxicology and ethnomedicinal uses of *K. galanga*. A total of 97 publications were collected after preliminary screening, among them, 24 publications used for traditional uses, 34 publications used for phytochemistry, 39 publications used for pharmacological activities. The search terms “*Kaempferia galanga* L” and “*K. galanga* essential oils” were used with no exact time limit. Identify potential full-texts of eligible papers, and check additional and unpublished citations for all relevant references.

## ETHNOMEDICINAL USES

*K. galanga* has been considered as an important herbal medicine with a long history in China, on the basis of its wide spectrum of biological activities. *K. galanga* was listed in the Chinese medical classic “Compendium of Materia Medica” (Ming dynasty), and it

had a good effect on the treatment of pains and cold-damp dysentery. According to the Pharmacopoeia of the People's Republic of China, *K. galanga* is pungent, warm natured in flavor and belonging to the stomach meridian, and has the action of activating Qi, warm interior, remove digestion and relieve pain.

In addition, *K. galanga* showed significant increase in urine volume and also increased level of sodium and potassium in urine which proves as a strong diuretic agent. Therefore, the results provided a quantitative basis to explain the traditional folkloric use of *K. galanga* as a diuretic agent (Mohammad et al., 2016).

The traditional methods of *K. galanga* are to decoct in water or mash for external use, and a dose of 6–9 g for oral medication is recommended by the Chinese Pharmacopoeia (China Pharmacopoeia Commission, 2015). In addition, although *K. galanga* was widely used, there were few studies on its side effects. The ethnomedicinal uses of *K. galanga* are listed in **Table 1**.

## PHYTOMEDICINAL FORMULATIONS

*K. galanga* has been used as a phyto-ingredient in some classical medicinal formulations. It was combined with other herb to treat common pains, cold, digestive disorders as formulations, and these formulations could be made into different dosage forms or decocted with water depending on the maximum efficacy to use them. (Kanjapothi et al., 2004). The traditional formulations containing *K. galanga* are listed in **Table 2**.

## TOXICOLOGY

Although *K. galanga* has long been used as TCHM, its systematic toxicity and safety evaluations are still unclear. The acute and subacute toxicity tests of its rhizomes ethanol extract (maximum single oral dose up to 5,000 mg/kg (b. w.), and daily dose of 1,000 mg/kg (b. w.) for 30 consecutive days) showed that it has no significant toxicity regarding to the morbidity and mortality (Amuamuta et al., 2017).

Similarly, Kanjanapothi et al. have reported that the maximum tolerated dose (MTD) of ethanol extract of rhizomes of *K. galanga* was up to 5,000 mg/kg and no death occurred in rats by oral administration. Hematological analysis showed no difference in any parameter tested between control and test group in male and female. Moreover, no abnormal in pathology and histopathology, and no irritation in the skin. Besides, in 28 days subacute toxicity studies, there was no death occurred when the ethanolic *K. galanga* extract was treated the dosage of 25, 50 or 100 mg/kg (Kanjapothi et al., 2004). Therefore, *K. galanga* is safe for the vital organs during treatment depending on the above toxicological studies.

## PHYTOCHEMISTRY

Chemical characteristics of *K. galanga* showed the existence of various types of secondary metabolites such as terpenoids, phenolics, cyclic dipeptides, diarylhaptanoids, flavonoids,

polysaccharides, and essential oils. A total of 97 compounds have been obtained from the rhizome of *K. galanga*. In this article, we will present each types of compounds in **Table 3**, and structures in **Figures 2-7**.

## Volatile Constituents

The species of the chemical constituents of essential oils has been studied for many years. They were isolated by steam distillation or supercritical fluid extraction, and analyzed by GC-MS. Volatile oils are generally composed of esters, hydrocarbons, terpenes and

aromatic compounds. The 19 major compounds of essential oils are esters and terpenoids such as ethyl cinnamate, p-methoxycinnamate, pentadecane,  $\delta$ -selinene, borneol, eucalyptol (Fan et al., 2005; Zhou et al., 2006; Zhang, 2007; Cui et al., 2008; Wang et al., 2009; Sutthanont et al., 2010; Liu et al., 2014; Luo et al., 2014; Raina and Abraham, 2016; Yang et al., 2018) (**Table 4; Figure 2**).

These essential oils show various promising pharmacological and therapeutic potentials, particularly, ethyl cinnamate and p-methoxycinnamate (Peter, 2004; Raina and Abraham, 2016).

97	β-daucosterol	C <sub>35</sub> H <sub>60</sub> O <sub>6</sub>	Yao (2018)

What's more, *K. galanga*. has always been used as food flavoring and aromatic, due to its flavor and fragrances, which might be up to ethyl p-methoxycinnamate (Srivastava et al., 2019).

## Terpenoids

Terpenoids were the representative class of compounds isolated from *K. galanga*. To date, 26 terpenoids (**1–26**, **Figure 3**) have been isolated and identified, which included monoterpenoids, sesquiterpenoids and diterpenoids. Most of them were isopimarane type diterpenoids with the typical structural features of two double bonds of  $\Delta^{15(16)}$ ,  $\Delta^{8(9)}$  and/or  $\Delta^{8(14)}$ .

Among them, 3-carene-5-one (**1**) was a monoterpene ketone, which was isolated from methanolic extract of *K. galanga* firstly (Kiuchi et al., 1987). More recently, four new diterpenoids **6**, **19**, **20**, **26** were isolated and elucidated. Kaemgalangol A (**6**) was

isolated from the chloroform fraction of methanol extract of *K. galanga*, and it was remarkable that **6** contained a rare 9,10-seco-isopimarane skeleton (Ningombam et al., 2018). From the hexane fraction of 95% ethanol extract of *K. galanga*, diterpenoids **19** and **20** were also identified (Tungcharoen et al., 2020). Compound **26** was isolated from the chloroform fraction of 75% ethanol extract of *K. galanga* (Yao, 2018).

## Phenolics

Phenolics (**27–41**, **Figure 4**) are compounds with a phenolic hydroxyl group (Li et al., 2017a; Hua et al., 2018). Depending on the existing literatures, 16 phenolic chemical constituents were found. Among them, **27–29** were hydroxybenzoic acids, and **35–37** were hydroxycinnamic derivatives. In addition, phenolic acids may be found in plants as in the form of glycosides (Masullo et al., 2015), such as **31** and **41** (Yao et al., 2018). Besides, **40** and

41 were first isolated and their structures were elucidated by the NMR, HR-MS and IR (Wu, 2016; Yao et al., 2018).

## Cyclic Dipeptides

Cyclic dipeptides (42–57, **Figure 5**) are formed by cyclization of two amino acids through peptide bonds. They are the simplest members in the most common cyclic peptide family found in nature. A total of 16 cyclic dipeptides have been reported (Yao, 2018).

## Flavonoids

The parent nucleus structure of flavonoids is 2-phenylchromone. The flavonoids isolated from *K. galanga* were all free monomers (58–60, **Figure 5**), and the substituents are usually methoxy and phenolic hydroxyl groups (Wu, 2016; Jiao et al., 2017). Kaempferol (58) (Chen et al., 2012) and luteolin (59) (Liu et al., 2018) had protective effects on lung injury by regulating multiple cellular pathways. Moreover, 58 (Schwarz et al., 2014) have been reported to exert anti-corona virus effects, indicating its potential in the treatment of COVID-19. Similarly, its relative, compound 59 could dose-dependently inhibit the SARS coronavirus cleavage activity with low micromole inhibitory activity ( $EC_{50} = 10.6 \mu M$ ) (Yi et al., 2004), particularly, it could also inhibit the 3CLPro of SARS-CoV2 with  $IC_{50}$  value of  $20.2 \mu M$  (Ryu et al., 2010). In silicon docking indicated that 59 could interact with a series of key targets of SARS-CoV-2 (3CLpro, PLpro, Spro and RdRp) to exert potential anti-corona virus activity (Yu et al., 2020).

## Diarylheptanoids

Diarylheptanoids (61–68, **Figure 6**) have a 1,7-diphenylheptane skeleton. Based on the skeleton, diarylheptanoids could be divided into linear and cyclic structural types. Linear diarylheptanoids occurred frequently in plants of Zingiberaceae family, and all the diarylheptanoids isolated from *K. galanga* were linear.

The first report of two novel sulfonated diarylheptanoid epimers focused on the identification of kaempulfonic acid A (67) and B (68) (Wang et al., 2013). More recently, cyclic diarylheptanoids were isolated and elucidated. The two compounds, 62 and 61 were very similar to each other, while the difference was the substituents, 62 had one phenolic hydroxyl replaced by one glucosyl moiety. In addition, a linear diarylheptanoid 65 was isolated and elucidated (Yao, 2018; Yao et al., 2018).

## Fatty Acids and Esters

Fatty acid and esters were included in *K. galanga*, currently, 11 fatty acid and esters (69–79, **Figure 6**) have been analyzed and identified from *K. galanga* (Wu, 2016; Yao, 2018).

## Polysaccharides

Recently, the water-soluble polysaccharides (80–88, **Figure 7**) from *K. galanga* (KGPs) were extracted and purified for the first time, and further investigated by different spectroscopic techniques such as HPGPC, FTIR, IC. Results showed that

fucose (80), arabinose (81), xylose (82), rhamnose (83), mannose (84), galactose (85), glucose (86), glucuronic acid (87), and galacturonic acid (88) were the main components of KGPs, and their the molar ratio is 0.37: 3.12: 1.23: 3.09: 1.00: 6.39: 1.36: 0.91: 1.27, which significantly indicated that KGPs were heterogeneous acidic polysaccharides (Yang et al., 2018).

## Other Compounds

Apart from those chemical constituents mentioned above (1–88), *K. galanga* also contained other eight compounds (89–97 **Figure 7**). Three pyroglutamic acids (89–91), two steroids (96–97) and three aromatic compounds (92–95) have been isolated and identified (Wu, 2016; Yao, 2018).

Molecular docking assay was used to investigate the effect of 92 as coronavirus polymerase (RdRp) inhibitor, and the results showed its potential anti-coronavirus activity with the binding energies showed  $-5.54$  kcal/mol. Moreover, further studies are required to determine the potential uses of 92 in COVID-19 treatment (El-Aziz et al., 2020). Meanwhile,  $\beta$ -sitosterol (96) have been reported to have inhibitory activity against the SARS-CoV 3CLpro with  $IC_{50}$  value of  $47.8 \mu g/ml$  (Lin et al., 2005).

## Elemental Composition

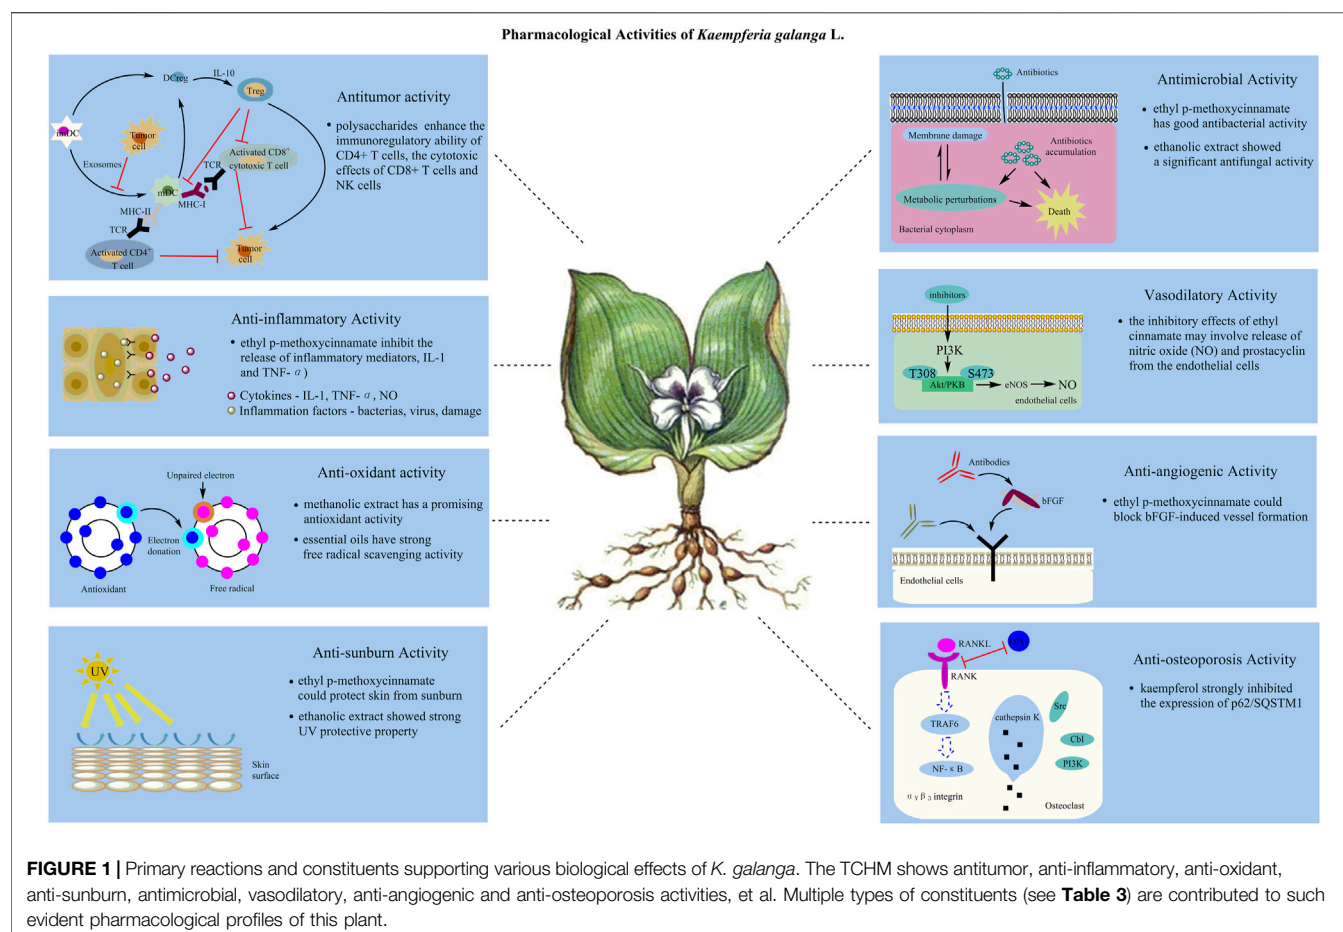

*K. galanga* was abounded with mineral elements K, P, Mg, Ca, Al, Fe, Na and Mn, and the content of K was the highest, amounting to  $18,600 \mu g/g$  (Huang et al., 2012).

## PHARMACOLOGICAL ACTIVITIES

*K. galanga* have gained much attention with its comprehensive pharmacological potential to treat a variety of human diseases. Modern pharmacological investigations have revealed that the extracts and natural products identified from *K. galanga* exhibited comprehensive bioactivities, including antitumor, antioxidant, anti-inflammatory and anti-tuberculosis, etc. Besides, the aqueous extract from its leaves have been reported to exert antinociceptive activity and anti-inflammatory activities in a dose dependently manner, supporting its traditional uses in the remedy of treat pain and mouth ulcer (Sulaiman et al., 2008). In addition, the kill of booklice by its essential oil, indicating its potential in the development of a natural insecticide and repellent for controlling stored grain pests (Liu et al., 2014). The more detailed pharmacological reviews were as follows.

### Antitumor Activity

According to the previous reports, the extracts and active components of *K. galanga* showed potential inhibitory effects on many types of tumors, such as gastric cancer, colon carcinogenesis, oral cancer and multiple myeloma. Although *K. galanga* preparations traditionally are used as an alternative medicine for tumor, there is little scientific evidence available about the use of *K. galanga* as an anticancer agent. Reports indicate that the anticancer signaling mechanisms of *K. galanga* extracts and

compounds include inhibition of the growth of tumor cells, apoptosis and cytotoxicity, among others.

Multiple constituents isolated from *K. galanga* showed antitumor activity. It is reported that both *trans*- and *cis*-ethyl p-methoxycinnamate (**34**, **39**) could exert anticarcinogenic effect in an *in vitro* EBV assay with IC<sub>50</sub> values of 5.5 and 9.5  $\mu$ M (Xue and Chen, 2002). *Trans*-ethyl p-methoxycinnamate (**34**) was examined on HSC-3 and Ca922 lines by MTT assay. The MTT assay showed **34** could exert potent cytotoxicity in HSC-3 (IC<sub>50</sub> = 0.075 mg/ml) and Ca922 (IC<sub>50</sub> = 0.085 mg/ml) cell lines (Ichwan et al., 2019). In addition, **34** could also dose dependently induce apoptosis, and affected the cell cycle progress of the cell cycle of HepG2 cells (Liua et al., 2010). *Trans*-p-methoxycinnamic acid (**37**) (40 mg/kg b.w.) exhibited ameliorating anticancer effects in DMH-induced rat colon carcinogenesis by regulating of various processes, such as proliferation, invasion, angiogenesis, apoptosis and inflammation (Gunasekaran et al., 2019). The diarylheptanoid compounds sandaracopimaradiene-9 $\alpha$ -ol (**10**), kaempulchraol I (**11**), kaempulchraol L (**14**) revealed anti-cancer effect in human HeLa (IC<sub>50</sub> = 75.1, 74.2 and 76.5  $\mu$ M, respectively) and HSC-2 cancer cells (IC<sub>50</sub> = 69.9, 53.3 and 58.2  $\mu$ M, respectively) by using MTT assay (Ningombam et al., 2018).

The essential oils from the *K. galanga* have displayed moderate antitumor activity. Flow cytometry (FCM) was used to evaluate the effect of volatile oil on cell cycle and apoptosis of MKN-45 cells. The growth inhibition rates of gastric cancer were 57.2, 28.0 and 5.0% respectively in the high-, medium-, and low-dose volatile oil-treated groups (1.56, 0.78, 0.39 g/d), and the gastric cancer cells (MKN-45 cells) were arrested at G0/G1 phase. The results showed the high-dose volatile oil-treated group was effective for inhibiting the growth of gastric cancer by comparing to cyclophosphamide (CTX)-treated group (78.9%) (Xiao et al., 2006). The ethanolic extract of *K. galanga* and its major bioactive constituent *trans*-ethyl p-methoxycinnamate (**34**) could exert cytotoxic activity against cholangiocarcinoma cells (CL-6). The ethanolic extract inhibited CL-6 cell growth at doses of 125 and 250  $\mu$ g/ml, with 80 and 94% inhibitory, and IC<sub>50</sub> values of 64.2 and 49.19  $\mu$ g/ml, respectively (Amuamuta et al., 2017). Recently, the methanolic and acetic extracts of *K. galanga* leaves have been reported to exert moderate cytotoxic activities (LC<sub>50</sub> = 4.78 and 0.11  $\mu$ g/ml, respectively) in the brine shrimp lethality bioassay (Rahman et al., 2019). The water-soluble polysaccharides isolated from *K. galanga* could inhibit the growth of H22 solid tumors, while exert protective effects on the thymus and spleen of solid tumor bearing mice (Yang et al., 2018).

**FIGURE 2 |** Chemical structures of main volatile components in *K. galanga*.

## Anti-Inflammatory Activity

The traditional applications of *K. galanga* in the remedy of abdominal pains and toothache are mostly depend on its anti-inflammatory effects. The mechanism behind the anti-inflammatory action of *K. galanga* is associated with the presence of bioactive metabolites by inhibiting the release of inflammatory factors.

The anti-inflammatory effect of *trans*-ethyl p-methoxycinnamate (**34**) was assessed using the cotton pellet granuloma assay in rats *in vivo*, and *in vitro* using the human macrophage cell line (U937). It strongly inhibited granuloma tissue formation in rats and the release of IL-1 and TNF- $\alpha$ , which were significantly inhibited in both *in vivo* and *in vitro* models (Umar et al., 2014). Kaempferol (**58**) exerted potent inhibitory activity on HMC-1 mast cell-mediated inflammatory response stimulated by lipopolysaccharide (LPS) demonstrated by MTT assay. The release of IL-6, IL-8, IL-1 $\beta$  and TNF- $\alpha$  significantly decreased at the dose of 40  $\mu$ mol/L (Zhou et al., 2015). Moreover, diarylheptanoids **61**, **63**, **65**, **66**, have been reported to inhibit nitric oxide (NO) production on LPS-induced macrophage RAW264.7 cell lines with IC<sub>50</sub> values of 27.85, 46.98, 26.98 and 17.26  $\mu$ M, respectively (Yao et al., 2018).

The leaves of *K. galanga* have been reported to exert potent anti-inflammatory activity in a modified carrageenan-induced

paw-edema test, supporting its traditional applications of ulcers and pains (Sulaiman et al., 2008). The various extracts of *K. galanga* exerted anti-inflammatory effects *in vivo*. In carrageenan induced acute inflammation test, the successive petroleum ether fraction (SPEF) showed 39.16% effect (300 mg/kg b.w., p.o.), followed by the successive ethyl acetate fraction (SEAF), alcohol fraction (SAF) and alcoholic extract with respective 10.0, 22.5 and 5.0% effects. In adjuvant-induced chronic inflammation test, the SPEF and diclofenac extract obviously reduced inflammation (5 and 100 mg/kg b.w., p.o., 7 days) (Jagadish et al., 2016).

## Anti-Oxidant Activity

The anti-oxidant activity is an important value for the further development of natural products, since oxidation reactions are associated with many diseases (Liu and Ng, 2000). In the past few years, crude extracts with anti-oxidant activity from *K. galanga* has been evaluated using several methods as follows.

It is reported that the essential oil extracted by ultrasound-enhanced subcritical water extraction (USWE) exerted significant DPPH, free radical and superoxide anion radical scavenging effects, suggesting its strong anti-oxidant effects (Ma et al., 2015). The methanolic extract of *K. galanga* showed high antioxidant activity

FIGURE 3 | Structures of terpenoids isolated from *K. galanga*.

FIGURE 4 | Structures of phenolics isolated from *K. galanga*.

in DPPH, ABTS, and NO scavenging assays ( $IC_{50}$  = 16.58, 8.24 and 38.16  $\mu$ g/ml, respectively) (Ali et al., 2018). Further, the *K. galanga* leaves showed weakly antioxidant activity in DPPH scavenging assay, and  $IC_{50}$  values were 611.82 and 702.79  $\mu$ g/ml, respectively (Rahman et al., 2019). The antioxidant activity of various extracts of *K. galanga* were tested by DPPH and ABTS assays respectively. The results showed that *K. galanga* had good antioxidant activity, among the five extracts, the activity of chloroform fraction was the best, and its  $SC_{50}$  on DPPH and ABTS were about 4 and 2 times that of the positive control ( $V_C$ ) respectively, followed by the ethyl acetate, n-butanol fraction, while petroleum ether fraction was poor and the water fraction was basically inactive (Xiang et al., 2018).

## Insecticidal and Repellent Activity

The methanolic extract and essential oil of *K. galanga* rhizome, as well as their isolates *trans*-ethyl p-methoxycinnamate (**34**) and *trans*-ethyl cinnamate (**38**) exhibited strong insecticidal and repellent properties.

Two compounds **34** and **38** with excellent nematocidal activity had been obtained from petroleum hexane extracts. After treatment 72 h, the  $LC_{50}$  of **34** against *Meloidotyne incongnita*, *Bursaphelenchus xylophilus*, *Ditylenchus destructor*, *M. eloidogyne hainensis*, *M. enterolobii* were 1.49, 2.81, 10.09, 26.67 and 14.47 mg/L. The  $LC_{50}$  values of **38** against *M. incongnita*, *B. xylophilus*, *D. destructor*, *M. eloidogyne hainensis*, *M. enterolobii* were 17.79, 29.70, 43.21, 57.64 and 36.94 mg/L, respectively

**FIGURE 5 |** Structures of cyclic dipeptides and flavonoids isolated from *K. galanga*.

**FIGURE 6 |** Structures of diarylheptanoids, fatty acids and esters isolated from *K. galanga*.

(Zhang et al., 2010). **34** and **38** also had potent insecticidal activity against the larvae of polyphagous insect *Spodoptera littoralis* (Noctuidae) ( $LD_{50} = 0.47$  and  $0.65 \mu\text{g/mL}$ , respectively) (Pandji et al., 1993).

The essential oil, and its main constituents, **38**, **34** and **39** showed contact toxicity against the booklouse *Liposcelis*

*bostrychophila* Badonnel. Among them, **38** was the most effective with  $LC_{50}$  value of  $21.4 \text{ g/cm}^2$ , **34**, **39** and the essential oil exhibited moderately effects with  $LC_{50}$  value of 44.6 and  $43.4 \text{ g/cm}^2$ , respectively. In addition, fumigant toxicity ( $LC_{50} = 1.5 \text{ mg/L air}$ ) of the essential oil against the booklouse also was observed (Liu et al., 2014). The essential oil as well as **34** and **38**

showed nematocidal activity against the cereal cyst nematode with  $LC_{50}$  value of 91.78, 83.04 and 100.60  $\mu\text{g/ml}$ , respectively, while borneol and 1, 8-cineole only showed slight nematocidal toxicity ( $LC_{50}$  = 734.89 and 921.21  $\mu\text{g/ml}$ , respectively) (Li et al., 2017b).

The toxicity of the methanol extracts against *Bursaphelenchus xylophilus* and *Meloidotyne incongnita* were tested. The results showed that the mortality of extracts from *K. galanga* against *B. xylophilus* and *M. incongnita* with 100% mortality at 1,000 mg/L after 24 h (Choi et al., 2006).

## Antimicrobial Activity

*Trans*-ethyl *p*-methoxycinnamate (**34**) exerted potent antibacterial activity against *Pseudomonas aeruginosa*, *Escherichia coli*, *Staphylococcus aureus*, *Aspergillus niger* and *Monilia albican* in disk diffusion and test tube experiments, and the MIC values were 0.625, 1.25, 2.5, 2.5 and 10 mg/ML, respectively (Han et al., 2011). The essential oil of *K. galanga* showed potent antimicrobial activity against *Candida albicans* (fungus); *Staphylococcus aureus* ATCC 25923, *S. faecalis* and *Bacillus subtilis* (three Gram-positive bacteria); *Salmonella typhi*, *Shigella flexneri*, *Escherichia coli* ATCC 25922 (three Gram-negative bacteria) in agar disc diffusion test, with the inhibition zones was 12–16 mm and 8–12 mm against Gram-positive and Gram-negative bacteria respectively, while it potently inhibited *C. albicans* with an inhibition zone of 31 mm, comparing to that (25 mm) of standard antifungal (Clotrimazole) (Tewtrakul et al., 2005). Similarly, agar well diffusion test was employed to assess antifungal potential of

ethanolic extract of *K. galanga*, and the results showed a potent antifungal effect of this extract against *Malassezia* spp. (MIC = 5 mg/ml) (Parjo et al., 2018).

## Antidiabetic Activity

Diabetes has become the third major non-infective disease threatening human health after cardiovascular disease and tumor (World Health Organization, 2013). The effect of kaempferol (**58**) on the correlation factors of chronic complications of type 2 diabetic rats was observed. Rats in administration group were given respective drug (50, 100, 200 mg/kg) every day, and set the model, normal control, and positive control (metformin hydrochloride 0.2 g/kg) groups. After 10 weeks, compared with diabetic model group, **58** administration could reduce blood lipid levels, along with reducing MDA, AR, TNF- $\alpha$ , and IL-6 levels and increasing SOD levels. Moreover, **58** could prevent and treat the chronic complications of type 2 diabetic rats by reducing blood glucose, insulin resistance, reducing the AR pathway as well as anti-oxidation and anti-inflammation. The antidiabetic activity of **58** was comparable to that of positive control at the dose of 200 mg/kg (Wu et al., 2015).

## Anti-Tuberculosis Activity

The anti-tuberculosis effect of **34** was determined by resazurin microtitre assay (REMA) on *Mycobacterium tuberculosis* H37Ra and H37Rv strains. The results demonstrated that **34** had a significant anti-tuberculosis activity, and its MIC values were in the range of 0.242–0.485 mM. This study showed *K. galanga* and

**TABLE 4 |** Major compounds of essential oils of *K. galanga*.

its isolate **34** had anti-tuberculosis effects, however, the molecular mechanisms of action of **34** should be further explored by in-depth studies and clinical trials (Lakshmanan et al., 2011).

## Vasodilatory Activity

Previous reports have shown that *trans*-ethyl cinnamate (**38**) could exert vasorelaxant activity, which was in line with traditional role of *K. galanga* in the treatment of high blood pressure. It could dose dependently inhibit the tonic contractions induced by high concentrations of K<sup>+</sup> and phenylephrine (PE) (IC<sub>50</sub> = 0.3 ± 0.05 and 0.38 ± 0.04 mM, respectively). Mechanistic studies revealed that its vasorelaxant activity could be attributed to the inhibition of influx of Ca<sup>2+</sup> into vascular cells and the release of prostacyclin and NO from the endothelial cells. Hence, the traditional use of the herb in treating hypertension may be

explained well by the vasorelaxant activity of **38** (Othman et al., 2002). In the anaesthetized rats, the dichloromethane extract of *K. galanga* could exert vasorelaxant activity by lowering the basal mean arterial pressure (MAP). Moreover, the active compound, **38** was identified by bioassay-guided fractionation and isolation (Othman et al., 2006).

## Sedative Activity

The hexane extract of *K. galanga* demonstrated potent sedative effects (1.5 and 10 mg) by reducing the activity of locomotor. Moreover, *trans*-ethyl p-methoxycinnamate (**34**) and *trans*-ethyl cinnamate (**38**) as well as showed significant sedative activity (14 and 12  $\mu$ g) (Huang et al., 2008). The acetone extract of *K. galanga* exerted sedative activity at the dose of 200 mg/kg in mice (b.w., p.o.) (Ali et al., 2015).

## Anti-Angiogenic Activity

The anti-angiogenic effects of ethanol extract, *trans*-ethyl p-methoxycinnamate (**34**) and kaempferol (**58**) of *K. galanga* exhibited potent anti-angiogenic effect assessed by zebrafish angiogenic assay. Further investigations for action mechanism of **34** indicated that it inhibited the migration and tube formation of human umbilical vein endothelial cells *in vitro*, and blocked vessel formation induced by bFGF on Matrigel plug assay *in vivo* (He et al., 2012).

## Anti-Osteoporosis Activity

Kaempferol (**58**) showed inhibitory effects of osteoclastogenesis in the autophagy inhibition process of RAW 264.7 cells in the presence of 50  $\mu$ M, and obviously inhibited the expression of p62/SQSTM1. Moreover, the potential role of **58** for the treatment of bone metabolism disorders could be explored through in-depth study of the role of p62/SQSTM1 in autophagy (Chang-Ju et al., 2018). Kaempferide (**60**) could prevent osteolysis induced by titanium particle and inhibit osteoclast genesis in mice at 12.5  $\mu$ M, indicating a potential agent with anti-osteoporosis activity (Jiao et al., 2017).

## Antithrombotic Effect

The ethanolic extract of *K. galanga* was orally administered (7, 14 and 28 mg/20 g b.w.) in a mouse thrombotic model induced by collagen-epinephrine. Bleeding time prolongation and the survival rate of mice was observed after 7 days extract pre-treatment. The results showed the greatest antithrombotic potency of *K. galanga* extract had similarities with the positive control (aspirin) at its highest dose (28 mg/20 g b.w.). Thus, the herb had great chance to be an antithrombotic agent in further studies (Saputri and Avatara, 2018).

## Hypopigmentary Effect

Kaempferol (**58**) was investigated for the effect on tyrosinase activity, melanin content, and cell proliferation in human normal melanocytes. The effects of various concentration (1–100  $\mu$ M) of kaempferol upon proliferation, melanin synthesis and tyrosinase activity in human normal melanocytes were observed. The results showed **58** could strongly inhibit tyrosinase activity and melanin content of melanocyte without more toxicity or adverse side effect on proliferation of melanocytes, and suggested **58** was a promising tyrosinase inhibitor (Shang et al., 2011).

## Anti-Sunburn Activity

It was reported that *trans*-ethyl p-methoxycinnamate (**34**) could protect skin from sunburn. In order to investigate anti-sunburn activity of **34**, *in vitro* percutaneous solution was established, and the percutaneous absorption of **34** was studied. Modified Franz diffusion cells were used for *in vitro* permeation studies, and the nude mouse skin was used as transdermal barrier. The concentration of **34** in the receptor solution was determined by HPLC, and it also displayed a certain extent of sunscreen efficacy. The results showed that, accumulative permeation amount of **34** within 10 h was 0.2949 mg/cm<sup>2</sup> and indicated it was suitable for the

development of natural sunscreen cosmetic products (Li et al., 2013).

The ethanolic rhizome extract of *K. galanga* and its main constituent **34** were evaluated for their UV protective properties. The results demonstrated *K. galanga* presented high UVB protection with SPF range of 8.57–22.34  $\mu$ g/ml, and its main constituent **34** also demonstrated UV protective effect (Panyakaew et al., 2020).

## CONCLUSION AND PERSPECTIVE

This review summarizes the latest researches of different extracts and active compounds of *K. galanga* in the fields of ethnomedicine uses, phytochemistry, toxicology and pharmacology. As stated above, the ninety-seven bioactive phytochemicals including terpenoids, phenolics, cyclic dipeptides, flavonoids, diarylheptanoids, fatty acids and esters, and others, have been isolated and identified from *K. galanga*, suggesting the presence of potential structural diversity of *K. galanga*, among them, isopimarane-type diterpenoids as the mainly characteristic constituents. Furthermore, numerous pharmacological studies have revealed that various crude extracts and some chemical components exerted multiple biological activities, in particular, antitumor, anti-inflammatory and anti-oxidant activities.

Although phytochemistry studies have isolated some compounds from the rhizomes of this plant, no study has documented the constituents separated from the leaves. Thus, the chemical studies on the leaves of this plant are necessary to strengthen. Besides, new compounds are need to be explored for enriching material basis of *K. galanga*.

Most pharmacological studies of *K. galanga* concentrated on the activities of its crude extracts, particularly volatile oil and ethanol extract. However, the underlying mechanisms of activities and exact chemical constituents are still little knowledge. Therefore, further elucidating the relationships of pharmacological mechanisms of bioactive constituents are still required. Gratefully, an emerging technology, DNA-encoded library (DEL) and especially the natural product DNA-encoded library (*n*DEL) has already showed their potential in identification of protein targets of natural products, thus could be used to handle this issue (Ma et al., 2019; Xie et al., 2020). Compounds that isolated from *K. galanga* could be efficiently annotated with unique DNA tags by using the *n*DEL technology to form a *K. galanga* focused *n*DEL. Screening of the *K. galanga* focused *n*DEL against various protein targets will definitely help to illuminate the target network of *K. galanga* in the future.

With regard to the safety profile of *K. galanga*, existing studies have provided only limited information. More systematic toxicology studies are still needed to be carried out in the future on the extracts and purified compounds of *K. galanga*.

For further improving the species, the following aspects also need to be paid attention to. Innovative breeding designs supported by information on the genomic resources and appropriate technologies could play a potential role to realize stable growth

in *K. galanga* productivity and quality (Bohra et al., 2020). In addition, to develop an agrotechnology to commercialize the production of *K. galanga* and bioprospect in *K. galanga* is required to identify secondary metabolite and develop novel technologies to overcome some diseases (Jnanesh and Kumar, 2018). On the other hands, clarifying biosynthetic pathways of bioactive natural products will make a significant contribution to pave the way for their manufacture. (Thomford et al., 2018; Gao and Lei, 2020). Moreover, plant proteomics of *K. galanga* could open new perspectives for ethnobotanical and phytomedicine research purposes, indicating the use of medicinal plants for the treatment of certain diseases (Pedrete, et al., 2019).

In terms of quality control, the information about the cultivation environment, cultivars, processing, transportation, storage time, and quantitative studies of the index components are scarcely in the existing studies. It is worth noting that the dual quality control, chemical benchmark and effect benchmark has been generally accepted (Li et al., 2019; Zhu et al., 2019). Therefore, the quality standard of it could be supported by the effect benchmark. Moreover, the effect benchmark offer basis to Q-biomarker research strategy, which could provide reference of methodology for the quality control study of *K. galanga* (Geng et al., 2019; Lu et al., 2020).

In summary, this review provides a comprehensive analysis on ethnomedicinal uses, phytochemistry, pharmacology and toxicology of *K. galanga*, and proposed future research directions. Based on this, we hope to highlight the potential value of *K. galanga* and provide some new research directions in further studies.

## AUTHOR CONTRIBUTIONS

S-YW, H-TX, UG, and BL conceived the presented research. S-YW, H-TX, and BL designed the structure of the paper. S-YW,

HZ, and H-TX drafted the manuscript. Y-SW, X-DH, and F-FX provided critical revision of this article. X-BY, UG, and BL supervised the findings of the work, and approved the manuscript for submission. All authors agreed with the final version of this manuscript.

## FUNDING

This work was supported by the Key-Area Research and Development Program of Guangdong Province (No. 2020B1111110007); the National Natural Science Foundation of China (Nos. 81202398, 81974565, and 81974571); The special foundation of Guangzhou Key Laboratory (No. 202002010004); Science and Technology Planning Project of Guangdong Province (No. 2017B030314166); the Specific Research Project of State Administration of TCM of China (No. JDZX2015207); Special Funds for State Key Laboratory of Dampness Syndrome of Chinese Medicine (Nos. SZ2021ZZ33, SZ2021ZZ36, SZ2021ZZ40, and SZ2021ZZ46); the Specific Research Fund for TCM Science and Technology of Guangdong Provincial Hospital of Chinese Medicine (No. YN2019MJ05) and the collaborative innovation project of “Double first class” and High-level University Construction of Guangzhou University of Chinese Medicine (Nos. 2021XK69 and 2021XK08).

Circadian Pharmacological Effects of  
Paeoniflorin on Mice With Urticaria-  
like Lesions.  
Front. Pharmacol. 12:639580.  
doi: 10.3389/fphar.2021.639580

Paeoniflorin (PF) is a monoterpene glucoside with various biological properties, and it suppresses allergic and inflammatory responses in a rat model of urticaria-like lesions (UL). In the present study, we treated OVA-induced mice presenting UL with PF at four circadian time points (ZT22, ZT04, ZT10, and ZT16) to determine the optimal administration time of PF. The pharmacological effects of PF were assessed by analyzing the scratching behavior; histopathological features; allergic responses such as immunoglobulin E (IgE), leukotriene B4 (LTB4), and histamine (HIS) release; inflammatory cell infiltration [mast cell tryptase (MCT) and eosinophil protein X (EPX)]; and mRNA levels of inflammatory cytokines such as interleukin (IL)-12, IL-6, interferon- $\gamma$  (IFN- $\gamma$ ), and IL-4. It was demonstrated that PF significantly alleviated scratching behavior and histopathological features, and ZT10 dosing was the most effective time point in remission of the condition among the four circadian time points. Moreover, PF decreased the serum levels of IgE, LTB4, and HIS, and PF administration at ZT10 produced relatively superior effectiveness. PF treatment, especially dosing at ZT10, significantly reduced the number of mast cells and granules and diminished the infiltration of MCT and EPX in the skin tissues of mice with UL. Furthermore, the oral administration of PF effectively decreased the inflammatory cytokine levels of IL-12 mRNA. In conclusion, different administration times of PF affected its efficacy in mice with UL. ZT10 administration demonstrated relatively superior effectiveness, and it might be the optimal administration time for the treatment of urticaria.

**Keywords:** urticaria-like lesion, paeoniflorin, allergic response, inflammatory cell infiltration, inflammatory cytokine, chronotherapeutic

## INTRODUCTION

Urticaria is characterized by the rapid appearance of pale to bright wheals, erythema, and pruritus on the skin (Schaefer, 2017). Sometimes, the condition is life-threatening and has detrimental effects on the quality of life of patients (Maurer et al., 2011) with angioedema and intense pruritus. Immunoglobulin E (IgE) mediates the accumulation and degranulation of mast cells play a

**Abbreviations:** EPX, eosinophil protein X; HIS, histamine; IgE, Immunoglobulin E; IL, interleukin; IOD, integrated optical density; IFN, interferon; i.p., intraperitoneally; LTB4, leukotriene B4; MCT, mast cell tryptase; NC, normal control; OVA, ovalbumin; PF, paeoniflorin; UL, urticaria-like lesions; ZT, zeitgeber time.

central role in the pathogenesis of urticaria, which results in the release of histamine (HIS) and other inflammatory mediators (Church et al., 2018). Furthermore, urticarial lesions are characterized by lymphocytic infiltration. Antihistamines or monoclonal antibodies are usually prescribed to treat urticaria. However, occasionally, little response, recurrence of symptoms, and side effects such as headache, drowsiness have been observed in some patients (Maurer et al., 2013; Bernstein et al., 2014; Cordeiro Moreira et al., 2016). Moreover, urticaria exacerbates nocturnally, displaying changing patterns in symptom attacks during the day and night (Maurer et al., 2009). Therefore, a safe, effective, selective, and optimal timing of therapy for urticaria has gained attention.

The physiological events and disorders of all creatures on the earth are interlinked to circadian rhythms, such as the sleep-wake cycle, body temperature, immune responsiveness, and anaphylactic reactions (Nakao et al., 2015). Although specific cellular and molecular mechanisms remain largely undefined, the circadian clock was regarded as a potent regulator of IgE/mast cell-mediated allergic reaction (Nakao et al., 2015). Nocturnal symptoms are common in atopic dermatitis and asthma, being related to the diurnal rhythm of inflammatory cell populations (Mackay et al., 1994; Lissoni et al., 1998; Raherison et al., 2006; Fishbein et al., 2015). Moreover, urticaria-like symptoms such as itching, wheals (hives), angioedema, or both, undergo circadian variations, and they exacerbate more frequently at night (Maurer et al., 2009). It has been long recognized that pharmacological effects could be enhanced by time-varying administering drugs of the disease displaying diurnal rhythmicity in severity (Koyanagi et al., 2003). We posit that time-varying drugs may function the treatment efficacy in urticaria.

Paeoniflorin (PF), extracted from the roots of *Paeonia lactiflora* Pall. (Shi et al., 2014; Wang et al., 2015), is a monoterpene glucoside with many biological properties. PF is one of the principal bioactive components of total glucosides, and it has been prescribed for redness, fever, and pain in rheumatoid arthritis patients in China for many years (Wang et al., 2015). Crucially, PF has been found to exhibit the therapeutic effects of various allergic diseases, such as asthma and contact dermatitis in mice. It was demonstrated that PF ameliorated asthma *via* the signaling pathway of phosphoinositide 3 kinase and serine/threonine kinase 1, to regulate the abnormal proliferation and migration of airway smooth muscle cells (Zhou et al., 2018). And PF acts as an immune-modulator to regulate the imbalanced secretion of inflammatory cytokines, such as interleukin (IL)-2, IL-4, IL-10, and IL-17, to treat allergic contact dermatitis in mice (Wang et al., 2015). Additionally, PF inhibits the maturation of dendritic cells and promotes their tolerogenic effects by inhibiting IL-12 production and enhancing the expression of anti-inflammatory cytokines such as IL-10 and transforming growth factor- $\beta$  (Shi et al., 2014).

In this study, we assessed the ability of PF as a chronotherapeutic to influence the ovalbumin (OVA) induced urticaria-like lesions (UL) in animal models. We explored whether and how the PF exerted effects on histopathological features either in the morning (ZT02) or evening (ZT14) to establish a UL mouse model then dosed at four circadian time

points. We also demonstrated whether and how the PF played the medicinal effect on allergic responses among time-varying administering drugs. We identified the role of PF played in the regulation of the Th1 and Th2 expression varied with different dosing time points. Our work may provide experimental evidence for optimal administration time of PF in UL treatment.

## MATERIALS AND METHODS

### Reagents and Chemicals

Aluminum hydroxide was dissolved in 0.9% NaCl solution to obtain a final concentration of 10 g/L. Furthermore, OVA (5 mg per mouse) (Merck KGaA, Darmstadt, Germany) was added to the mixture to obtain the resulting solution, which will be injected into animals. PF, with a purity quotient of  $\geq 98\%$ , was obtained from the Beijing Solarbio Science and Technology Co., Ltd. (Beijing, China). To obtain the stock solution, PF was dissolved in 50 ml of sterilized 0.9% NaCl at a concentration of 2000 mg/ml (Shi et al., 2015). The working solutions were diluted with saline.

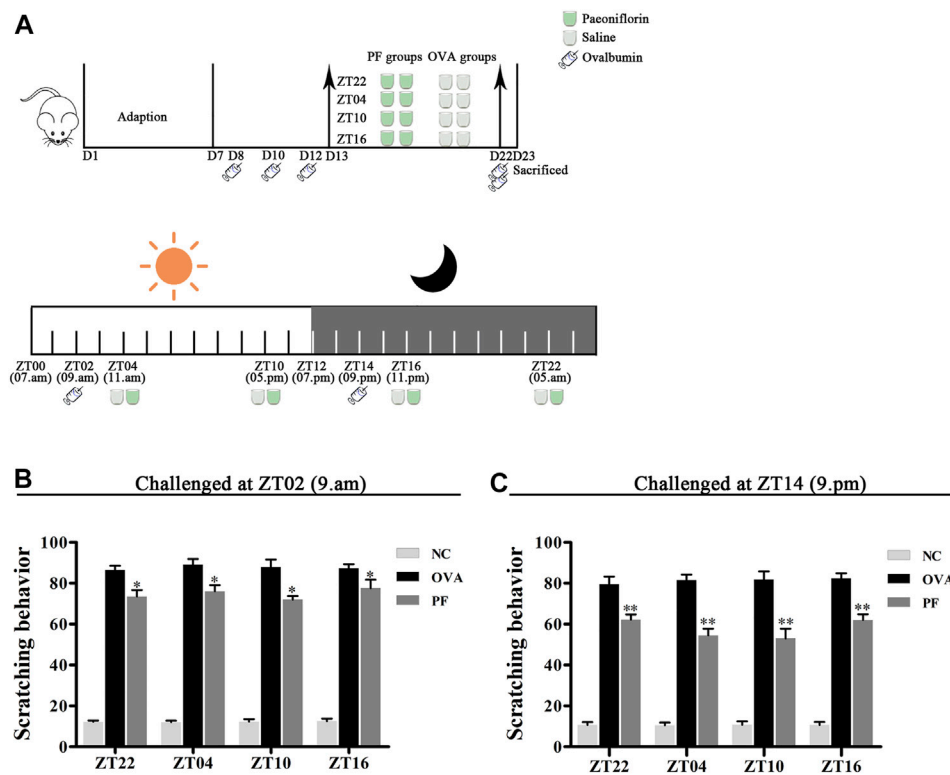

### Animals

One hundred and forty-four BALB/c mice (male) were purchased from Chengdu Dashuo Experimental Animal Co., Ltd. (Chengdu, China), and were housed in the Animal Experimental Center, Chengdu University of Traditional Chinese Medicine (Chengdu, China). All mice were maintained at a temperature of  $22 \pm 2^\circ\text{C}$  and relative humidity of  $55 \pm 10\%$  with a 12-h light/dark cycle [lights on at 7:00 am (zeitgeber time (ZT) 0) and lights off at 7:00 pm (ZT12)], and *ad libitum* access to water and food was provided. All mice were 8–9 weeks old, and their body weights were 16–20 g. All procedures were approved by the Institutional Animal Care and Use Committee of Chengdu University of Traditional Chinese Medicine (approval no. 2019-11).

### Induction and Treatment of Animal Models for Urticaria

After 7 days of adaptation, one hundred and forty-four male BALB/c mice were randomly divided into the following groups ( $n = 6$  in each group): normal control (NC) groups treated with saline, including 1) NC ZT22, 2) NC ZT04, 3) NC ZT10, and 4) NC ZT16; model groups injected intraperitoneally (i.p.) with OVA/aluminium hydroxide, including 5) OVA + saline ZT22, 6) OVA + saline ZT04, 7) OVA + saline ZT10, and 8) OVA + saline ZT16; and PF groups induced with OVA/aluminium hydroxide and treated with 100 mg/kg of PF per day (Shi et al., 2015), including 9) OVA + PF ZT22, (10) OVA + PF ZT04, 11) OVA + PF ZT10, and 12) OVA + PF ZT16. To induce UL, all mice except the controls were sensitized at ZT02 or ZT14 on days 8, 10, and 12 using an i.p. injection of 1 ml aluminium hydroxide solution containing 1 mg of OVA, and were challenged at ZT02 or ZT14 on day 22 with an i.p. injection containing 2 mg of OVA in aluminium hydroxide solution. All animals were orally administered saline or PF solution from day 13 to day 22 for

**FIGURE 1 |** Experimental design (A) and Effect of PF treatment on scratching frequency (B,C). 144 male BALB/c mice (urticaria-like animals) were randomly divided into 12 groups as follows modeled at ZT02 or ZT14 ( $n = 6$  in each group): normal control (NC) groups treated with saline, including 1) NC ZT22, 2) NC ZT04, 3) NC ZT10, and 4) NC ZT16; model groups injected intraperitoneally (i.p.) with ovalbumin (OVA)/aluminium hydroxide, including 5) OVA + saline ZT22, 6) OVA + saline ZT04, 7) OVA + saline ZT10, and 8) OVA + saline ZT16; and PF groups induced with OVA/aluminium hydroxide and treated with 100 mg/kg per day of paeoniflorin (PF), including 9) OVA + PF ZT22, 10) OVA + PF ZT04, 11) OVA + PF ZT10, and 12) OVA + PF ZT16. To induce urticaria-like lesions (UL), all mice except those in NC groups were sensitized i.p. with 1 ml of aluminium hydroxide solution containing 1 mg of OVA at ZT02 or ZT14 on days 8, 10, and 12, and they were challenged i. p. with 2 mg OVA in aluminium hydroxide at ZT02 or ZT14 on day 22. All animals were orally administered saline or PF solution from day 13 to day 22 for 10 days once a day at ZT22, ZT04, ZT10, and ZT16. As shown in (A), on day 23, the dorsal region of all animals were shaved. After ZT14, 500  $\mu$ L of the blood sample was collected through the cardiac puncture, and skin tissues were obtained under anesthesia with sodium pentobarbital (60 mg/kg i.p.). Furthermore, animals were humanely euthanized via cervical dislocation after sampling. The PF treatment significantly inhibited OVA/aluminium hydroxide-induced scratching reaction. Data are displayed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points.

10 days once a day at ZT22, ZT04, ZT10, and ZT16. On day 23, the dorsal region of all animals was shaven (Figure 1A). After ZT14, 500  $\mu$ L of blood samples were collected through the cardiac puncture, and skin tissues were obtained by inducing anesthesia using pentobarbital sodium (60 mg/kg i.p., Merck KGaA, Darmstadt, Germany). Furthermore, animals were humanely authorized via cervical dislocation after sampling.

### Assessment of Scratching Behavior

After challenging for 10 min on day 22, the frequencies of scratching and foot licking were measured for 20 min. The lifting of paws; rubbing of dorsal skin, hind paws, nose, or ears; and then returning the paws to the floor is defined as scratching (Choi et al., 2018; Purushothaman et al., 2018).

### Histopathological Analysis

For histopathological observation, the dorsal skin lesions were dissected, dipped in 10% paraformaldehyde (Chengdu Cologne Chemical Co., Ltd., Chengdu, China) overnight, hydrated with

ethanol, embedded in paraffin wax (Shanghai Hualing Rehabilitation Equipment Factory, Shanghai, China), and cut into thin sections (3  $\mu$ m). Skin sections were stained with hematoxylin (Wuhan Seville Biotechnology Co., Ltd., Wuhan, China) and eosin (Zhuhai Bezo Biotechnology Co., Ltd., Zhuhai, China) for detection of edema and inflammatory cell infiltration, images were captured randomly by the pathologist using a light microscope (OLYMPUS, Tokyo, Japan), and they were viewed at a magnification of  $\times 100$  ( $\times 10$  ocular lens and  $\times 10$  objective lens). The degree of edema, telangiectasia, and inflammatory cell infiltration was scored on a subjective scale of 0–3 as follows which from three fields per hematoxylin and eosin-stained sections: 0, no edema; no telangiectasia; no inflammatory cell infiltration; 1, slight edema; slight telangiectasia; slight inflammatory cell infiltration; 2, moderate edema; moderate telangiectasia; moderate inflammatory cell infiltration; 3, severe edema; severe telangiectasia; severe inflammatory cell infiltration. The histologic score of each animal was the average of the total scores of 3 pathological features from 3 visual fields.

## Determination of Serum IgE, Leukotriene B4 (LTB4), and HIS Levels

Blood samples from mice with UL were centrifuged at 3,000 × g to obtain the serum samples, which were then stored at −80°C until quantitative analysis. The serum levels of IgE, LTB4, and HIS were detected using the respective ELISA kits (ZCI BIO, Shanghai, China), and their optical densities (ODs) were determined using a microplate reader (Shanghai Jizhou chemical industry technology co., ltd., Shanghai, China) at 450 nm according to the manufacturer's instructions. The concentrations of IgE, LTB4, and HIS were determined based on their standard curves.

## Mast Cell Detection

To evaluate the number and degranulation of mast cells, the skin tissues were fixed with 10% paraformaldehyde (Chengdu Cologne Chemical Co., Ltd., Chengdu, China), dehydrated with ethanol, embedded in paraffin, sectioned, stained with toluidine blue (Shanghai Ruji Biological Technology Development Co., Ltd., Shanghai, China) solution at 37°C for 10 min, and then sealed with a resin. Stained mast cells were enumerated using a microscope (OLYMPUS, Tokyo, Japan) by randomly observing three fields per section at a magnification of ×100 and 400×.

## Detection of Mast Cell Tryptase (MCT) and Eosinophil Protein X (EPX)

After the skin tissues were dewaxed, they were stored in 0.01 mol/L citrate to retrieve the antigen, microwaved for 20 min to expose the antigen, immersed in 0.03% H<sub>2</sub>O<sub>2</sub> for 15 min to inactivate endogenous peroxidase, and blocked with goat serum blocking solution for 20 min at room temperature. Subsequently, sections were incubated with primary mouse monoclonal anti-MCT antibody (Abcam, Cambridge, United Kingdom) and rabbit polyclonal anti-EPX antibody (Biorbyt, Cambridge, United Kingdom) at 4°C overnight. After rewarming at 37°C for 1 h, samples were washed with phosphate-buffered saline, incubated with a secondary antibody and biotin-labeled goat anti-rabbit IgG at 37°C for 30 min, incubated with biotin-labeled streptavidin at 37°C for 30 min, developed with a DAB kit (ZSGB Bio, Beijing, China), counterstained with hematoxylin, and sealed with a neutral resin. Microphotographs were obtained using a light microscope. Images of each slide were photographed randomly for three fields using a light microscope at ×200 magnification. Image-Pro Plus 6.0 software (MEDIA CYBERNETICS, Maryland, USA) was used to detect the integrated optical density (IOD) of each field. The mean IOD of the three fields was displayed as the semi-quantitative levels of MCT and EPX.

## Measurement of Th2/ Th1 Expression in the Dorsal Skin

The mRNA levels of IL-12, IL-6, interferon (IFN)-γ, and IL-4 in the dorsal tissues were detected using qRT-PCR. Fresh skin tissues were lysed with TRIzol (Hefei Bomei Biotechnology Co., Ltd., Hefei, China) to extract total RNA. PrimeScript RT Reagent Kit (Baori

Medicine Biotechnology Co., Ltd., Beijing, China) was used to perform reverse transcription experiments to obtain cDNA for each sample. The cDNA was diluted 10-fold, and it was used as a template for qRT-PCR, which was performed using the Thermo Scientific PikoReal software real-time fluorescent quantitative PCR instrument (Thermo Fisher, Waltham, MA, USA) according to the manufacturer's instructions. The following cycle was performed 45 times: predegeneration at 95°C for 30 s, degeneration at 95°C for 5 s, annealing at 55°C for 30 s, and extension at 72°C for 30 s. β-actin (Sangon Biotech (Shanghai) Co., Ltd., Shanghai, China), and GAPDH (Wuhan servicebio technology Co., Ltd., Wuhan, China) were used as the reference and internal control mRNA, and the 2<sup>−ΔΔCT</sup> method was used to count the relative mRNA expression. The primer sequences were used as follows: β-actin, 5'-GAAGATCAA GATCATTGCTCC-3' (sense) and 5'-TACTCCTGCTTGCTGATC CA-3' (anti- sense); GAPDH, 5'-CCTCGTCCCGTAGACAAA ATG-3' (sense) and 5'- TGAGGTCAATGAAGGGGTCGT-3' (anti- sense); 5'-CCTCGTCCCGTAGACAAAATG-3' (sense) and 5'-TGAGGTCAATGAAGGGGTCGT-3' (anti- sense); IL-12, 5'-TCCAGCATGTGTCAATCAGCTACCT-3' (sense) and 5'-AGC CAGGCAACTCTCGTTCTTGTTGA-3' (anti- sense); 5'-CCATCA ACGCAGCACTTCAGA-3' (sense) and 5'-GCTCAGATAGCC CATCACCT-3' (anti- sense); IL-6, 5'-TGGAGCCACCAAGA ACGATAGTCAA-3' (sense) and 5'-TGTCACCAGCATCAGTCC CAAGAAGG-3' (anti- sense); 5'-CCCCAATTTCCAATGCTC TCC-3' (sense) and 5'-CGCACTAGGTTTGCCGAGTA-3' (anti- sense); IL-4, 5'-AGGAGCCATATCCACGGATGCGACAA-3' (sense) and 5'-GCGAAGCACCTTGGAAGCCCTACAG-3' (anti- sense); 5'-GATAAGCTGCACCATGAATGAGT-3' (sense) and 5'-CCATTTGCATGATGCTCTTTAGG-3' (anti- sense); IFN-γ, 5'-GCCATCAGCAACAACATAAGCGTCAT-3' (sense) and 5'-CCC GAATCAGCAGCGACTCCTTT-3' (anti- sense); 5'-CTCAAGTGG CATAGATGTGGAAG-3' (sense) and 5'-TGACCTCAAACCTTGG CAATACTC-3' (anti- sense);

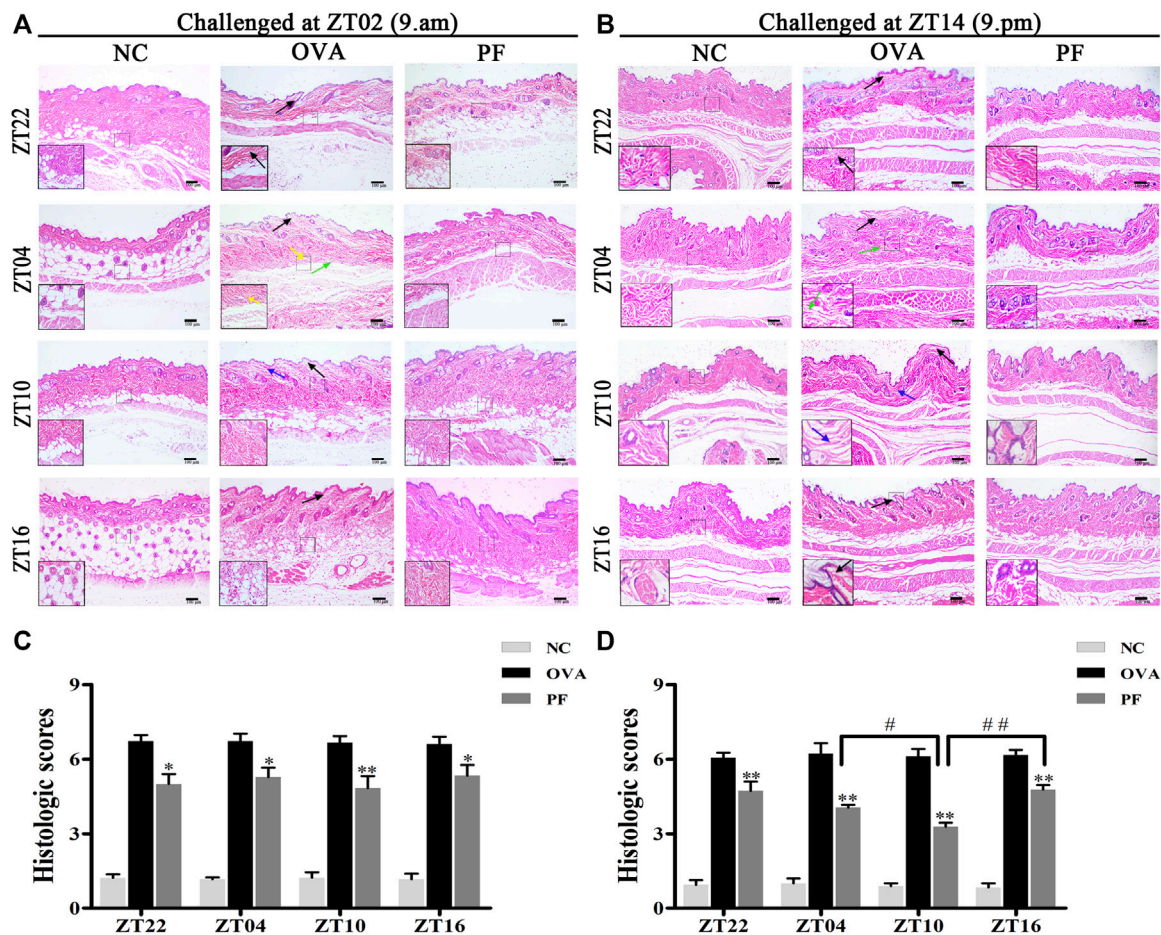

## Statistical Analysis

All statistical analyses were performed using SPSS 25.0 software (IBM, New York, USA), and data were presented as mean ± SEM. One-way analysis of variance was used to compare the mean statistical differences between experimental groups at the same time point and between PF groups at different time points. A *p*-value < 0.05 was considered as statistically significant. A factorial design was applied to compare the effects of time and treatment (time × treatment). A *p*-value < 0.05 was considered as statistically significant. Levene's test was used to assess homoscedasticity, least significant difference test was used to assess the data variance, and Dunnett's *t*-test was used to assess unequal variances.

## RESULTS

### Effect of PF on Scratching Behavior

In the scratching test, after being challenged with OVA/ aluminium hydroxide solution, an obvious scratching reaction was observed in the mice in the OVA and PF groups at all dosing time points as compared with those in the NC groups both modeled in the morning (ZT02) and evening (ZT14). Compared

**FIGURE 2 |** Effect of PF treatment on histopathological features (A,B) and histologic scores (C,D) in OVA/aluminum hydroxide-induced urticaria-like mice.

Representative images of hematoxylin and eosin staining in the dorsal skin. BALB/c mice in the NC group, showing normal architecture. OVA-treated urticaria-like mice showed obvious edema in the upper dermis (black arrows), widening of collagen fiber bundles (blue arrows), with telangiectasia (green arrows), and inflammatory cell infiltration (yellow arrows). PF treatment, especially at ZT10, improved the wheal conditions. The magnification were  $\times 100$  and  $400\times$ . NC groups have noted less or even no edema, telangiectasia, or inflammatory cell infiltration, OVA groups displayed increased histologic scores, while PF induced significant inhibition of the histologic scores. \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points. # $p < 0.05$ , ## $p < 0.01$  represents the comparison of PF ZT10 versus the other three PF indicated time points.

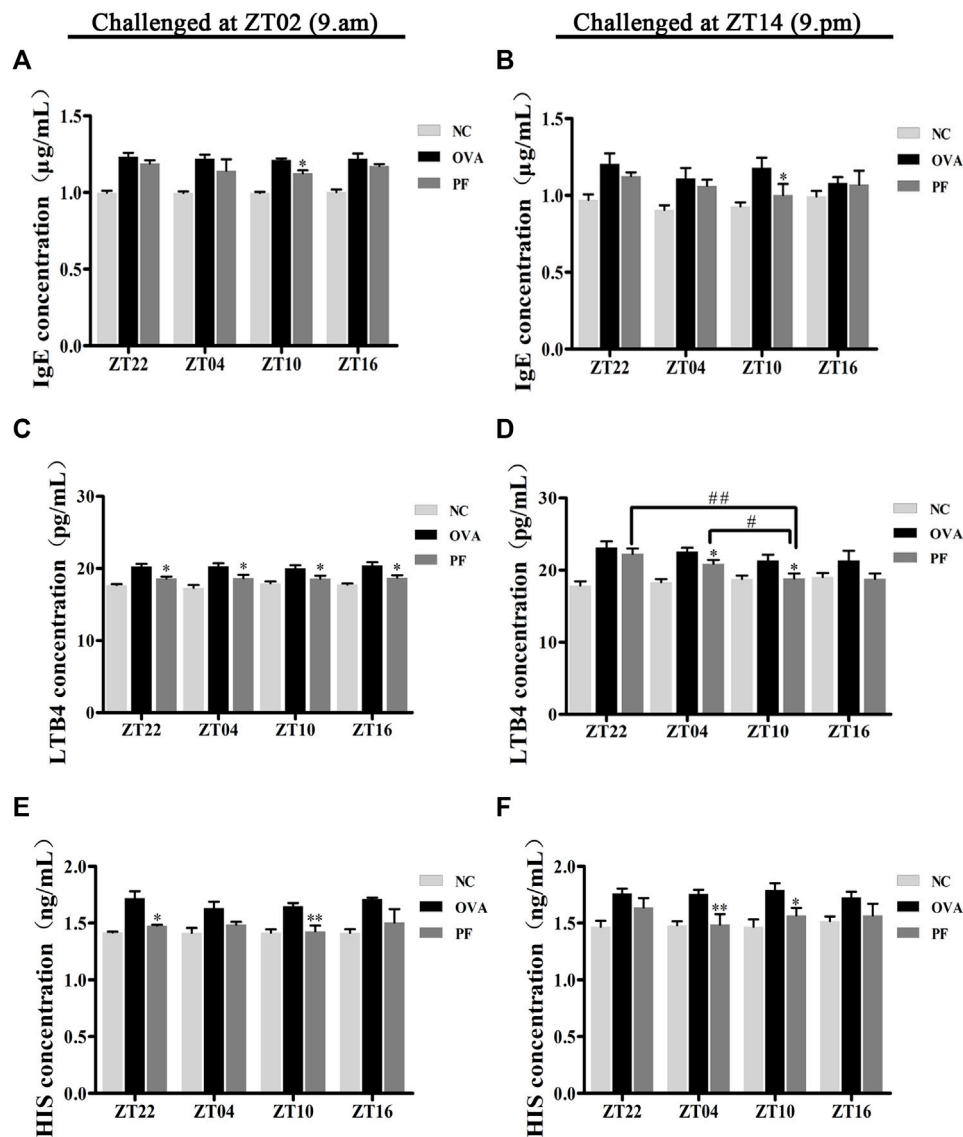

to the OVA groups, both PF groups demonstrated a significant decrease in scratching number ( $p < 0.05$ , modeled at ZT02, and  $p < 0.01$ , modeled at ZT14). However, the PF dose at four circadian time points showed no significance in comparison with each other among the two challenged time points (Figures 1B,C). The scratching behaviors demonstrated that PF relieved the pruritus of the mice with UL, and ZT10 dosing showed the best results (Figures 1B,C).

## Effect of PF on the Histopathological Features and Histologic Scores of UL

Oral administration of PF significantly inhibited the UL in mice induced by OVA/aluminum hydroxide at ZT02 (resting phase) and ZT14 (active phase). Following hematoxylin and eosin staining, compared to the NC groups, obvious edema, mainly in the upper dermis, and widening of collagen fiber bundles with

light pink staining was observed in many OVA groups. At the same time, telangiectasia and inflammatory cell infiltration in skin tissues were observed using light microscopy. As expected, PF showed pharmacological effects on the UL in mice at different dosing time points. The dose at ZT10 improved the histopathological conditions as compared with that at other circadian time points regardless of the modeling time in the morning (ZT02) or evening (ZT14) (Figures 2A,B).

The histological findings demonstrated that the NC groups have noted less or even no edema, telangiectasia, or inflammatory cell infiltration while the OVA groups displayed apparent edema, telangiectasia, and inflammatory cell infiltration at all dosing time points, both performed OVA at ZT02 and ZT14. Whereas PF induced significant inhibition of the histologic scores [PF dosing at ZT22 ( $p < 0.05$ , modeled at ZT02 and  $p < 0.01$ , modeled at ZT14), PF dosing at ZT04 ( $p < 0.05$ , modeled at ZT02 and  $p < 0.01$ , modeled at ZT14), PF dosing at ZT10 ( $p < 0.01$ , modeled at

**FIGURE 3** | Effect of PF treatment on the secretion of allergic cytokines such as (A,B) immunoglobulin E (IgE), (C,D) leukotriene B4 (LTB4), and (E,F) histamine (HIS) from the serum samples of OVA/aluminium hydroxide-challenged mice. PF downregulated the expression of allergic cytokines. Data are expressed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points. # $p < 0.05$ , ## $p < 0.01$  represents the comparison of PF ZT10 versus the other three PF groups.

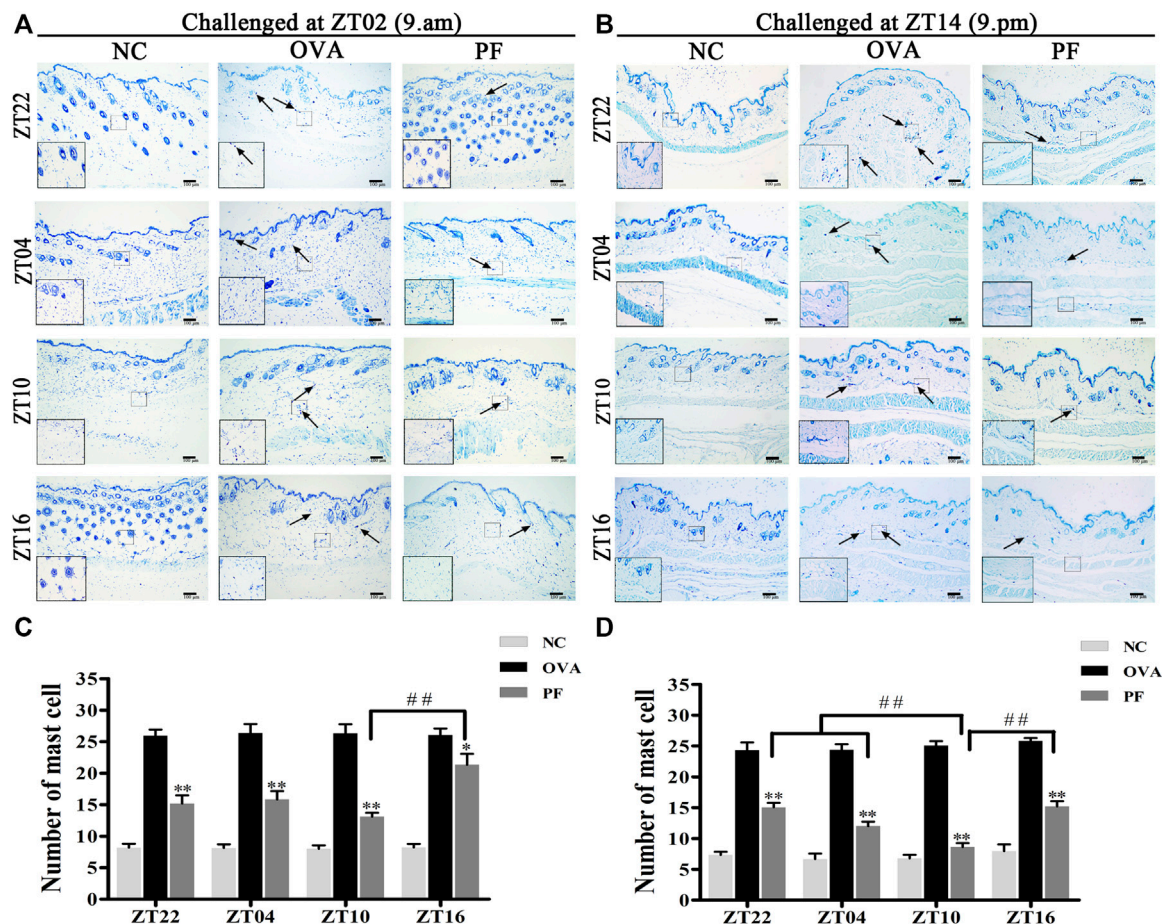

ZT02 and ZT14), PF dosing at ZT16 ( $p < 0.05$ , modeled at ZT02 and  $p < 0.01$ , modeled at ZT14)], compared with the OVA groups among all the dosing time points. Furthermore, when sensitized at ZT14, histologic scores were significantly inhibited by PF dosing at ZT10 ( $p < 0.05$  vs. ZT04 and  $p < 0.01$  vs. ZT16,  $p = 0.052$  vs. ZT22). PF dosing at four indicated time points did not differ significantly among sensitized at ZT02, but ZT10 showed slightly better efficacy than others (Figures 2C,D).

### Effect of PF on the Serum Levels of IgE, LTB4, and HIS

Since IgE, HIS, and LTB4 play major roles in the etiology of urticaria, their expression varies greatly with the time of the day.

Thus, the study of the effect of PF administration at different time points on anti-allergic response markers is of great interest. The levels of IgE, LTB4, and HIS in the serum of urticaria-like animal models were determined using ELISA. Dosing at ZT22 ( $p < 0.01$ , modeled at ZT02 and ZT14), ZT04 ( $p < 0.01$ , modeled at ZT02 and  $p < 0.05$ , at ZT14), and ZT10 ( $p < 0.01$ , modeled at ZT02 and ZT14), and ZT16 ( $p < 0.01$ , modeled at ZT02) increased the IgE levels in OVA groups as compared to those in the NC groups, respectively (Figures 3A,B). A decrease in IgE excretion was observed in PF-treated mice as compared to that of the OVA group at ZT10 ( $p < 0.05$ , modeled at ZT02 and ZT14) (Figures 3A,B). However, the levels of IgE at the other three circadian time points did not decrease in PF groups statistically significant, compared with the OVA groups (Figures 3A,B). The levels of

**FIGURE 4 |** Representative low-magnification light photomicrographs (A,B), and numbers (C,D) displaying toluidine blue staining of mast cell degranulation (black arrows). The mast cell degranulation increased with OVA/aluminium hydroxide administration. Oral administration of PF resulted in a significant reduction in mast cell degranulation. Data are expressed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points. ## $p < 0.01$  represents the comparison of PF ZT10 versus the other three PF groups. The magnification were  $\times 100$  and  $400\times$ .

LTB4 at the four circadian time points were much higher in the OVA groups [ZT22 ( $p < 0.01$ , modeled at ZT02 and ZT14), ZT04 ( $p < 0.01$ , modeled at ZT02 and ZT14), ZT10 ( $p < 0.01$ , modeled at ZT02 and  $p < 0.05$ , modeled at ZT14), and ZT16 ( $p = 0.004$ , modeled at ZT02 and  $p = 0.103$ , modeled at ZT14)] than those in the NC groups. The levels of the serum LTB4 are reduced in both ZT22 ( $p < 0.05$ , modeled at ZT02), PF ZT04 ( $p < 0.05$ , modeled at ZT02 and ZT14), and ZT10 ( $p < 0.05$ , modeled at ZT02 and ZT14), and ZT16 ( $p < 0.05$ , at ZT02) as compared to the OVA treated mice. However, treatment with PF at ZT22 and ZT16 showed no significant difference in the levels of LTB4 between the OVA groups modeled at ZT14. Furthermore, the PF dosing at ZT10 led to a lower serum level of LTB4 compared to the doses at ZT22 ( $p < 0.01$ ) and ZT04 ( $p < 0.05$ ) modeled in the evening (Figures 3C,D). Compared with the NC groups, the OVA groups showed an increase in the expression of HIS [ZT22 ( $p < 0.05$ ), ZT04 ( $p < 0.05$ ), ZT10 ( $p < 0.01$ ), ZT16 ( $p < 0.01$ ) modeled at ZT02, ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), ZT10 ( $p < 0.01$ ) modeled at ZT14]. PF ZT22 ( $p < 0.05$ , modeled at ZT02), ZT04 ( $p < 0.01$ ,

modeled at ZT14) and PF ZT10 ( $p < 0.01$ , modeled at ZT02, and  $p < 0.05$ , modeled at ZT14) dosing significantly repressed the expression of HIS in the PF groups compared to that in the OVA groups. However, PF-treated at different circadian time points showed no significance in comparison with each other (Figures 3E,F). These results indicate that PF treatment alleviates the allergic conditions of UL mice (Figure 3).

## Effect of PF on Mast Cell Infiltration and Degranulation

Urticaria is a mast cell-driven disease. MCT is the most abundant serine protease in mast cells, with mature and immature forms. In urticaria, activated mast cells secrete mature tryptase. One of the biological functions of MCT is correlated with pro-inflammatory effects, involving tissue edema and remodeling, chemokine secretion, and neutrophil recruitment. To determine the infiltration and degranulation of mast cells, we performed toluidine blue staining (Figures 4A,B) to analyze the numbers

**FIGURE 5 |** Representative low-magnification light photomicrographs (A,B) and integrated optical density (C,D) displaying immunohistochemistry of mast cell tryptase (MCT) (black arrows). The PF treatment at ZT10 did possess the best effect on the release of MCT than the other three PF circadian time points. Data are expressed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points. ## $p < 0.01$  represents the comparison of PF ZT10 versus the other three PF groups. The magnification was  $\times 200$ .

and degranulation of mast cells and immunohistochemistry to determine the IOD of MCT (Figures 5A,B). The OVA challenged in the morning and evening [ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), ZT10 ( $p < 0.01$ ), and ZT16 ( $p < 0.01$ )] resulted in a marked and significant increase of mast cell granules compared with the observations in the NC groups. Treatment of mice with PF resulted in a significant reduction in the number of mast cells and granules at ZT22 ( $p < 0.01$  vs. OVA), ZT04 ( $p < 0.01$  vs. OVA), ZT10 ( $p < 0.01$  vs. OVA), with modeling at ZT02 and ZT14, and ZT16 ( $p < 0.05$  vs. OVA, modeled at ZT02, and  $p < 0.01$  vs. OVA, modeled at ZT14). At ZT10, PF induced a significant reduction [( $p < 0.01$  vs. ZT16) modeled at ZT02, ( $p < 0.01$  vs. ZT22), ( $p < 0.01$  vs. ZT04), and ( $p < 0.01$  vs. ZT16) modeled at ZT14] in mast cell granules in comparison with other three circadian time points (Figures 4C,D). The results of MCT were consistent with these results in the OVA groups [ZT22 ( $p < 0.01$  vs. NC), ZT04 ( $p < 0.01$  vs. NC), ZT10 ( $p < 0.01$  vs. NC), and ZT16 ( $p < 0.01$  vs. NC)] with modeling in the morning and evening. Compared to the OVA groups, PF [ZT22 ( $p < 0.01$ ),

ZT04 ( $p < 0.01$ ), ZT10 ( $p < 0.01$ ), and ZT16 ( $p < 0.05$ ) modeled at ZT02 and ZT14] significantly decreased the IOD of MCT. The PF dosing at ZT10 [ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), and ZT16 ( $p < 0.01$ ), modeled at ZT14] displayed the best treatment efficacy to decrease the IOD of MCT (Figures 5C,D).

### Effect of PF on EPX in Skin Tissues

To assess the effect of dosing time on EPX, mice with UL were administered PF using an oral gavage at four circadian time points (ZT16, ZT22, ZT04, and ZT10). EPX as an eosinophilic marker, and released by activated eosinophils, which function in immune responses (Weller and Spencer, 2017; Kim et al., 2020). The IOD of EPX in the OVA groups both for the two challenged time points [ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), ZT10 ( $p < 0.01$ ), and ZT16 ( $p < 0.01$ )] was significantly elevated at the four circadian time points compared to that in NC groups. However, the expression levels of EPX reduced in all circadian time groups after treatment with PF [ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), ZT10 ( $p < 0.01$ ), and ZT16 ( $p < 0.05$ ) modeled at ZT02 and ZT22 ( $p < 0.05$ ), ZT04 ( $p < 0.01$ ), ZT10

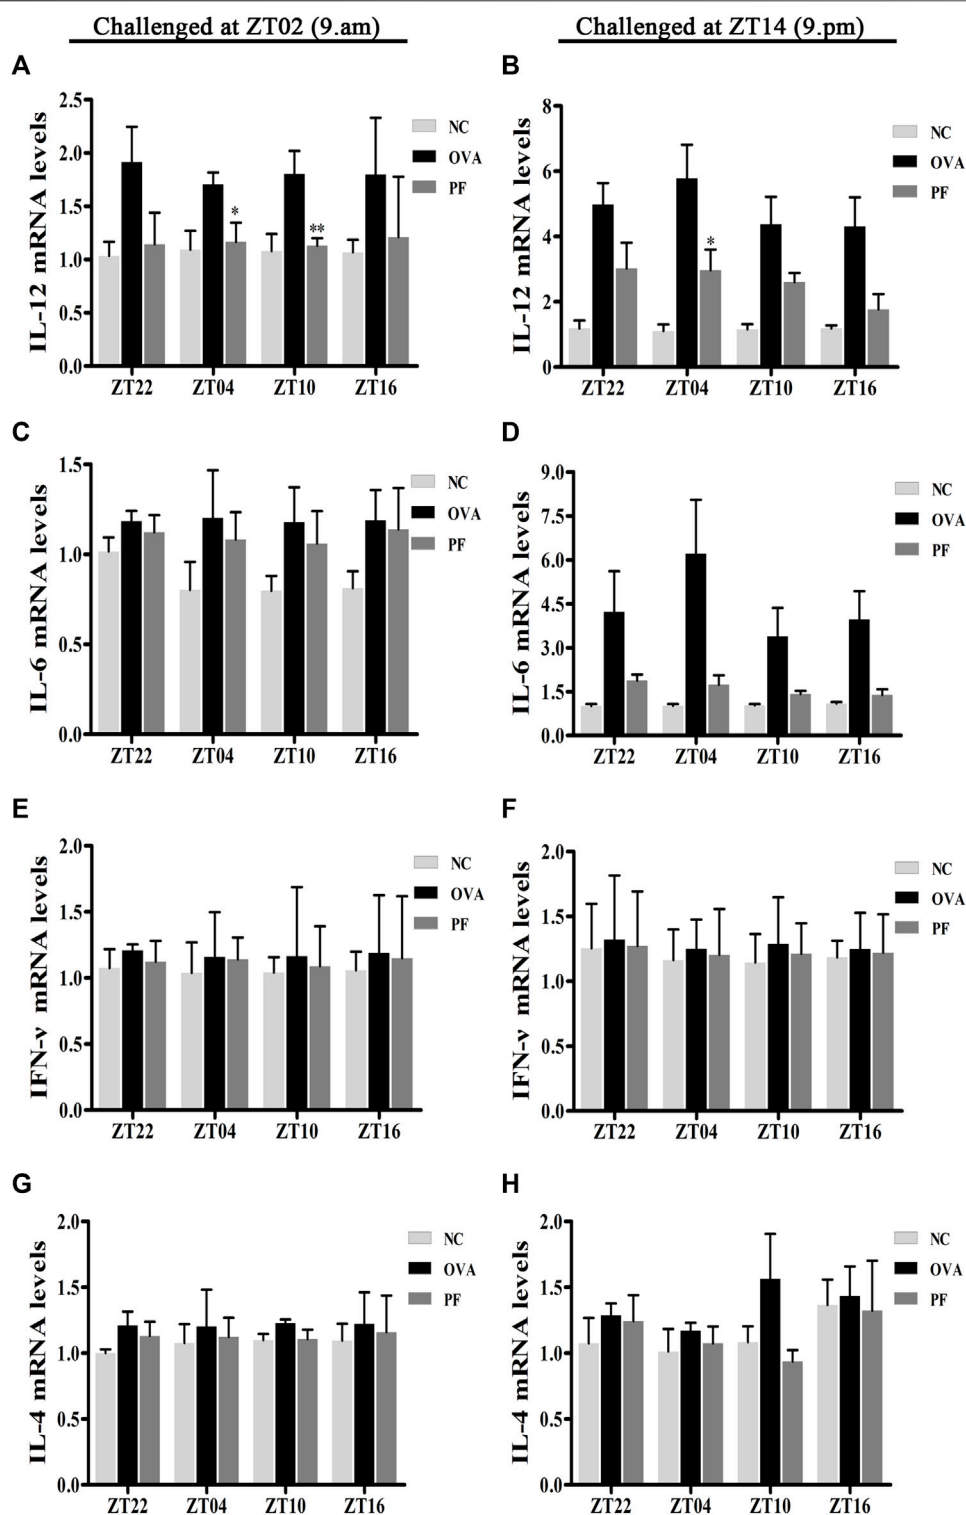

**FIGURE 6 |** Representative low-magnification light photomicrographs (A,B) and integrated optical density (C,D) displaying immunohistochemistry of eosinophil protein X (EPX) (black arrows). The PF treatment at ZT10 had a greater effect on EPX production. Data are expressed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points. # $p < 0.05$ , ## $p < 0.01$  represents the comparison of PF ZT10 versus the other three PF groups. The magnification was  $\times 200$ .

( $p < 0.01$ ), and ZT16 ( $p < 0.01$ ), modeled at ZT14]. Furthermore, PF ZT10 [( $p < 0.01$  vs. ZT22), ( $p < 0.05$  vs. ZT04), and ( $p < 0.01$  vs. ZT16), modeled at ZT14] dosing was more effective in decreasing the IOD levels of EPX (Figures 6A–D).

### Effect of PF on the mRNA Levels of IL-12, IL-6, IFN- $\gamma$ , and IL-4

To elucidate the effects of PF on the inflammatory cytokine release in urticaria, we measured the mRNA levels of IL-12, IL-6, IFN- $\gamma$ , and IL-4 in skin lesions using qRT-PCR. Dosing at ZT22 ( $p < 0.05$ ), ZT04 ( $p < 0.05$ ), ZT10 ( $p < 0.01$ ) modeled at ZT02, and dosing at ZT22 ( $p < 0.01$ ), ZT04 ( $p < 0.01$ ), and ZT10 ( $p < 0.05$ ), ZT16 ( $p < 0.05$ ) modeled at ZT14 expressed a higher IL-12 mRNA level in the OVA groups with UL as compared to that in the NC groups (Figures 7A,B). However, the expression of IL-12 mRNA at PF ZT04 ( $p < 0.05$ , modeled at ZT02), ZT10 ( $p < 0.01$ , modeled at ZT02), and PF ZT04 ( $p < 0.05$ , modeled at ZT14) decreased as compared to that in the OVA-treated

animals (Figures 7A,B). As compared with OVA-treated, no significant differences of PF-treated were observed in the other dosing circadian time points. Additionally, no significant difference was observed in the PF groups between the dosing at ZT16, ZT22, ZT04, and ZT10. For the two indicated model time points, the IL-6 mRNA levels were higher in the OVA-induced mice than that in the NC mice. Moreover, PF treatment at the four dosing circadian time points reduced the levels of IL-6 mRNA. However, the results were not statistically significant (Figures 7C,D). The levels of IFN- $\gamma$  mRNA elevated in OVA-induced UL mice, and they were reduced after PF administration. However, the data presented no statistical significance (Figures 7E,F). The levels of IL-4 mRNA showed no statistical difference in OVA-induced UL mice when compared to the levels in the NC groups at the four circadian time points. When compared with the OVA groups, PF groups showed no administration time-dependent effects on regulating the expression of IL-4 mRNA (Figures 7G,H).

**FIGURE 7 |** Effect of PF treatment on the release of inflammatory cytokines such as (A,B) interleukin (IL)-12, (C,D) IL-6, (E,F) interferon (IFN)- $\gamma$ , and (G,H) IL-4 from the skin tissues of OVA/aluminium hydroxide-challenged mice. PF reduced the expression of IL-12 mRNA at ZT04 and ZT10. Data are expressed as mean  $\pm$  SEM ( $n = 6$ ). \* $p < 0.05$ , \*\* $p < 0.01$  versus OVA mice at the same time points.

## DISCUSSION

The prevalence of chronic urticaria ranges from 0.5 to 5% among the general population, leading to a heavy economic burden on the patients. At 19 hospitals in different provinces of China, 60% of urticaria patients experienced their nocturnal attack as reported (Zhong et al., 2014). Nocturnal symptoms attack predominantly around 9 p.m. (ZT14), from another statistical data of 352 patients in China (Huang et al., 2016). The mice were sensitized and challenged at ZT14 to be synchronized with nocturnal symptoms of humans. In our study, the pharmacological effects of PF on urticaria-like symptoms varied with different dosing time points, and PF dosing at ZT10 demonstrated better effects than that at other circadian time points.

Urticaria, a common immune-mediated inflammatory skin disease, causing edema and itching, is associated with IgE-mediated mast cell degranulation and histamine release. IgE is regarded as a potential trigger for the development of urticaria due to its ability to transfer allergen reactivity (Galli and Tsai, 2012; Platts-Mills et al., 2016) and stimulate the degranulation of mast cells. Activated mast cells can secrete pro-inflammatory triggers such as HIS, prostaglandin E-2, and LTB4 to initiate and amplify hypersensitivity (Galli et al., 2005). MCT, released by mast cells during degranulation, is regarded as a pro-inflammatory mediator in allergic diseases. EPX is a cytotoxic preformed protein, released by the potent pro-inflammatory cells, eosinophil granulocytes. High concentrations of EPX can maintain the secretory activity of mast cells by dissolving mast cells and binding the dissolved matter (Henderson et al., 1980). Injection of OVA and aluminum hydroxide solution stimulated UL in mice at ZT02 or ZT14, leading to an increase in scratching behavior, histopathological changes such as edema, inflammatory cell infiltration, increase in the levels of IgE, HIS, and LTB4, enhance the number of mast cell granules, and concentration of MCT and EPX. These results concur with published data in the literature (Goto et al., 1997; Gu et al., 2004; Hayashi and Fujii, 2008). In addition, abnormalities of the above-mentioned indicators in UL mice were reduced after PF treatment, especially at ZT10.

The circadian rhythm is exhibited by almost all tissues and organs in our body, and disorders in the rhythm induce diseases including urticaria (Smolensky et al., 2015). Metabolic, endocrine, and behavioral functions are governed by circadian rhythms. The number of lymphocytes, T cells, and EPX in human peripheral blood and activation of mast cells exhibit nocturnal peak levels (Pelegri et al., 2003; Wolthers and Heuck, 2003; Baumann et al., 2013). Pro-inflammatory cytokine levels of IL-12 and IFN- $\gamma$  are high in the late evening or early morning in human blood (Petrovsky et al., 1998). In addition, blood histamine peaks at the end of the light phase and maintains throughout the dark phase in rats (Friedman and Walker, 1969). These modifications may be responsible for nighttime symptoms, such as itching, wheals.

In our study, oral administration of PF once a day exerted therapeutic effects on mice with UL, although pharmacokinetic study revealed that PF with characteristics of fast absorption rate, short retention time, and low bioavailability (below 5%) (Wang et al.,

2008; Wu et al., 2009). *In vivo*, PF is distributed rapidly and widely in various tissues such as the stomach, intestine, spleen, pancreas, and ovary in rats after oral administration of total glycosides of paeony. Besides, the amount of drug in immune organs, such as the spleen and thymus, is greater than in plasma, suggesting that PF may have immune-modulating effects *in vivo* (Fei et al., 2016). Studies also provided the most promising evidence that PF has been widely used as the immune-regulatory agent in immune disorder diseases, including inflammatory bowel disease, psoriasis, asthma, and so on (Gu et al., 2017; Yu et al., 2017; Shou et al., 2018).

Previous studies have reported an imbalance in Th1 and Th2 cells contribute to the progression of UL. IL-4 potentially triggers and sustains mast cells, programs the Th2 cytokine differentiation (Morawetz et al., 1996), and switches B cells to the IgE isotype to induce allergic reactions (Bradding, 1996). IFN- $\gamma$ , a Th1 effector cytokine, is related to the mitigation of allergic diseases (Teixeira et al., 2005). It is well known that IL-12 promotes Th1 cell polarization, which is associated with the secretion of IFN- $\gamma$  by T cells (Youssef et al., 2002; Cho et al., 2010). The levels of IL-4, IFN- $\gamma$ , and IL-6 significantly increase in the dorsal skin of animals with inflammatory diseases such as atopic dermatitis (Choi et al., 2018). In our study, the level of IL-12 mRNA, IL-6 mRNA, IFN- $\gamma$  mRNA, and IL-4 mRNA were on the rise in UL mice. And PF administration produced a decreasing trend of the cytokines, although our data showed no significance. The persistence of Th1 or Th2 cells predominate is the leading cause of chronic course in some diseases. Th1 cells have been reported to persist in chronic inflammatory diseases, are potent inducers of inflammation due to being repeatedly activated (Niesner et al., 2008; Yamada et al., 2008). And persistent Th2 cells infiltration was associated with the allergic responses of asthma (Wells et al., 2009). Th1 and Th2 are the effector cell subsets of CD4+T cells through the differentiation, which were promoted by cytokines (Mosmann et al., 1986). Furthermore, memory CD4+T cells retain a lifelong ability to mediate protective immunity after vaccination in lymphoid tissues (Amara et al., 2004; Lees and Farber, 2010). To sum up, regulating CD4+T cells is essential for their long-lasting property. Considering the high concentration of PF in the immune organs, and PF-induced regulatory effects on the imbalance in Th1 and Th2 cells, we speculated that PF may exert a continuing medicinal effect through immunoregulatory.

The literature recorded that the intestine could absorb an amount of PF, the unabsorbed fraction is mainly metabolized in intestinal bacteria (Takeda et al., 1997). Bacteroides is one of the intestinal bacteria, playing an important role to convert PF to metabolites (Hattori et al., 1985). It has been reported that gut characteristic metabolite of PF (Benzoic acid) could through the blood-brain barrier to alleviate depressive symptoms in the central nervous system (Yu et al., 2019). Furthermore, gut microbiota and the immune system interact with each other (Kehrmann et al., 2020). *Bacteroides fragilis*-derived Polysaccharide A can differentiate CD4+T-cell into Treg cells, which are a major role in decreasing inflammation (Lahl et al., 2007; Round and Mazmanian, 2010). Another significant aspect is that the majority of the bacterial strains persist for years or even for a lifetime in the host body, which may influence biological functions. In addition, microbiota changed over

time, but, more than 70% of bacterial strains remain stable over 1 year for the individual's microbiota (Faith et al., 2013). The evidence implied that gut microbiota may contribute to the therapeutic role of PF on UL mice persist for some time, which warrants further development.

The activation of mast cells, lymphocytes, T cells, EPX, and cytokines exhibit circadian variations in allergic reactions, showing a high level at night than day. On the other hand, PF is distributed rapidly in the stomach and intestine, the absorption capability of which was high at night compared with day in mice (Hussain and Pan, 2009; Pan and Hussain, 2009). The abundance of bacteroidetes experience diurnal oscillation, peaking at ZT16, troughing around ZT0 in mice, continue to rise during ZT0 to ZT8, slightly fall to ZT12, then rise to ZT16 (Liang et al., 2015). PF dosing at ZT10, therefore, experienced a period of relatively longer detention time to be absorbed then underwent the phase of abundant metabolites producing, which may reinforce the effect. The above information provided some explanation to dosing at ZT10 demonstrated better effects on prophylaxis and treatment than others before symptom onset.

The primary outcome of interest in our experiment was the efficacy of PF on the nocturnal seizures with urticaria, the mice were therefore sensitized and challenged at ZT14 so as to mimic nocturnal symptoms. In order to get more detailed information about antigen challenge and phenotype evaluation at different circadian time points, we performed OVA challenged at ZT02 corresponding to ZT14 so as to imitate morning symptoms of urticaria, and then administrated at ZT22, ZT04, ZT10, and ZT16. The supplementary experiment indicated that the symptoms, histopathological features, mast cell infiltration were severe during the morning, and they were resolved after PF treatment. PF dosing at ZT10 demonstrated better efficacy in comparison to the other three treated indicated time points. Once more, these results provided strong evidence that PF administration at ZT10 produced relatively superior effectiveness to the urticaria symptoms (**Figure 1B**; **Figures 2A,C**; **Figures 3A,C,E**; **Figures 4A,C**; **Figures 5A,C**; **Figures 6A,C**; **Figures 7A,C,E,G**).

The present study preliminarily revealed the circadian pharmacological effects of PF on mice with UL. However, there were some limitations noted. For instance, detailed mechanisms underlying the circadian pharmacological effects of PF remain to be elucidated. Moreover, since the pathogenesis of urticaria involves a complex multistep process which is affected by many target cells, we would investigate the mechanism of the optimal administration time of PF specific to a single target cell in subsequent studies. The expression of IL-6 mRNA, IFN- $\gamma$  mRNA, IL-4 mRNA showed no statistical differences, which may be due to the small sample size or the possibility that the cytokines were not the targets for PF-induced therapeutic effects.

In summary, the symptoms, pathologies factors, and metabolism express diurnal rhythmicity may be the reasons for the difference induced among circadian PF administration timing. In our study, oral administration of PF at four circadian time points (ZT22, ZT04, ZT10, and ZT16) alleviated UL mice, including pruritus, histopathological changes, decreased the levels of IgE, LTB<sub>4</sub>, and HIS, mast cell infiltration, MCT, EPX, and regulated disorders of Th1 and Th2 cells. It is worth noting

that PF administration at ZT10 produced relatively superior effectiveness regardless of whether the UL symptoms attack in the morning or the evening. PF may be used as a potential natural alternative for the prevention and treatment of urticaria before their nocturnal symptoms outbreak.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/**Supplementary Material**.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Institutional Animal Care and Use Committee of Chengdu University of Traditional Chinese Medicine.

## AUTHOR CONTRIBUTIONS

LP, LW, and JZe designed the experiments. LP and QW carried out the experiments. XZ collected the details. LW and JZh carried out the statistical analysis. LP accomplished manuscript. JG and JZe revised the contents. All authors read and approved the submitted manuscript.

## FUNDING

This work was supported by the National Natural Science Foundation of China (grant nos. 82074443 and 81873310), the Sichuan Provincial Central Government Leading Local Science and Technology Development Special Project (grant nos. 2021ZYD0089), the “Xing-lin Scholars” Project of Chengdu University of TCM (grant nos. QNXZ2019017 and ZYTS2019009) and the “Hundred Talents Program” of the Hospital of Chengdu University of Traditional Chinese Medicine (grant nos. 21-Y17, 20-B01, 20-Q03 and 20-Q05).

## ACKNOWLEDGMENTS

We greatly acknowledge the statistical analyses assistance from Miss Tian Ren. We would like to thank Editage ([www.editage.com](http://www.editage.com)) for English language editing. We also thank the editors of *frontiers* for their work on this article.

# Advantages of publishing in Frontiers

## OPEN ACCESS

Articles are free to read  
for greatest visibility  
and readership

## FAST PUBLICATION

Around 90 days  
from submission  
to decision

## HIGH QUALITY PEER-REVIEW

Rigorous, collaborative,  
and constructive  
peer-review

## TRANSPARENT PEER-REVIEW

Editors and reviewers  
acknowledged by name  
on published articles

## Frontiers

Avenue du Tribunal-Fédéral 34  
1005 Lausanne | Switzerland

**Visit us:** [www.frontiersin.org](http://www.frontiersin.org)

**Contact us:** [frontiersin.org/about/contact](http://frontiersin.org/about/contact)

## REPRODUCIBILITY OF RESEARCH

Support open data  
and methods to enhance  
research reproducibility

## DIGITAL PUBLISHING

Articles designed  
for optimal readership  
across devices

## FOLLOW US

@frontiersin

## IMPACT METRICS

Advanced article metrics  
track visibility across  
digital media

## EXTENSIVE PROMOTION

Marketing  
and promotion  
of impactful research

## LOOP RESEARCH NETWORK

Our network  
increases your  
article's readership
